NXP Semiconductors
Reference Manual

Document identifier: IMXRT700RM
Rev. 5, 2025-10-31

i.MX RT700 Crossover Microcontrollers Reference Manual

Supports i.MX RT735S, i.MX RT758S and i.MX RT798S

Contents

Chapter 1 About This Manual..... 15
1.1 Audience.....15
1.2 Organization..... 15
1.3 Module descriptions.....15
1.4 Register descriptions..... 18
1.5 Conventions.....20
1.6 Editorial changes..... 21

Chapter 2 Introduction..... 23
2.1 Overview.....23
2.2 Feature summary..... 25
2.3 Architecture overview..... 32
2.4 Applications..... 40

Chapter 3 Memory Map Overview..... 42
3.1 Introduction.....42
3.2 System memory map.....42
3.3 Peripheral memory map..... 46

Chapter 4 Interrupt and DMA Events Assignments..... 53
4.1 Overview.....53
4.2 System interrupts.....53
4.3 DMA assignments..... 64

Chapter 5 Fusemap..... 70
5.1 Overview.....70
5.2 Boot fusemap..... 70
5.3 Fusemap descriptions table.....70
5.4 Shadow register reload.....71

Chapter 6 External Signals and Pin Multiplexing..... 72
6.1 Introduction.....72
6.2 Muxing options..... 72
6.3 Pin assignments..... 126

Chapter 7 Cortex-M33 Platform Overview..... 206
7.1 Overview.....206
7.2 Functional description.....208

Chapter 8 External Memory Controllers.....210
8.1 Overview.....210
8.2 Modules.....210

Chapter 9 Boot ROM..... 212
9.1 Overview.....212
9.2 High level boot flow..... 212
9.3 Pin allocation..... 214
9.4 Boot configuration and boot image.....222
9.5 Prime boot from XSPI NOR.....225
9.6 Prime boot from eMMC..... 247
9.7 Boot from serial NAND (XSPI).....251
9.8 Recovery boot..... 273

Chapter 10 ROM API.....276
10.1 Overview.....276
10.2 Functional description.....276

Chapter 11 In-System Programming (ISP)..... 291
11.1 Overview.....291
11.2 Functional description.....292
11.3 In-System programming protocol..... 294
11.4 Bootloader packet types.....295
11.5 Bootloader command set.....302
11.6 Bootloader Status Error Codes.....322
11.7 UART ISP.....327
11.8 I2C In-System Programming..... 330
11.9 SPI In-System programming..... 333
11.10 USB In-System Programming..... 338

Chapter 12 Power Overview.....341
12.1 Introduction.....341
12.2 Power architecture.....341
12.3 Power modes.....347
12.4 Power mode transitions.....357
12.5 SLEEPCON and PMC.....366
12.6 RAM Arbiter and shared memory power considerations.....368
12.7 Chip operation in low-power modes..... 369

Chapter 13 Clock Overview..... 372
13.1 Overview.....372
13.2 Clocking considerations.....373
13.3 Clock sources.....373
13.4 Generated clock sources.....374
13.5 Clock root generation..... 374
13.6 Clock Gating.....375

Chapter 14 Graphics Overview.....376
14.1 Overview.....376
14.2 Functional description.....379

Chapter 15 Timers Overview..... 381
15.1 Introduction.....381

Chapter 16 System Debug.....385
16.1 Overview.....385
16.2 Functional description.....385

Chapter 17 Audio Overview.....392
17.1 Audio overview.....392
17.2 Functional description.....394

Chapter 18 Analog Overview.....397
18.1 Analog Overview.....397

Chapter 19 Security Overview.....401
19.1 Overview.....401
19.2 Functional description.....403

Chapter 20 IO PAD Controller (IOPCTL).....405
20.1 Chip-specific IOPCTL information.....405
20.2 Overview.....405
20.3 Functional description.....407
20.4 Signals.....408
20.5 Initialization.....408
20.6 Memory map and register definition.....408

Chapter 21 Pin Interrupt and Pattern Match (PINT).....429
21.1 Chip-specific PINT information.....429
21.2 Overview.....430
21.3 Functional description.....431
21.4 External signals.....434
21.5 Initialization.....434
21.6 Application information.....434
21.7 Memory map and register definition.....437

Chapter 22 General-Purpose Input/Output (GPIO).....456
22.1 Chip-specific GPIO information.....456
22.2 Overview.....458
22.3 Functional description.....458
22.4 External signals.....461
22.5 Initialization.....462
22.6 Application information.....462
22.7 Memory map and register definition.....462

Chapter 23 Performance Monitor (CMX_PERFMON).....484
23.1 Chip-specific CMX_PERFMON information.....484
23.2 Overview.....485
23.3 Functional description.....486
23.4 External signals.....487
23.5 Initialization.....487
23.6 Memory map and register definition.....487

Chapter 24 Cache Memory Controller (XCACHE)....496
24.1 Chip-specific XCACHE information....496
24.2 Overview....496
24.3 Functional description....497
24.4 External signals....503
24.5 Initialization....503
24.6 Application information....504
24.7 XCACHE register descriptions....504

Chapter 25 Semaphores2 (SEMA42)....513
25.1 Chip-specific SEMA42 information....513
25.2 Overview....513
25.3 Functional description....515
25.4 External signals....517
25.5 Initialization....517
25.6 Memory map/register definition....517

Chapter 26 Messaging Unit (MU)....522
26.1 Chip-specific MU information....522
26.2 Overview....523
26.3 Functional description....524
26.4 External signals....527
26.5 Initialization....527
26.6 Application information....527
26.7 Register definition....532

Chapter 27 Power Management Controller (PMC)....579
27.1 Chip-specific PMC information....579
27.2 Overview....580
27.3 Functional description....582
27.4 External signals....601
27.5 Initialization....601
27.6 Application information....601
27.7 Memory map and register definitions....607

Chapter 28 Clock Controller (CLKCTL)....867
28.1 Chip-specific CLKCTL information....867
28.2 Overview....867
28.3 System clocks....869
28.4 Functional description....883
28.5 External signals....901
28.6 Initialization....902
28.7 CLKCTL register descriptions....902

Chapter 29 System Controller (SYSCON)....1240
29.1 Chip-specific SYSCON information....1240
29.2 Overview....1240
29.3 Functional description....1242
29.4 External signals....1247
29.5 Initialization....1247

29.6 Memory map and register definition..... 1247

Chapter 30 Sleep Controller (SLEEPCON)..... 1402
30.1 Chip-specific SLEEPCON information.....1402
30.2 Overview.....1402
30.3 Functional description.....1404
30.4 Memory map and register definition..... 1407

Chapter 31 Reset Controller (RSTCTL).....1617
31.1 Chip-specific RSTCTL information..... 1617
31.2 Overview.....1617
31.3 Functional description.....1619
31.4 External signals..... 1623
31.5 RSTCTL register descriptions..... 1624

Chapter 32 FRO Clock Generator (FRO)..... 1706
32.1 Chip-specific FRO information.....1706
32.2 Overview.....1707
32.3 Functional description.....1708
32.4 External signals..... 1710
32.5 Initialization.....1710
32.6 FRO register descriptions.....1711

Chapter 33 Frequency Measurement (FREQME)..... 1726
33.1 Chip-specific FREQME information.....1726
33.2 Overview.....1726
33.3 Functional description.....1727
33.4 External signals..... 1728
33.5 Initialization.....1728
33.6 Memory map and register definition..... 1729

Chapter 34 Nano Power 32 kHz Oscillator (OSC32KNP).....1738
34.1 Chip-specific OSC32KNP information..... 1738
34.2 Overview.....1738
34.3 Functional description.....1739
34.4 External signals..... 1740
34.5 Initialization.....1740
34.6 OSC32KNP register descriptions..... 1740

Chapter 35 Real Time Clock Subsystem (RTC_SS).....1745
35.1 Chip-specific RTC_SS information..... 1745
35.2 Overview.....1745
35.3 Functional description.....1746
35.4 External signals..... 1747
35.5 Initialization.....1747
35.6 Memory map and register description..... 1747

Chapter 36 Real Time Clock (RTC)..... 1754

36.1 Chip-specific RTC information....1754
36.2 Overview....1755
36.3 Functional description....1756
36.4 External Signals....1762
36.5 Memory map and registers....1762

Chapter 37 Process, Voltage and Temperature Sensor (PVTS)....1807
37.1 Chip-specific PVTS information....1807
37.2 Overview....1808
37.3 Functional description....1809
37.4 Application information....1811
37.5 Memory map and registers....1813

Chapter 38 Analog-to-Digital Converter (ADC)....1817
38.1 Chip-specific ADC information....1817
38.2 Overview....1818
38.3 Functional description....1820
38.4 External signals....1830
38.5 Initialization....1830
38.6 ADC register descriptions....1832

Chapter 39 Comparator (ACMP)....1881
39.1 Chip-specific ACMP information....1881
39.2 Overview....1882
39.3 CMP functional description....1885
39.4 DAC functional description....1887
39.5 CMP external signals....1888
39.6 Initialization....1888
39.7 ACMP register descriptions....1888

Chapter 40 Ultra Secured Digital Host Controller (uSDHC)....1899
40.1 Chip-specific uSDHC information....1899
40.2 Overview....1900
40.3 Functional description....1903
40.4 External signals....1933
40.5 Application information....1935
40.6 uSDHC memory map and register definition....1954
40.7 Glossary....2052

Chapter 41 External Serial Peripheral Interface (XSPI)....2054
41.1 Chip-specific XSPI information....2054
41.2 Overview....2057
41.3 Functional description....2058
41.4 External signals....2125
41.5 Initialization....2127
41.6 Application information....2131
41.7 Memory map and register definition....2148
41.8 Flash memory mapped AMBA bus....2297

Chapter 42 Cache Controller (CACHE64_CTRL)..... 2299
42.1 Chip-specific CACHE64_CTRL information..... 2299
42.2 Overview..... 2300
42.3 Functional description..... 2300
42.4 External signals..... 2307
42.5 Initialization..... 2307
42.6 Memory map and registers..... 2307

Chapter 43 CACHE64 Policy Select (CACHE64_POLSEL)..... 2316
43.1 Chip-specific CACHE64_POLSEL information..... 2316
43.2 Overview..... 2317
43.3 Functional description..... 2317
43.4 Application information..... 2318
43.5 Memory map and register definition..... 2319

Chapter 44 Memory Map Unit (MMU)..... 2323
44.1 Chip-specific MMU information..... 2323
44.2 Overview..... 2324
44.3 Functional description..... 2324
44.4 External signals..... 2328
44.5 Initialization..... 2328
44.6 Memory map and register definition..... 2328

Chapter 45 Neural Processing Unit (NPU)..... 2343
45.1 Chip-specific NPU information..... 2343
45.2 Overview..... 2343
45.3 Functional description..... 2347
45.4 External signals..... 2350
45.5 Initialization..... 2350
45.6 Memory map and register definitions..... 2350

Chapter 46 EZ Handler RISC-V (EZH-V)..... 2351
46.1 Chip-specific EZH-V information..... 2351
46.2 Introduction..... 2352
46.3 Features..... 2352
46.4 Block diagram..... 2353
46.5 Functional description..... 2353

Chapter 47 JPEG Decoder (JPEGDEC)..... 2355
47.1 Chip-specific JPEGDEC information..... 2355
47.2 Overview..... 2355
47.3 Functional description..... 2356
47.4 External signals..... 2356
47.5 Initialization..... 2356
47.6 Memory map and register definition..... 2356

Chapter 48 JPEG Decoder Wrapper (JPGDECWRP)..... 2357
48.1 Chip-specific JPGDECWRP information..... 2357
48.2 Overview..... 2357

48.3 Functional description....2359
48.4 External signals....2360
48.5 Initialization....2360
48.6 Memory map and register descriptions....2360

Chapter 49 PNG Decoder (PNGDEC)....2383
49.1 Chip-specific PNGDEC information....2383
49.2 Overview....2383
49.3 Functional description....2384
49.4 External signals....2386
49.5 Initialization....2386
49.6 PNGDEC register descriptions....2386

Chapter 50 Vector Graphics Processing Unit (VGPU)....2404
50.1 Chip-specific VGPU information....2404
50.2 Overview....2404
50.3 Functional description....2406
50.4 Software API....2412

Chapter 51 Universal Serial Bus Controller (USB)....2414
51.1 Chip-specific USB information....2414
51.2 Overview....2415
51.3 Functional description....2415
51.4 External signals....2450
51.5 Initialization....2451
51.6 Application information....2452
51.7 USB noncore memory map and register definitions....2454
51.8 USB core memory map and register definitions....2475

Chapter 52 Universal Serial Bus 2.0 PHY (USBPHY)....2575
52.1 Chip-specific USBPHY information....2575
52.2 Overview....2575
52.3 Functional description....2576
52.4 External signals....2582
52.5 Initialization....2582
52.6 Application information....2582
52.7 USBPHY register descriptions....2583

Chapter 53 USB Device Charger Detection Module (USBDCD)....2633
53.1 Chip-specific USBDCD information....2633
53.2 Overview....2633
53.3 Functional description....2634
53.4 External signals....2648
53.5 Initialization....2648
53.6 Application information....2649
53.7 USBDCD register descriptions....2649

Chapter 54 Mobile Industry Processor Interface and Display Serial Interface Controller (MIPI_DSI_HOST)....2661

54.1 Chip-specific MIPI_DSI_HOST information.....2661
54.2 Overview.....2662
54.3 DSI Host Controller Core.....2663
54.4 DSI D-PHY.....2675
54.5 DPHY Programming.....2684
54.6 Packet Data and Pixel Formats.....2685
54.7 MIPI_DSI_HOST Memory Map/Register Definition.....2686

Chapter 55 LCD Interface (LCDIF).....2746
55.1 Chip-specific LCDIF information.....2746
55.2 Overview.....2746
55.3 Functional description.....2749
55.4 External signals.....2777
55.5 Initialization.....2778
55.6 LCDIF register descriptions.....2783

Chapter 56 Sigma Delta Analog-to-Digital Converter (SDADC).....2869
56.1 Chip-specific SDADC information.....2869
56.2 Overview.....2869
56.3 Functional description.....2871
56.4 External signals.....2875
56.5 Initialization.....2875
56.6 Application information.....2875
56.7 Memory map and register definition.....2876

Chapter 57 PDM Microphone Interface (MICFIL).....2920
57.1 Chip-specific MICFIL information.....2920
57.2 Overview.....2920
57.3 Functional description.....2922
57.4 External signals.....2933
57.5 Initialization.....2933
57.6 Application information.....2936
57.7 MICFIL register descriptions.....2937

Chapter 58 Synchronous Audio Interface (SAI).....2968
58.1 Chip-specific SAI information.....2968
58.2 Overview.....2970
58.3 Functional description.....2971
58.4 External signals.....2977
58.5 Initialization.....2978
58.6 Memory map and register definition.....2978

Chapter 59 HiFi 1 DSP Platform (HiFi1).....3024
59.1 Chip-specific HiFi1 information.....3024
59.2 Overview.....3025
59.3 Functional description.....3026
59.4 Signals.....3028

Chapter 60 HiFi 4 DSP Platform (HiFi4).....3030

60.1 Chip-specific HiFi4 information....3030
60.2 Overview....3031
60.3 Functional description....3033
60.4 Signals....3035

Chapter 61 Micro-Tick Timer (UTICK)....3036
61.1 Chip-specific UTICK information....3036
61.2 Overview....3037
61.3 Functional description....3037
61.4 External signals....3038
61.5 Initialization....3038
61.6 UTICK register descriptions....3038

Chapter 62 Standard Counter/Timers (CTIMER)....3045
62.1 Chip-specific CTIMER information....3045
62.2 Overview....3047
62.3 Functional description....3049
62.4 External signals....3051
62.5 Initialization....3052
62.6 Application information....3052
62.7 CTIMER register descriptions....3052

Chapter 63 OS Event Timer (OSTIMER)....3072
63.1 Chip-specific OSTIMER information....3072
63.2 Overview....3072
63.3 Functional description....3074
63.4 External signals....3075
63.5 Initialization....3075
63.6 Memory map and register definition....3075

Chapter 64 SCTimer (SCT)....3104
64.1 Chip-specific SCT information....3104
64.2 Overview....3105
64.3 Functional description....3107
64.4 External signals....3113
64.5 Initialization....3113
64.6 Application information....3113
64.7 Memory map and register definition....3117

Chapter 65 Multi-Rate Timer (MRT)....3166
65.1 Chip-specific MRT information....3166
65.2 Overview....3166
65.3 Functional description....3167
65.4 External signals....3169
65.5 Initialization....3169
65.6 Memory map and register descriptions....3169

Chapter 66 Windowed Watchdog Timer (WWDT)....3179
66.1 Chip-specific WWDT information....3179

66.2 Overview....3180
66.3 Functional description....3182
66.4 External signals....3184
66.5 Initialization....3185
66.6 Memory map and register definition....3185

Chapter 67 Flexible I/O (FLEXIO)....3193
67.1 Chip-specific FLEXIO information....3193
67.2 Overview....3193
67.3 Functional description....3195
67.4 External signals....3205
67.5 Initialization....3205
67.6 Application information....3206
67.7 Memory map and registers....3225

Chapter 68 Low-Power Flexible Communications Interface (LP_FLEXCOMM)3274
68.1 Chip-specific LP_FLEXCOMM information....3274
68.2 LP_FLEXCOMM....3276
68.3 Low-Power Inter-Integrated Circuit (LPI2C)....3282
68.4 Low Power Serial Peripheral Interface (LPSPI)....3367
68.5 Low Power Universal Asynchronous Receiver/Transmitter (LPUART)....3417

Chapter 69 Improved Inter-Integrated Circuit (I3C)....3473
69.1 Chip-specific I3C information....3473
69.2 Overview....3474
69.3 Functional description....3476
69.4 External signals....3489
69.5 Initialization....3489
69.6 Application information....3491
69.7 I3C register descriptions....3492

Chapter 70 Input Multiplexing (INPUTMUX)....3601
70.1 Chip-specific INPUTMUX information....3601
70.2 Overview....3601
70.3 Functional description....3602
70.4 External signals....3603
70.5 Initialization....3604
70.6 Memory map and register definition....3604

Chapter 71 Enhanced Direct Memory Access (eDMA)....3637
71.1 Chip-specific eDMA information....3637
71.2 Overview....3638
71.3 Functional description....3640
71.4 External signals....3645
71.5 Initialization....3645
71.6 Memory map and register definition....3658

Chapter 72 Network Interconnect Component (NIC)....3800
72.1 Chip-specific NIC information....3800

72.2 Overview....3802
72.3 Functional description....3803
72.4 External signals....3809
72.5 Initialization....3809
72.6 Memory map and register definition....3809
72.7 Glossary....3826

Chapter 73 On-Chip OTP Controller (OCOTP_CTRL)....3828
73.1 Chip-specific OCOTP_CTRL information....3828
73.2 Overview....3828
73.3 Functional Description....3829
73.4 External Signals....3833
73.5 Fuse Map....3833
73.6 Memory Map/Register Definition....3833

Chapter 74 Cyclic Redundancy Check (CRC)....3874
74.1 Chip-specific CRC information....3874
74.2 Overview....3874
74.3 Functional description....3875
74.4 External signals....3878
74.5 Initialization....3878
74.6 Use cases....3878
74.7 Memory map and register descriptions....3881

Appendix A Release notes....3886
A.1 About This Manual changes....3886
A.2 Introduction changes....3886
A.3 Memory Map Overview changes....3886
A.4 Interrupts and DMA Events Assignments changes....3886
A.5 Fusemap changes....3886
A.6 External Signals and Pin Multiplexing changes....3886
A.7 Cortex-M33 Platform Overview changes....3886
A.8 External Memory Controllers Overview changes....3886
A.9 Boot ROM changes....3886
A.10 ROM API chapter changes....3886
A.11 ISP changes....3887
A.12 Power Overview changes....3887
A.13 Clock Overview changes....3887
A.14 Graphics Overview changes....3887
A.15 Timers Overview changes....3887
A.16 System Debug changes....3887
A.17 Audio Overview changes....3887
A.18 Analog Overview changes....3887
A.19 Security Overview changes....3887
A.20 IO PAD Controller (IOPCTL)....3887
A.21 Pin Interrupt and Pattern Match (PINT)....3888
A.22 General-Purpose Input/Output (GPIO)....3888
A.23 Performance Monitor (CMX_PERFMON)....3888
A.24 Cache Memory Controller (XCACHE)....3888
A.25 Semaphores2 (SEMA42)....3889
A.26 Messaging Unit (MU)....3889

A.27 Power Management Controller (PMC)....3889
A.28 Clock Controller (CLKCTL)....3889
A.29 System Controller (SYSCON)....3889
A.30 Sleep Controller (SLEEPCON)....3890
A.31 Reset Controller (RSTCTL)....3890
A.32 FRO Clock Generator (FRO)....3890
A.33 Frequency Measurement (FREQME)....3890
A.34 Nano Power 32 kHz Oscillator (OSC32KNP)....3891
A.35 Real Time Clock Subsystem (RTC_SS)....3891
A.36 Real Time Clock (RTC)....3891
A.37 Process, Voltage and Temperature Sensor (PVTS)....3891
A.38 Analog-to-Digital Converter (ADC)....3891
A.39 Comparator (ACMP)....3892
A.40 Ultra Secured Digital Host Controller (uSDHC)....3892
A.41 External Serial Peripheral Interface (XSPI)....3892
A.42 Cache Controller (CACHE64_CTRL)....3892
A.43 CACHE64 Policy Select (CACHE64_POLSEL)....3893
A.44 Memory Map Unit (MMU)....3893
A.45 Neural Processing Unit (NPU)....3893
A.46 EZ Handler RISC-V (EZH-V)....3894
A.47 JPEG Decoder (JPEGDEC)....3894
A.48 JPEG Decoder Wrapper (JPGDECWRP)....3894
A.49 PNG Decoder (PNGDEC)....3894
A.50 Vector Graphics Processing Unit (VGPU)....3894

Chapter 1
About This Manual

1.1 Audience

This reference manual (RM) is intended for system software, hardware developers, and applications programmers who need to develop products using this chip. It assumes that its users understand operating systems, microprocessor system design, and basic principles of software and hardware.

1.2 Organization

This manual has two main sets of chapters.

- Chapters in the first set contain information that applies to all components on the chip.
- Chapters in the second set are organized into functional groupings that detail particular areas of functionality.
  - Examples of these groupings are clocking, timers, and communication interfaces.
  - Each grouping includes chapters that provide a technical description of individual modules.

1.2.1 Attachments

This manual includes key information in the files attached to it. For example, memory map and I/O details. Use the content in these attachments in conjunction with this manual's content.

NOTE

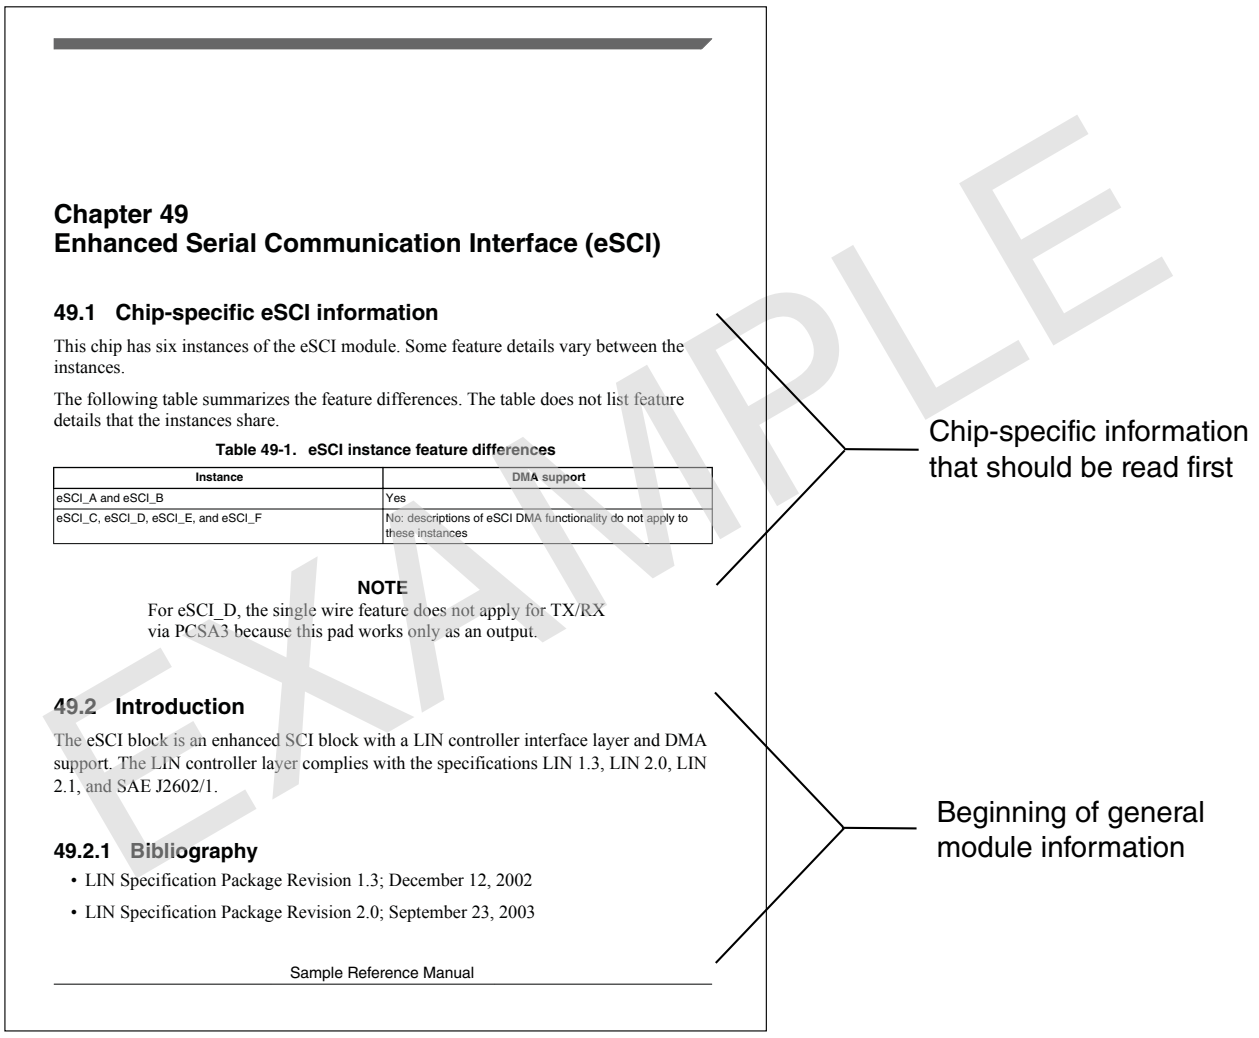
Select the paperclip icon on the left side of the PDF window to see the list of attachments.

1.3 Module descriptions

Each module chapter has two main parts:

- The first section, *chip-specific [module name]* information, provides details such as the number of module instances on the chip and connections between that module and the other ones. Read this section *first* because its content is crucial for understanding the information in the other sections of the chapter.
- The subsequent sections provide general information about the module, including its signals, registers, and functional description.

The following figure shows you an example of this demarcation.



Chapter 49
Enhanced Serial Communication Interface (eSCI)

49.1 Chip-specific eSCI information

This chip has six instances of the eSCI module. Some feature details vary between the instances.

The following table summarizes the feature differences. The table does not list feature details that the instances share.

Table 49-1. eSCI instance feature differences

Instance	DMA support
eSCI_A and eSCI_B	Yes
eSCI_C, eSCI_D, eSCI_E, and eSCI_F	No; descriptions of eSCI DMA functionality do not apply to these instances

NOTE
For eSCI_D, the single wire feature does not apply for TX/RX via PCSA3 because this pad works only as an output.

49.2 Introduction

The eSCI block is an enhanced SCI block with a LIN controller interface layer and DMA support. The LIN controller layer complies with the specifications LIN 1.3, LIN 2.0, LIN 2.1, and SAE J2602/1.

49.2.1 Bibliography

- LIN Specification Package Revision 1.3; December 12, 2002
- LIN Specification Package Revision 2.0; September 23, 2003

EXAMPLE

Figure 1. Example of chapter chip-specific information and general module information

1.3.1 Chip-specific information that clarifies content in the same chapter

The following figure shows an example of chip-specific information that clarifies general module information presented later in the chapter. In this case, the chip-specific register reset values supersede the reset values that appear in the register diagram.

System Integration Unit Lite2 (SIUL2)

Chapter 9
System Integration Unit Lite2 (SIUL2)

9.1 Chip-specific SIUL2 information

9.1.1 Feature configurations

In this device, the SIUL2_0 module instance does not support the following features described in the generic description:

- Interrupts
- DMA channels

9.1.2 Notes for IMCR

Out of reset, PA_00, PA_04, and PA_05 pads have JTAG input functionality selected by default. It should be disabled in the corresponding IMCR registers (IMCR61, IMCR60, and IMCR50 respectively) in order to use other functionality such as GPIO.

9.2 Introduction

9.2.1 Overview

The System Integration Unit Lite2 provides control over all the electrical pin controls and ports with 16 bits of bidirectional, general-purpose input and output signals. One of the most important functions of the SIUL2 is to enable the user to select the functions and electrical characteristics that appear on external device pins. It also controls the multiplexing of internal signals from one module to another and controls chip I/O. It supports as many as 32 external interrupts with trigger event configuration. The following figure is the block diagram of SIUL2 and its interfaces to other system components.

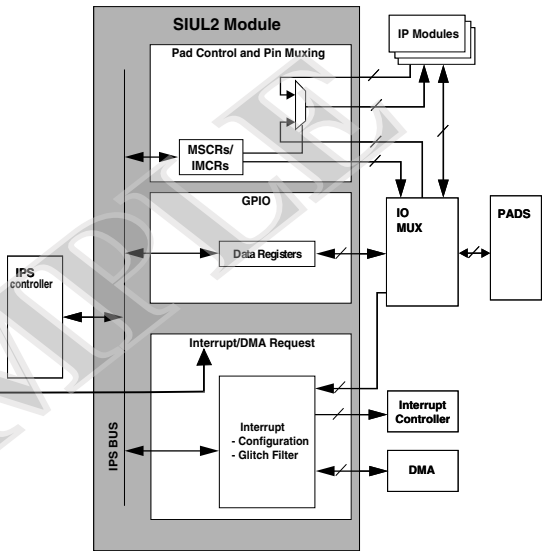

Figure 23. System Integration Unit Lite2 block diagram

This module provides dedicated pad control to general-purpose pads that can be configured as either inputs or outputs. The SIUL2 module provides registers that enable user software to read values from GPIO pads configured as inputs, and write values to GPIO pads configured as outputs:

- When configured as output, you can write to an internal register to control the state driven on the associated output pad.
- When configured as input, you can detect the state of the associated pad by reading the value from an internal register.
- When configured as input and output, the pad value can be read back, which can be used as a method of checking if the written value appeared on the pad.

To assist software development, GPIO data registers can be accessed using various mechanisms. These differing mechanisms allow support for port access or for bit manipulation without the need to use read-modify-write operations:

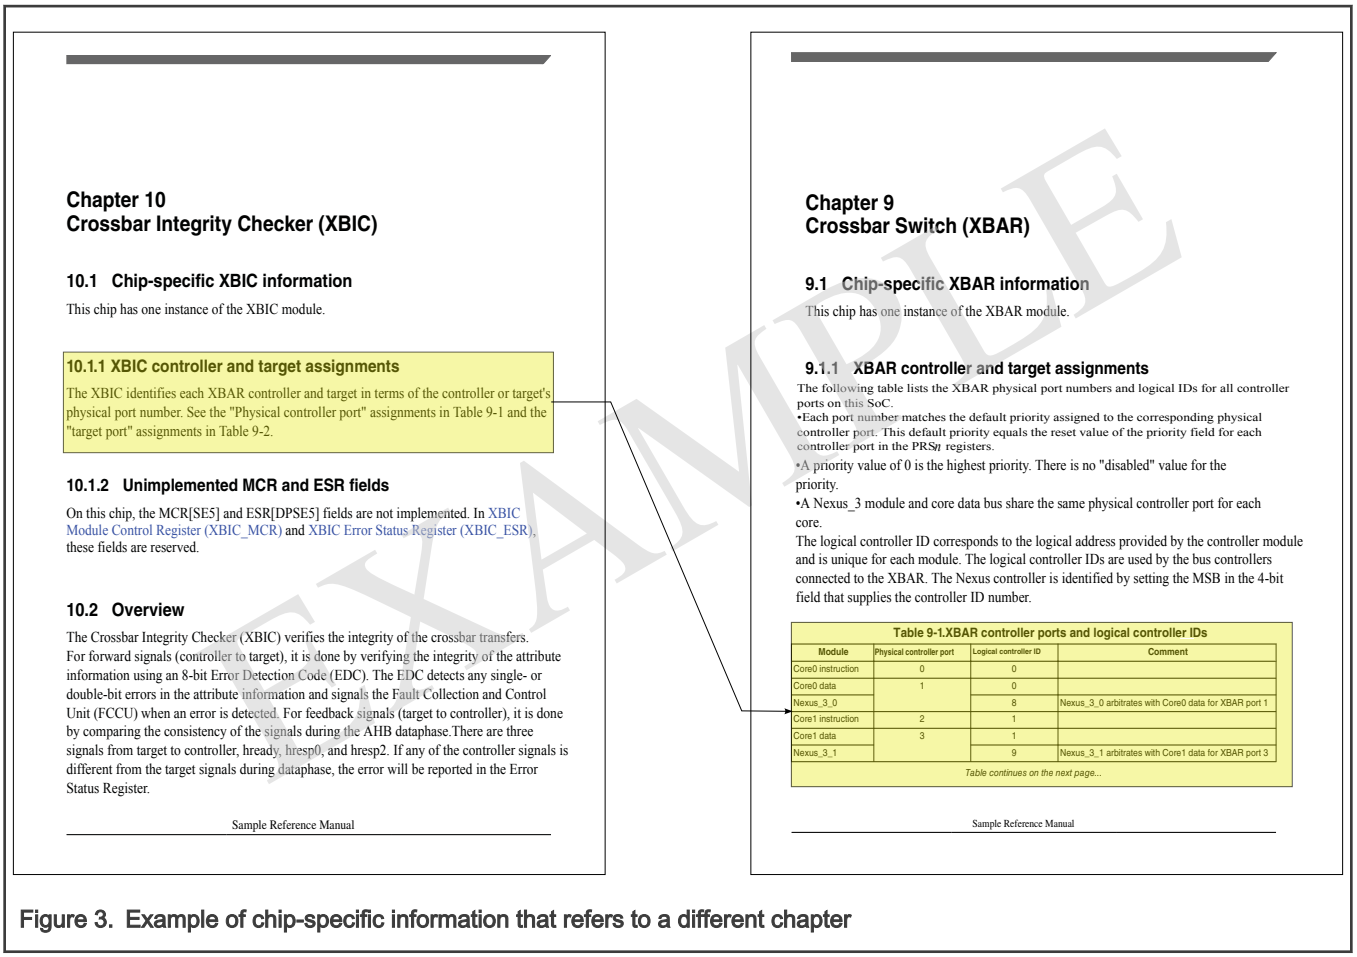
- Access to two 16-bit ports in one access
- Read/write access to a single bit
- A 16-bit port write with a bit mask, using single 32-bit access.

EXAMPLE

Figure 2. Example of chip-specific information that clarifies content in the same chapter

1.3.2 Chip-specific information that refers to a different chapter

Related chip-specific information may be provided in different chapters of the manual. The following figure shows an example of two such connected pieces of information. In this case, read both before you proceed.



Chapter 10
Crossbar Integrity Checker (XBIC)

10.1 Chip-specific XBIC information

This chip has one instance of the XBIC module.

10.1.1 XBIC controller and target assignments

The XBIC identifies each XBAR controller and target in terms of the controller or target's physical port number. See the "Physical controller port" assignments in Table 9-1 and the "target port" assignments in Table 9-2.

10.1.2 Unimplemented MCR and ESR fields

On this chip, the MCR[SE5] and ESR[DPSE5] fields are not implemented. In XBIC Module Control Register (XBIC_MCR) and XBIC Error Status Register (XBIC_ESR), these fields are reserved.

10.2 Overview

The Crossbar Integrity Checker (XBIC) verifies the integrity of the crossbar transfers. For forward signals (controller to target), it is done by verifying the integrity of the attribute information using an 8-bit Error Detection Code (EDC). The EDC detects any single- or double-bit errors in the attribute information and signals the Fault Collection and Control Unit (FCCU) when an error is detected. For feedback signals (target to controller), it is done by comparing the consistency of the signals during the AHB dataphase.There are three signals from target to controller, hready, hresp0, and hresp2. If any of the controller signals is different from the target signals during dataphase, the error will be reported in the Error Status Register.

Sample Reference Manual

Chapter 9
Crossbar Switch (XBAR)

9.1 Chip-specific XBAR information

This chip has one instance of the XBAR module.

9.1.1 XBAR controller and target assignments

The following table lists the XBAR physical port numbers and logical IDs for all controller ports on this SoC.

- Each port number matches the default priority assigned to the corresponding physical controller port. This default priority equals the reset value of the priority field for each controller port in the PRSn registers.
- A priority value of 0 is the highest priority. There is no "disabled" value for the priority.
- A Nexus_3 module and core data bus share the same physical controller port for each core.

The logical controller ID corresponds to the logical address provided by the controller module and is unique for each module. The logical controller IDs are used by the bus controllers connected to the XBAR. The Nexus controller is identified by setting the MSB in the 4-bit field that supplies the controller ID number.

Table 9-1.XBAR controller ports and logical controller IDs

Module	Physical controller port	Logical controller ID	Comment
Core0 instruction	0	0	
Core0 data	1	0	
Nexus_3_0		8	Nexus_3_0 arbitrates with Core0 data for XBAR port 1
Core1 instruction	2	1	
Core1 data	3	1	
Nexus_3_1		9	Nexus_3_1 arbitrates with Core1 data for XBAR port 3

Table continues on the next page...

Sample Reference Manual

EXAMPLE

Figure 3. Example of chip-specific information that refers to a different chapter

1.4 Register descriptions

Module chapters present register information in the following:

- Memory maps, which contain:
  - An offset from the module's base address
  - The mnemonic and name of each register
  - The width of each register (in bits)
  - The reset value of each register
- Register figures
- Field-description tables
- Associated text

The following figure shows register figure conventions used throughout the manual.

Access type	Access description	DITA output	Effect of Write on Value	Readback Value
RW	Read/write	R / W: Mnemonic	Changes to Written Value	Current Value
RO	Read-only	R: Mnemonic / W:	No Effect	Current Value
RU	Reserved, unimplemented	R / W: Reserved	No Effect	Value Undefined
ROZ	Reserved, Read-only zero	R: 0 / W:	No Effect	Returns All Zero
ROO	Reserved, Read-only one	R: 1 / W:	No Effect	Returns All Ones
WO	Write-only	R: / W: Mnemonic	Changed to Written Value	Value Undefined
WOZ	Reserved, Write-only zero	R: / W: 0	Write Value Must Be All 0s.	Value Undefined
WOO	Reserved, Write-only one	R: / W: 1	Write Value Must Be All 1s.	Value Undefined
W0C	Write zero to clear	R: Mnemonic / W: w0c	If a Bit in the Written Value is a 0, the Corresponding Bit in the Field is Set to 0. Otherwise, the Field Bit is Not Affected.	Current Value
W1C	Write one to clear	R: Mnemonic / W: w1c	If a Bit in the Written Value is a 1, the Corresponding Bit in the Field is set to 0. Otherwise, the Field Bit is Not Affected.	Current Value
R2C	Read to clear		Value is cleared following the read operation	Current Value
ROWZ	Read-only, writes zero	R: Mnemonic / W: 0	Write Value Must Be All 0s	Current Value
ROWO	Read-only writes one	R: Mnemonic / W: 1	Write Value Must Be All 1s	Current Value
ROWU	Ready-only writes undefined	R: Mnemonic / W: —	Writes Operation Undefine	Current Value
WORZ	Write-only reads zero	R: 0 / W: Mnemonic	Changes to Written Value	Returns All Zero
WORO	Write-only reads one	R: 1 / W: Mnemonic	Changes to Written Value	Returns All Ones
WORU	Write-only reads undefined	R: — / W: Mnemonic	Changes to Written Value	Value Undefined

Figure 4. Register figure conventions

NOTE

Reset values of reserved locations documented in this manual are subject to change and must not be used for diagnostic purposes.

1.5 Conventions

1.5.1 Notes and cautions

Specific information is provided as part of notes and cautions throughout this manual.

NOTE

Emphasizes information that deserves extra attention.

CAUTION

Informs you of situations that could lead to highly undesirable outcomes—such as damage to the chip or irreversible malfunction.

1.5.2 Numbering systems

The following suffixes identify different numbering systems:

Table 1. Numbering systems

This suffix	Identifies a
b	Binary number. For example, the binary equivalent of the number 5 is mentioned as 101b. In some cases, *0b* is prefixed to binary numbers.
d	Decimal number. Decimal numbers are followed by this suffix only when there is a possibility of confusion. In general, decimal numbers are used without a suffix.
h	Hexadecimal number. For example, the hexadecimal equivalent of the number 60 is mentioned as 3Ch. In some cases, *0x* is prefixed to hexadecimal numbers.

1.5.3 Typographic notation

The following typographic notations are used throughout this document:

Table 2. Typographic notation

Example	Description
x and other italicized text	The italicized, lowercase *x* is used as a placeholder for replaceable numbers. In general, italicized text is used for titles of publications and for emphasis. Additionally, italics could be used for metasymbols in syntax descriptions. Plain lowercase letters are used as placeholders for single letters and numbers.
`code font`	Fixed-width font (such as Courier) used for code. It is used for a letter, word, or phrase that you want the user to type. For example, "Type `Read` and press Enter." This type of font is also used for instruction mnemonics, directives, symbols, subcommands, parameters, operators, computer-language elements, code listings, commands that appear in running text, and for sample code. Instruction mnemonics and directives in text and tables are mentioned in all caps; for example, BSR.
SR[SCM]	A mnemonic in square brackets represents the name of a register field. This example refers to the Scaling Mode (SCM) field in the Status Register (SR).
REVNO[6:4], XAD[7:0]	Numbers in brackets that are separated by a colon represent either: • A subset of a register's named field

Table continues on the next page...

Table 2. Typographic notation (continued)

Example	Description
	For example, REVNO[6:4] refers to bits 6-4 that are part of the COREREV field occupying bits 6-0 of the REVNO register. • A continuous range of individual signals of a bus For example, XAD[7:0] refers to signals 7-0 of the XAD bus.
MOD.REG	A period separates the elements of a hierarchy: subsystem.module.register. For example: • SWT.TO means that the TO register is located in the SWT module. • SMU.XRDC.CR means that the CR register is located in the XRDC module within the SMU subsystem.

1.5.4 Special terms

The following terms have special meanings.

Table 3. Special terms

Term	Meaning
Asserted	Refers to the state of a signal as follows: • An active-high signal is asserted when high (1). • An active-low signal is asserted when low (0).
Deasserted	Refers to the state of a signal as follows: • An active-high signal is deasserted when low (0). • An active-low signal is deasserted when high (1). In some cases, deasserted signals are described as *negated*.
Reserved	Refers to memory space, register, field, or programming setting. Writes to a reserved location can result in unpredictable functionality or behavior. You must: • Before writing to a location which contain reserved bits user must make sure the write operation will write the reserved bit with value specified as the reset value in NXP reference manual. • Consider undefined locations in memory to be reserved as reset value 0 shall be assumed. You might get a BERR(transfer error) response on access to undefined locations in memory. • If user reads data from memory area containing reserved bit, the value of reserved bits should be ignored and not used for any functional purposes. **NOTE** BootROM could modify the reserved bit values after reset. Please refer to the BootROM settings attachment.
Write 1 to clear (w1c)	Refers to the access type of a register field that is used to clear the field by writing the value 1 to it.
Undefined (u)	Refers to undefined reset values

1.6 Editorial changes

Each new release of this document includes editorial improvements such as:

- Spelling
- Grammar
- Punctuation
- Voice
- Tense
- Capitalization
- Formatting
- Presentation
- Navigation

Chapter 2
Introduction

2.1 Overview

The i.MX RT700 chip contains a rich set of peripherals within multiple functional chip domains. These domains include application core complexes, DSPs, on-chip SRAM, and several high-bandwidth interfaces to access off-chip flash. The chip is architected to be low-power by using advanced clock and power gating techniques, DVFS, and independent power control of specific chip domains. The chip features many highlights, including NXP proprietary machine-learning IP supported by the eIQ™ toolkit, a vector graphics processing unit (VGPU), and a 24-bit Sigma-Delta ADC.

2.1.1 System diagram

The system bus network, primary peripherals, and external interfaces for the chip are illustrated in the diagram below.

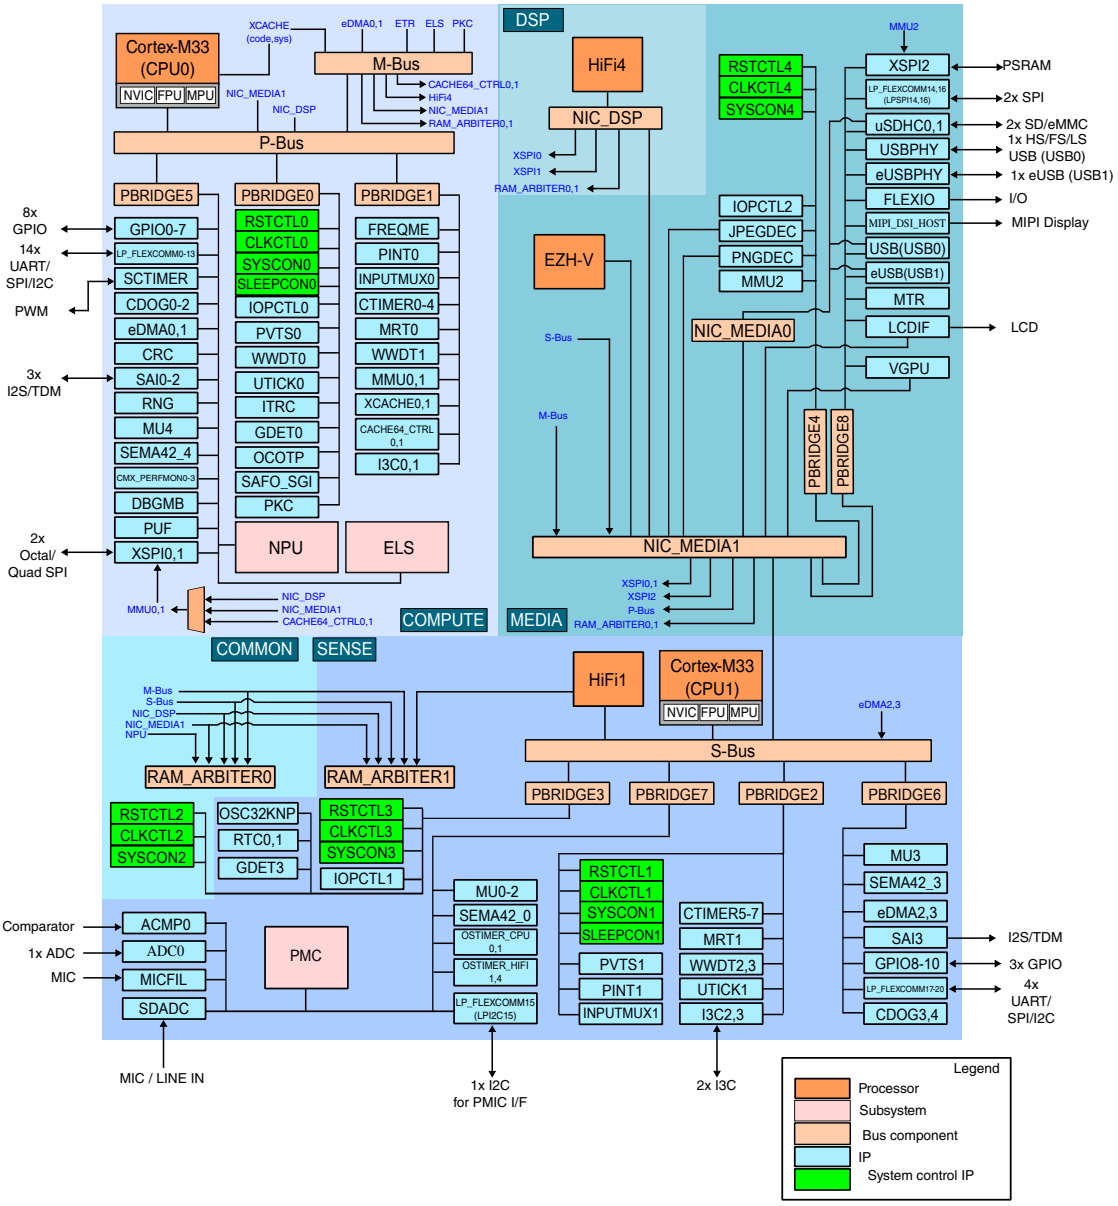


Figure 5. System bus diagram

The following map of the functional domains to the related power domains on the chip are noted in the table below:

Functional domain	Power domain	IP modules
Compute	VDD2_COMP	All modules in power domain
	VDD2_COM	RSTCTL0, CLKCTL0, SYSCON0, SLEEPCON0, IOPCTL0, OCOTP
Common	VDD2_COM	RAM_ARBITER
	VDDN_COM	RSTCTL2, CLKCTL2, SYSCON2, IOPCTL2

Table continues on the next page...

Table continued from the previous page...

Functional domain	Power domain	IP modules
DSP	VDD2_DSP	All modules in power domain
Media	VDD2_MEDIA	All modules in power domain
	VDDN_MEDIA	All modules in power domain
	VDDN_COM	XSPI2
	VDD1V8_PMC	All modules in power domain
	VDD1V8_AON	All modules in power domain
Sense	VDD1_SENSE	All modules in power domain

2.2 Feature summary

The following table shows the chip features organized by function.

Feature	Module	Description
Arm platform and debug	CPU0	• One Compute Domain CPU - Arm Cortex-M33 processor with Trustzone and built-in: — Nested Vectored Interrupt Controller (NVIC) — Non-maskable interrupt (NMI) input — Memory Protection Unit (MPU) — Hardware Floating Point Unit (FPU) — ETM Trace — System Tick Timer (SysTick).
	CPU1	• One Sense Domain CPU - Arm Cortex-M33 co-processor with Trustzone and built-in: — Nested Vectored Interrupt Controller (NVIC) — Non-maskable interrupt (NMI) input — Memory Protection Unit (MPU) — Hardware Floating Point Unit (FPU) — System Tick Timer (SysTick). **NOTE** The configuration of CPU1 does not include ETM.
	Floating Point Unit (FPU)	• Two FPUs (CPU0, CPU1) are single-precision floating point computation units compliant to the IEEE Standard for Floating-Point Arithmetic (IEEE 754).

Table continues on the next page...

Table continued from the previous page...

	Memory Protection Unit (MPU)	• Two MPUs (CPU0, CPU1) provide support for eight unified protection regions, overlapping protection regions with ascending region priority, and access permissions. MPU mismatches and permission violations invoke the Hard Fault handler.
	Nested Vectored Interrupt Controller (NVIC)	• Two NVICs(CPU0, CPU1) implement a relocatable vector table supporting external interrupts, a single non-maskable interrupt (NMI), and priority levels.
	System Tick Timer (SysTick)	See the ARMv8M Architecture Reference Manual for more information about this system timer.
	Cache Controller (CACHE64_CTRL)	• Two CACHE64_CTRLs - cache memory controllers and blocks of high-speed memory locations that contain address information (commonly known as a tag) and its associated data. CACHE64_CTRLs decrease the average time of a memory access.
	CACHE64 Policy Select (CACHE64_POLSEL)	• Two CACHE64_POLSELs monitor incoming bus addresses to define the policy that the cache controllers (CACHE64_CTRL) use. CACHE64_POLSELs and the cache controllers work in tandem with each other.
	Performance Monitor (CMX_PERFMON)	• Four CMX_PERFMONs (System Cache, Code Cache, XSPI0,1 Cache) - contain counters that you can configure to count events, which can be used to monitor the performance of a CPU, cache, or memory. You can configure CMX_PERFMON to select the events to be counted for each counter. An additional instruction counter is available to count CPU instruction fetches.
	Cache Memory Controller (XCACHE)	• Two XCACHEs (System Cache, Code Cache) - general-purpose AMBA AHB bus protocol caches that provide lower latency access to slower memories.
	Memory Map Unit (MMU)	• Three MMUs - remap AHB bus access address to another address indicated by MMU Look Up Table (LUT) SRAM. The remapped address in LUT SRAM can be configured via the internal register bus. • MMU modules are implemented separate from XSPI.
	Semaphores2 (SEMA42)	• Three SEMA42s - memory-mapped modules that provide robust hardware support needed in multi-core systems for implementing semaphores and provide a simple mechanism to achieve "lock and unlock" operations via a single write access. The hardware semaphore modules provide hardware-enforced gates as well as other useful system functions related to the gating mechanisms.
	Messaging Unit (MU)	• Five MUs - enable two processors on a chip to communicate and coordinate by passing messages (e.g. data, status, and control) through the MU interfaces. MUs also provide the ability for one processor to signal the other processor using interrupts.

Table continues on the next page...

Table continued from the previous page...

	Debug Mailbox (DBGMB)	• One DBGMB outlines the debug capabilities implemented in this chip.
Chip IO	IO PAD Controller (IOPCTL)	• Three IOPCTLs provide IO pad control functions. Each port pin PIOm_n has one IOPCTL register assigned to control the characteristics of the pin.
	Pin Interrupt and Pattern Match (PINT)	• Two PINTs provide interrupt functionality for a selected set of GPIO pins.
	General-Purpose Input/ Output (GPIO)	• Eleven GPIOs - communicate to the processor core via a zero wait-state interface for maximum pin. performance. • Up to 217 general purpose I/O (GPIO) pins with configurable pull-up/ pull-down resistors, and adjustable output driver slew rates. • Ports can be set, clear, toggle in bitwise • Mirrored, secure GPIO. • Individual GPIO pins can be used as edge and level-sensitive interrupt sources, each with its own interrupt vector. • All GPIO pins can contribute to one of two ganged (OR'd) interrupts from the GPIO module. • A group of up-to 8 GPIO pins (from Port0/1) can be selected for Boolean pattern matching which can generate interrupts and/or drive a "pattern-match" output.
Clock, power, and reset	Power Management Controller (PMC)	One PMC interfacing to CPU0 (PMC0) and CPU1 (PMC1), manages the hardware functions and connections that support the internal LDO supply and external PMIC supply interface for the VDD1, VDD2, VDDN, and VDD 1.8 V domains. Subsystem Features • Five VDDIO supplies (can be shared or independent) • RBB to provide additional control over power/performance trade-offs
	Clock Controller (CLKCTL)	• Five CLKCTLs (2 Sense, 2 Common, 1 Media) - contain and configure clock sources for peripherals and CPUs. • Crystal Oscillator (XTALOSC) 24 MHz source • Main System PLL: — Allows CPU max frequency operation without the need for a high-frequency crystal. Main System PLL may be run from an FRO, XTALOSC, or the CLKIN pin. — 4 PFD outputs provide flexible clock source to various peripherals.. • Audio PLL for the audio and other modules.
	System Controller (SYSCON)	• Five SYSCONs (2 Sense, 2 Common, 1 Media) provide controls and configures the system and peripherals for the multiple functions.

Table continues on the next page...

Table continued from the previous page...

	Sleep Controller (SLEEPCON)	• Two SLEEPCONs (1 Sense, 1 Common) - programmable low-power controllers to save power for applications.
	Reset Controller (RSTCTL)	• Five RSTCTLs (2 Sense, 2 Common, 1 Media) control module resets.
	FRO Clock Generator (FRO)	• Three FROs provide trimmable system clocks. — Two programmable internal 150-325 MHz FRO with 1% accuracy. — One Internal 192 MHz FRO oscillator with 1% accuracy.
	Frequency Measurement (FREQME)	• One FREQME accurately measures the frequency of an on- or off-chip target clock using a selectable on-chip reference clock.
	Nano Power 32 kHz Oscillator (OSC32KNP)	• One OSC32KNP - an analog interface to an external oscillator to provide a 32.768 kHz (32k) clock and includes a digital module to configure the analog interface, and monitor the 32k clock stability.
	Real Time Clock Subsystem (RTC_SS)	• Two RTC_SSs provide wakeup timers and miscellaneous functions for RTC modules
	Real Time Clock (RTC)	• Two RTCs, RTC0 (CPU0, controller) and RTC1 (CPU1, target) • low-power module that provides time keeping and calendaring functions. RTC can also be used to provide additional security measures and compensate against variations in the 32 kHz oscillator source. • Contains an independent power supply and dedicated oscillator. • Integrated wake-up timer can be used to wake the device up from low-power modes. • The RTC resides in the Always-on voltage domain. • 32 kHz real-time clock (RTC) oscillator that can optionally be used as a system clock.
Security	EdgeLock Secure (ELS)	• One ELS - a security subsystem supporting a wide range of cryptographic algorithms and provides strong key isolation from the rest of the chip.
On-chip memory	RAM Arbiter	• 7.5 MB of system SRAM accessible by the VDD2_COMP and VDD1_SENSE processing domain, DMA engines, and bus controllers
	Misc	• Additional SRAMs - uSDHC FIFOs, GPU, Display controller, MIPI PHY, and XSPI caches, PKC, M33 caches, NPU • Up to 96 KB of cache (32 KB instruction / 64 KB data) on the DSP HiFi4 interface to shared system RAM • 16 kbits OTP Fuses • Up to 256 KB ROM memory for factory-programmed drivers and APIs

Table continues on the next page...

Table continued from the previous page...

External memories and mass storage	Ultra Secured Digital Host Controller (uSDHC)	• Two SD/eMMC memory card interfaces with dedicated DMA controllers. One interface supports eMMC 5.0 with HS400/DDR operation.
	External Serial Peripheral Interface (XSPI)	• Three XSPI (octal/quad) Flash interfaces and x16 PSRAM memories: up to 400 MHz DDR/200 MHz SDR (at least 166 MHz at 1.0 V) with 32 KB cache for XSPI0 and XSPI1 interfaces. • XSPI0 and XSPI1 control 128 MB memories and XSPI2 controls 256 MB memories. See System memory map for more details. • XSPI0 and XSPI1 modules include on-the-fly encryption/decryption for execute-in-place, address-remapping to support dual-image boot, and garbage collection capabilities. DMA supported.
Images, graphics, video, and ML processing	Neural Processing Unit (NPU)	• One NPU- a Neural Network (NN) processing accelerator to accelerate NN matrix computations by deploying parallel Multiply Accumulate (MAC) blocks.
	JPEG Decoder (JPEGDEC)	• One JPEGDEC - a high-performance JPEG decoder for still image and video decompression applications.
	JPEG Decoder Wrapper (JPGDECWRP)	• One JPEGDECWRP - provides the bus interface and DMA engine for JPEGDEC.
	PNG Decoder (PNGDEC)	• One PNGDEC - decodes pictures in the PNG source format.
	Vector Graphics Processing Unit (VGPU)	• One VGPU - 2.5D VGPU provides a high-performance/area UI-based graphic core to enable hardware acceleration of the OpenVG API and display vector graphics on a variety of consumer devices, runnint at frequencies up to 325 MHz.
Display	Mobile Industry Processor Interface and Display Serial Interface Controller (MIPI_DSI_HOST)	• One MIPI_DSI provides an interface that allows communication with MIPI_DSI_HOST-compliant peripherals. • Supports transfer rates up to 895.1 Mbps with two lanes.
	LCD Interface (LCDIF)	• One LCDIF - a high-performance, low-power display processor unit (DPU), which outputs video and graphic streams from a single output panel with up to 720p display resolution.
Audio	HiFi 4 DSP Platform (HiFi4)	• Compute Domain DSP CPU - HiFi4 is an audio engine with a highly optimized audio digital signal processor (DSP), with an extended set of instructions for linear algebra, running at frequencies up to 325 MHz. • Up to 128 KB of DSP HiFi4 local TCM RAM (64 KB instruction / 64 KB data). These RAMs can be accessed by the M33 or the DMA engines via the inbound PIF port.

Table continues on the next page...

Table continued from the previous page...

	HiFi 1 DSP Platform (HiFi1)	• Sense Domain DSP CPU - HiFi1 is low-power audio DSP, running at frequencies up to 250 MHz.
	EZH-V with DSP extensions	• EZH-V Event / Algorithm Handler with 32 KB EZH code RAM and 64-bit I/D TCM.
	Sigma Delta Analog-to-Digital Converter (SDADC)	• One SDADC- a low-power high-performance audio ADC module that supports analog microphones, line inputs, and enables acoustic noise and echo cancellation.
	PDM Microphone Interface (MICFIL)	• One MICFIL - delivers audio from microphones to the processor in several applications • Supports up to 8 channels with associated decimators and Voice Activation Detect. One pair of channels can be streamed directly to SAI. • Supports DMA.
	Synchronous Audio Interface (SAI)	• Four SAIs - provide interfaces that support full-duplex serial digital audio interfaces with frame synchronization formats such as I2S, AC97, TDM, and Codec/DSP interfaces.
Connectivity	Universal Serial Bus Controller (USB)	• One high speed USB (USB0) — provides high-performance USB functionality that conforms to Universal Serial Bus Specification, Rev. 2.0. — USB high-speed host/device controller with on-chip PHY and dedicated DMA controller • One high speed eUSB (USB1) — provides high-performance USB functionality that conforms to Universal Serial Bus Specification, Rev. 2.0 and Embedded Universal Serial Bus 2.0 (eUSB) electrical specification. — eUSB high-speed host/device controller with dedicated DMA controller and on-chip PHY supports both native and repeater modes
	Universal Serial Bus 2.0 PHY (USBPHY)	• One USBPHY - interfaces with the USB host and device system at a low-speed (LS) rate of 1.5 Mbit/s, full-speed (FS) rate of 12 Mbit/s, or USB 2.0 highspeed (HS) rate of 480 Mbit/s.
	USB Device Charger Detection Module (USBDCD)	• One USBDCD - works with the USB transceiver to detect whether the USB device is attached to a charging port, either a Dedicated Charging Port (DCP) or a Charging Downstream Port (CDP).
Low-speed Communications	Flexible I/O (FLEXIO)	• One FLEXIO - emulates of a variety of serial/parallel communication protocols. • Flexible 16-bit timers with support for a variety of trigger, reset, enable, and disable conditions. • Can be configured to provide a parallel interface to an LCD

Table continues on the next page...

Table continued from the previous page...

	Low-Power Flexible Communications Interface (LP_FLEXCOMM)	• Eighteen configurable Universal Serial Interface LP_FLEXCOMM modules. LP_FLEXCOMM 0-13 are used for the VDD2_COMP domain, and LP_FLEXCOMM 17-20 are for the VDD1_SENSE domain. Each module contains an integrated FIFO and has DMA support. Each of the eighteen modules can be configured as: — Low-Power Universal Asynchronous Receive/Transmit (LPUART) with asynchronous transmit and receive. — Low-Power Serial Peripheral Interface (LPSPI) controller or responder, with up to four peripheral chip selects. — Low-Power Inter-Integrated Circuit (LPI2C) with separate controller and responder functions. • Two additional high-speed LPSPI interfaces supporting 50 MHz operation (LP_FLEXCOMM 14 and 16) • One additional LPI2C interface with pseudo open-drain pads (LP_FLEXCOMM15) for PMIC application and used as controller only.
	Improved Inter-Integrated Circuit (I3C)	• Four I3C bus interfaces, that act as an extension of the I2C bus protocol supporting higher speeds.
Timers	Micro-Tick Timer (UTICK)	• Two UTICKs (one for Compute domain and one for Sense domain) - 31-bit timers that each provides a fixed time interval between interrupts. • Ultra-low power micro-tick timer running from the watchdog oscillator, with capture capability for timestamping. • UTICK can be used to wake up the chip from Sleep mode and Deep Sleep mode.
	Standard Counter/ Timers (CTIMER)	• Eight (5 in the Compute domain and 3 in the Sense domain) standard 32-bit Counter/Timers modules with PWM capability
	OS Event Timer (OSTIMER)	• One 64-bit OSTIMER interfaces to CPU0, CPU1, HiFi1 and HiFi4 with individual match/capture and interrupt generation logic.
	SCTimer (SCT)	• One 32-bit SCT- multi-purpose timer with extensive event-generation, match/compare, and complex PWM and output control features with minimal or no CPU intervention. — 10 general-purpose/PWM outputs, 8 general-purpose inputs — Supports DMA and can trigger external DMA events — Supports fractional match values for high resolution
	Multi-Rate Timer (MRT)	• Two (one for Compute Domain and one for Sense Domain) 24-bit multi-rate timer modules with 4 channels each capable of generating repetitive interrupts at different, programmable frequencies.
	Windowed Watchdog Timer (WWDT)	• Four WWDTs, each with a dedicated watchdog oscillator (1 MHz LPOSC), which help reset or interrupt an erroneous microcontroller within a programmable time.

Table continues on the next page...

Table continued from the previous page...

Analog	Analog-to-Digital Converter (ADC)	• One ADC - a low-power 16-bit successive approximation ADC with sampling rates up to 35k samples per second with an enhanced ADC controller • Supports up to 14 single-ended channels or 7 differential channels • DMA supported.
	Comparator (ACMP)	• One ACMP - provides a circuit for comparing two analog input voltages.
Interconnects, crossbars and DMA	Input Multiplexing (INPUTMUX)	• Two INPUTMUXes - provide signal routing for internal peripherals.
	Enhanced Direct Memory Access (eDMA)	• Four eDMAs, each with a general purpose DMA engine, capable of performing complex data transfers with minimal intervention from a host controller. — eDMA can be configured such that one pair is secure and the other non-secure. — eDMA can also be configured as one-pair dedicated for the control CPUs and the other for the DSPs.
	Crossbar Switch Lite (AXBS_Lite)	• AXBS_Lite connects bus controllers and bus targets using a crossbar switch structure.
	Peripheral Bridge (AIPS_Lite)	• AIPS_Lite converts the crossbar switch interface to an interface that can access most of the target peripherals on this chip.
	Peripheral Bridge (PBRIDGE2)	• PBRIDGE2 converts an AMBA AHB interface to a peripheral interface.

2.3 Architecture overview

The RT700 is architected for sustained low power operation while supporting advanced peripherals and secure applications. The chip is a general purpose MCU, but is well-suited for IoT and wearable applications. It has five independent chip domains (Compute, Sense, Common, DSP, Media), two of which serve as the primary processing domains – the Compute and Sense Domains.

The Compute and Sense Domains each have a Cortex-M33 processor, co-located with a DSP, and an extensive set of peripherals, which include a Machine Learning module (NPU), a Graphics module (VGPU), and an advanced security subsystem (ELS). Each domain also has access to various global SoC resources, including shared system RAM, analog modules, and GPIO.

NOTE

For power architecture information, refer to the Power Overview chapter.

2.3.1 Processing Domains

2.3.1.1 Sense Domain

The Sense Domain implements a light-version of the Cortex M33 complex and a HiFi1 DSP. The primary feature of the Sense Domain is its ability to support primary MCU functions while maintaining low-energy consumption. This functional chip domain is essentially part of the Always-on (AON) power domain. With all other domains powered off, the Sense Domain can be configured to identify keywords, and upon a positive classification, wakeup other domains to carry out the remainder of the power heavy application processes.

2.3.1.2 Compute Domain

The Compute Domain implements a full-featured Cortex M33 complex and a HiFi4 DSP. The DSP can run at a different frequency from the M33 and the other modules in the domain, similar to the M33 and DSP in the Sense Domain. Each of the two domains can be independently powered-off allowing this chip to operate under minimum power consumption when the Compute Domain is not in use.

The Compute Domain features a split bus architecture to minimize power consumption. The bus is split into a memory bus (M-Bus) and a periphery bus (P-Bus) to keep toggling activity minimized to only required memory accesses.

Another architectural feature introduced in the Compute Domain is the integration of a cache controller associated to the M33. This provides a quasi single-cycle access to the shared SRAM, and helps eliminate power consumption dependence on the physical position of the SRAM. The SRAM is divided into individual partitions, which can independently be placed in low-power retention mode or powered off entirely. The chosen SRAM instances are also configured to minimize active power consumption, while maintaining low leakage in Deep Sleep Mode.

2.3.2 Processors

2.3.2.1 Cortex M33 CPU in the Compute Domain – CPU0

CPU0 serves as the main control CPU for this chip. CPU0 is responsible for conducting the booting process and interfacing with external memories including XSPI flash, USB, SPI, I2C, UART and eMMC. Boot source selection will be specified via OTP. Following boot-up and part initialization, CPU0 can be placed into sleep mode under software control. For more information on CPUs, refer to the Cortex-M33 platform overview.

2.3.2.2 Cortex M33 CPU in the Sense Domain – CPU1

CPU1 resides in the Sense Domain. This CPU has access to all peripherals in the Sense Domain and the shared region. System-level resources are configured and managed by the M33 in the Compute Domain (CPU0) . For more information on the CPUs, refer to the Cortex-M33 platform overview.

2.3.2.3 HiFi4 and HiFi1 DSP

The HiFi4 DSP is adjacent from the Compute Domain and serves as the DSP core for execution of audio voice codecs, pre- and post-processing modules, and offloading machine learning functions for accelerated processing. The HiFi1 DSP resides in the Sense Domain and is primarily intended for Always-on applications, Bluetooth LE audio, and Sensor HiFi1.

These DSP cores can access many of the on-chip peripherals including the audio modules, LP_FLEXCOMM, I3C, and an assortment of timers and other general system resources. The HiFi4 also has access to the 24-bit SDADC (mic input) in the Common Domain.

The audio modules include interfaces for 8 mic inputs (MICFIL - four channel-pairs) with decimators, filters, and hardware voice-activation detect (one channel). When voice is detected, an interrupt can wakeup the DSP CPU for voice/pattern matching.

2.3.2.4 EZH-V

The EZH-V is primarily implemented to provide a “smart DMA” engine for post-processing graphics data assembled by either or both the GPU and CPU, and then passing it to the FLEXIO for output. Processing operations may include data packing and endianness adjustment. The EZH-V is available for any other general-purpose handling that may be required and supports an extensive selection of trigger inputs from GPIOs and most on-chip peripherals.

2.3.3 Peripherals

This section covers several of the key peripherals on the chip, which complement the general peripherals and system control modules.

2.3.3.1 SDADC - Sigma Delta Analog-to-Digital Converter

This ADC is a high dynamic range audio ADC that supports both line input and microphone input. It provides low latency decimation to enable Acoustic Noise Cancellation and Acoustic Echo Cancellation. It has a high input impedance to reduce its loading to input sources and to improve its robustness to interference. The DAC inside ADC can be used as a standalone DAC to provide a low-impedance voltage output.

This intended use of the sigma delta converter is in systems using wide dynamic range analog mems microphones. These systems ranges from hearable devices, wearable devices, to battery operated devices for always-on listening. The battery powered devices have a broad application from remote controls to security devices. Since primary use for these converters is battery powered devices power consumption is an important spec.

The reason for implementing an SDADC on the chip include:

- Analog mic has a smaller footprint.
- Analog mic has better SNR than the digital mic alternative (dependent on sigma delta implementation)
- Analog mic is lower in power than the digital mic alternative (dependent on sigma delta implementation)

2.3.3.2 LP_FLEXCOMM – Low-power SPI, I2C, UART

Each LP_FLEXCOMM, except for the three dedicated LP_FLEXCOMMs, may be configured by the user either as a LPUART, LPSPI, or LPI2C module.

Two dedicated LPSPI LP_FLEXCOMM instances are provided. These standalone high-speed SPIs provide 50 MHz transfer rates. The pins associated with each of these modules are fixed on one set of specific GPIOs. (accessible by both CPUs and DSPs, and DMA controllers. DMA requests may be MUXed with other functions)

One dedicated LPI2C LP_FLEXCOMM instance is provided to communicate with the PMIC. This LPI2C uses pseudo open-drain pads and does not support DMA.

2.3.3.3 XSPI – serial memory controller

This chip includes three XSPI serial memory controllers. These controllers support serial flash and serial RAM memory devices. The interface is up to x16 depending on the XSPI instance being used. See XSPI instances features for more details about the three XSPI instances.

XSPI0 is primarily intended for code execution and boot from an off-chip SPI NOR flash memory. It supports execute-in-place (XIP) and on-the-fly (OTF) decryption using the Inline PRINCE encryption and decryption (IPED) sub-module integrated as part of the XSPIs. Because XSPI0 is intended for code execution it supports IPED CTR and GCM modes.

XSPI1 can be used for either as a boot source (connected to an off-chip SPI NOR flash memory) or as RAM expansion (connected to an off-chip pSRAM/HyperRAM device). XSPI1 supports execute-in-place (XIP) and on-the-fly (OTF) decryption using the Inline PRINCE encryption and decryption (IPED) sub-module integrated as part of the XSPIs. Because XSPI1 can be used for code or data, its IPED supports IPED CTR, GCM, and XEX modes.

XSPI2 is intended for RAM expansion (connected to an off-chip pSRAM/HyperRAM device). In particular, XSPI2 can be used for storing graphics and data used by the MEDIA domain.

Each of the XSPI instances is also integrated with an MMU. The MMU can be used for remapping memory ranges. For the XSPI boot instances (XSPI0 and XSPI1), the ROM uses the MMU module to support dual-image boot.

Figure 6 shows the initiators that access the external memory via each XSPI instance, see System memory map for more details about the initiators. As shown in the diagram, XSPI0 and XSPI1 are both interfaced to a CACHE64_CTRL; however, only the M-Bus initiator access path goes through the caches. All bus initiator accesses route through the MMUs. Only one initiator can access an XSPI instance at a time. For XSPI0 and XSPI1, you can configure the priority for arbitration between the three main ports to the XSPIs using SYSCON0.AXBS_CTRL.

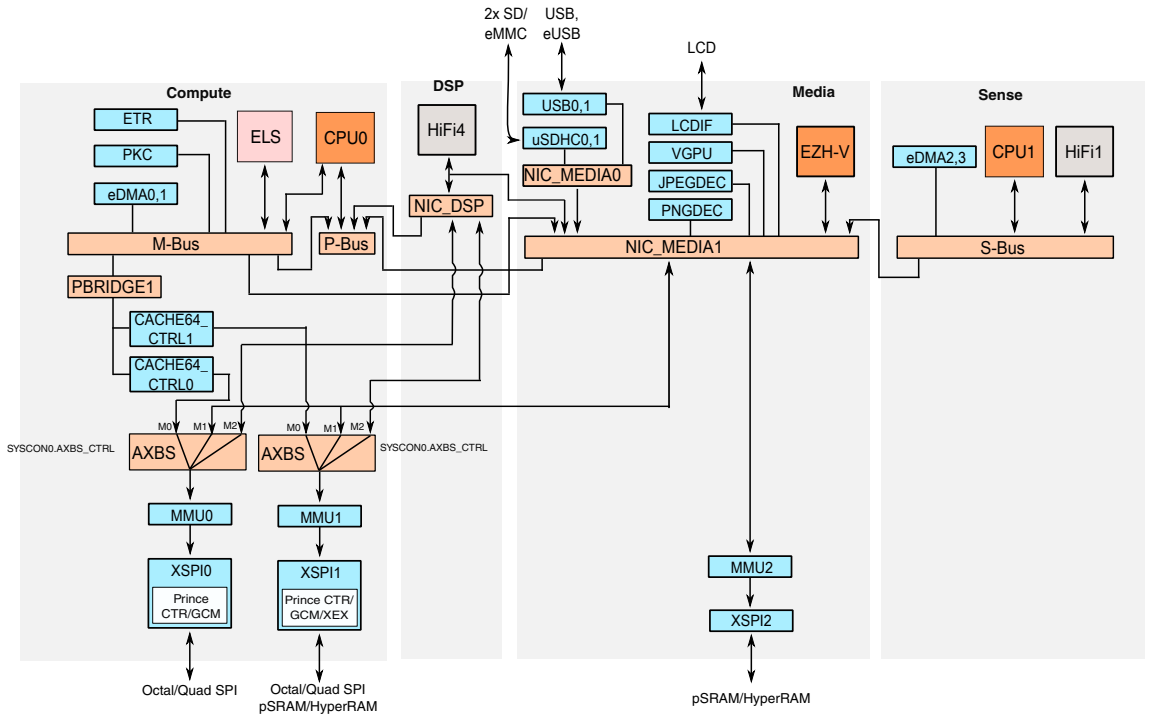

Figure 6. External memory initiators

2.3.3.4 eUSB Host/Device with on-chip PHY

eUSB (USB1) is introduced to address the following:

- IO power efficiency: Improve link power efficiency (active and idle)
- Process scalability: Provide a low voltage USB2.0 PHY solution
- Implementation simplicity: The PHY analog content is reduced. Digital mechanisms are employed for PHY functionality, for example, device disconnect detect.
- Support both USB2.0 inter-chip and out-of-the-box devices: Although eUSB and USB2.0 are not electrically compatible, a mechanism is defined for eUSB to support standard USB2.0 devices

2.3.4 Display interface

This chip has a pad segment devoted to driving a memory in pixel display. As a typical application, the display uses 2-bit color for a total of 6 data lines and has horizontal sync, vertical sync and clock signals. In addition, the chip can provide the panel back plane signals that are driven from the 32 kHz RTC clock.

2.3.5 System control modules

The chip implements local clock, reset, and power control across the main power domains. System control modules are instantiated in the VDD2_MEDIA, VDD2_COM, VDDN_COM, and twice in the VDD1_SENSE power domains. Refer to the related Clock overview, Power overview, PMC, RSTCTL, CLKCTL, SYSCON, SLEEPCON and IOPCTL chapters for more information.

2.3.5.1 RSTCTL – Reset Controller

The RSTCTL module is instantiated in the Common, Sense (main, private), Media, and VDDN domains. The module configures the local resets for associated peripherals in the domain. The details of supported domain resets, reset handling, and reset sources are detailed in the RSTCTL chapter.

2.3.5.2 CLKCTL – Clock Controller

The CLKCTL module is instantiated in the Common, Sense (main, private), Media, and VDDN domains. This module controls the source selection and clock generation of system and peripheral clocks. This module also captures the peripheral clock gate assignments across the chip. For more information about clock generation and peripheral clock gating, refer to the CLKCTL chapter.

2.3.5.3 SYSCON – System Controller

This module configures system resources to critical peripherals. The SYSCON controls bus accesses, NMI source selection, debug access to processors, clock gating to memory and peripherals, controls security features, temperature detect, GPIO config, and supports a gray-to-binary converter. Refer to SYSCON chapter for more information.

2.3.5.4 SLEEPCON – Sleep Controller

The SLEEPCON configures the low-power control for the chip. This module is instantiated with the PMC and CLKCTL instances in the VDD2_COM and VDD1_SENSE power domains. The module works in conjunction with the CLKCTL and PMC to coordinate power mode transitions, and enables wakeup interrupts. Refer to the SLEEPCON chapter for more information.

2.3.6 Bus architecture

The chip is categorized by voltage domains and functional domains. Some functional domains straddle multiple voltage domains, but are functionally grouped by the bus fabric within the domain. The bus fabric includes bus controllers, crossbars, and peripheral bridges, which connect sets of associated peripherals on the chip. Arbitration and priority for some of the bus components is managed by SYSCON or directly by the NIC.

NOTE

NIC_DSP and NIC_MEDIA0 have static configurations. Only NIC_MEDIA1 is configurable. See the NIC chapter for more information.

NOTE

SYSCON module controls several functions relating to the bus fabrics and crossbars, including priority. See SYSCON for more information.

The diagram below illustrates the initiators (cores), bus fabric (NICs and buses), and target (peripheral and internal SRAM) connections.

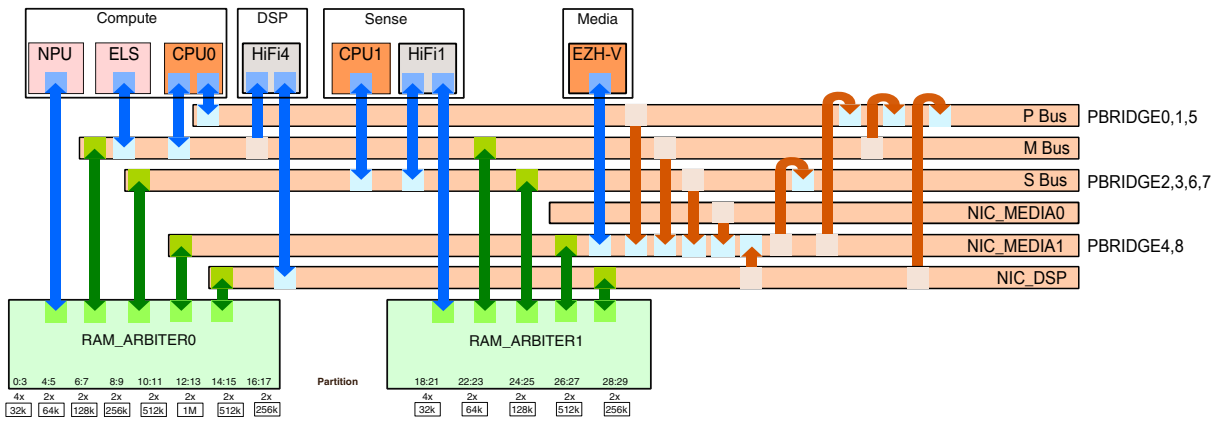

Figure 7. Chip bus topology diagram

NOTE

Initiator access to target peripherals are noted in the memory map. See the memory map for detailed peripheral access information.

2.3.6.1 RAM arbiters

The chip uses RAM arbiters to interface to the internal SRAM through the various buses on the chip. The RAM arbiters and SRAM reside in the Compute and Sense domains, which can operate in separate voltage domains. The Compute and Sense domains have access to each other's memory. RAM_ARBITERn consists of dedicated arbiters for each RAM partition. Table 4 and Table 5 show the ports on each bus and NIC via which initiators can access the RAM arbiters and SRAM partitions. A port on buses or NICs may connect to one or more memory partitions, but it can access one partition at a time.

NOTE

Ensure a shared memory partition is accessed by only one initiator at a time for better performance. The chip supports to access one memory partition by several initiators, but if several initiators access the a memory partition at the same time, it will reduce the performance because of latency.

The figure and tables below cover the initiators to the RAM arbiters.

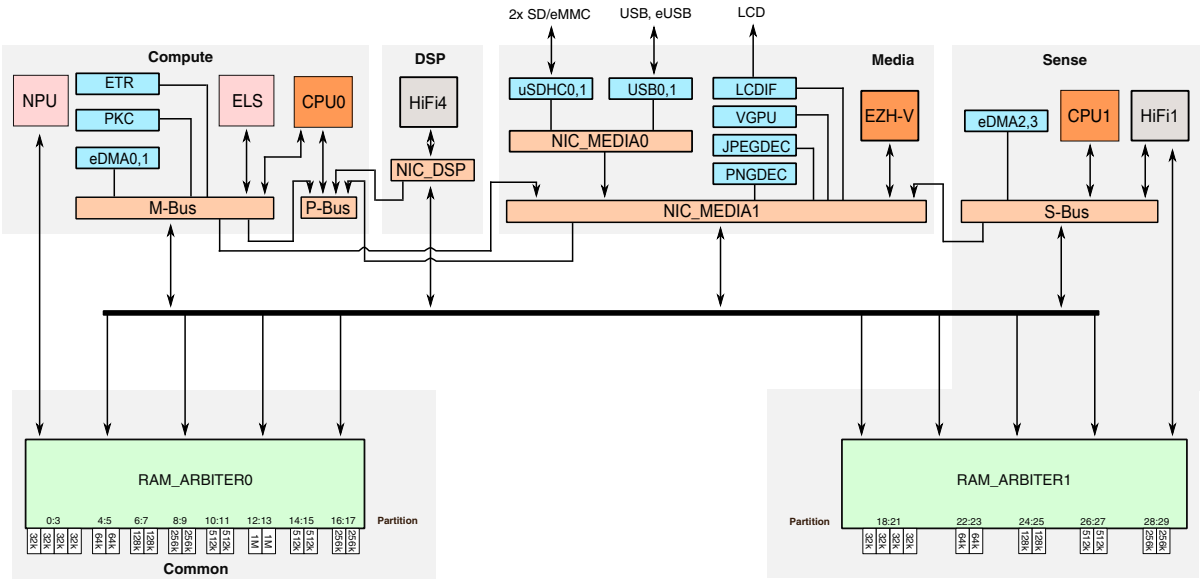

Figure 8. RAM arbiter initiators

Table 4. RAM_ARBITER0 shared SRAM partitions

Shared SRAM partition	Start address	End address	Initiator via ports on				
			NIC_MEDIA1 [1]	M-Bus	S-Bus	NIC_DSP	NPU

P29	2074_0000	2077_FFFF					

1. See Interconnection for initiators connect to each AMIB port.

Table 6 provides baseline cycle counts for bus initiators to access RAM partitions based on the primary bus fabric that initiator uses. For example, CPU0 uses the M-Bus and can access RAM_ARBITER0 partitions in two clock cycles, but takes thirteen clock cycles to access RAM_ARBITER1 partitions. Memories are endpoints and take the clock of the bus trying to connect to it. Therefore, the cycle counts in Table 6 are based on the bus clock for the initiator. The cycle counts provided here are the minimum number of cycles to access the RAM. The actual cycle count will depend on RAM activity (how often the RAM is accessed and if it is accessed by multiple initiators), RAM clocking, and bus arbitration.

In general, there is no synchronization required to connect to memories using this arbitration scheme. However, if the partition was last accessed by an initiator using a different clock, then it takes two clock cycles to switch to the new initiator clock. The RAMs also support auto clock gating that turns off the clock to each partition if that partition is not accessed for a period. If the clock to a partition is off at the time an access starts, it takes 10 clock cycles to wake up the memory. This feature can be turned off, but memories will consume more power. See RAM Arbiter and shared memory power considerations for more details on low power features.

Table 6. Initiators access SRAM partition cycles via buses and NICs

Shared SRAM partition	M-Bus (cycles)	NIC_MEDIA 1 (cycles)	S-Bus (cycles)	NIC_DSP (cycles)	HiFi1 TCM (cycles)	NPU (cycles)
0-17	2	2	13	2	NA	2
18-29	13	13	1	13	1	NA

2.3.6.2 Compute domain

The Compute domain contains the main Cortex-M33 (CPU0) complex, HiFi4 DSP core, NPU core, and a diverse set of peripherals. One of the new architectural features is cache support for CPU0. In this scheme, shared SRAM is cached, but the peripheral set is directly accessed by CPU0. There are separate cache controllers for CPU0's code and system buses. The Compute domain has a split bus architecture, an M-Bus Matrix that primarily connects core Initiator to (shared) memory, and a P-Bus Matrix that interfaces to peripherals. The M-Bus and P-Bus are connected together through a Target port on the M-Bus to an Initiator port on the P-Bus.

This connection allows core Initiators other than CPU0 and HiFi4 to have memory and periphery access. This choice of architecture mitigates toggling activity as it separates memory access from peripheral access for the sake of low power consumption. The HiFi4 has a private cache controller, independent of CPU0's access the shared memory. The chip's security subsystem is also located in the Compute domain. This system is the ELS security subsystem. It is makes use of the hardware accelerator PKC.

2.3.6.3 Sense domain

The Sense domain has its own bus, S-Bus, which connects the other Cortex-M33 core (CPU1), a HiFi1 DSP, and two DMA controllers as core Initiators. The domain has shared SRAM (P18-P29). It also offers a simple set of peripherals, and a Messaging Unit (MU) with Semaphore (SEMA42) for local CPU1 – HiFi1 intercommunication.

The CPU1 of the Sense domain can access SRAM for code and data via S-Bus. The HiFi1 DSP does not have a private cache memory, instead its dual memory TCM bus interfaces are connected to shared memory.

The RTC0/1, LPI2C15, MICFIL, ACMP0 and ADC0 in Sense domain are shared modules which can be controlled by both CPU0 and CPU1. The rest of the modules in this Sense domain are private modules which are controlled by CPU1 only.

2.3.6.4 Common domain

The common domain holds modules related to system control, clock generation, reset control, pin characteristic control, and internal power regulators, as well as the shared SRAM (P0-P17, see System memory map) and peripherals such as the memory interface of XSPI0-2.

2.3.6.5 Media domain

The purpose of the Media domain is to hold peripherals that require high-performance. The Media domain includes a NIC interface (NIC_MEDIA0, NIC_MEDIA1 controllers), the uSDHC (NAND) controllers, the USB (USB0) and eUSB (USB1) IPs, and the graphics subsystem integrated by the JPEG decoder, PNG decoder, VGPU, LCDIF, DSI host interface, as well as a MIPI PHY.

The use cases with graphics involve access to external memory via XSPI2, with the corresponding memory map unit (MMU2) within the domain. The Media domain includes high-speed SPIs, and the smart DMA EZH-V. The Media domain has cross links to the Compute and Sense domains, and direct access to the shared memory.

2.3.6.6 Inter-domain communications

2.3.6.6.1 Messaging unit

The Messaging Unit (MU) is a shared peripheral with a separate IP bus interface and interrupt request for each host processor. The MU exposes a set of registers to each processor which facilitate inter-processor communication. The MU module enables two processors within the chip to communicate and coordinate by passing messages (e.g. data, status and control) through the MU interface. The MU also provides the ability for one processor to signal the other processor using interrupts. The MU ports are assigned by such rule as: MUA is always used for the Compute domain and MUB for Sense domain, and then within a domain MUA is assigned to the CPU core and the MUB is assigned to the DSP core.

2.3.6.6.2 Semaphore

The Hardware Semaphore module provides the hardware support needed in multi-core systems for implementing semaphores and provides a simple mechanism to achieve "lock/unlock" operations via a single write access.

2.3.7 Reference manual organization

The arrangement of the Reference Manual is based on the functional domains of the chip. See the specific functional overview chapters for more information covering the related peripherals and system related information.

2.4 Applications

This chip supports a broad-array of defined use cases and numerous general use applications. Below is a list of common applications and segments the chip supports, based on a full-featured part.

Table 7. Supported applications

Segment	Applications
Display and graphics	• Battery powered devices • Multiple display options (including OLED 24-bit color) • Augmented reality glasses
Audio	• Line in, analog and digital microphones • Battery powered Always-on listening
Machine learning (ML)	• Voice activation detection (VAD) • Keyword spotting gesture recognition
Wearable	• On-wrist devices • Fitness trackers
Hearable	• On-ear devices • Over-the-ear devices • Head mounted devices
Battery powered devices	• Remote control devices • Security devices toys

Chapter 3
Memory Map Overview

3.1 Introduction

This section introduces the memory architecture of the chip.

NOTE

Accessing the reserved memory regions can result in unpredictable behavior.

3.2 System memory map

The system memory map represents the system memory view for all processors. The memory slots in the table represent the non-secure address region.

NOTE

See i.MX RT700 Security Reference Manual for secure address region.

Table 8. System memory map

Start address	End address	Size	Allocation	Cached	Access[1]
0000_0000	0000_7FFF	32 KB	SRAM P0 alias	CPU0 code	CPU0

E004_0000	E00F_FFFF	768 KB	PPB_EXT	No	CPU0, CPU1

1. Media domain controllers include uSDHC0, uSDHC1, USB0, USB1, LCDIF, MIPI_DSI_HOST, JPEGDEC, PNGDEC, VGPU.
2. Ensure only one initiator accesses the Shared RAM partition at a time for better performance.

3.3 Peripheral memory map

The peripheral memory map represents the peripheral slot assignments and the access rights for all processors. The memory slots in the table represent the non-secure address region.

NOTE

See i.MX RT700 Security Reference Manual for secure address region and secure peripheral slot assignments and the access rights for all processors.

Table 9. Peripheral memory map

Start address	End address	Size (KB)	Allocation	Processor access to resource				
				CPU0[1]	HiFi4	CPU1[2]	HiFi1	EZH-V

1. Peripherals that can be accessed by CPU0 can also be accessed by eDMA0 and eDMA1.
2. Peripherals that can be accessed by CPU1 can also be accessed by eDMA2 and eDMA3.

Chapter 4
Interrupt and DMA Events Assignments

4.1 Overview

This chapter provides information on the assignments of the interrupts and DMA.

4.2 System interrupts

The Nested Vectored Interrupt Controller (NVIC) collects interrupt request sources and provides an interface to the Cortex-M cores (CPU0 and CPU1) and DSP cores (HiFi1 and HiFi4).

NOTE

The NVIC IRQ assignments on secure modules are not described here, see i.MX RT700 Security Reference Manual for details.

Table 10. CPU0 NVIC IRQ assignments

Vector offset address	IRQ	Module	Description
0x0000_0040	0	-	Reserved
0x0000_0044	1	UTICK0	UTICK0 interrupt
0x0000_0048	2	MRT0	MRT0 ored interrupt (repeat interrupt, shot interrupt or shot bus stall interrupt)
0x0000_004C	3	CTIMER0	CTIMER0 interrupt
0x0000_0050	4	CTIMER1	CTIMER1 interrupt
0x0000_0054	5	SCT0	SCT0 interrupt
0x0000_0058	6	CTIMER3	CTIMER3 interrupt
0x0000_005C	7	LP_FLEXCOMM0	LP_FLEXCOMM0 interrupt
0x0000_0060	8	LP_FLEXCOMM1	LP_FLEXCOMM1 interrupt
0x0000_0064	9	LP_FLEXCOMM2	LP_FLEXCOMM2 interrupt
0x0000_0068	10	LP_FLEXCOMM3	LP_FLEXCOMM3 interrupt
0x0000_006C	11	LP_FLEXCOMM4	LP_FLEXCOMM4 interrupt
0x0000_0070	12	LP_FLEXCOMM5	LP_FLEXCOMM5 interrupt
0x0000_0074	13	LPSPI14	LPSPI14 interrupt
0x0000_0078	14	LPI2C15	LPI2C15 interrupt
0x0000_007C	15	ADC0	ADC0 interrupt
0x0000_0080	16	SDADC	SDADC interrupt
0x0000_0084	17	ACMP0	ACMP0 interrupt
0x0000_0088	18	MICFIL	MICFIL interrupt for read data or error
0x0000_008C	19	MICFIL	MICFIL hardware voice activity detector interrupt or error interrupt

4.3 DMA assignments

NOTE

The eDMA slot assignments on secure modules are not described here, see i.MX RT700 Security Reference Manual for details.

The tables below show the DMA request signals for the peripherals in the chip:

NOTE

All DMA requests are disabled by default. You need to enable the DMA requests of eDMA0 and eDMA1 to see them by SYSCON0.EDMA0_EN0-SYSCON0.EDMA0_EN3 and SYSCON0.EDMA1_EN0-SYSCON0.EDMA1_EN3 registers.

Table 14. eDMA0 and eDMA1 slot assignments

eDMA0/eDMA1 slots	Module	Descriptions
0	-	Reserved
1	MICFIL	MICFIL DMA request for out data read
2	XSPI0	XSPI0 RX FIFO drain DMA request

Table continues on the next page...

Table 14. eDMA0 and eDMA1 slot assignments (continued)

eDMA0/eDMA1 slots	Module	Descriptions
3	XSPI0	XSPI0 TX FIFO fill DMA request
4	XSPI1	XSPI1 RX FIFO drain DMA request
5	XSPI1	XSPI1 TX FIFO fill DMA request
6	XSPI2	XSPI2 RX FIFO drain DMA request
7	XSPI2	XSPI2 TX FIFO fill DMA request

52	LPI2C15	LPI2C15 transmit request

Chapter 5
Fusemap

5.1 Overview

This chapter details the various fuses and their associated configuration settings. This chapter also describes various modes and the selection of the required boot devices.

NOTE

The fuses marked as “Reserved” are reserved for NXP internal (and future) use only, or are security related. Customers must not attempt to burn these, because the IC behavior may be unpredictable. The reserved fuses can be read as either '0' or '1'. Security-related fuses are described in the Security Reference Manual (SRM) for this device.

5.1.1 Lock bits

There are two kinds of lock bits, write lock and read lock.

The write lock bits are used by the controller to control writing/programming of the fuse bits and the shadow registers (which hold the value read from the fuses). Each word can be write locked independently, which means that it can no longer be programmed. If the word is write locked, only read is permitted and the overwriting of the shadow registers is not permitted. If the word is not locked, then it can be read sensed and programmed and the shadow registers can be overwritten (to allow emulation of programming without actually blowing fuses). The supplemental array of fuses are always override locked.

Read lock bits are a specific set of fuses that give you the ability to block bus access to specific words. Read locks are on parts of the array consisting of multiple words. The bits for these are stored in the supplementary array section in the last word.

See Lock Fuses tab in attached i.MXRT700_Fusemap.xlsx spreadsheet for details about lock fuses.

5.2 Boot fusemap

This section describes the various modes and the selection of the required boot devices. A separate map is given for each and every boot device. The device select is specified by the BOOT_CFG0[1:0] fuses.

Table 16. Boot device select

Boot Device	BOOT_CFG0[1]	BOOT_CFG0[0]
Boot pins determine the source	0	0
XSPI flash	0	1
uSDHC flash	1	0
Serial boot (ISP)	1	1

NOTE

The fuses marked as “Reserved” are reserved for NXP internal (and future) use only. Customers **must not** attempt to burn these, because the IC behavior may be unpredictable. The reserved fuses can be read as either '0' or '1'. Security-related fuses are described in the Security Reference Manual (SRM) for this device.

The Fuse Word Index and Fuse Bit Index mapping for the BOOT_CFGn fuses is provided in the following table.

See "Boot Fusemap" tab in i.MXRT700_Fusemap.xlsx for details about boot fusemap.

5.3 Fusemap descriptions table

This section provides the chip fusemap descriptions.

The following two mechanism are used by the fuse block to ensure that its values are correct:

- Redundancy (RED) mode: In this case only 16 of the 32 bits are available (bits 15:0 are automatically copied to bits 31:16) and checked on read. Each pair of bits can be programmed at different times. This allows for multiple programming operations on a word, so bits can be configured at different times.
- ECC mode: The ECC is generated for the whole word. The whole word must be setup at one time and individual bits cannot be modified independently.

See "Fusemap descriptions" in i.MXRT700_Fusemap.xlsx spreadsheet for details.

5.4 Shadow register reload

All fuse words in fusemap are shadowed. Once an OTP fuse word is programmed, the value will be loaded into corresponding OTP shadow register of OCOTP after either:

- power-on reset in all life cycle states
- or warm reset when the life cycle is in-field state or after.

See Shadow Register Reload for more details.

Chapter 6
External Signals and Pin Multiplexing

6.1 Introduction

Pins have several functions available via signal multiplexing to optimize functionality in small packages. This chapter illustrates which chip's signals are multiplexed on which external pin.

NOTE

Not all the pins are available for each package. You need to configure the module functions according to the package pin availability.

6.2 Muxing options

6.2.1 Muxing options (324FOWLP)

The pinmux selection is done through the FSEL field of the IOPCTL instance associated to the corresponding PIO pad. Alternate pin functions are selected through the AMENA field for analog inputs or through the corresponding boot mode selection detailed in the Boot chapter.

Table 17. Muxing options (324FOWLP)

Module	External signal	Pad	FSEL assignment
ACMP0	CMP0_INA	PIO10_8	Alternate pin function
	CMP0_INB	PIO10_9	Alternate pin function
	CMP0_INC, SDADC_INP3	PIO10_16	Alternate pin function
	CMP0_IND, SDADC_INN3	PIO10_17	Alternate pin function
	CMP0_OUT	PIO10_5	Function 3
	CMP0_OUT	PIO8_6	Function 4
	CMP0_OUT	PIO8_19	Function 4
ADC0	ADC0_A0	PIO10_0	Alternate pin function
	ADC0_A1	PIO10_2	Alternate pin function
	ADC0_A2	PIO10_4	Alternate pin function
	ADC0_A4, SDADC_INP1	PIO10_12	Alternate pin function
	ADC0_A5, SDADC_INP2	PIO10_14	Alternate pin function
	ADC0_B0	PIO10_1	Alternate pin function
	ADC0_B1	PIO10_3	Alternate pin function
	ADC0_B2	PIO10_5	Alternate pin function
	ADC0_B4, SDADC_INN1	PIO10_13	Alternate pin function
	ADC0_B5, SDADC_INN2	PIO10_15	Alternate pin function
BOOT	ISP boot select 0	PIO1_7	Alternate pin function

Table continues on the next page...

Table 17. Muxing options (324FOWLP) (continued)

Module	External signal	Pad	FSEL assignment
	00b - SDHC0 (eMMC or SD set in OTP) 01b - XSPI0 10b – Auto ISP (UART, SPI, I2C, USB-HID, eUSB) 11b - XSPI1		
	ISP boot select 1 00b - SDHC0 (eMMC or SD set in OTP) 01b - XSPI0 10b – Auto ISP (UART, SPI, I2C, USB-HID, eUSB) 11b - XSPI1	PIO1_8	Alternate pin function

1. The MCLK indirectly connects SAI via CLKCTL, see CLKCTL for more details.

6.2.2 Muxing options (256WLCSP)

The pinmux selection is done through the FSEL field of the IOPCTL instance associated to the corresponding PIO pad. Alternate pin functions are selected through the AMENA field for analog inputs or through the corresponding boot mode selection detailed in the Boot chapter.

Table 18. Muxing Options (256WLCSP)

Module	External signal	Pad	FSEL assignment
ACMP0	CMP0_INA	PIO10_8	Alternate pin function

Chapter 7
Cortex-M33 Platform Overview

7.1 Overview

There are two CM33 cores modules in this chip. CPU0 is the control processor in the Compute domain. CPU1 is the control processor in the Sense domain.

Each Cortex-M33 implements a modified Harvard memory architecture using two 32-bit bus interfaces: the code and system buses. The bus interfaces are activated by address range and can include both instruction fetches and operand data references on a given bus port. The code bus is typically used for instruction fetching and data accesses of PC-relative data, while the system bus is typically used for operand data references to the on- and off-chip memories and peripheral accesses. The bus structure fully supports concurrent instruction fetch and data accesses, but the Cortex-M33 implementations can generate both types of references on each bus.

7.1.1 CPU0 and CPU1 block diagrams

Block diagrams are shown below:

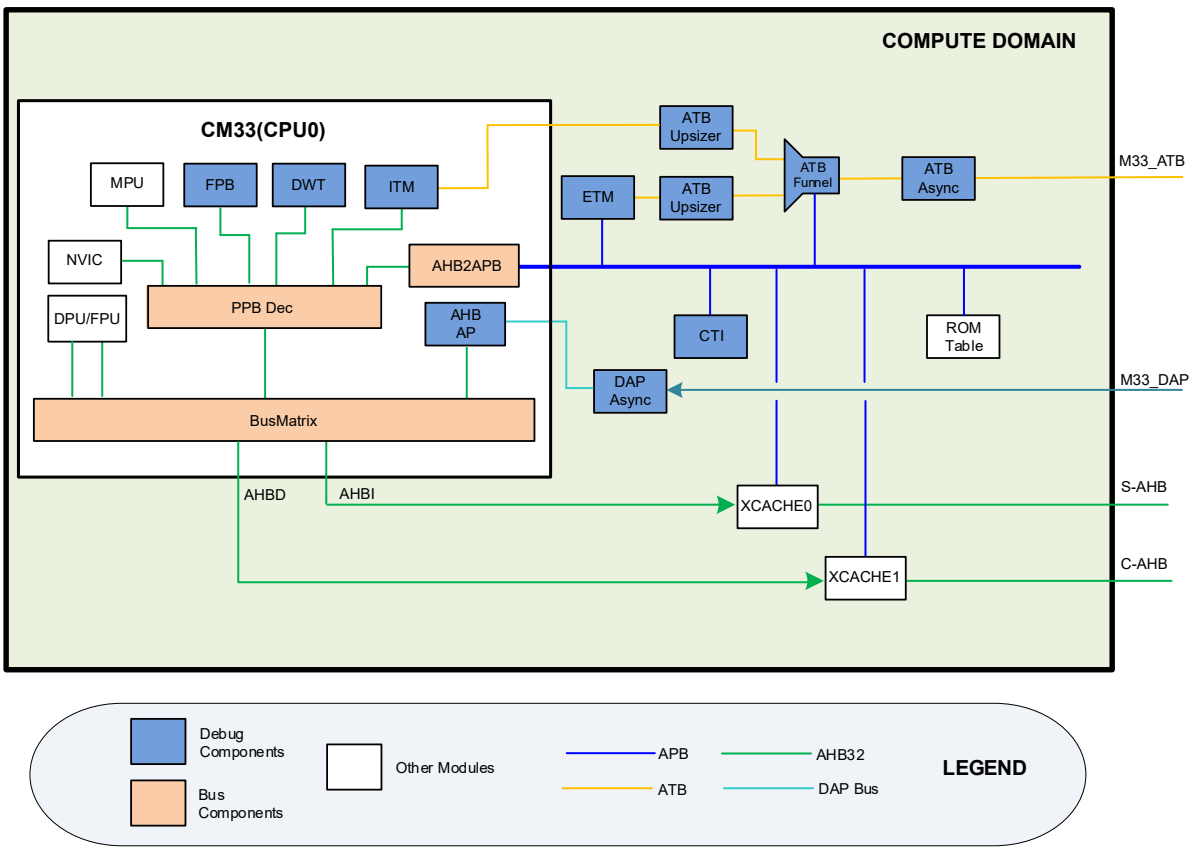

Figure 9. CPU0 platform diagram

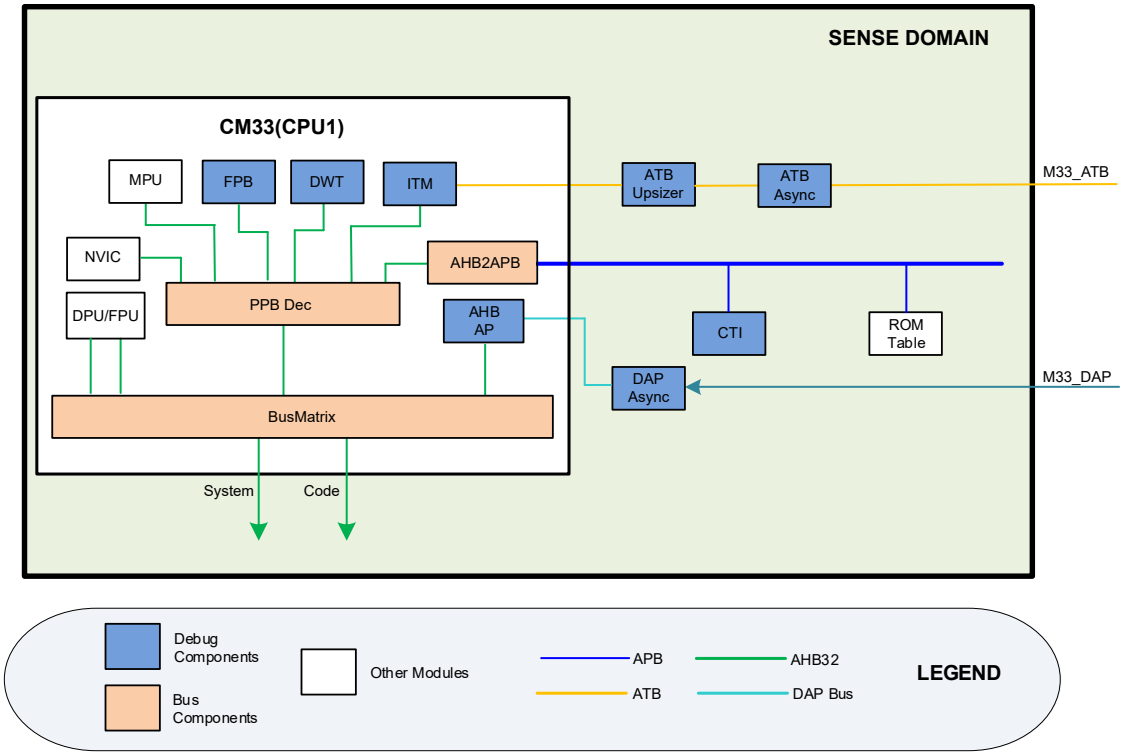

Figure 10. CPU1 platform diagram

7.1.2 Cortex-M33 configuration

Table 21. CM33 configuration for CPU0 and CPU1

Feature	CPU0	CPU1
Domain	COMPUTE	SENSE
Arm TrustZone®	supported	supported
Arm Cortex-M33 built-in Memory Protection Unit (MPU) supporting eight regions	supported	supported
Hardware Floating Point Unit (FPU)	supported	supported
Arm Cortex-M33 built-in Nested Vectored Interrupt Controller (NVIC)	supported	supported
Non-maskable Interrupt (NMI) input	supported	supported
ETM trace (with external buffer), eight breakpoints, four watchpoints	supported	not supported
Instrumentation Trace Macrocell (ITM)	supported	supported
Cortex M33 system tick timer	supported	supported

NOTE

It is recommended that performance critical code be located such that it fetches from the code bus interface as defined by addresses < 0x2000_0000.

7.2 Functional description

7.2.1 CPU0 and CPU1

- CPU0 is the control processor in the Compute domain
  - It is the main control CPU for the chip
  - Responsible for conducting the booting process
  - Responsible for releasing HiFi-4 DSP out of reset and enabling the DSP clock
  - Interfaces with external memories including xSPI Flash, USB, SPI, I2C, UART and eMMC
- CPU1 is the control processor in the Sense domain
  - Accesses all peripherals in the Sense domain and the shared region (peripherals accessible for both Sense and Compute domains)
  - Responsible for releasing HiFi-1 DSP out of reset and enabling the DSP clock

NOTE

Some shared, system-level resources are configured and managed by CPU0.

7.2.2 Nested Vectored Interrupt Controller (NVIC)

CPU0 and CPU1 each include a Nested Vectored Interrupt Controller (NVIC). They both support 8 priority levels for interrupts. The NVIC IPR registers define 3 bits per IRQ.

7.2.3 Floating Point Unit (FPU)

CPU0 and CPU1 both support the Floating Point Unit (FPU). The FPU implements FPv5 floating-point extensions, which supports single-precision add, subtract, multiply, divide, multiply and accumulate, and square root operations. The FPU also provides conversions between fixed-point and floating point data formats, and floating-point constant instructions.

The FPU is compliant with the ANSI/IEEE Std 754-2008 standard.

7.2.4 Memory Protection Unit (MPU)

CPU0 and CPU1 support the Memory Protection Unit (MPU). The MPU supports independent attribute settings for each region and ability to export memory attributes.

In addition, a Secure MPU is also supported.

A processor generates a fault if the core access hits the overlapping regions in the case of overlapping memory regions.

Instruction accesses and data accesses in a given region have the same region settings.

7.2.5 Debug

See the Debug overview for more information about the CM33 debug components.

7.2.6 Code bus access

CPU0 and CPU1 code bus can access memory and peripherals as shown in the bus matrix block diagram. CPU0 code bus access is routed to XCACHE1. This controller then processes the cacheable accesses as needed, while bypassing the non-cacheable accesses or forwarding the cache write-through and cache miss accesses to the downstream memories through the controller port of this cache controller.

7.2.7 System bus access

All system bus accesses are routed to the target address in destination memories through multilayer AHB matrix target port, see System diagram for more details. CPU0 system bus access is routed to XCACHE0.

7.2.8 Access control

CPU0 code and system bus accesses are checked by the core access control logic, that is, IDAU/SAU and MPU. All requests that miss or bypass the cache are checked by downstream secure AHB bus logic. The caches include protection control signals (HPROT[3:0]) and processing domain bits as part of the tags. If a fetch address hits the cache but the protection control and/or domain bits are different, the cache controller forces a miss with the allocate location the same as the address hit location in the cache. This policy allows all the downstream checks to take place, and this new miss is loaded in the cache with the updated protection control and domain bits overwriting the line with the same address. This keeps the cache coherent while always checking accesses that need to see the downstream checks.

CPU1 access is controlled by secure AHB control.

The CPU0 and CPU1 access to the on chip memory is checked in the AHBSC. See i.MX RT700 Security Reference Manual for more details about AHBSC.

Chapter 8
External Memory Controllers

8.1 Overview

This chip has the following external memory interfaces and controllers:

- Ultra Secured Digital Host Controller (uSDHC) supporting SD, SDIO, eMMC
- External Serial Peripheral Interface (XSPI) Controller supporting flash and PSRAM memory
- Two Universal Serial Bus (USB) Controllers supporting flash memory

8.1.1 System-Level diagram

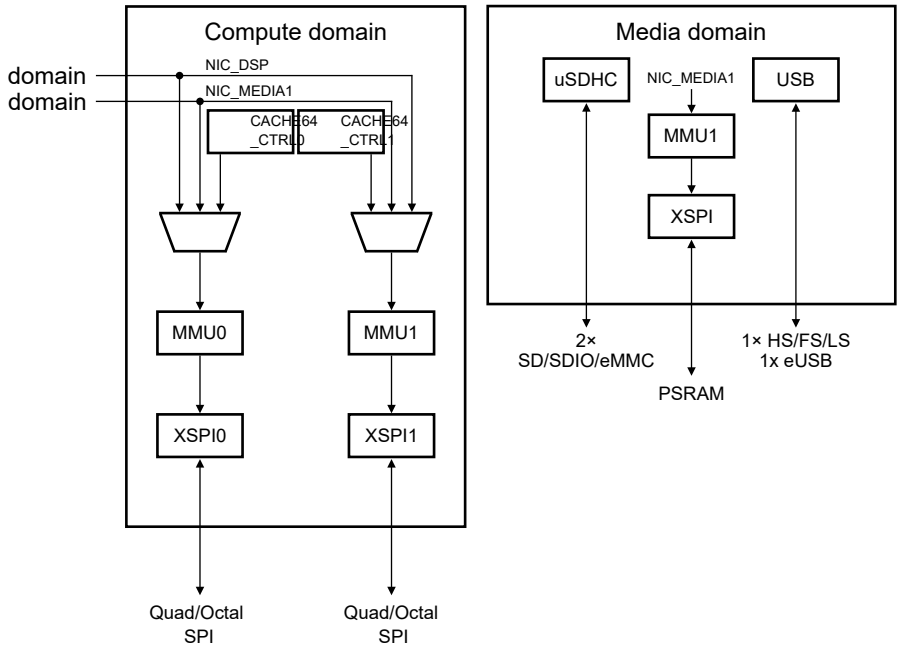

Figure 11. External memory controllers block diagram

8.2 Modules

Table 22. Modules

Modules	Instances	Description	Main features
Ultra Secured Digital Host Controller (uSDHC)	Media domain x2	uSDHC acts as a bridge, passing host bus transactions to the eMMC, SD card, and SDIO by sending commands and performing data accesses to/from the cards.	Conforms to the SD Host Controller Standard Specification version 2.0/3.0 Compatible with the eMMC System Specification version 4.2/4.3/4.4/4.41/4.5 Compatible with the SDIO Specification version 2.0/3.0

Table continues on the next page...

Table 22. Modules (continued)

Modules	Instances	Description	Main features
			Support for various SD, eMMC, SD card, or SDIO data transfer modes Configurable data buffer to transfer data Internal DMA eMMC/SD card detection Power management
External Serial Peripheral Interface (XSPI)	Compute domain x2 Media domain x1	XSPI acts as an interface to a single serial flash memory device.	Support for up to hex mode for data transfers and up to octal mode operation transfers Support for up to eight bidirectional data lines on XSPI0, and up to 16 on XSPI1 and XSPI2 Support for Double Data Rate (DDR)/Double Transfer Rate (DTR) mode Flash memory data strobe signal to support data sampling in DDR and Single Data Rate (SDR) mode Support for PSRAM Memory mapped read/write access by AHB bus Programmable sequence engine
Universal Serial Bus (USB)	Media domain x2	USB controller block provides high performance USB functionality that conforms to the Universal Serial Bus Specification Revision 2.0.	EHCI-compatible for host mode High Speed (HS), Full Speed (FS) and Low Speed (LS) operation in host mode Support for HS and FS operation in device mode Support for low-power suspend mode Support for low-power sleep mode Embedded DMA controller

Chapter 9
Boot ROM

9.1 Overview

NOTE

This chapter is also available in the i.MX RT700 Security Reference Manual, with differences related to security functionality. The chapter in the Reference Manual does not show the security relevant information in it.

ROM bootloader runs from internal read-only memory (ROM). After a power-on reset or warm reset, the ROM bootloader is executed.

The 256 KB on-chip ROM bootloader supports the following features:

- Prime boot from external memories including XSPI NOR, XSPI NAND and eMMC
- Recovery boot from LP_FLEXCOMM (LPSPI) NOR memory.
- In-System Programming (ISP) via USB0 (HS USB), USB1 (eUSB), LPUART, LPSPI and LPI2C.
- Debug Mailbox (DBGMB)
- ROM APIs.

The ROM bootloader resides in the memory region starting at address 0x1300_0000. The diagram below illustrates the memory map utilized during ROM execution. During bootloader operation, the first 84 KB of SRAM (0x3000_0000 – 0x3001_4FFF) must be reserved and not used by other components. As a result, load-to-RAM images should be placed in memory regions starting from 0x0001_5000 (secure alias: 0x1001_5000) or 0x2001_5000 (secure alias: 0x3001_5000). Once the system has successfully booted, the reserved 84 KB of SRAM becomes available for general use.

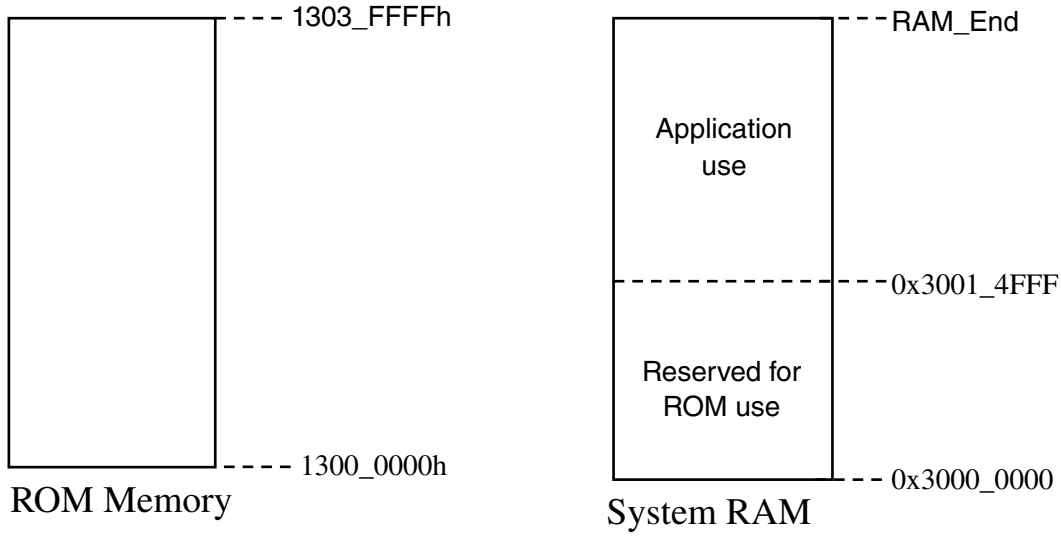

Figure 12. ROM bootloader memory usage

9.2 High level boot flow

On this chip, Boot ROM first downloads boot image from external memory to RAM based on boot mode and information in the image header. For execute-in-place (XIP) boot image, Boot ROM will skip the download operation. Then, Boot ROM validates the boot image. Lifecycle, boot configuration and information in the image decide which validation method is used for this image. If the boot image is valid, Boot ROM jumps to the image and executes.

Following are the boot modes available for the boot ROM:

- Prime boot from XSPI NOR
- Prime boot from serial NAND connected to XSPI
- Prime boot from eMMC
- Recovery boot from LPSPI NOR

Boot mode can be selected using Boot pins, ROM scratch register or fuses. Recovery boot is executed when prime boot fails, and recovery boot is enabled in fuse.

Boot ROM can do simple image check, CRC check or ECDSA authentication at Develop lifecycle when secure boot is not enforced.

If secure boot is enforced or lifecycle is after Develop:

- for XIP image, ECDSA authentication is enforced
- for copy-to-RAM image, it must be in secure binary (SB3) format on original external memory. CRC check or ECDSA authentication can be done for image downloaded to RAM.

The following figure shows the high level boot flow:

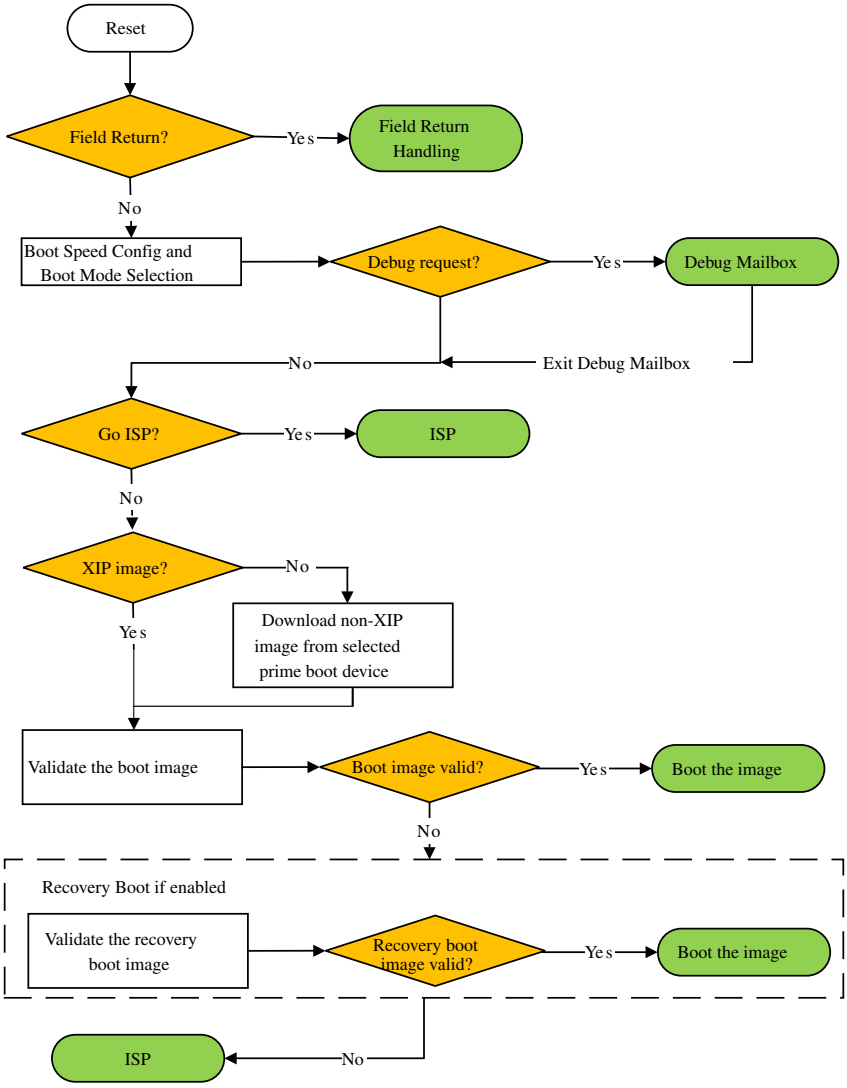

Figure 13. High level boot flow

9.3 Pin allocation

9.3.1 Boot pin allocation

PIO1_8 and PIO1_7 are allocated as Boot pins which select the prime boot source or forces entry to ISP mode. Boot pins work only when, in BOOT_CFG0, BOOT_SRC[1:0] = 00b and ISP_MODE_PIN_DIS = 0b.

Table 23. Boot pin allocation

PIO1_8	PIO1_7	Definition
0	0	Boot from eMMC connected to uSDHC0
0	1	Boot from serial NOR connected to XSPI0
1	0	Enter ISP (UART, SPI_target, I2C_target, USB0, USB1)
1	1	Boot from serial NOR connected to XSPI1

9.3.2 Boot interface pin allocation

Boot ROM provides flexibility that you can configure the boot interface according to your hardware design.

When fuse BOOT_SRC[1:0] is not set (00b), Boot pin can be used to determine which source is used to boot. Fuse BOOT_SRC and BOOT_IF_INST can be configured together to determine the boot source.

For prime boot from serial NOR or NAND, the memory can be connected to XSPI0 or XSPI1. Boot ROM also supports copying code from the boot medium to an external pSRAM connected to XSPI0 or XSPI1.

For prime boot from eMMC, the memory can be connected to uSDHC0 or uSDHC1.

Boot ROM supports recovery boot from 1-bit serial NOR connected to LP_FLEXCOMM (LPSPI) if fuse REC_BOOT_EN is set. You can choose any one instance among LP_FLEXCOMM0 to LP_FLEXCOMM13 to connect serial NOR by setting fuse REC_BOOT_FC. You can select Chip-Select (CS) pin in CS0 to CS3 by using fuse REC_BOOT_FC_PCS and select LP_FLEXCOMM (LPSPI) baudrate by using fuse REC_BOOT_FC_BAUDRATE.

Detailed pin allocation for each boot interface is described in the table below.

9.3.3 ISP interface pin allocation

ROM bootloader provides in-system programming (ISP) utility that operates over a serial connection on the MCUs. It enables quick and easy programming of MCUs through the entire product lifecycle. Users can utilize host tools to download application to memory medium via serial interfaces including UART, USB0, USB1, SPI or I2C. Table below shows the pin allocation of ISP interfaces.

Table 43. ISP interface pin allocation

ISP interface	Pin allocation	
UART		
	PIO0_31	LP_FLEXCOMM0_P0/RXD
	PIO1_0	LP_FLEXCOMM0_P1/TXD
USB0		
	USB0_VBUS_DETECT	
	USB0_DP	
	USB0_DM	
USB1 (eUSB)		
	EUSB_DM	
	EUSB_DP	
SPI targets		
	PIO3_0	LPSPI14_SOUT
	PIO3_1	LPSPI14_SCK
	PIO3_2	LPSPI14_SIN
	PIO3_3	LPSPI14_PCS0

Table 43. ISP interface pin allocation (continued)

ISP interface	Pin allocation	
I2C targets		
	PIO1_17	LP_FLEXCOMM3_P1/SCL
	PIO1_18	LP_FLEXCOMM3_P0/SDA

9.4 Boot configuration and boot image

9.4.1 Boot speed

Three different boot speeds (compute_main_clk) are supported, which can be configured from fuse BOOT_SPEED[1:0]. Boot ROM configures clock based on configuration in BOOT_SPEED[1:0] early in the boot flow. The default boot speed is 192 MHz. Table below is the fuse definition.

Table 44. Fuse definition

Fuse	Fuse word	Bits	Definition
BOOT_SPEED	136 BOOT_CFG0	13:12 (2 bits)	System clock speed during boot. • 00 - Normal boot (192 MHz) – VDD2 = 1.0 V • 01 - High speed boot (300 MHz) – VDD2 = 1.1 V • 10 - Low speed boot (32 MHz) – VDD2 = 1.0 V • 11 - Normal boot (192 MHz) – VDD2 = 1.0 V **NOTE** If the VDD2 voltage is supplied externally, then one of the 1.0 V boot speed options must be used. The high speed boot option should not be selected.

9.4.2 Boot source selection from fuses

Fuse configuration for boot source selection in word 0 BOOT_CFG0:

Table 45. Fuse configuration for boot source selection

Fuse	Fuse word	Bits	Definition	Description
BOOT_SRC[1:0]	136	2	00 - Boot pins determine the source 01 - XSPI NOR flash 10 - uSDHC flash 11 - XSPI NAND flash	These two bits specify the boot source

Table continues on the next page...

Table 45. Fuse configuration for boot source selection (continued)

Fuse	Fuse word	Bits	Definition	Description
BOOT_IF_INST[2]		1	0 - Instance 0 (XSPI0 or uSDHC0) 1 - Instance 1 (XSPI1 or uSDHC1)	This bit specifies boot instance when XSPI or uSDHC is selected as boot source

Image offset definition for various boot media:

Table 46. Image offset definition for various boot media

Boot media	Image Offset
XSPI NOR boot	4000h
XSPI NAND boot	0000h
eMMC boot	1000h
LP_FLEXCOMM 1-bit NOR recovery boot	1000h

9.4.3 Image header

After completing boot mode detection, the bootloader starts validating the vector table and image header if the image is present in the boot media (external flash memory).

The boot ROM does the following for image validity check:

- Validates the image using header and fuse settings when secure boot is enabled. See the "Secure Boot ROM" chapter in the *Security Reference Manual* for details.
- Validates the image using CRC32 when secure boot is not enabled, if the CRC check is present in the image header.
- Validates whether SP and PC are valid RAM and NVM addresses of the chip.
- Validates the TZ-M image type if the aforementioned image checks pass.

The beginning of the image follows the format described in Table 47. The bootloader begins scanning for user images by examining the image type marker located at offset 24h. If the value matches any supported image type markers, the image header's validation begins, and after its completion, the qualification continues by examining the TZ-M "imageType" field:

- If it is a CRC image, you use the "image length" field value as the length to perform a CRC calculation based on the image in the flash memory (see Table 47 for more). The CRC calculation begins at offset 0h from the beginning of the image header and continues up to the number of bytes specified by the image length, which does not include the "offsetToExtendedHeader" field that makes up the CRC value field. This means that the calculated CRC skips the CRC value field. The result is then compared to the "offsetToExtendedHeader" entry in the structure and the image is considered valid if a match exists; otherwise, the image is considered invalid. The CRC calculation is not performed if the image is not a CRC image.
- If it is a signed image, the "image length" field value is used as the length to perform authentication (ECDSA), which is performed on the image in the external flash memory. The authentication begins at offset 0h from the beginning of the image header, and continues up to the number of bytes specified by the image length. The "offsetToExtendedHeader" field value points to the offset that holds the certificates.

Table 47. Image header in vector table

Offset (hex)	Size (bytes)	Symbol	Description
00	4	Initial SP	Stack pointer
04	4	Initial PC	Application's first execution instruction
08	24	Vector table	Cortex-M33 core's vector table entries
20	4	image length	Length of the current image (total length, including the signature), which is set to the actual image length if the image type is another value
24	4	imageType	Bit [7:0]: Image type • 0h - Plain image • 2h - Plain image with CRC • 4h - Signed image • 6h - SB3 manifest • Other values are reserved. Bit [12:8]: Reserved Bit [13]: Indicates whether the image includes TZM preset data: • 0 - Image does not contain TZM preset data. • 1 - Image contains TZM preset data. Bits[31:14]: Reserved.
28	4	offsetToExtendedHeader	Offset to extended header: • For a signed image (imageType = 4h), this is the offset to the certificate header block • For a CRC image (imageType = 2h), this is the crcChecksum value
2C	8	Vector table	Cortex-M33 core's vector table entries
34	4	imageExecutionAddress	The execution address of the image is: • Set to 0 for XIP image • Set to actual image execution address load_to_RAM image
38		Vector table	Cortex-M33 core's vector table entries

NOTE

Load_to_RAM image: The image must have a nonzero imageExecutionAddress and image_length in the image header.

9.4.4 Image version and anti-rollback

Boot ROM supports anti-rollback for signed image and SB3.1 image. It compares the version of image with the version value programmed in fuse and only boots the image with version equal to or greater than the version in fuse. See details of signed image and SB3 image structure in i.MXRT700 Security Reference Manual.

For signed image, ROM compares the image version with fuse SEC_FW_VER (word 128 - 131). Boot ROM does not boot image with version lower than the version in fuse. For fuse SEC_FW_VER (secure firmware version), value 1b means version 1, value 11b means version 2, value 111b means version 3, etc. For SB3.1 image, users can enable image version check using SB3.1 fwVersionCheck command. Boot ROM checks the version of SB3.1 image with the fuse required in checkFwVersion command, either NS_FW_VER (non-secure firmware version, word 112 - 127) or SEC_FW_VER. Fuse NS_FW_VER works similarly like SEC_FW_VER, value 1b means version 1, value 11b means version 2, value 111b means version 3, etc.

NOTE

- SEC_FW_VER fuse can be used for major or critical updates and NS_FW_VER fuse can be used for minor or non-critical updates.
- Only lower 16 bits are active for both fuse words (SEC_FW_VER/NS_FW_VER). Hence, there can be up to 64 updates when using SEC_FW_VER fuse and up to 256 updates when using NS_FW_VER fuse.
- If an application doesn't use SB3.1 fwVersionCheck command with kNBOOT_CNT_nonsecure counter ID, then fuse words 112-127 can be re-purposed as customer defined counters (CUST_CTR9 – CUST_CTR24). A potential use case is implementing non-volatile counters required by the TF-M framework.

9.5 Prime boot from XSPI NOR

Boot ROM supports prime boot from Quad NOR, Octal NOR and HyperFlash connected to XSPI instance 0 or 1. Both execute-in-place (XIP) and load-to-RAM boot image are supported for XSPI NOR. For load-to-RAM boot image, the image can be loaded to on-chip SRAM (starts from offset 15000h), or pSRAM connected to the other XSPI instance. For example, if XSPI0 is selected as boot source and NOR is connected to it, the ROM can load the boot image from XSPI0 NOR to pSRAM connected to XSPI1. Note that Boot ROM only supports XSPI instance 0 and 1.

At Develop (3h) lifecycle, XIP image and load-to-RAM image can be any image with valid image header. When secure boot is enforced or lifecycle is after Develop (3h), the XIP image must be correctly signed image to boot successfully, and copy-to-RAM image must be in SB3 format and the image to generate SB3 should either be CRC image or signed image.

There are three ways to start XSPI boot.

- BOOT_SRC[1:0] = 00b.
  - If BOOT_PIN_MODE = 01b, XSPI0 is selected as boot source.
  - If BOOT_PIN_MODE = 11b, XSPI1 is selected as boot source.
- BOOT_SRC[1:0] = 01b, Boot ROM directly boots from XSPI NOR, and XSPI instance is selected via BOOT_IF_INST
- Use runBootloader API with EB04_*n*000h (*n* is 0 or 1 to select XSPI instance) as the parameter

Once XSPI NOR boot is selected, Boot ROM configures XSPI based on FCB or AutoProbe value and tries to find the boot image at offset 4000h of the XSPI NOR. XSPI NOR image layout is like figure below, first 4000h is platform configuration, and XSPI NOR boot support dual image boot if fuses are configured correctly, see sections below for more details.

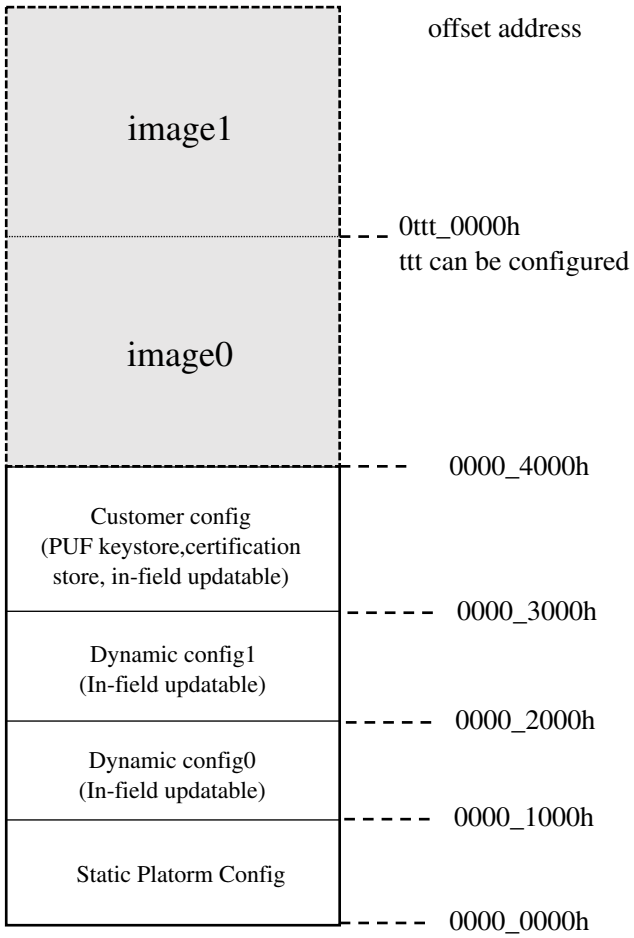

Figure 14. XSPI dual image boot

9.5.1 Platform configuration

First 4000h of XSPI NOR is platform configuration which is divided into two groups:

1. Static or factory programmed platform configuration including flash configuration block (FCB) of NOR, and optional configuration for pSRAM.

```
typedef struct {
 uint8_t xspi_fcb_block[768];// Configure structure for boot device connected to XSPI0/XSPI1
interface.
 uint8_t psram_config_block[768];// Configure structure for pSRAM device connected to XSPI0/
XSPI1 interface.
 uint8_t xspi2_fcb_block[768];// Configure structure for pSRAM device connected to XSPI2
interface. Only for users' usage, Boot ROM doesn't use this part
 uint8_t reserved[1792];// Reserved for future usage
} static_platform_config_t;
```

2. Dynamic or in-field updatable configuration.

```
typedef struct {
 uint32_t tag;// Check this tag to see if the dynamic config is programmed
```

```
 uint32_t cfg_version; // Version of this structure. Used for identifying the active
configuration by picking the page which has the higher number between ping & pong pages.
 uint32_t arb_version;// anti-roll back version to be compared with SEC_FW_VER or NS_FW_VER
monotonic counter fields in OTP.
 uint8_t reserved[4]; // Reserved area for future
}

typedef struct IPED_CTX_CFG_t{
uint32_t iv_lsb_erase_count;// IV for each context.
uint32_t iv_msb;// Random number generated on each erase operation.
uint64_t aad_data;//IPED context specific AAD data. This field used for GCM mode only. Ignored
in XEX & CTR modes.
uint32_t start_addr;// Start address of the context. The bit-field layout is same as
IPEDCTXaSTART register including GCM mode bit & AHB_ERROR bit.
uint32_t end_Addr;// End address of the context. The bit-field layout is same as IPEDCTXaEND
register. Lower bits for locking the context.
} enc_ctx_cfg[NUM_CTX]; //AES-GCM Encrypted. For RT700 NUM_CTX = 16.

typedef struct IPED_CTX_CFG_t psram_ctx_cfg[XSPI1_NUM_CTX];// For systems where XSPI0 is
connected to flash and XSPI1 connected to pSRAM. For RT700 XSPI1_NUM_CTX = 16.For systems where
flash is connected XSP1.
```

9.5.2 XSPI boot configuration

The boot ROM supports access to different Quad and Octal SPI NOR flash memory chips from various vendors via the XSPI interface using 1-bit, 4-bit (Quad), or 8-bit (Octal) mode. It uses the flash memory configuration block (FCB) located at offset 0h on the flash memory chip or flash memory auto-probe feature that fuse specifies:

- If XSPI_FLASH_AUTO_PROBE_EN in word 152 XSPI_CFG0 is blown, the bootloader performs the flash memory auto-probe sequence using parameters blown in:
  - The XSPI_FLASH_PROBE_TYPE field that defines the flash memory auto-probe type.
  - The XSPI_FLASH_TYPE fields that define the flash memory type.
  - The XSPI_FLASH_BOOT_FREQ field that defines the flash memory access speed.
- If XSPI_FLASH_AUTO_PROBE_EN is not blown, the bootloader looks at offset 0h on the flash memory chip; if data at offset 0h is equal to 4246_4346h, the bootloader reads the whole 576-byte FCB into the on-chip SRAM and configures the XSPI controller using this FCB accordingly.

  After performing the aforementioned operation, the bootloader starts performing the normal boot flow.

Table 48. XSPI boot configurations in fuse index 152 (XSPI_CFG0)

Fuse	Definition	Settings	Shipped value
XSPI_CFG0[0]	XSPI_FLASH_AUTO_PROBE_EN	Quad SPI or Octal SPI flash memory auto-probe feature enable 0 - Disable 1 - Enable	0
XSPI_CFG0[3:1]	XSPI_FLASH_PROBE_TYPE	Quad SPI or Octal SPI flash memory probe type 000 - Quad SPI NOR flash memory 001 - Macronix Octal flash memory	0

Table continues on the next page...

Table 48. XSPI boot configurations in fuse index 152 (XSPI_CFG0) (continued)

Fuse	Definition	Settings	Shipped value
		010 - Micron Octal flash memory 011 - Adesto Octal flash memory 100 - Octal SDR 101 - Octal DDR 110 - Reserved 111 - Reserved	
XSPI_CFG0[6:4]	XSPI_FLASH_TYPE	Typical serial NOR flash memory types 000 - Quad SPI flash memory address (by default, the chip supports 3B read) 001 - Reserved 010 - HyperFlash 1.8 V 011 - HyperFlash 3.3 V 100 - MXIC Octal DDR 101 - Micron Octal DDR 110 - Reserved 111 - Reserved	0
XSPI_CFG0[10:7]	XSPI_FLASH_DUMMY_CYCLES	Quad SPI or Octal SPI dummy cycles for read command 0000 - Dummy cycles probed automatically Other value - Number of dummy cycles	0

XSPI_CFG1[6:0]	XSPI_DELAY_CELL_NUM	Delay cell numbers for flash read 0 - Use the Delay cell value calcu Others - Use the Delay cell value
XSPI_CFG0[16:7]	XSPI_FLASH_SEC_IMAGE_OFFSET	Offset of the second image
XSPI_CFG1[23:17]	XSPI_FLASH_IMAGE_SIZE	Size of the second image
XSPI_CFG1[24]	XSPI_FLASH_ENHANCE_MODE	XSPI enhance mode 000 - Disable 101 - Force using interanal loopba Others - Reserved
XSPI_CFG1[31:25]	Reserved	

Table 50. XSPI FCB settings

Field	Offset (hex)	Size (bytes)	Description
tag	000	4	Configuration block tag Setting: 4246_4346h
version	004	4	Configuration block that the boot ROM uses internally Setting: 5601_0000h
Reserved	008	4	Reserved
readSampleClkSrc	00C	1	Read sampling clock source options: 0h – Internal sampling 1h – Reserved 2h – DQS pad loopback 3h – External DQS signal
csHoldTime	00D	1	CS hold time in terms of flash memory clock cycles Recommended value is 3h.

Table continues on the next page...

Table 50. XSPI FCB settings (continued)

Field	Offset (hex)	Size (bytes)	Description
csSetupTIme	00E	1	CS set up time in terms of flash memory clock cycles The recommended value is 3h.
columAddressWidth	00F	1	Column address width: • Set to 3h for HyperFlash NOR flash memories. • Set to 0h for other flash memory chips.
deviceModeCfgEnable	010	1	Enables the chip mode configuration sequence: 1h – Enable 0h – Disable
deviceModeType	011	1	Argument for Device mode configuration For example, Quad enable setting in Status Register2 for some Quad SPI flash memory devices: 0h – No mode change 1h – Quad enable (switch from SPI to Quad mode) 2h – Spi2Xpi (switch from SPI to DPI, QPI, or OPI mode) 3h – Xpi2Spi (switch from DPI, QPI, or OPI to SPI mode)
waitTimeCfgCommands	012	2	Wait time (in terms of 100 µs) for Device mode configuration command
deviceModeSeq	014	4	Device mode configuration sequence: Byte 0 – Number of required sequences Byte 1 – Sequence index
deviceModeArg	018	4	Argument for Device mode configuration For example, Quad enable setting in Status Register2 for some Quad SPI flash memory devices
configCmdEnable	01C	1	Configuration command enable: 0h – Ignores configuration command 1h – Enables configuration command
configModeType	01D	3	Configuration command type that supports up to three types; each type is combined with a configuration command sequence
configCmdSeqs	020	12	Configuration command that supports up to three sequences
Reserved	02C	4	Reserved
configCmdArgs	030	12	Configuration command that supports up to three arguments

Table continues on the next page...

Table 50. XSPI FCB settings (continued)

Field	Offset (hex)	Size (bytes)	Description
Reserved	03C	4	Reserved
controllerMiscOption	040	4	Miscellaneous controller configuration options: Bit 0 – Differential clock enable: set to 1 for HyperFlash NOR flash memory 1.8 V device and set to 0 for other devices Bit 3 – WordAddressableEnable: set to 1 for HyperFlash NOR flash memory and set to 0 for other devices Bit 4 – SafeConfigFreqEnable: set to 1 if expecting to configure the chip with a safe frequency Bit 6 – DDR mode enable: set to 1 if DDR read is expected Other bits – Reserved; set to 0
deviceType	044	1	Device type 1h – Serial NOR flash memory
sflashPadType	045	1	Data pad used in Read command: 1h – Single pad 2h – Dual pads 4h – Quad pads 8h– Octal pads
serialClkFreq	046	1	Serial clock frequency 1h – 30 MHz 2h – 50 MHz 3h – 60 MHz 4h – 80 MHz 5h – 100 MHz 6h - 120 MHz 7h - 133 MHz 8h - 166 MHz 9h - 200 MHz
lutCustomSeqEnable	047	1	LUT customization enable—required when you cannot perform the program and erase operations using one LUT sequence (currently, only one is applicable to HyperFlash NOR flash memory)
Reserved	048	8	Reserved for future use
sflashA1Size	050	4	Size of flash memory connected to A1

Table continues on the next page...

Table 50. XSPI FCB settings (continued)

Field	Offset (hex)	Size (bytes)	Description
sflashA2Size	054	4	Size of flash memory connected to A2
csPadSettingOverride	060	4	Pad override value for CS pin Use this value (if nonzero) to configure the CS pin; otherwise, use the default boot ROM setting
sclkPadSettingOverride	064	4	Serial clock pad setting override value
dataPadSettingOverride	068	4	Data pad setting override value
dqsPadSettingOverride	06C	4	DQS pad setting override value
timeoutInMs	070	4	Timeout value (in terms of ms) to terminate the busy check
commandInterval	074	4	CS deselect interval between two commands
dataValidTime	078	4	Clock edge to data valid time
busyOffset	07C	2	Busy offset, valid value: 0-1Fh
busyBitPolarity	07E	2	Busy flag polarity: 0h – Busy flag is 1 when the flash memory device is busy 1h – Busy flag is 0 when the flash memory device is busy
lookupTable	080	360	18 LUT sequences—each sequence consists of four words (see XSPI chapter for more information)
lutCustomSeq	1E8	48	Customizable LUT sequences
dllCraSdrVal	218	4	Customizable DLLCRA for SDR setting
smprSdrVal	21C	4	Customizable SMPR SDR setting
dllCraDdrVal	220	4	Customizable DLLCRA for DDR setting
smprDdrVal	224	4	Customizable SMPR DDR setting
pageSize	228	4	Page size of Serial NOR
sectorSize	22C	4	Sector size of Serial NOR
ipcmdSerialClkFreq	230	1	Serial clock frequency for IP commands: 0h – The same with read command Others – The same definition as that of the serial clock frequency
isUniformBlockSize	231	1	Indicates whether the sector size is the same as the block size:

Table continues on the next page...

Table 50. XSPI FCB settings (continued)

Field	Offset (hex)	Size (bytes)	Description
			0h – No 1h – Yes
isDataOrderSwapped	232	1	Data order (D0, D1, D2, D3) is swapped with (D1, D0, D3, D2)
Reserved	233	1	Reserved
serialNorType	234	1	Serial NOR flash memory type: 0, 1, 2, and 3
needExitNoCmdMode	235	1	Exits NoCmd mode before other IP commands
halfClkForNonReadCmd	236	1	Half serial clock for nonread command: true or false
needRestoreNoCmdMode	237	1	Restores NoCmd mode after IP command execution
blockSize	238	4	Flash memory block size
flashStateCtx	23C	4	Flash memory state context
Reserved	240	40	Reserved

9.5.2.1 Reset

During XSPI boot, the boot process requires the XSPI flash memory device to be in a certain mode, specially, 1-bit SPI compatible mode. The flash memory device is, by default, in this mode after a POR reset. That is because the power-up sequence resets it along with the boot ROM device. However, the flash memory device does not remain in 1-bit SPI compatible mode if you configure it in DPI, QPI, or Octal mode when any non-POR resets happen (for example, watchdog timer and external pin reset). In such a case, the boot process requires special processing to restore the flash memory device to 1-bit SPI compatible mode before accessing it. You can achieve this by using a GPIO to assert a reset pin on the flash memory device. The bootloader can perform the reset process and reset the flash memory device to 1-bit SPI compatible mode if the XSPI_RESET_PIN_EN field is a nonzero value in fuse, using the GPIO that the XSPI_RESET_PIN_PORT and XSPI_RESET_PIN_GPIO fields specify in combination.

NOTE

If using FCB mode and the FLASH is configured to QPI/OPI mode, you should always program the FLASH state context to the correct value in order to restore the FLASH to SPI mode after warm reset.

You can also achieve this by maintaining the FLASH state context via the FLASH context register (General Purpose (GPR) register in RTC_SS, address 4006_8C10h) or FCB flashStateCtx (See Table 50), which logs the below information:

- FLASH default working mode on POR reset
- Current FLASH working mode
- Sequence to reset to default working mode

Before accessing the FLASH device, ROM reads the context parameter and resets the FLASH to the default working mode via the specified reset pattern first. The FLASH device is in the default operating mode, and consequently, software can access FLASH as expected (including rebooting, configure-memory command, or the FLASH API call).

The following section explains the detailed information about the FLASH context register.

```
typedef union
{
  struct
```

```
  {
    uint8_t reserved ;
    uint8_t current_mode;
    uint8_t reserved ;
    uint8_t restore_sequence;
  } B;
  uint32_t U;
} FLASH_run_context_t;
```

Table 51. Flash context register

Field	Description	Definition
current_mode	FLASH Device current running mode	kFlashInstMode_ExtendedSpi = 0x0 kFlashInstMode_0_4_4_SDR = 0x1 kFlashInstMode_0_4_4_DDR = 0x2 kFlashInstMode_DPI_SDR = 0x21 kFlashInstMode_DPI_DDR = 0x22 kFlashInstMode_QPI_SDR = 0x41 kFlashInstMode_QPI_DDR = 0x42 kFlashInstMode_OPI_SDR = 0x81 kFlashInstMode_OPI_DDR = 0x82
restore_sequence	FLASH reset sequence of standard SPI mode	kRestoreSeqence_None = 0 kRestoreSeqence_QPI_4_0xFFs = 2 kRestoreSeqence_QPI_Mode_0x00 = 3 kRestoreSeqence_Send_F0 = 5 kRestoreSeqence_Send_66_99 = 6 kRestoreSeqence_Send_6699_9966 = 7 kRestoreSeqence_Send_06_FF = 8 kRestoreSeqence_QPI_5_0xFFs = 9 kRestoreSeqence_Send_QPI_8_0xFFs = 10 kRestoreSeqence_Wakep_0xAB = 11 kRestoreSeqence_Wakep_0xAB_54 = 12

Take IMXRT700 EVK board for example, if the user needs to reset the FLASH to XSPI mode, such as waking up the FLASH from deep power-down mode, or reconfigure the FLASH use ISP command, or use the ROM auto probe boot feature(when the FLASH is in OPI DDR mode), the user needs to do below actions.

FLASH Type: MX25UM51345G:

```
FLASH_run_context_t run_ctx = {.U = 0 };
run_ctx.B.current_mode = kFLASHInstMode_OPI_DDR; // Set the current FLASH mode
run_ctx.B.restore_sequence = kRestoreSeqence_Send_6699_9966; // Select the FLASH reset sequences
*(volatile uint32_t *)(0x40068C10) = run_ctx.U // Update the context register
```

After this operation, the context register stores the current running mode of the NOR FLASH. In ISP reconfiguring or rebooting, ROM uses the context value to decides the way to reset the FLASH. For the FLASH resetting sequence, please refer to the flash device data sheet for Send_66_99, Send_6699_9966, Send_06_FF.

9.5.2.2 External Memory Configuration Data (XMCD)

For comprehensive or feature-rich applications, the on-chip RAM may not be enough for the application use. Usually, such an application requires a large capacity of RAM and needs to run on the external RAM for high execution performance. However, enabling the external RAM on the chip is relatively complicated, and the settings are chip specific. The Boot ROM on the chip simplifies the external RAM configuration by introducing the XMCD.

The XMCD data structure resides out of the program image, and the offset is fixed to 300h.

XMCD consists of a XMCD header and a memory specific configuration block. On this chip, the following type of external RAM devices is supported and it has a specific configuration block.

- HyperRAM/APMemory via XSPI – XSPI RAM configuration block

9.5.2.2.1 XMCD Header

The header definition is as follows.

Table 52. XMCD Header Definition

[31:28] Tag	[27:24] Version	[23:20] Memory Interface	[19:16] Instance	[15:12] Configuration Block Type	[11:0] Configuration block size
Valid value = Ch	Fixed value of '0'	0 - XSPI	0 - XSPI0 1 - XSPI1	0 - Simplified Configuration Option Block 1 - Full Configuration Block	Configuration block size (including the XMCD Header itself).

9.5.2.2.2 XSPI RAM simplified configuration option clock

The XMCD offers a simplified XSPI RAM configuration option block which can meet the typical usage of the pSRAM (HyperRAM or APMemory) devices.

9.5.2.2.2.1 Simplified XSPI RAM Configuration Option Structure

The simplified XSPI RAM configuration option structure is shown in the following tables.

Table 53. Simplified XSPI RAM Configuration Option 0

[31:28] Tag	[27:24] Option Size	[23:20] device type	[19:16] Reserved	[15:12] Misc.	[11:8] Maximum frequency	[7:0] Size in MB
Fixed to Ch	0 - Option words = 1 1 - Option words = 2 Others - Reserved	0 - HyperRAM 1 - APMemory	Reserved	For HyperRAM 0 - Differential clock driven 1 - Single-ended clock driven	0 - Invalid 1 - 30 MHz 2 - 50 MHz 3 - 60 MHz 4 - 80 MHz	0 - Auto detection Others - Size in MB

Table continues on the next page...

Table 53. Simplified XSPI RAM Configuration Option 0

[31:28] Tag	[27:24] Option Size	[23:20] device type	[19:16] Reserved	[15:12] Misc.	[11:8] Maximum frequency	[7:0] Size in MB
					5 - 100 MHz 6 - 120 MHz 7 - 133 MHz 8 - 166 MHz 9 - 200 MHz Others - Reserved	

Table 54. Simplified XSPI RAM Configuration Option 1

[31:28] RAM_CONNECTION	[27:24] Reserved	[23:20] Reserved	[19:16] Reserved	[15] Bus width	[14:8] Maximum CS Low time	[7:4] Write dummy cycles	[3:0] Read dummy cycles
0 - PORTA	Reserved	Reserved	Reserved	• 0 - X8 mode • 1 - X16 mode	Max CS low interval = value x 0.1 µs	0 - Auto detection Others - Specified dummy cycles	0 - Auto detection Others - Specified dummy cycles

9.5.2.2.2.2 Example of XMCD for HyperRAM Support

The following table shows an example of XMCD for HyperRAM support.

Table 55. Example XMCD block for HyperRAM

Offset	Field	Description
0h	C001_0008h	Tag = Ch Version = 0 Memory Interface: XSPI Instance: 1 - XSPI1 Configuration block type: Simplified Configuration block size: 8 (4-byte header + 4-byte option block, option word1 not used)
4h	C000_0700h	Tag = Ch Option_Size = 0 DeviceType: HyperRAM Reserved: 0

Table continues on the next page...

Table 55. Example XMCD block for HyperRAM (continued)

Offset	Field	Description
		Misc: 0 = differential clock Max Freq: 7 = 133 MHz Memory Size: Auto-detection

9.5.3 Program XSPI NOR using ISP

The boot ROM supports the booting of the image from an external XSPI NOR flash memory device. This section describes how to use the blhost tool to program the image into an external nonvolatile memory for booting. The blhost tool uses supported serial peripherals to communicate with the ROM code via ROM ISP mode. See In-System Programming.

See Boot interface pin allocation for XSPI pin assignments of NOR flash memory connections.

9.5.3.1 Configuring the XSPI NOR flash memory device

9.5.3.1.1 Configuration options, settings, and parameters

9.5.3.1.1.1 Options

Table 56. XSPI serial NOR flash memory configuration options

Offset	Field	Description
0	Option0	See Table 57 for details.
4	Option1	Optional; effective only if the "option_size" field in option0 configuration is a non-zero value. See Table 58 for more information.

9.5.3.1.1.2 Option 0 field descriptions

Table 57. Option 0 field descriptions

Field	Bits	Description
tag	31:28	Tag of the configuration option, fixed to Ch
option_size	27:24	Size in bytes = (option size + 1) × 4 Set to 0 if only option0 is used.
device_type	23:20	Device detection type: 0 – Read SFDP for SDR commands 1 – Read SFDP for DDR read commands 2 – Reserved 3 – HyperFlash 3V 4 – Macronix Octal DDR 6 – Micron Octal DDR

Table continues on the next page...

Table 57. Option 0 field descriptions (continued)

Field	Bits	Description
		8 – Adesto EcoXiP DDR
query_pad	19:16	Data pads during Query command: (read SFDP or read MID) 0 – 1 2 – 4 3 – 8
cmd_pad	15:12	Data pads during flash memory access command: 0 – 1 2 – 4 3 – 8
quad_mode_setting	11:8	Quad SPI mode enable setting: 0 – Not configured 1 – Set bit 6 in Status register 1 2 – Set bit 1 in Status register 2 3 – Set bit 7 in Status register 2 4 – Set bit 1 in Status register 2 by using the 0x31 command **NOTE** This field is effective only if the chip is compliant with JESD216 (9 longword SFDP table).
misc_mode	7:4	Miscellaneous mode setting: 0 – Disabled 1 – Enable 0-4-4 mode for high random read performance 3 – Data Order Swapped mode (for MXIC octal flash memory only)
max_freq	3:0	Maximum flash memory operation speed: For SDR: 1 – 30 MHz 2 – 50 MHz 3 – 60 MHz 4 – 80 MHz (default) 5 – 100 MHz 6 - 120 MHz 7 - 133 MHz

Table continues on the next page...

Table 57. Option 0 field descriptions (continued)

Field	Bits	Description
		8 – 166 MHz 9 – 200 MHz

9.5.3.1.1.3 Option 1 field descriptions

Table 58. Option 1 field descriptions

Field	Bits	Description
Reserved	31:8	Reserved for future use
dummy_cycles	7:0	Dummy cycles for the Read command: 0 – Use detected dummy cycle Others – Use dummy cycles provided in the flash memory data sheet

9.5.3.1.1.4 Option settings

The following table shows typical XSPI serial NOR flash memory configuration option settings.

Table 59. XSPI serial NOR flash memory configuration option settings

XSPI mode name	Access type	Setting
Quad SPI NOR	Quad SPI SDR read	Option0 = C000_0002h (50 MHz)
Quad SPI NOR	Quad SPI DDR read	Option0 = C010_0002h (50 MHz)
HyperFlash 3V0	—	Option0 = C033_3002h (50 MHz)
MXIC OPI DDR (OPI DDR enabled by default)	—	C043_3001h (30 MHz)
Micron Octal DDR	—	Option0 = C060_0002h (50 MHz)
Micron OPI DDR	—	Option0 = C060_3002h (50 MHz)
Micron OPI DDR (DDR read enabled by default)	—	Option0 = C063_3002h (50 MHz)
Adesto OPI DDR	—	Option0 = C080_3002h (50 MHz)

9.5.3.1.2 Configuring, erasing, and programming via blhost

9.5.3.1.2.1 Configure via blhost

To configure a XSPI NOR flash memory device, the configuration parameter must be stored in RAM first. Consider Macronix MX25L25645G, which connects to the XSPI interface, as an example. The following figure shows the configuration parameter for XSPI, which is C000_0001h. You select a configuration parameter according to the flash memory type.

```
C:\blhost>blhost.exe -p com4 fill-memory 0x2001f000 4 0xc0000001
Ping responded in 1 attempt(s)
Inject command 'fill-memory'
```

```
Successful generic response to command 'fill-memory'
Response status = 0 (0x0) Success.
```

Code Listing 1. Setting the XSPI configuration parameter in RAM

9.5.3.1.2.2 Read, erase, and program via blhost

Use the configuration parameter stored in RAM (see Configure via blhost) to configure XSPI, as shown in the following figure. After that, you can read, erase, and program the flash memory. For details related to blhost tool commands, use the help section of the blhost tool. The memory id of XSPI is Bh, The starting address of image in XSPI0 is 2800_4000h and the starting address of image in XSPI1 is 0800_4000h.

```
C:\blhost>blhost.exe -p com4 configure-memory 0xb 0x2001f000
Ping responded in 1 attempt(s)
Inject command 'configure-memory'
Successful generic response to command 'configure-memory'
Response status = 0 (0x0) Success.
```

Wrote 5796 of 5796 bytes.
```

Code Listing 5. Programming the boot image into NOR flash memory via the blhost tool

9.5.3.1.2.3 Generate and program FCB via blhost

Generate and program the XSPI NOR FCB into the flash memory for XSPI boot, with an FCB of 768 bytes at offset 0h. You use this FCB to configure the XSPI interface when booting the image from an external NOR flash memory via the XSPI interface. You can generate the FCB using the previous XSPI configuration parameter (C000_0002h). Store the configured FCB and program parameter into RAM (see Code Listing 6). The boot ROM uses these in the next step to automatically generate and program the FCB into flash memory at offset 0800_0000h (see Code Listing 7).

```
C:\blhost>blhost.exe -p com4 fill-memory 0x2000f000 4 0xf000000f
Ping responded in 1 attempt(s)
Inject command 'fill-memory'
Successful generic response to command 'fill-memory'
Response status = 0 (0x0) Success.
```

Code Listing 6. Storing the configured FCB parameter into RAM

```
C:\blhost>blhost.exe -p com4 configure-memory 0x9 0x2000f000
Ping responded in 1 attempt(s)
Inject command 'configure-memory'
Successful generic response to command 'configure-memory'
Response status = 0 (0x0) Success.
```

```

Code Listing 8. Reading the FCB back via the blhost tool

9.5.3.1.3 Typical configuration parameters

You require different configuration parameters for different XSPI NOR flash memory types. The following table shows some typical flash memory configuration parameters.

Table 60. Typical NOR flash memory configuration parameters

Device vendor	Device type	Flash memory type	Configuration parameter	Flash memory mode	Comment
Adesto	Octal SPI flash memory	ATXP032	C080_3001h	DDR	ATXP032 has three versions, REV A, REV B, and REV C. For REV A, the boot ROM only supports auto probe boot. You must configure XSPI_CFG0[3:0] as 7h, with no need to configure FCB.
Cypress	HyperFlash memory	S26KS512S	C023_3001h	DDR	For HyperFlash boot, you must configure XSPI_CFG0[XSPI_FLASH_TYPE] as 010b before boot.
Macronix	Quad SPI flash memory	MX25L25645G	C000_0001h	SDR	—
Macronix	Quad SPI flash memory	MX25L25645G	C010_0001h	DDR	—
Macronix	Octal SPI flash memory	MX25UM51345G	C040_3001h	DDR	—
Micron	Octal SPI flash memory	MT35XL512ABA	C060_3001h	DDR	—

9.5.3.2 Programming the boot image into the flash memory

The following table lists the procedure and corresponding commands to program the boot image into the external flash memory with all data encrypted (see Configuring the XSPI NOR flash memory device for more information).

Table 61. XSPI NOR flash memory configuration

Step number	Step	Command to perform the step
1	Fill in the flash configuration parameter.	`blhost.exe -p com4 fill-memory 0x20020000 4 0xc0000001`
2	Enable the flash memory.	`blhost.exe -p com4 configure-memory 0xb 0x20020000`
3	Fill in the FCB generation parameters.	`blhost.exe -p com4 fill-memory 0x20020004 4 0xf000000f`
4	Program FCB at flash memory offset 0h.	`blhost.exe -p com4 configure-memory 0xb 0x20020004`
5	Erase the flash memory region from 0800_4000h to 0801_4000h.	`blhost.exe -p com4 flash-erase-region 0x08004000 0x10000`
6	Program the boot image into the flash memory from offset 0800_4000h.	`blhost.exe -p com4 write-memory 0x08004000 image.bin`

9.5.4 Dual image boot

XSPI supports dual image boot. For dual image boot, Boot ROM first tries to boot the image with higher image version. If boot fails, the boot ROM tries to boot the other image. If the boot still fails, it will go to recovery boot if REC_BOOT_EN is enabled. Before using this feature, you need to configure the XSPI_FLASH_SEC_IMAGE_OFFSET. The value of XSPI_FLASH_SEC_IMAGE_OFFSET is the offset of the second image (converted to KB) divided by 128.

In another word,

- Write image0 to the offset address of 4000h (default offset address) of XSPI flash:
  - For XSPI0 NOR, write image0 to 2800_4000h
  - For XSPI1 NOR, write image0 to 0800_4000h
- write image1 to the offset address of XSPI_FLASH_SEC_IMAGE_OFFSET × 128 KB of XSPI flash:
  - For XSPI0 NOR, write image1 to 2800_0000h + XSPI_FLASH_SEC_IMAGE_OFFSET × 128 KB
  - For XSPI1 NOR, write image1 to 0800_0000h + XSPI_FLASH_SEC_IMAGE_OFFSET × 128 KB.

Take booting from XSPI0 as an example. Set the XSPI_FLASH_SEC_IMAGE_OFFSET to 1, then image1 is at 2802_0000h. Commands below show the steps to program those two images.

```
// Initialize XSPI
C:\blhost>blhost.exe -p com4 -- fill-memory 0x20070000 0x4 0xc0000007
C:\blhost>blhost.exe -p com4 -- fill-memory 0x20070004 0x4 0x00000000
C:\blhost>blhost.exe -p com4 -- configure-memory 0xb 0x20070000
// Erase a piece of memory to write two images
C:\blhost>blhost.exe -p com4 -- flash-erase-region 0x28000000 0x4000 0xb
C:\blhost>blhost.exe -p com4 -- flash-erase-region 0x28004000 0x4000 0xb
C:\blhost>blhost.exe -p com4 -- flash-erase-region 0x28020000 0x4000 0xb
// Write image0
C:\blhost>blhost.exe -p com4 -- write-memory 0x28004000 boot_image0.bin 0xb
// Write image1
C:\blhost>blhost.exe -p com4 -- write-memory 0x28020000 boot_image1.bin 0xb
```

9.5.4.1 Basic remapping function

Boot ROM supports dual image boot by using the MMUs with XSPI. It allows user to use same linker file for the two images and keep both images on the XSPI NOR with different versions. Boot ROM boots the image with higher version. If the version of image0 located at offset 4000h (default offset) is lower than image1 located at higher offset, Boot ROM will remap the whole image1 (size specified by fuse field of XSPI_FLASH_IMAGE_SIZE in fuse word 153) to offset 4000h and boot the image. Figure below shows the XSPI NOR layout before remapping (left) and after remapping (right).

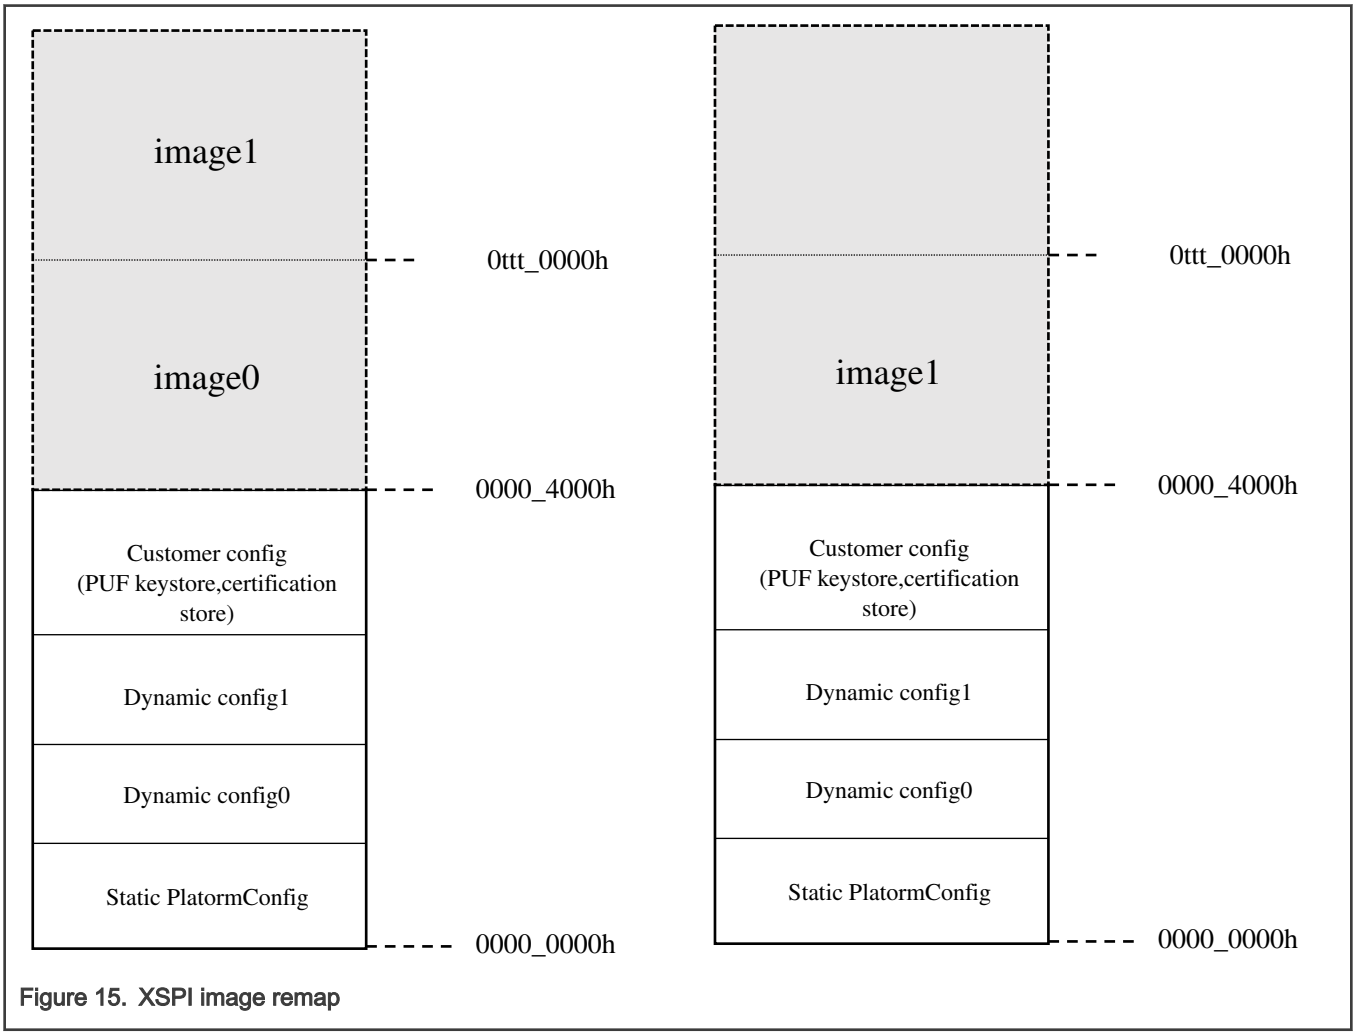

Figure 15. XSPI image remap

9.5.4.2 Image remap offset and size configuration

The configuration related to XSPI dual-image boot is in XSPI_CFG[1]. See the following table for more information.

Table 62. Boot image 1 remap offset (XSPI_CFG[1])

Name that is filled	Bit offset	Width	Value	Description
XSPI_FLASH_SEC_IMAGE_OFFSET (second image offset based on XSPI start address of 2800_0000h or 0800_0000h)	7	10	*x*	*x* multiplied by 128 KB

Table 63. Boot Image size (XSPI_CFG[1])

Name that is filled	Bit offset	Width	Value	Description
XSPI_FLASH_IMAGE_SIZE	17	7	0	Same size as the image offset (XSPI_IMAGE_OFFSET)
			1	128 KB
			2	256 KB
			m	m × 128 KB (m=3-7)
			8	1 MB
			n	(n-7) × 1 MB (n=8-71)

NOTE

XSPI remap size cannot exceed the start address of boot image1.

9.5.4.3 Dual image boot flow

Figure below shows the dual image boot flow done by Boot ROM.

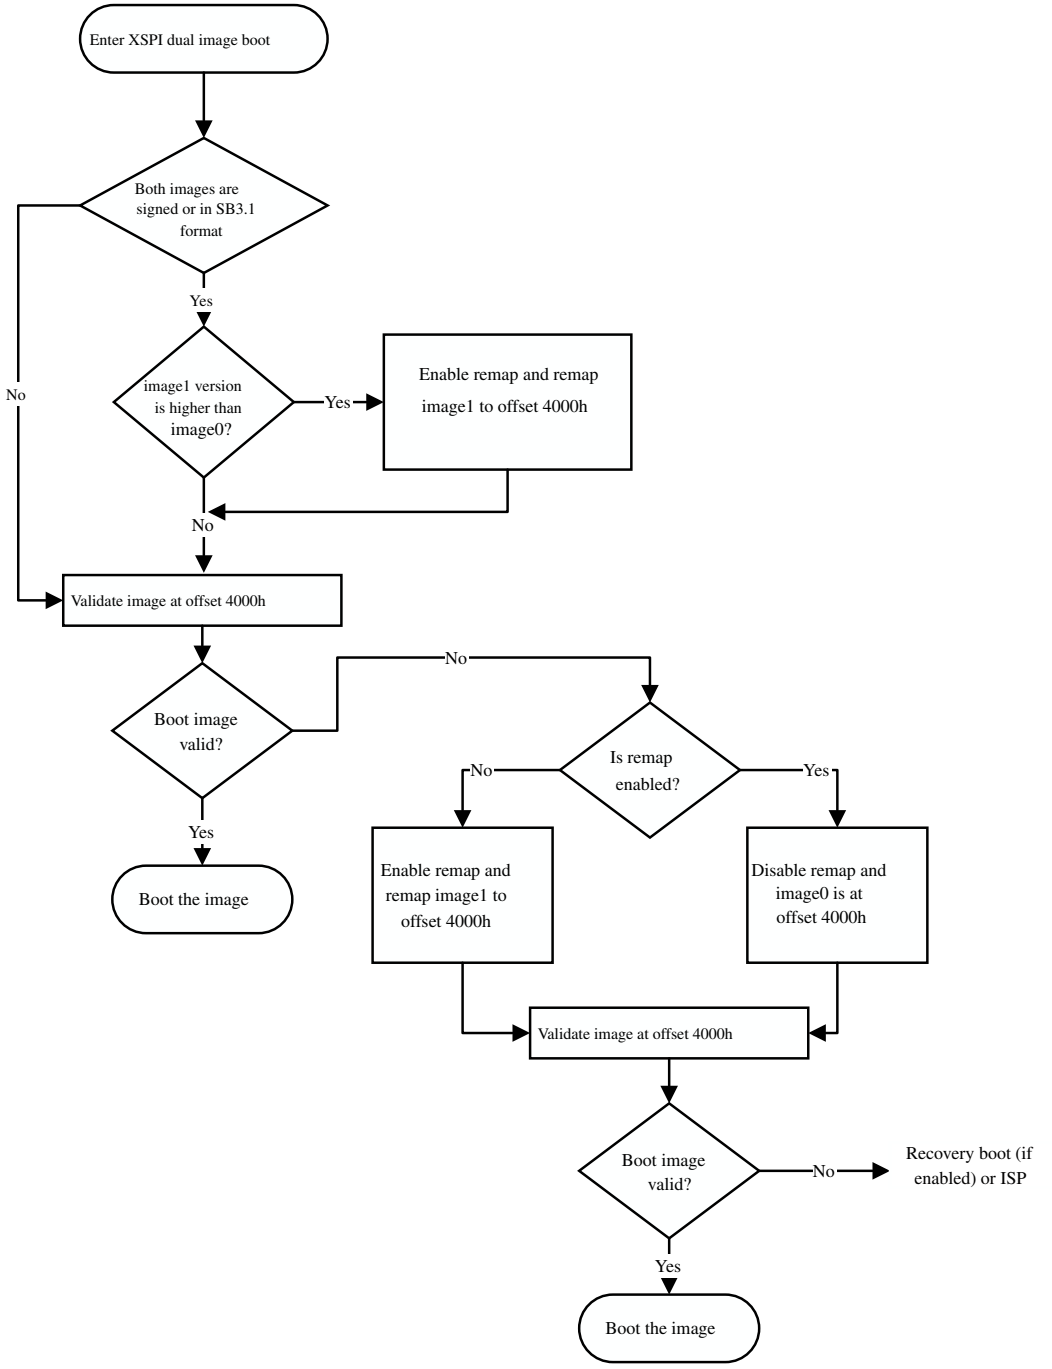

Figure 16. Dual image boot flow

9.6 Prime boot from eMMC

Boot ROM supports prime boot from eMMC connected to uSDHC instance 0 or 1. Load-to-RAM boot image is supported for eMMC. Boot ROM supports load the boot image from eMMC to on-chip SRAM (starts from offset 15000h) and XSPI pSRAM to boot.

At Develop (3h) lifecycle, load-to-RAM image can be any image with valid image header. When secure boot is enforced or lifecycle is after Develop (3h), the load-to-RAM image must be in SB3 format and the image to generate SB3 should either be CRC image or signed image.

You can start eMMC boot by:

- BOOT_SRC[1:0] = 00b and BOOT_PIN_MODE = 00b, uSDHC0 will be selected as boot source
- BOOT_SRC[1:0] = 10b, Boot ROM will directly boot from uSDHC flash, and uSDHC instance is selected via BOOT_IF_INST

Once eMMC boot is selected, Boot ROM tries to find the boot image from offset 1000h of the eMMC. XMCD is also supported by eMMC primary boot. XMCD for eMMC boot should be programed at offset 300h.

9.6.1 eMMC boot configuration

The eMMC boot can be performed using the uSDHC ports. Selected uSDHC port can be configured using fuses from fuse word 158 and 159 for different conditions. See table below for details:

Table 64. eMMC boot configuration

FUSE_WORD	Bits	Field name	Shipped value	Settings
158 SDHC_CFG0 for uSDHC0 159 SDHC_CFG1 for uSDHC1	1:0	SDHC_BUS_WIDTH	00	eMMC bus width selection • 00 - 4 bits • 01 – 8 bits • 10 – 4 bits DDR • 11 – 8 bits DDR
	2	SDHC_PWR_CYCLE_EN	0	Power cycle enable • 0 – No power cycle • 1 – Power cycle enabled via RST pad
	4:3	SDHC_PWR_CYCLE_WAIT	0	Power down wait selection • 00 – 20 ms • 01 – 10 ms • 10 – 5 ms • 11 – 2.5 ms
	6:5	SDHC_PWR_STABLE_WAIT	0	Power up wait selection • 00 – 5 ms • 01 – 2.5 ms • 10 – Reserved • 11 - Reserved
	7	SDHC_PWR_POL	0	uSDHC reset polarity selection • 0 – Reset active low • 1 – Reset active high
	8	Reserved	0	—

Table continues on the next page...

Table 64. eMMC boot configuration (continued)

FUSE_WORD	Bits	Field name	Shipped value	Settings
	9	SDHC_RESET_PRE_IDLE	0	eMMC disable pre-idle selection • 0 – Enable • 1 – Disable
	10	SDHC_MMC_SPEED	0	eMMC speed selection • 0 – Normal speed • 1 – High speed
	31:11	Reserved	0	—

The boot code support standards: eMMCv4.4 or higher.

9.6.2 eMMC boot flow

During the initialization, the eMMC frequency is set to 400 kHz. When the eMMC card enters the identification portion of the initialization, the voltage validation is performed, and Boot ROM checks the high-voltage settings and the card capacity. Boot ROM supports both the high-capacity and low-capacity eMMC cards. The boot partition can be selected for an MMC4.x card after the card initialization is complete.

To boot from eMMC card, it is mandatory to take below actions for a successful eMMC boot:

1. Configure eMMC card with configuration words at ISP mode
2. Program image to eMMC card at offset 1000h
3. Program XMCD at offset 300h if target load address is pSRAM connected to XSPI. For detailed XMCD configuration, see External Memory Configuration Data (XMCD)
4. Program eMMC boot fuse configuration and reset to enter eMMC boot via related configurations. See Prime boot from eMMC for methods to enter eMMC boot.

9.6.3 Program eMMC card using ISP

Boot ROM has implemented In-System-Programming (ISP) to enable programming eMMC flash via available peripherals and thus can be utilized to configure and program eMMC card.

For configuration of eMMC card, fill-memory with configuration words and configure-memory command can be used. Boot ROM will always store the configuration words to RAM with fill-memory command, and then apply configuration to configure the memory device via configure-memory. For eMMC configuration words when ISP mode, detailed definition is described as below.

Table 65. eMMC configuration block definition

Word index	Bits	Name	Description
Word0	[31:28]	TAG	eMMC configuration block tag used to mark if the block is valid or not • Ch: Valid block • Others: Invalid

Table continues on the next page...

Table 65. eMMC configuration block definition (continued)

Word index	Bits	Name	Description
	[27]	Reserved	—
	[26:24]	PARTITION_ACCESS	Select eMMC partition where the image or data write to • 0h: User data area • 1h: Boot partition 1 • 2h: Boot partition 2 • 3h: RPMB • 4h: General Purpose partition 1 • 5h: General Purpose partition 2 • 6h: General Purpose partition 3 • 7h: General Purpose partition 4
	[23:16]	Reserved	—
	[15:12]	TIMING_INTERFACE	Select the bus timing when accesses eMMC memory • 0h: Normal • 1h: HS • 2h-Fh: Reserved

	[7:0]	Reserved	—
Word1	[31:26]	Reserved	—
	[25:24]	PWR_DOWN_TIME	eMMC power down delay time before power up the eMMC card Only valid when PWR_ CYCLE_ENABLE is enabled • 0h: 20 ms • 1h: 10 ms • 2h: 5 ms

Table continues on the next page...

Table 65. eMMC configuration block definition (continued)

Word index	Bits	Name	Description
			• 3h: 2.5 ms
	[23]	PWR_POLARITY	eMMC power control polarity. Only valid when PWR_CYCLE_ENABLE is enabled • 0h: Power down when uSDHC.RST set low • 1h: Power down when uSDHC.RST set high
	[22:21]	Reserved	—
	[20]	PWR_UP_TIME	eMMC power up delay time to wait voltage regulator output stable Only valid when PWR_CYCLE_ENABLE is enabled • 0h: 5 ms • 1h: 2.5 ms
	[19]	PWR_CYCLE_ ENABLE	Execute a power cycle before starting the SD initialization progress • 0h: Disable • 1h: Enable
	[18:4]	Reserved	—
	[3:0]	USHDC_INSTANCE	Select uSDHC instance as interface • 0h: uSDHC0 • 1h: uSDHC1 • Others: Reserved

Once eMMC card is correctly configured, Write-memory can be used to program boot image to eMMC card. Memory id of eMMC is 121h, and the offset of image is 1000h.

Below is an example of configuring eMMC boot image:

```
//Initialize EMMC
blhost -p com4 -- fill-memory 0x20070000 0x4 0xc0000000
blhost -p com4 -- fill-memory 0x20070004 0x4 0x00000000
blhost -p com4 -- configure-memory 0x121 0x20070000
//Erase memory
blhost -p com4 -- flash-erase-region 0x0 0x4000 0x121
//Write image to EMMC
blhost -p com4 -- write-memory 0x1000 boot_image.bin 0x121
```

9.7 Boot from serial NAND (XSPI)

BootROM supports load-to-RAM (load to SRAM and XSPI pSRAM are both supported) boot from serial NAND connected on XSPI0 or XSPI1. The boot ROM supports several Serial NAND Flash devices from different vendors.

You can start XSPI NAND boot by:

- BOOT_SRC[1:0] = 11b, Boot ROM will directly boot from XSPI NAND flash, and XSPI instance is selected via BOOT_IF_INST.
- ROM API bootloader entry path by setting the valid tag, prime boot mode, and the XSPI NAND interface and with the specific instance, Boot ROM will directly boot from XSPI NAND flash.

9.7.1 Serial NAND eFUSE configuration

The boot ROM determines the configuration of external serial NAND flash by parameters, which are provided by eFUSE during boot. See below table for parameters details.

Table 66. eFuse definition for serial NAND over XSPI

Fuse	Definition	Settings	Shipped Value
XSPI_CFG0[18:16]	XSPI_RESET_PIN_PORT	GPIO port. This field is valid only if XSPI_RESET_PIN_EN is set.	0
XSPI_CFG0[23:19]	XSPI_RESET_PIN_GPIO	GPIO pin number. This field is valid only if XSPI_RESET_PIN_EN is set.	0
OTP_XSPI_NAND_CFG9 (XSPI_NAND)[0]	XSPI_NAND_SEARCH_CNT	0b - Search at most 1 block (for BCB) 1b - Search at most 2 blocks	0
OTP_XSPI_NAND_CFG9 (XSPI_NAND) [1]	XSPI_NAND_COL_ADDR_WIDTH	0b - 11 bits (for 2 KB-page devices) 1b - 12 bits (for 4 KB-page devices)	0
OTP_XSPI_NAND_CFG9 (XSPI_NAND) [3:2]	XSPI_NAND_CS_INTERVAL	CS de-asserted interval between two commands 00b - 100 ns 01b - 200 ns 10b - 400 ns 11b - 50 ns	0
OTP_XSPI_NAND_CFG9 (XSPI_NAND) [5:4]	XSPI_NAND_SEARCH_STRIDE	BCB search step/stride, aligned with block size 00b - 64 pages 01b - 128 pages 10b - 256 pages 11b - 32 pages	0
OTP_XSPI_NAND_CFG9 (XSPI_NAND) [7:6]	XSPI_NAND_HOLD_TIME	Hold time before interaction with NAND 00b - Wait until NAND is idle (by polling NAND's status register) 01b - 500 µs 10b - 1ms 11b - 3 ms	0

Table continues on the next page...

Table continues on the next page...

Table 66. eFuse definition for serial NAND over XSPI (continued)

Fuse	Definition	Settings	Shipped Value
		Others - Reserved	

NOTE

All the fuse fields in BOOT_CFG9 (XSPI_NAND) are there for FCB derivation stage. After successful FCB derivation, XSPI is re-configured as per FCB.

9.7.2 XSPI NAND flash boot flow and boot control blocks (BCB)

There are two BCB data structures:

- FCB
- DBBT

As part of the NAND media initialization, the ROM driver uses safe NAND timings to search for a Firmware Configuration Block (FCB) that contains the optimum NAND timings, page address of Discovered Bad Block Table (DBBT) Search Area and start page address of primary and secondary firmware.

The built-in hardware ECC in serial NAND device is used during data read, the FCB data structure is protected using CRC checksum. The driver reads raw 1024 bytes of the first sector and runs through CRC check that determines whether FCB data is valid or not.

If the FCB is found, the optimum NAND timings are loaded for further reads. If the ECC fails, or the fingerprints do not match, the Block Search state machine increments page number to Search Stride number of pages to read for the next BCB until SearchCount pages have been read.

If search fails to find a valid FCB, the NAND driver responds with an error and the boot ROM falls back to the main boot flow (e.g., turn to recovery boot).

The FCB contains the page address of DBBT Search Area, and the page address for primary and secondary boot images. ROM searches DBBT Search Area for DBBT, resembling the search for FCB. After the FCB is derived, the DBBT is loaded, and the primary or secondary boot image is loaded using the starting page address from FCB.

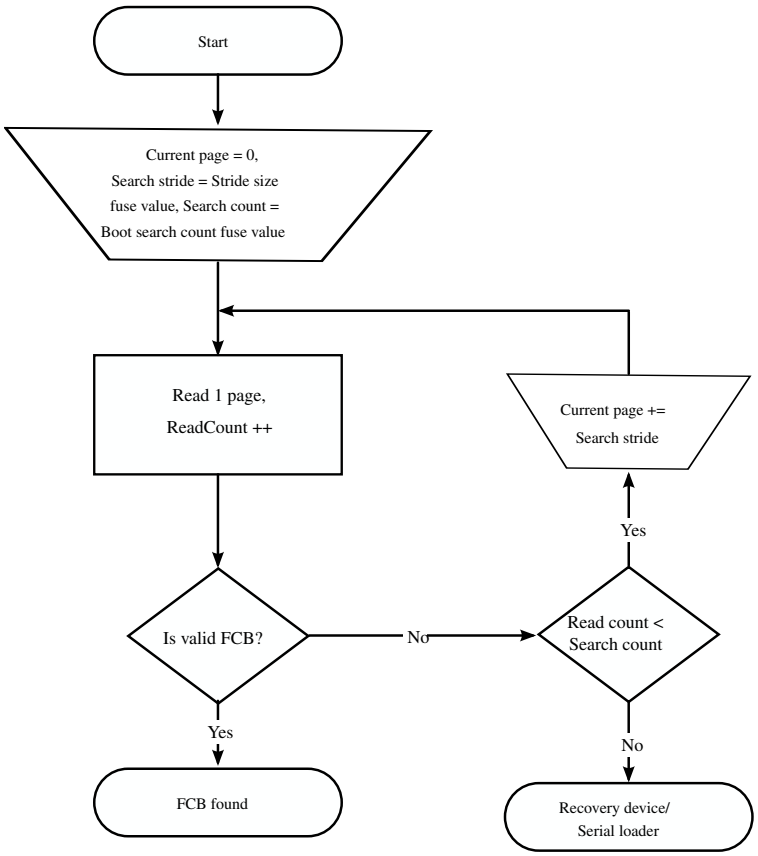

Figure 17. FCB search flow

After FCB is found, the boot ROM searches for the Discovered Bad Blocks Table (DBBT). If DBBTSearchStartPage is 0 in the FCB, then ROM assumes that there are no bad blocks in the NAND device boot area. See figure below for the DBBT search flow.

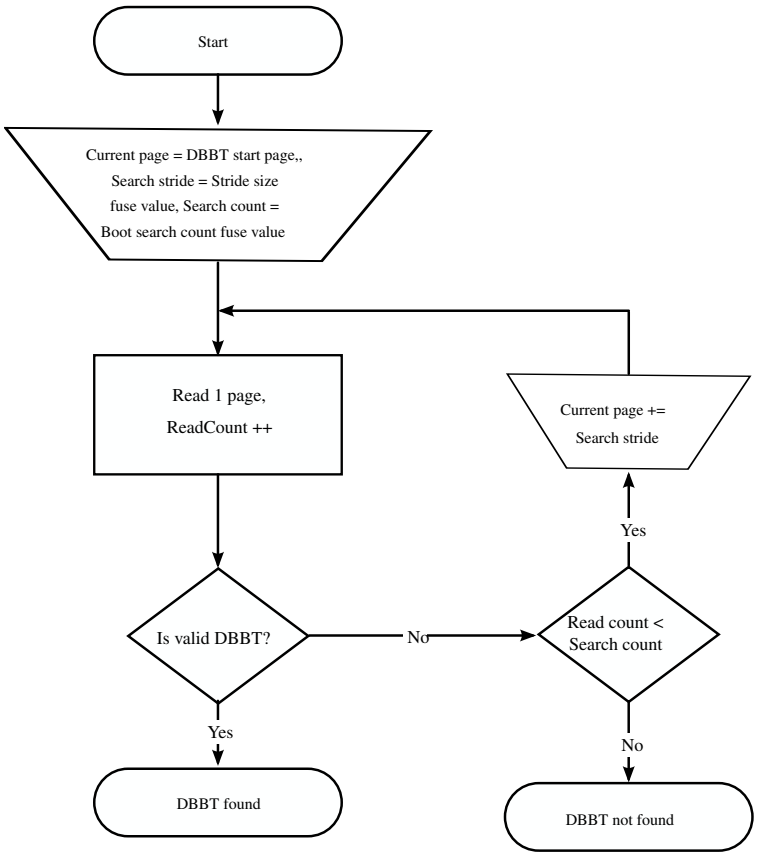

Figure 18. DBBT search flow

After finding the valid FCB data, if the FCB has the valid XMCD data, the device will configure the external pSRAM memory based on the XMCD configuration, and then load the NAND image into the pSRAM region and boot the NAND image.

If during primary image read a page has more errors than ECC can correct or other boot fails, the boot ROM will try the redundant boot hander flow and set the API Entry register SYSCON_S0->ROM_SCRATCH1_POR with increment boot_image_index and try a redundant image boot. The redundant boot number depends on the firmwareCopies value in the FCB, call the redundant boot hander flow until the NAND image boot pass. If all the redundant boots fail, the boot ROM goes back to main boot flow (Recovery Device boot or Serial Loader Flow).

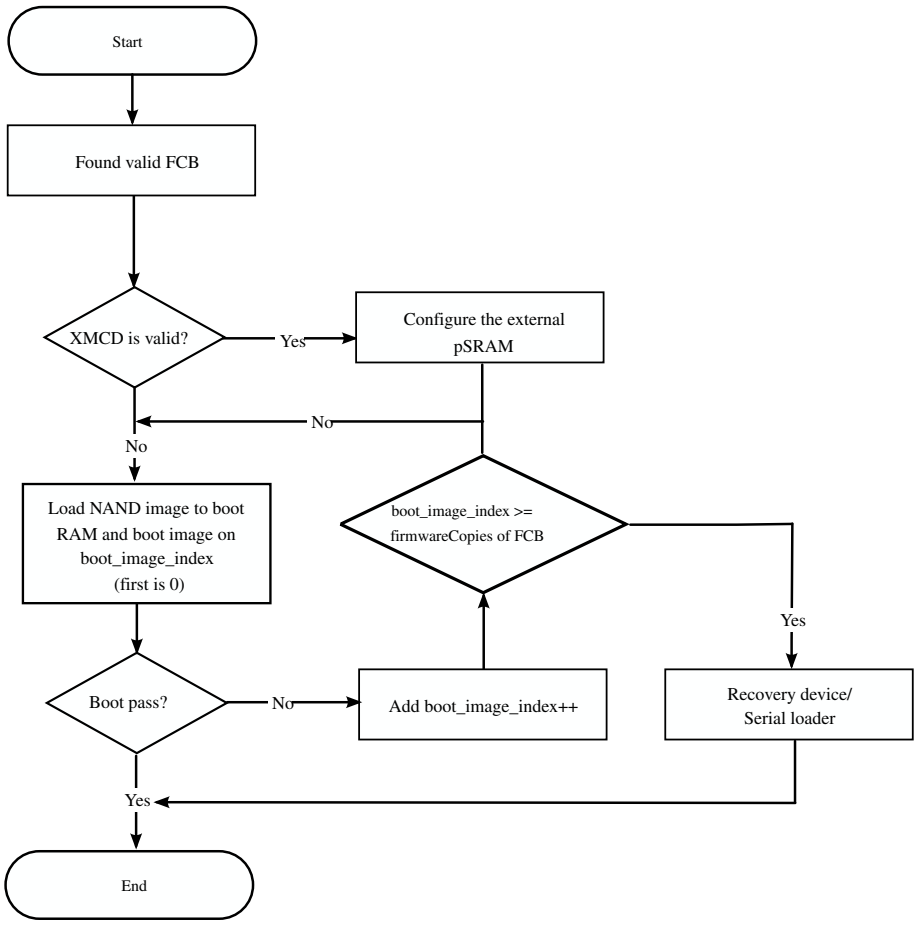

Figure 19. NAND image boot flow

9.7.3 Firmware Configuration Block (FCB)

The Firmware Configuration Block (FCB) is at the first page in the good block which is searched by searchStride (XSPI_NAND_SEARCH_STRIDE in the efuse region) step. The FCB should be present at each search stride of the search area.

The search area contains copies of the FCB at each stride distance. When the first serial NAND block becomes corrupted, ROM will find its copy in the next serial NAND block. The search area should span over at least two serial NAND blocks. The location information for DBBT search area and images are all specified in the FCB. The following table shows the flash control block structure.

Table 67. Flash control block structure

Name	Offset	Size bytes	Description
crcChecksum	000h	4	Checksum. This is calculated with an MPEG2 variant of CRC-32. See Table 68 for more details. it calculates from fingerprint to the end of FCB, 1020 bytes in total.
fingerprint	004h	4	4E46_4342h ASCII: “NFCB”

9.7.3.2 External Memory Configuration Data (XMCD)

On-chip RAM may not be enough for comprehensive or feature-rich applications. An application requires a large capacity of RAM and needs to run on the external RAM for high execution performance. However, enabling the external RAM on the chip is complicated, and the settings are chip specific. The Boot ROM on the chip simplifies the external RAM configuration by introducing the XMCD. The XMCD data structure resides at offset 368h starting from NAND FCB.

The XMCD consists of an XMCD header and a memory specific configuration block. On this chip, the following types of external RAM devices are supported. Each type of RAM device has a specific configuration block.

9.7.3.2.1 Simplified XSPI RAM configuration option structure

The simplified XSPI RAM configuration option structure is shown in the following tables.

Table 70. XMCD header definition

[31:28] Tag	[27:24] Version	[23:20] Memory interface	[19:16] Instance	[15:12] Configuration block type	[11:0] Configuration block size

9.7.4 Discovered Bad Blocks Table (DBBT)

Table 75. DBBT structure

Name	Offset	Size (bytes)	Description
crcChecksum	000h	4	Checksum. Calculated from Fingerprint to the end of DBBT, 1052 bytes in total
Fingerprint	004h	4	32-bit word with a value of 4442_4254h in ASCII “DBBT”
Version	008h	4	32-bit version number, this version of DBBT is 0000_0001h
Reserved	00Ch	4	Reserved
badBlockNumber	010h	4	Number of bad blocks. The maximum value is 0000_0100h.
Reserved	014h	12	Must be filled with all 0s
Bad block entries	020h	1024 (256 x 4)	Each bad block entry is a 32-bit value specifying the number of a found bad block. The number of valid bad block entries is specified by the badBlockNumber field, where valid bad block entries are stored sequentially starting at the beginning of the bad block entries segment. Unused bad block entries (those beyond the badBlockNumber) should be filled with all Fs.

9.7.4.1 Bad block handling in ROM

During the firmware boot, at the block boundary, the Bad Block table is searched for a match to the next block. If no match is found, the next block can be loaded. If a match is found, the block must be skipped and the next block will be checked.

9.7.5 Serial NOR and NAND flash configuration based on XSPI interface

The ROM software supports serial NOR flash and serial NAND flash based on XSPI module, using a 448-bytes common XSPI configuration block and several specified parameters for serial NOR flash and serial NAND flash respectively. See the following sections for more details.

9.7.5.1 XSPI configuration block

XSPI configuration block consists of parameters regarding specific flash devices including read command sequence, quad mode enablement sequence (optional), etc.

Table 76. XSPI configuration block

Name	Offset	Size(bytes)	Description
Tag	000h	4	4246_4346h, ascii: 'FCFB'
Version	004h	4	[07:00] bugfix = 0 [15:08] minor [23:16] major = 1

Table continues on the next page...

Table 76. XSPI configuration block (continued)

Name	Offset	Size(bytes)	Description
			[31:24] ASCII 'V'
Reserved	008h	4	—
readSampleClkSrc	00Ch	1	• 00h – internal loopback • 01h – loopback from DQS pad • 03h – Flash provided DQS
csHoldTime	00Dh	1	Serial flash CS Hold Time Recommend default value is 03h
csSetupTime	00Eh	1	Serial flash CS setup time Recommended default value is 03h
columnAdressWidth	00Fh	1	03h – For HyperFlash 0Bh/0Ch – For Serial NAND, see data sheet of your NAND flash for the value 00h – Other devices
deviceModeCfgEnable	010h	1	Device mode configuration enable feature • 00h – Disabled • 01h –Enabled
deviceModeType	011h	1	• 00h - Generic • 01h - Quad Enable • 02h - SPI-to-XSPI mode • 03h - XSPI-to-SPI mode • 04h - SPI-to-NoCmd mode
waitTimeCfgCommands	012h	2	Wait time for all configuration commands, unit 100 µs. Available for device that support XSPI configuration block. If it is greater than 0, ROM will wait waitTimeCfgCommands x 100 µs for all device memory configuration commands instead of using read status to wait until these commands complete.
deviceModeSeq	014h	4	Sequence parameter for device mode configuration Bit[7:0] - number of LUT sequences for Device mode configuration command
			Bit[15:8] - starting LUT index of Device mode configuration command Bit[31:16] - must be 0

Table continues on the next page...

Table 76. XSPI configuration block (continued)

Name	Offset	Size(bytes)	Description
deviceModeArg	018h	4	Device mode argument, effective only when deviceModeCfgEnable = 01h
configCmdEnable	01Ch	1	Configure command enable feature • 00h – Disabled • 01h – Enabled
configModeType	01Dh	3	Configure mode type • 00h - Generic • 01h - Quad Enable • 02h - SPI-to-XSPI mode • 03h - XSPI-to-SPI mode • 04h - SPI-to-NoCmd mode
configCmdSeqs	020h	12	Sequences for configure command, allow 3 separate configuration command sequences.
ipedMode	02Ch	1	IPED mode • 00h - kxSpiIpedModeNone • 01h - kxSpiIpedModeCtr • 02h - kxSpiIpedModeGcm • 03h - kxSpiIpedModeXex • Others - Reserved
x16DllaSlvFineOffset	02Dh	1	Fine offset delay elements in incoming DQS1
maxCsLowInterval	02Eh	1	Configure pSRAM tcsm, unit 0.1 µs
ahbAlignment	02Fh	1	AHB alignment, • 00b - No limit • 01b - 256 B • 10b - 512 B • 11b - 1 KB • Others - Reserved
cfgCmdArgs	030h	12	Arguments for each separate configuration command sequence.
ahbSplitEn	03Ch	1	Enable AHB transaction split for pSRAM
Reserved	03Dh	3	—
controllerMiscOption	040h	4	Bit0 – differential clock enable Bit1 – CK2 enable, must set to 0 Bit2 – ParallelModeEnable

Table 76. XSPI configuration block (continued)

Name	Offset	Size(bytes)	Description
			Bit3 – wordAddressableEnable Bit4 – Safe Configuration Frequency enable set to 1 for the devices that support DDR Read instructions Bit5 – Pad Setting Override Enable Bit6 – DDR Mode Enable, set to 1 for device supports DDR read command Bit 7 - Pad Setting Override Enable Bit 8 - Second Pin group Bit 9 - Second DQS pin group Bit 10 - Write Mask Enable Bit 11 - Write Opt1 Clear Other bits - Reserved
deviceType	044h	1	• 01h – Serial NOR • 02h – SerialNAND • 03h - Serial RAM (HyperRAM/APMemory)
sflashPadType	045h	1	• 01h – Single pad • 02h – Dual pads • 04h – Quadpads • 08h – Octalpads
serialClkFreq	046h	1	• 01h – 30 MHz • 02h – 50 MHz • 03h – 60 MHz • 04h – 80 MHz • 05h – 100 MHz • 06h – 120 MHz • 07h – 133 MHz • 08h – 166 MHz • Others: 30 MHz
lutCustomSeqEnable	047h	1	• 00h– Use pre-defined LUT sequence index and number • 01h- Use LUT sequence parameters provided in this block
Reserved	048h	8	—
sflashA1Size	050h	4	For XSPI NOR, need to fill with actual size

Table continues on the next page...

Table 76. XSPI configuration block (continued)

Name	Offset	Size(bytes)	Description
			For XSPI NAND, need to fill with actual size x 2
sflashA2Size	054h	4	For XSPI NOR, need to fill with actual size For XSPI NAND, need to fill with actual size x 2
sflashB1Size	058h	4	For XSPI NOR, need to fill with actual size For XSPI NAND, need to fill with actual size x 2
sflashB2Size	05Ch	4	For XSPI NOR, need to fill with actual size For XSPI NAND, need to fill with actual size x 2
csPadSettingOverride	060h	4	Overriding pad setting of CS with this value if it is not 0h
sclkPadSettingOverride	064h	4	Overriding pad setting of SCLK with this value if it is not 0h
dataPadSettingOverride	068h	4	Overriding pad setting of data signals with this value if it is not 0h
dqsPadSettingOverride	06Ch	4	Overriding pad setting of DQS with this value if it is not 0h
timeoutInMs	070h	4	Maximum wait time with the unit of ms during read busy status • 0000_0000h – Disabled timeout checking feature • Other value – Timeout if the wait time exceeds this value
commandInterval	074h	4	Unit: ns Currently, it is used for XSPI NAND only at high frequency
dataValidTime	078h	4	Time from clock edge to data valid edge, unit ns. This field is used when the XSPI1 Root clock is less than 100 MHz and the read sample clock source is device provided DQS signal without CK2 support. • [31:16] data valid time for DLLB in terms of 0.1 ns • [15:0] data valid time for DLLA in terms of 0.1 ns
busyOffset	07Ch	2	busy bit offset, valid range :0000h-001Fh
busyBitPolarity	07Eh	2	• 0000h – busy bit is 1 if device is busy • 0001h – busy bit is 0 if device is busy
lookupTable	080h	360	Lookup table
lutCustomSeq	1E8h	48	Customized LUT sequence, see Table 77 for details.

smprSdrVal	21Ch	4	Customizable SMPR SDR setting
dllCraDdrVal	220h	4	Customizable DLLCRA for DDR setting
smprDdrVal	224h	4	Customizable SMPR DDR setting

9.7.5.2 Serial (XSPI) NAND, the pre-defined LUT

Table 77. LUT sequence definition for serial NAND

Command index	Name	Index in lookup table	Description
0	ReadFromCache	0	Read from cache
1	ReadStatus	1	Read status
2	WriteEnable	3	Write Enable
3	BlockErase	5	Erase block
4	ProgramLoad	9	Program load
5	ReadPage	11	Read page to cache
6	ReadEccStatus	13	Read ECC status
7	ProgramExecute	14	Program execute
8	ReadFromCacheOdd	4	Read from cache while page in odd plane
9	ProgramLoadOdd	10	Program load for pages within odd blocks
Others	Reserved	2,6,7,8,12,15	All reserved indexes can be freely used for other purposes

NOTE

All the pre-defined LUT indexes are only applicable to boot stage. User application can use the whole 16 LUT entries freely based on their requirement.

9.7.6 Program XSPI NAND using ISP

Boot ROM has implemented In-System-Programming (ISP) to enable programming XSPI NAND flash via available peripherals and thus can be utilized to configure and program XSPI NAND.

For configuration of XSPI NAND, fill-memory with configuration words and configure-memory command can be used. Boot ROM will always store the configuration words to RAM with fill-memory command, and then apply configuration to configure the memory device via configure-memory. For XSPI NAND configuration words in ISP mode, detailed definition is described as below.

```
kSpiNandMemory_MaxFirmware = 8U,
typedef struct _spinand_img_option
{
    union
    {
        struct
```

```
        {
            uint32_t size : 4;          //!< Size in longword
            uint32_t reserved0 : 4;     //!< Reserved for future use
            uint32_t address_type : 4;  //!< NAND Adress type: 0 - byte address, 1 - block address
            uint32_t reserved1 : 8;     //!< Reserved for future use
            uint32_t search_stride : 4; //!< Search Stride: 0-64 pages, 1-128 pages, 2-256 pages,
3-32 pages.
            uint32_t search_count : 4;  //!< 1 - 1, 2 -2 ,3 - 3, 4 - 4
            uint32_t tag : 4;           //!< tag, fixed to 0x0C
        } B;
        uint32_t U;
        struct
        {
            uint32_t cf9_field : 20; //!< CFG data field, Choose the XSPI instance
            uint32_t magic : 12;     //!< Magic, must be 0xcf9 (standing for "CFG")
        } P;                         // Preconfig
    } option0;
    uint32_t nand_option_addr;
    struct
    {
        uint16_t block_count; //!!< Maximum block count for an application image
        uint16_t block_id;    //!< Image start block ID
    } image_info[kSpiNandMemory_MaxFirmware];
} spinand_img_option_t;
```

Table 78. XSPI NAND configuration block definition

Option index	>Bits	Name	Description
Option0	Select XSPI instance if [31:20] is CF9h		
	[31:20]	magic	Magic number, must be CF9h for CFG
	[19:0]	cf9_field	XSPI instance
	Option0 for configuring XSPI NAND if [31:20] is not CF9h		
	[31:28]	tag	fixed to 0Ch
	[27:24]	search_count	Search count for FCB and DBBT • 1h - 1 • 2h - 2 • 3h - 3, • 4h - 4
	[23:20]	search_stride	Search stride for FCB and DBBT • 0h - 64 pages • 1h - 128 pages • 2h - 256 pages • 3h - 32 pages
	[19:12]	Reserved	—

	[23:16]	eccCheckMask	ECC check mask
	[15:8]	eccFailureMask	ECC failure mask
	[7:0]	manufacturer_id	Manufacturer ID

NOTE

See External Memory Configuration Data (XMCD) for spinand_xmc_info_t structure.

Below is an example of configuring XSPI NAND(W25N02JW) boot image with block address access:

```
//Initialize XSPI NAND
// Choose the XSPI instance 0 for NAND interface
blhost -p com4 -- fill-memory 0x20020000 0x4 0xcf900000
blhost -p com4 -- configure-memory 0x102 0x20020000
// Configure the FCB generated arguments, search_count:1, search_stride: 64 pages, address_type:
block address, size: 3 words in the options
blhost -p com4 -- fill-memory 0x20020000 0x4 0xc1000103
// The spinand_option_t options address
blhost -p com4 -- fill-memory 0x20020004 0x4 0x2002000c
// nand image block_id set as 2 means the image loaded in the block2 region, the block_count set as 1
means the image payload max block number is 1 block.
blhost -p com4 -- fill-memory 0x20020008 0x4 0x00020001
// The spinand_option_t options, Quad, 2Gbit, no multiplanes, 64 pages per block, 2048B per page,
166Mhz running clock
blhost -p com4 -- fill-memory 0x2002000c 0x4 0xc0020024
blhost -p com4 -- configure-memory 0x102 0x2002000c
//Erase NAND memory, start block id is 2, and erase block size is 1 block
blhost -p com4 -- flash-erase-region 0x2 0x1 0x102
//Write image to NAND
blhost -p com4 -- write-memory 0x00000002 boot_image.bin 0x102
```

Below is an example of configuring XSPI NAND(W25N02JW) boot image with physical address access:

```
//Initialize XSPI NAND
// Choose the XSPI instance 0 for NAND interface
blhost -p com4 -- fill-memory 0x20020000 0x4 0xcf900000
blhost -p com4 -- configure-memory 0x102 0x20020000
// Configure the FCB generated arguments, search_count:1, search_stride: 64 pages, address_type:
physical address, size: 3 words in the options
blhost -p com4 -- fill-memory 0x20020000 0x4 0xc1000003
// The spinand_option_t options address
blhost -p com4 -- fill-memory 0x20020004 0x4 0x2002000c
// nand image block_id set as 2 means the image loaded in the block2 region, the block_count set as 1
means the image payload max block number is 1 block.
blhost -p com4 -- fill-memory 0x20020008 0x4 0x00020001
// The spinand_option_t options, Quad, 2Gbit, no multiplanes, 64 pages per block, 2048B per page,
166Mhz running clock
blhost -p com4 -- fill-memory 0x2002000c 0x4 0xc0020024
blhost -p com4 -- configure-memory 0x102 0x2002000c
//Erase NAND memory, start block address is 0x40000, which is the block2 start offset address, and
erase block size is 0x2000
blhost -p com4 -- flash-erase-region 0x40000 0x2000 0x102
```

```
//Write image to NAND
blhost -p com4 -- write-memory 0x40000 boot_image.bin 0x102
```

Below is an example of configuring XSPI NAND(W25N02JW) boot image with block address access and configure the PSRAM by XMCD :

```
//Initialize XSPI NAND
// Choose the XSPI instance 0 for NAND interface
blhost -p com4 -- fill-memory 0x20020000 0x4 0xcf900000
blhost -p com4 -- configure-memory 0x102 0x20020000
// Configure the FCB generated arguments, search_count:1, search_stride: 64 pages, address_type:
block address, size: 3 words in the options
blhost -p com4 -- fill-memory 0x20020000 0x4 0xc1000103
// The spinand_option_t options address
blhost -p com4 -- fill-memory 0x20020004 0x4 0x2002000c
// nand image block_id set as 2 means the image loaded in the block2 region, the block_count set as 1
means the image payload max block number is 1 block.
blhost -p com4 -- fill-memory 0x20020008 0x4 0x00020001
// The spinand_option_t options, Quad, 2Gbit, no multiplanes, 64 pages per block, 2048B per page,
166Mhz running clock
blhost -p com4 -- fill-memory 0x2002000c 0x4 0xc2020024
blhost -p com4 -- fill-memory 0x20020010 0x4 0xc0010008
blhost -p com4 -- fill-memory 0x20020014 0x4 0xc0000700
blhost -p com4 -- configure-memory 0x102 0x2002000c
//Erase NAND memory, start block id is 2, and erase block size is 1 block
blhost -p com4 -- flash-erase-region 0x2 0x1 0x102
//Write image to NAND
blhost -p com4 -- write-memory 0x00000002 boot_image.bin 0x102
```

9.8 Recovery boot

If prime boot fails, Boot ROM can start recovery boot routine if recovery boot is enabled. Recovery boot can be enabled by configuring fuse (BOOT_CFG1[REC_BOOT_EN] = 1). And recovery boot is booting from serial nor flash connected to selected LP_FLEXCOMM. Boot ROM always read the first 64 bytes image header from offset 1000h of serial memory device for recovery boot, copy the image to the destination and then validate the image. If everything is fine, a successful recovery boot is done and jump to the application, else ROM will enter ISP mode. See Figure 13 for the high level boot flow for recovery boot.

9.8.1 Recovery boot configuration

The following parameters need to be configured for recovery boot:

- LP_FLEXCOMM instance, which can be selected by fuse feild BOOT_CFG5[REC_BOOT_FC].
- Chip-Select (CS) pin, which can be chosen by fuse feild BOOT_CFG5[REC_BOOT_FC_PCS].
- Baud rate of LPSPI, which can be configured by fuse field BOOT_CFG5[REC_BOOT_FC_BAUDRATE]

See Boot pin allocation for detailed port and pin allocations.

To make recovery boot work, recovery boot configuration fuses and recovery NOR memory should be correctly configured before using. And image should be programed to device at offset1000h.

Fuse	Definition	Shipped value	Settings
REC_BOOT_EN (BOOT_CFG1[4])	Recovery boot enable	0	Enable recovery boot through LP_FLEXCOMM. 0 - Disable

Table continues on the next page...

Table continued from the previous page...

Fuse	Definition	Shipped value	Settings
			1 - Enable
REC_BOOT_FC (BOOT_CFG5[19:16])	Port Selection. Specifies the LP_FLEXCOMM instance connected to 1-bit SPI flash used for recovery boot.	0000	This field is valid only if REC_BOOT_EN is set. Valid value: 0-13 *x*d - LP_FLEXCOMM instance *x* is selected as interface.
REC_BOOT_FC_PCS (BOOT_CFG5[21:20])	Specifies LP_FLEXCOMM PCS connected to 1-bit SPI flash used for recovery boot. This field is valid only if REC_BOOT_EN is set.	00	00 - PCS0 01 - PCS1 10 - PCS2 11 - PCS3
REC_BOOT_FC_BAUDRATE (BOOT_CFG5[23:22])	Specifies LP_FLEXCOMM baudrate with 1-bit SPI flash used for recovery boot. This field is valid only if REC_BOOT_EN is set.	00	00 - 20 MHz 01 - 10 MHz 10 - 5 MHz 11 - 2 MHz

9.8.2 Program LPSPI NOR using ISP

In general, the following actions need to be taken to program memory device:

- Configure the memory
- Erase the memory
- Program the memory

Below table shows the configurable parameters when programing boot image for recovery boot at ISP mode

Table 80. LPSPI configuration

Offset	Field	Size	Description		
0	option0	4	EEPROM/NOR configuration options		
			Offset	**Field**	**Description**
			31:28	tag	Fixed Ch
			27:24	Reserved	—
			23:20	spi_index	LPSPI instance 0 - LPSPI0 x - LPSPIx 13 - LPSPI13
			19:16	pcs_index	CS index of the LPSPI module 0 - PCS0

Table continues on the next page...

Table 80. LPSPI configuration (continued)

Offset	Field	Size	Description		
					1 - PCS1 2 - PCS2 3 - PCS3
			15:12	memory_type	Memory device type 0 - NOR, parameters specified 2 - NOR, parameters auto detected
			11:8	memory_size	Memory size
					(0≤n≤11): 512 KB x 2^n
					(12≤n≤15): 32 KB x 2^{n-12}
			7:4	sector_size	Sector size n(0≤n≤1): 4 KB x 2^n n(2≤n≤5): 32 KB x 2^{n-2}
			3:0	page_size	Page size n(0≤n≤2): 256 B x 2^n n(3≤n≤5): 32 B x 2^{n-3}
4	Option1	4	**Offset**	**Field**	**Description**
			31:4	Reserved	Reserved
			3:0	speed	LPSPI clock speed 0 - 20 MHz (default) 1 - 10 MHz 2 - 5 MHz 3 - 2 MHz

Example for programing the serial memory for recovery boot.

```
    //Take below actions under ISP mode
    //Step1. Configure the device according to the device used
    blhost -p com4 -- fill-memory 0x30080000 0x4 0xc0312000; //Configuration word0: LPSPI3 used,
PCS1 as CS port, auto probe for nor device
    blhost -p com4 -- fill-memory 0x30080004 0x4 0x00000000; //Configuration word1: LPSPI speed is
20 mbps
    blhost -p com4 -- configure-memory 0x110 0x30080000; //Configure serial memory device.
    //Step2. Erase the region
    blhost -p com4 -- flash-erase-region 0x0 0x40000 0x110
    //Program boot image to destination
    blhost -p com4 -- write-memory 0x1000 C:\recovery_boot.bin 0x110
```

Chapter 10
ROM API

10.1 Overview

This section provides an introduction to the ROM API in this device.

NOTE

This chapter is also available in the i.MX RT700 Security Reference Manual, with differences related to security functionality. The chapter in the Reference Manual does not show the security relevant information in it.

10.1.1 Features

- The ROM API supports OTP-eFuse read and programming.
- The ROM API provides native support for Nboot API in the user application.
- The ROM API supports In-application-programming functionality by the IAP API, via the unified memory interface or the Sbloader API.

10.2 Functional description

This section introduces the ROM API structure first, then describes the OTP API, IAP API and NBOOT APIs. This section also demonstrates the typical usage of each API.

- OTP API provides the functionality to advance lifecycle; program/read critical one-time programmable parameters and some general-purpose one-time programmable FUSE field.
- IAP API enables the flexibility of doing in-application-programming by SBloader API.

NOTE

All ROM APIs are callable from secure world only. Therefore, all function pointers use secure address aliases. Applications should switch to secure mode and then call ROM API or create NSC veneers for ROM APIs.

10.2.1 ROM API structure

The ROM API table locates at address 0x1303fc00. See Figure 20.

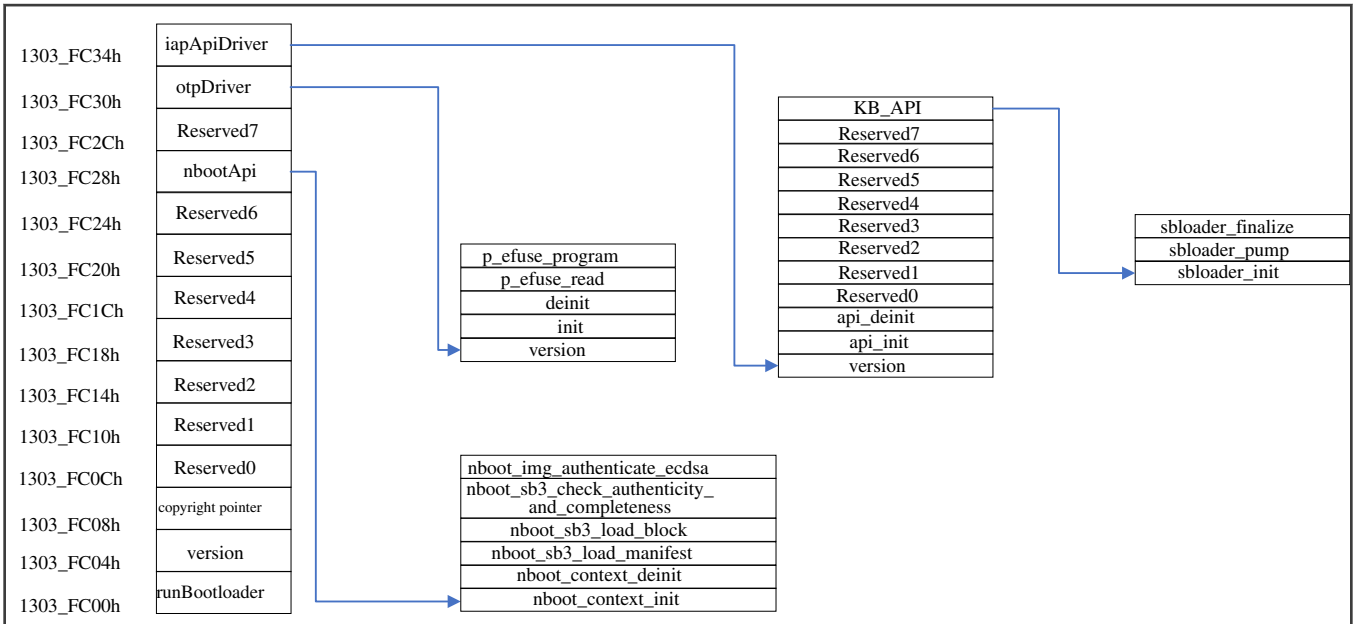

Figure 20. ROM API structure

10.2.2 runBootloader API

The ROM bootloader provides an API for the user application to enter boot mode or ISP mode based on the designated ISP interface mode.

Prototype

```
void (*runBootloader)(void *arg);
```

Table 81. runBootloader API arg fields

Field	Offset	Description	
Tag	[31:24]	Fixed value: EBh (enter boot)	
Boot mode	[23:20]	0000b - Prime boot mode	
		0001b - ISP mode	
		0010b - ProvFw mode. It requests ROM bootloader to handle provisioning firmware resides in SRAM P4 and P5. Provisioning firmware should be in SB3.1 format and it should be preloaded to start of SRAM P4 before calling runBootloader API to enter ProvFw mode. For this mode, bit 0-19 of this arg don't need to be set.	
Boot interface	[19:16]	**ISP boot mode**	**Prime boot mode**
		0h - UART	4h – XSPI NOR
		1h - I2C	5h – 1-bit LPSPI NOR
		2h - LPSPI	6h – Reserved
		3h - USB-HID (USB0)	7h – eMMC

Table continues on the next page...

Table 81. runBootloader API arg fields (continued)

Field	Offset	Description	
		8h - eUSB (USB1)	9h – XSPI NAND
		Fh - Auto detection	Other values – Reserved
Instance	[15:12]	Instance number when Boot Mode is configured as Prime boot mode and the Boot interface is configured as XSPI NOR (4h), LPSPI NOR (5h) or eMMC (7h): If Boot interface = 4h • 0000b - XSPI0 • 0001b - XSPI1 • Others - Reserved If Boot interface = 5h • 0000b - LPSPI0 • …. • 1101b - LPSPI13 • Others - Reserved If Boot interface = 7h • 0000b - eMMC0 • 0001b - eMMC1 • Others - Reserved	
Reserved	[11:8]	—	
recovery_boot_cfg1	[7:6]	Recovery boot interface configuration 1	
recovery_boot_cfg0	[5:4]	Recovery boot interface configuration 0	
Reserved	[3:0]	—	

Example:

In the application image boot process, use runbootloader api to reset rom boot from XSPI0.

```
#define ROM_API_TREE ((uint32_t*)0x1303fc00)
#define RUN_BOOTLOADER_API_TREE ((void (*)(void *)) ROM_API_TREE[0])
uint32_t arg = 0xEB040000U;
RUN_BOOTLOADER_API_TREE->runBootloader(&arg);
```

After the application image, which calls the above runBootloader API, has booted successfully, the device will boot image from XSPI0.

10.2.3 OTP-eFuse APIs

10.2.3.1 Version

This fields indicates the version number of the OTP API in this device.

Prototype :

```
standard_version_t version;
```

Table 82. Definition of the version Field in OTP API tree

Parameter	Description
standard_version_t	Pointer to version structure to store current eFuse driver version information uint8_t bugfix; /* bugfix version [7:0] */ uint8_t minor; /* minor version [15:8] */ uint8_t major; /* major version [23:16] */ char name; /* character name is "E", where "E" stands for eFuse. Character name and version are fixed */

Example:

```
#define ROM_API_TREE ((uint32_t*)0x1303fc00)
#define OTP_API_TREE ((efuse_driver_t *)ROM_API_TREE[12])
uint32_t otpDriverVersion = OTP_API_TREE-> version;
```

In this device, the OTP driver version is "0x45010100", it means the OTP driver version is 1.1.0.

Following is the efuse_driver_t definition:

```
//!@brief EFUSE driver API Interface
typedef struct
{
    standard_version_t version; //!< efuse driver API version number.
    void (*init)(uint32_t src_clk_freq);
    status_t (*deinit)(void);
    status_t (*p_efuse_read)(uint32_t addr,      uint32_t *data);
    status_t (*p_efuse_program)(uint32_t addr, uint32_t data);
} efuse_driver_t;
```

10.2.3.2 efuse_init

The API is used for initializing the OTP clock. The *efuse_init* API should be called before all the other OTP APIs. The parameter src_clk_freq is the frequency of OTP module source clock. On this chip, it is the frequency of COMPUTE_MAIN_CLK.

Prototype :

```
void (*init)(uint32_t src_clk_freq);
```

Example :

```
//efuse init
 debug_printf("Start efuse init! \r\n");
 OTP_API_TREE->init (192000000);
```

See the possible status codes in Table 85. If the status is kStatus_Success return value, it means OTP driver initialization completed successfully.

10.2.3.3 efuse_deinit

This API is used to disable eFuse controller clock.

Prototype :

```
status_t (*deinit)(void);
```

Example :

```
uint32_t status = OTP_API_TREE->deinit ();
```

See the possible status codes in Table 85. If the status is kStatus_Success return value, it means OTP driver deinitialization completed successfully.

10.2.3.4 efuse_read

This API is used to read data from OTP-eFuse controller.

Prototype :

```
status_t (*p_efuse_read)(uint32_t addr, uint32_t *data);
```

Table 83. Parameters used in otp_read API

Parameter	Description
addr	eFuse index.
data	Pointer to the buffer used for storing the read 32 bit data.

Example :

```
uint32_t efuseIndex = 472;
uint32_t fuseReadVal = 0;

//efuse read
uint32_t status = OTP_API_TREE-> p_efuse_read (efuseIndex, &fuseReadVal);
```

See the possible status codes in Table 85. If the status is kStatus_Success return value, it means the OTP data read completed successfully.

10.2.3.5 efuse_program

This API is used to program data to specified OTP Word.

Prototype :

```
status_t (*p_efuse_program)(uint32_t addr, uint32_t data);
```

Table 84. Parameters used in the otp_program API

Parameter	Description
addr	Pointer to the eFuse index that specifies the EFUSE word to be programmed
data	Pointer to the 32-bit source data used for programming into the eFuse region.

Example:

```
#define EFUSE_INDEX (472)
uint32_t eFuseData = 0x01010101;
uint32_t status = OTP_API_TREE-> p_efuse_program (EFUSE_INDEX, & eFuseData);
```

See the possible status codes in Table 85. If the status is kStatus_Success return value, it means no error has been reported for this program operation. Normally, it means the data 0x01010101 has been programmed into the eFuse word 472. However, if it is already programmed before, then its value will not be changed to 0x01010101 without error reported from this API. For a programmed ECC OTP word, calling this API will return kStatus_Success but the word value will not be changed.

10.2.3.6 Possible return codes of OTP API

Table 85. Return codes for OTP APIs

Error Code	Value (h)	Description
kStatus_Success	5AC3C35A	Operation succeeded without error.
kStatus_Fail	C35AC35A	The operation failed with a generic error.
kStatus_OTP_ProgramFail	CE42	Fail to program the OTP field

10.2.3.7 OTP-eFuse APIs Example

This section provides an example of OTP API usage.

NOTE

The OTP-eFuse program is only-program-once, user need to make sure the program data is valid value.

Example:

```
#define ROM_API_TREE ((uint32_t*)0x1303fc00)
#define OTP_API ((efuse_driver_t *)ROM_API_TREE[12])

OTP_API->init(192000000);
        debug_printf("efuse init succeess! \r\n");

        uint32_t fuseProgramVal = 0x12345678u;
        uint32_t fuseReadVal = 0;
        uint32_t efuseIndex1 = 472;
      uint32_t efuseIndex2 = 473;
        status_t status = kStatus_Success;

        //efuse read
        status = OTP_API->p_efuse_read(efuseIndex1,&fuseReadVal);
        if(status != kStatus_Success)
```

```
        {
            debug_printf("efuse_read failed ! efuseIndex = %d \r\n",efuseIndex1);
            break;
        }
        debug_printf("efuse_read efuseIndex = %d, fuseReadVal = %x \r\n",efuseIndex1,fuseReadVal);

        //efuse program
        status = OTP_API->p_efuse_program(efuseIndex2,fuseProgramVal);
        if(status != kStatus_Success)
        {
            debug_printf("efuse_program failed ! efuseIndex = %d \r\n",efuseIndex2);
            break;
        }
        debug_printf("efuse_program success! efuseIndex = %d, fuseProgramVal = %x
\r\n",efuseIndex2,fuseProgramVal);
        //efuse read and verify
        status = OTP_API->p_efuse_read(efuseIndex2,&fuseReadVal);
        if(status != kStatus_Success)
        {
            debug_printf("efuse_read failed ! efuseIndex = %d \r\n",efuseIndex2);
            break;
        }
        if(fuseProgramVal != fuseReadVal)
        {
            debug_printf("efuse program verifying FAILED, read value = %x, efuseIndex = %d
\r\n",fuseReadVal,efuseIndex2);
            status = kStatus_Fail;
            break;
        }
        debug_printf("efuse verify success! efuseIndex = %d \r\n",efuseIndex);

        status = OTP_API->deinit();
        if(status != kStatus_Success)
        {
            debug_printf("efuse deinit failed! \r\n");
            break;
        }
```

10.2.4 IAP APIs

10.2.4.1 General description

IAP is in–application–programming.

The bootloader IAP APIs are organized in the iap_api_interface_t structure, see the details from the below data structure. See the details of each API in the subsequent sections.

```
typedef struct iap_api_interface_struct
{
    standard_version_t version; //!< IAP API version number.
    status_t (*api_init)(api_core_context_t *coreCtx, const kp_api_init_param_t *param);
    status_t (*api_deinit)(api_core_context_t *coreCtx);
    const uint32_t reserved0 ;
    const uint32_t reserved1 ;
    const uint32_t reserved2 ;
    const uint32_t reserved3 ;
    const uint32_t reserved4 ;
    const uint32_t reserved5 ;
```

```
    const uint32_t reserved6 ;
    const uint32_t reserved7 ;
    status_t (*sbloader_init)(api_core_context_t *ctx);
    status_t (*sbloader_pump)(api_core_context_t *ctx, uint8_t *data, uint32_t length);
    status_t (*sbloader_finalize)(api_core_context_t *ctx);
} iap_api_interface_t;
```

Each IAP API depends on the common context named api_core_context_t. The detail of the context is defined as bellow:

```
/* @brief The API context structure */

typedef struct api_core_context
{
    uint32_t reserved0[166];
    ldr_Context_v3_t *sbloaderCtx;
    nboot_context_t *nbootCtx;
    uint32_t reserved1[5];
} api_core_context_t;

struct _ldr_Context_v3
{
    pLdrFnc_v3_t Action;        //!< pointer to loader action function
    uint32_t block_size;        //!< size of each block in bytes
    uint32_t block_data_size;   //!< data size in bytes (NBOOT_SB3_CHUNK_SIZE_IN_BYTES)
    uint32_t block_data_total;  //!< data max size in bytes (block_size * data_size
    uint32_t block_buffer_size; //!< block0 and block size
    uint32_t block_buffer_position;
    uint8_t block_buffer[MAX(NBOOT_SB3_MANIFEST_MAX_SIZE_IN_BYTES,
       NBOOT_SB3_BLOCK_MAX_SIZE_IN_BYTES)]; //! will be used for both block0 and blockx
    uint32_t processedBlocks;

    uint8_t data_block_offset; //! data block offset in a block.
    bool in_data_block;        //!< in progress of handling a data block within a block
    uint8_t *data_block;
    uint32_t data_block_position;

    bool in_data_section; //!< in progress of handling a data section within a data block
    uint32_t data_section_handled;
    sb3_section_header_t data_section_header;

    bool in_data_range; //!< in progress of handling a data range within a data section
    uint32_t data_range_handled;
    uint32_t data_range_gap;
    sb3_data_range_header_t data_range_header;
    bool has_data_range_expansion;
    sb3_data_range_expansion_t data_range_expansion;

    uint32_t commandSet; //!< support command set during sb file handling

    uint32_t data_position;
    uint8_t data_buffer[SB3_DATA_BUFFER_SIZE_IN_BYTE]; //!< temporary data buffer

    // options from ROM API
    kb_options_t fromAPI;
};
```

The kp_api_init_param_t is defined as below:

```
typedef struct kb_api_parameter_struct
{
    uint32_t allocStart;
    uint32_t allocSize;
} kp_api_init_param_t;
```

The IAP APIs require a dedicated RAM region as the buffer for each operation. The user application needs to prepare an unused RAM region organized as the *kp_api_init_param_t* structure, and pass this structure to the iap_api_init API. The allocSize in the iap_api_init API call is used to store the different flash context which is used in the api_core_context_t. The minimum size can be set to at least the size of (api_core_context_t).

These fields are managed by api_core_context_t parameter, the user application doesn't need to touch it.

NOTE

Before IAP APIs are used, caller needs to make sure that ELS clocks are enabled. This is required for correct operation of kb API on devices with security subsystem.

10.2.4.2 version

The version field indicates the IAP API version number in the device.

Prototype :

```
standard_version_t version;
```

Table 86. Definition of the version in IAP API tree

Parameter	Description

standard_version_t	Pointer to version structure to store current FLASH driver version information
	uint8_t bugfix; //!< bugfix version [7:0]
	uint8_t minor; //!< minor version [15:8]
	uint8_t major; //!< major version [23:16]
	char name; //!< character name is 0x49 = "I".

Example:

```
#define ROM_API_TREE ((uint32_t*)0x1303fc00)
#define IAP_API_TREE ((iap_api_interface_t*)ROM_API_TREE[13])
uint32_t IAPVersion = IAP_API_TREE-> version;
```

In this SoC, the version of IAP Driver is "0x49010100", it means the API version is 1.1.0.

10.2.4.3 iap_api_init

The API is used for initializing the IAP API context for the other IAP APIs, this API must be called prior to other IAP APIs.

Prototype :

```
status_t iap_api_init(api_core_context_t *coreCtx, const kp_api_init_param_t *param);
```

Table 87. Parameters used in iap_api_init API

Parameter	Description
coreCtx	Pointer to IAP API core context structure.
param	Pointer to IAP API initialization data structure, used for storing the data during execute the IAP APIs.

Example:

```
api_core_context_t api_ctx = {0};
kp_api_init_param_t params = {0};
params.allocStart = 0x20350000u;
params.allocSize = 0x6000u;
uint32_t status = IAP_API_TREE->api_init(&api_ctx,&params);
```

See the possible status codes in Table 89. If the status is kStatus_Success return value, it means the IAP API operating environment has been init successfully.

10.2.4.4 iap_api_deinit

The API is used for deinitializing the IAP API context.

Prototype :

```
status_t iap_api_deinit(api_core_context_t *coreCtx);
```

Table 88. Parameters used in iap_api_deinit API

Parameter	Description
coreCtx	Pointer to IAP API core context structure.

Example:

```
uint32_t status = IAP_API_TREE->api_deinit(&api_ctx);
```

See the possible status codes in Table 89. If the status is kStatus_Success return value, it means the IAP API operating environment has been freed and cannot call the other IAP APIs.

10.2.4.5 Possible return codes for IAP driver APIs

Table 89. Return and Error codes for IAP APIs

Error Code	Value	Description
kStatus_IAP_Success	0	IAP API execution succeeded
kStatus_IAP_Fail	1	IAP API execution failed
kStatus_Success	0	Operation succeeded without error.

Table continues on the next page...

Table 89. Return and Error codes for IAP APIs (continued)

Error Code	Value	Description
kStatus_Fail	1	The operation failed with a generic error.
kStatus_Invalidargument	4	The requested command's argument is undefined.
kStatusRomLdrSectionOverrun	10100	means reached the end of the sb file processing
kStatusRomLdrSignature	10101	the signature or version are incorrect
kStatusRomLdrSectionLength	10102	the bootOffset/ new section count is out of range
kStatusRomLdrEOFReached	10104	the end of the image file is reached
kStatusRomLdrChecksum	10105	The checksum of a command tag block is invalid.
kStatusRomLdrCrc32Error	10106	The CRC-32 of the data for a load command is incorrect.
kStatusRomLdrUnknownCommand	10107	An unknown command was found in the SB file.
kStatusRomLdrIdNotFound	10108	There was no bootable section found in the SB file.
kStatusRomLdrDataUnderrun	10109	The SB state machine is waiting for more data.
kStatusRomLdrJumpReturned	10110	The function that was jumped to by the SB file has returned.
kStatusRomLdrCallFailed	10111	The call command in the SB file failed.
kStatusRomLdrKeyNotFound	10112	A matching key was not found in the SB file's key dictionary to unencrypt the section.
kStatusRomLdrSecureOnly	10113	The SB file sent is unencrypted, and security on the target is enabled.
kStatusRomLdrResetReturned	10114	The SB file reset operation has unexpectedly returned.
kStatusRomLdrRollbackBlocked	10115	An Image version rollback event detected
kStatusRomLdrInvalidSectionMacCount	10116	Invalid Section MAC count detected in the SB file
kStatusRomLdrUnexpectedCommand	10117	The command tag in the sb-file is unexpected
kStatusRomLdrBadSBKEK	10118	Bad SBKEK detected

10.2.4.6 KB APIs

KB API is used in the application to update the firmware of device to process Secure Binary (SB) file. It include a set of SBloader APIs. The flow diagram of the SBloader APIs call demo is as below.

NOTE

KB APIs can't be called from SRAM alias address.

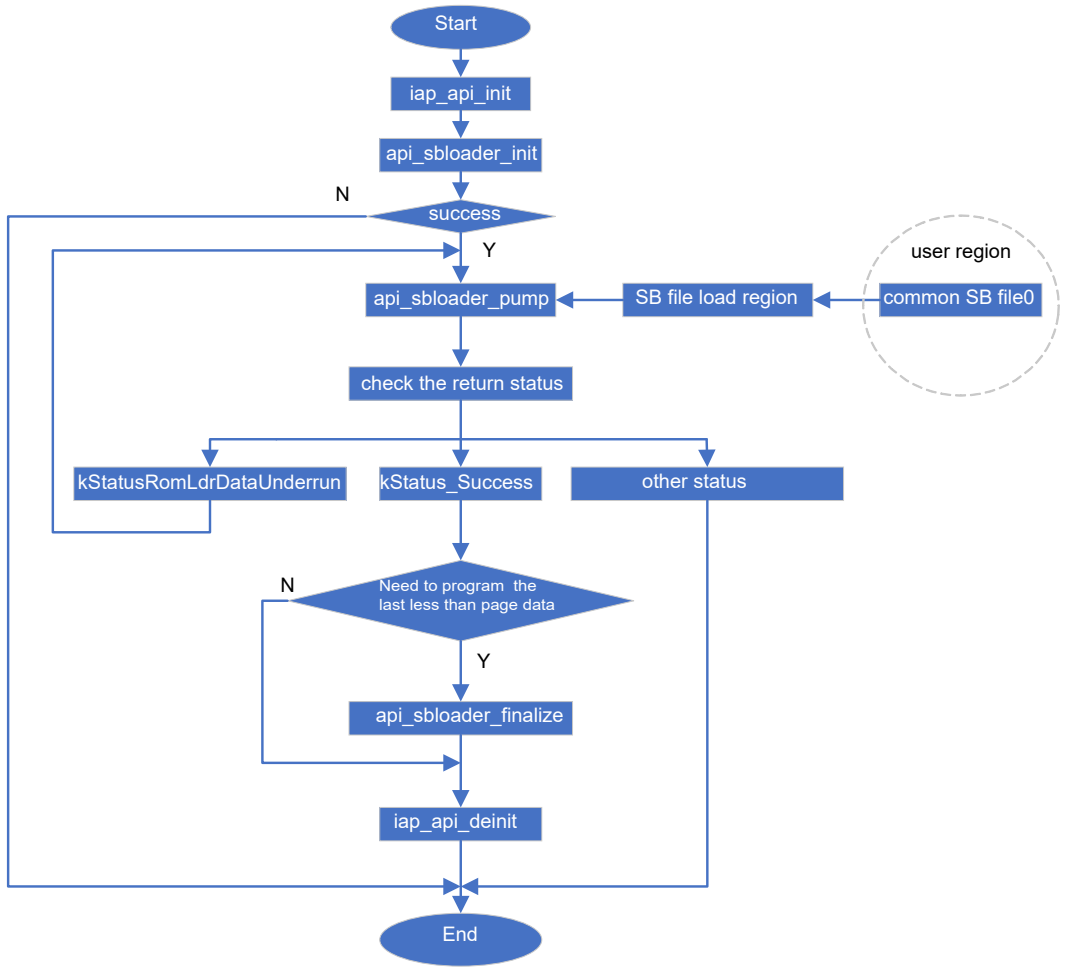

Figure 21. Flow diagram of the SBloader APIs call demo

The above flow diagram mainly introduces the SBloader APIs call flow. When the valid SB3.1 file has been generated and the necessary running environment(ROKTH and KeyBlob) has been setup up, the mainly details can be referred to the SB file chapter. From the flow diagram, the iap_api_init will be called first to initialize and configure the IAP API core context. And then call the api_sbloader_init to initialize the loader state machine. If the api_sbloader_init return status is success, then the spi_sbloader_pump will be called to process the SB file data stream, which is transferred from the user region.

In the running process of the api_sbloader_pump function, the return status includes three kinds of the results, which can be referred to in Table 89.Return and Error codes for IAP APIs. If the return status is kStatusRomLdrDataUnderrun, it indicates that more data in the common SB_file0 should be transferred to the api_sbloader_pump to process, and the process has not reached the end of the SB file data. When the kStatus_Success has been received, it indicates that common SB_file0 has been completely received and processed to update the firmware in the SB_file0 successfully. The other status will be thought that api_sbloader_pump API failed to execute. And the iap_api_deinit should be executed to clear the IAP APIs context parameters.

In addition, in the process of executing the SB file in the api_sbloader_pump, only the load address of the SB file data will be transferred to the api_sbloader_pump, the data of the SB file is executed with the packet chunk. Users should get and load the packet chunk of the SB file into the ram region like the following function get_data_from_sbfile(), and then call the api_sbloader_pump to process the ram data repeatedly until to the end of the SB file. In transferring the SB file chunk to the device, the user can use different channels to receive the chunk data like UART, SPI, I2C, USB, OTP interface.

10.2.4.6.1 api_sbloader_init

This API is used for initializing the sbloader state machine before calling the api_sbloader_pump. This API should be called after the iap_api_init API.

Prototype :

```
status_t api_sbloader_init(api_core_context_t *ctx);
```

Table 90. Parameters used in api_sbloader_init API

Parameter	Description
ctx	Pointer to IAP API core context structure.

Example:

```
uint32_t status = IAP_API_TREE-> sbloader_init (&apiCoreCtx);
```

See the possible status codes in Table 89. If the status is kStatus_Success return value, it means the sbloader runtime environment has been initialized successfully.

10.2.4.6.2 api_sbloader_pump

This API is used for handling the secure binary (SB3.1 format) data stream, which is used for image update, lifecycle advancing, etc. This API should be called after the iap_api_init and api_sbloader_init APIs.

Prototype :

```
status_t api_sbloader_pump(api_core_context_t *ctx, uint8_t *data, uint32_t length);
```

Table 91. Parameters used in api_sbloader_pump API

Parameter	Description
ctx	Pointer to IAP API core context structure.
data	Pointer to source data that is the sb file buffer data.
length	Points to the size of the process buffer data.

Example:

```
/* load the SB file chunk-by-chunk into chunk_processing_buffer */

get_chunk_from_SB_file(uint8_t * chunk_processing_buffer, uint8_t * SBfile_incoming_chunk, uint32_t
chunk_size);
status = IAP_API_TREE-> sbloader_pump(context, & chunk_processing_buffer, chunk_size);
```

See the possible status codes in Table 89. If the status is kStatus_Success return value, it means the sb data has been processed successfully.

10.2.4.6.3 api_sbloader_finalize

The API is used for finalizing the sbloader operations.

Prototype :

```
status_t api_sbloader_finalize(api_core_context_t *ctx)
```

Table 92. Parameters used in api_sbloader_finalize API

Parameter	Description
ctx	Pointer to IAP API core context structure.

Example:

```
status = IAP_API_TREE-> sbloader_finalize (context);
```

See the possible status codes in Table 89. If the status is kStatus_Success return value, it means the last sb data has programed successfully.

10.2.4.7 IAP API examples

The section will provide the example to introduce All the IAP APIs usage and help users understand and use more deeply.

```
#define ROM_API_TREE ((uint32_t*)0x1303fc00)
#define IAP_API ((iap_api_interface_t*)ROM_API_TREE[13])
api_core_context_t api_ctx = {0};
kp_api_init_param_t params = {0};
params.allocStart = 0x20350000u;
params.allocSize = 0x6000u;

status = IAP_API->api_init(&api_ctx,&params);
if (status != kStatus_Success)
{
return status;
}
status = IAP_API->sbloader_init(&api_ctx);
if (status != kStatus_Success)
{
return status;
}
uint8_t user_buf[1024]; uint32_t size;
while ((status = get_data_from_sbfile(&buffer, &size)) == kStatus_Success)
{
status = IAP_API ->sbloader_pump(&api_ctx, &buffer, size); if (status == kStatusRomLdrDataUnderrun)
{
/* continue to receive the data from SB file for processing */ debug_printf("Warning: Success to
execute ROM API erase, but need more data \n");
}
else if (status == kStatus_Success)
{
debug_printf("Completed: Success to execute ROM API erase\n"); break;    /* finish the SB file
firewarre update and break */
}
else if (status != kStatus_Success)
```

```
{
debug_printf("Error: Failed to run API kb_execute, status is hex(%x) \n", (uint32_t)status); return
status;    /* return the fail status or other actions */
}
}
status = IAP_API_TREE->sbloader_finalize (&api_ctx); if (status != kStatus_Success)
{
debug_printf("Error: Failed to sbloader_finalize\n"); return status;
}
status = IAP_API->api_deinit(&api_ctx);
```

Chapter 11
In-System Programming (ISP)

11.1 Overview

This chip includes in-system programming (ISP) functions to support image programming from the serial interface (UART, I2C, SPI), USB1 and USB0.

In-System Programming supports:

- UART, I2C, SPI, USB1 and USB0 peripheral interfaces
- Automatic detection of the active peripheral
- UART peripheral implements auto-baud detection
- Common packet-based protocol for all peripherals
- Protection of RAM used by the bootloader while it is running
- Retrieval the properties of the device, such as Flash and RAM size
- Support for external memory(XSPI Nor Flash/XSPI NAND Flash/eMMC/Serial Nor Flash/fuse) access
- Support for encrypted image download

Each ISP interface can be enabled or disabled by fuse. The following table lists fuse bits to control ISP entry methods.

Table 93. BOOT_CFG0 fuse bit configuration for ISP

Bit name	Bits	Default value	Definition	Description
ISP_UART_DIS	3	0	0 - Enabled 1 - Disabled	Disable LPUART interface during ISP/serial boot mode.
ISP_SPI_DIS	4	0	0 - Enabled 1 - Disabled	Disable LPSPI interface during ISP/serial boot mode.
ISP_I2C_DIS	5	0	0 - Enabled 1 - Disabled	Disable LPI2C interface during ISP/serial boot mode.
ISP_USB_DIS	6	0	0 - Enabled 1 - Disabled	Disable USB0 interface during ISP/serial boot mode.
ISP_eUSB_DIS	7	0	0 - Enabled 1 - Disabled	Disable USB1 (eUSB) interface during ISP/ serial boot mode.
ISP_MODE_PIN_DIS	8	0	0 - Enabled 1 - Disabled	Disable boot mode selection using ISP mode pins.
ISP_DM_DIS	9	0	0 - Enabled 1 - Disabled	Disable ISP mode entry through debug mailbox command.

Table continues on the next page...

Table 93. BOOT_CFG0 fuse bit configuration for ISP (continued)

Bit name	Bits	Default value	Definition	Description
ISP_FT_DIS	10	0	0 - Enabled 1 - Disabled	Disable ISP mode entry as a fall through if valid image is not found in boot media.
ISP_API_DIS	11	0	0 - Enabled 1 - Disabled	Disable ISP mode entry using ROM API.

11.1.1 Features

- Peripheral interfaces:
  - UART
  - I2C
  - SPI
  - USB0
  - USB1
- Automatic detection of the active peripheral
- UART peripheral implements auto-baud detection
- A common packet-based protocol for all peripherals
- Packet error detection and retransmission
- Protection of RAM used by the bootloader while it is running
- Retrieval of the properties of the device, such as flash memory and RAM size
- Multiple options for executing the bootloader, either at system startup or under application control at runtime
- Support for encrypted image downloading
- External flash memory access

11.2 Functional description

11.2.1 Bootloader

ISP stores the boot code in internal ROM. After a reset, the Arm processor starts its code execution from this memory. ISP executes the bootloader code every time the part is powered on, is reset, or is woken up from a deep power-down, low-power mode.

The bootloader provides a flash memory and OTP-eFuse programming utility that operates over a serial connection on the MCUs. It enables quick and easy programming of MCUs through the entire product lifecycle, including application development, final product manufacturing, and beyond. The host-side command line and GUI tools are available to communicate with the bootloader. Users can use host tools to upload and download application code and to perform manufacturing via the bootloader.

For the bootloader operation and boot pin, see Overview.

11.2.2 ISP (In-system programming)

Serial booting and other related functions are supported in several different ways:

- For details of the ISP protocol, see In-System programming protocol.
- For details of the ISP packet, see Bootloader packet types.

- For details of the ISP commands, see Bootloader command set.
- For details of UART In-System Programming, see UART ISP.
- For details of I^2C In-System Programming, see I2C In-System Programming.
- For details of SPI In-System Programming, see SPI In-System programming.
- For details of USB0 and USB1 In-System programming, see USB In-System Programming.

11.2.3 Memory map after reset

The boot ROM is located in the memory region beginning with the address 1300 0000h. Both the ISP and IAP software use parts of the on-chip RAM. Use of the RAM is described in ISP interrupt and SRAM use.

Based on the ISP fuse configuration or boot pin settings, the ROM enters ISP mode and can auto-detect activity on these interfaces:

- I2C
- SPI
- UART
- USB0/USB1

The auto-detect looks for activity on these interfaces and selects the appropriate interface when a properly formed frame is received. If an invalid frame is received, the data is discarded and scanning resumes. Communications for these interfaces are described in In-System programming protocol and Bootloader packet types.

11.2.4 ISP interrupt and SRAM use

11.2.4.1 Interrupts during IAP

When the user application code starts executing, the interrupt vectors from the SRAM are active. Before making any IAP call, you must disable the interrupts. The IAP code does not use or disable interrupts.

11.2.4.2 RAM used by the ISP command handler

ISP reserves the regions designated below for bootloader use when the bootloader is running.

Table 94. RAM used by ROM during ROM execution

RAM region	Purpose
2000_0000h–2001_4FFFh	• BSS • RW • Stack • Heap

11.2.5 ISP flow

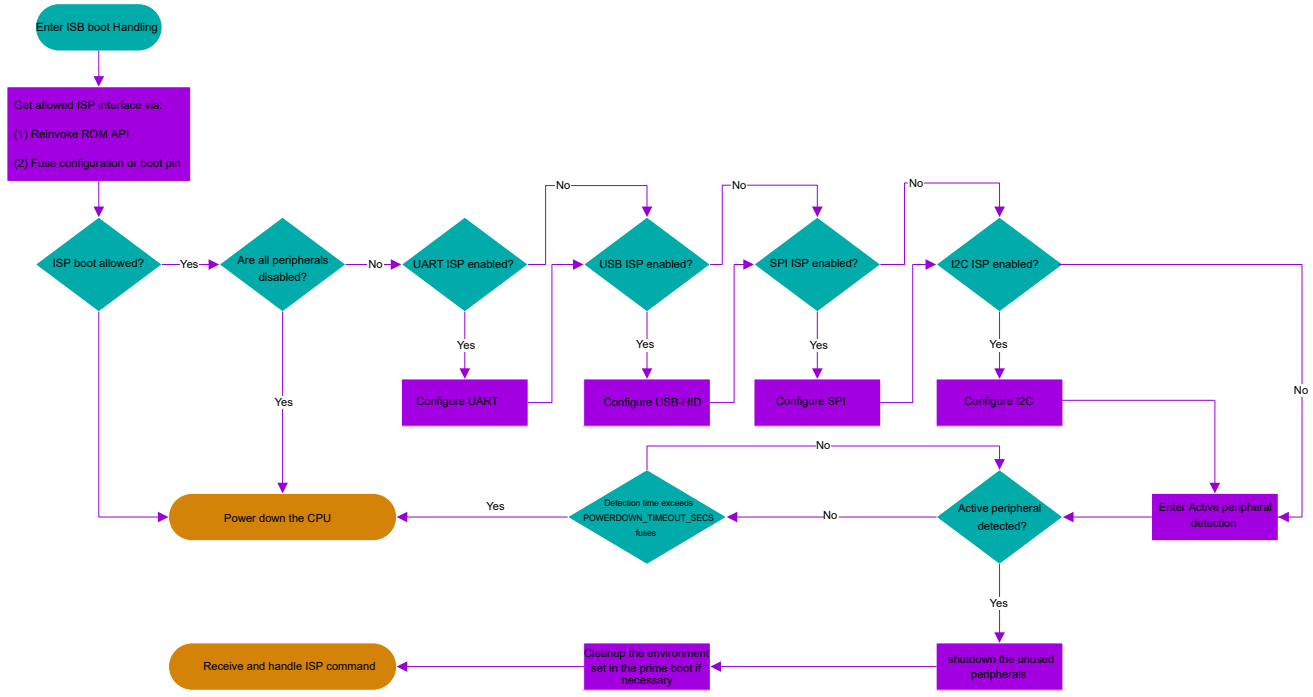

Figure 22. ISP flow

11.3 In-System programming protocol

This section explains the general protocol for the packet transfers between the host and the bootloader. The description includes the transfer of packets for different transactions, such as commands with no data phase and commands with incoming or outgoing data phase. The next section describes various packet types used in a transaction.

Each command sent from the host is replied to with a response command.

Commands may include an optional data phase.

- If the data phase is incoming (from the host to the bootloader), it is part of the original command.
- If the data phase is outgoing (from the bootloader to host), it is part of the response command.

11.3.1 Command with no data phase

The protocol for a command with no data phase contains:

1. Command packet (from the host).
2. Generic response command packet (to host).

The ACK sent in response to a command or a data packet can arrive at any time before, during, or after the command or data packet has been processed. Refer the diagrams in the Bootloader command set section.

11.3.2 Command with the incoming data phase

The protocol for a command with incoming data phase contains:

1. Command packet (from host) (kCommandFlag_HasDataPhase set).
2. Generic response command packet (to host).

3. Incoming data packets (from the host).
4. Generic response command packet to host.

Note:

- The host may not send any further packets while it is waiting for the response to a command.
- The data phase is aborted if the Generic Response packet prior to the start of the Data phase does not have a status of kStatus_Success.
- Data phases may be aborted by the receiving side by sending the final GenericResponse early with a status of kStatus_AbortDataPhase. The host may abort the data phase early by sending a zero-length data packet.
- The final Generic Response packet sent after the data phase includes the status of the entire operation.

11.3.3 Command with outgoing data phase

The protocol for a command with an outgoing data phase contains:

1. Command packet (from the host).
2. ReadMemory Response command packet (to host) (kCommandFlag_HasDataPhase set).
3. Outgoing data packets (to host).
4. Generic response command packet (to host).

- The data phase is considered part of the response command for the outgoing data phase sequence.
- The host may not send any further packets while the host is waiting for the response to a command.
- The data phase is aborted if the ReadMemory Response command packet, prior to the start of the data phase, does not contain the kCommandFlag_HasDataPhase flag.
- Data phases may be aborted by the device sending the final Generic Response early with a status of kStatus_AbortDataPhase. The sending side may abort the data phase early by sending a zero-length data packet.
- The final Generic Response packet sent after the data phase includes the status of the entire operation.

11.4 Bootloader packet types

11.4.1 Introduction

The bootloader device works in target mode. All data communications are initiated by a host, which is either a PC or an embedded host. The bootloader device is the target, which receives a command or data packet. All data communications between host and target are packetized.

There are six types of packets used:

- Ping packet.
- Ping Response packet.
- Framing packet.
- Command packet.
- Data packet.
- Response packet.

All fields in the packets are in little-endian byte order.

11.4.2 Ping packet

The Ping packet is the first packet sent from a host to the target to establish a connection on the selected peripheral in order to run autobaud detection. The Ping packet can be sent from host to target at any time that the target is expecting a command packet.

If the selected peripheral is UART, a Ping packet must be sent before any other communications. For other serial peripherals, it is optional.

In response to a Ping packet, the target sends a Ping response packet, discussed in the later sections.

Table 95. Ping packet format

Byte #	Value	Name
0	0x5A	Start byte
1	0xA6	Ping

11.4.3 Ping response packet

The target sends a Ping response packet back to the host after receiving a Ping packet. If communication is over a UART peripheral, the target uses the incoming Ping packet to determine the baud rate before replying with the Ping response packet. After the Ping response packet is received by the host, the connection is established, and the host starts sending commands to the target.

Table 96. Ping response packet format

Byte	Value	Parameter
0	0x5A	Start byte
1	0xA7	Ping response code
2	0x00	Protocol bugfix
3	0x03	Protocol minor
4	0x01	Protocol major
5	0x50	Protocol name = 'P' (0x50)
6	0x00	Options low
7	0x00	Options high
8	0xfb	CRC16 low
9	0x40	CRC16 high

For the UART peripheral, it must be sent by the host when a connection is first established, in order to run autobaud. For other serial peripherals, it is optional but recommended to determine the serial protocol version. The version number is in the same format as the bootloader version number returned by the GetProperty command.

11.4.4 Framing packet

The framing packet is used for flow control and error detection for the communications links that do not have such features built in. The framing packet structure sits between the link layer and the command layer. It wraps command and data packets as well.

Every framing packet containing data sent in one direction results in a synchronizing response framing packet in the opposite direction.

The framing packet described in this section is used for serial peripherals including the UART, CAN, I^2C, and SPI. The USB HID peripheral does not use framing packets. Instead, the packetization inherent in the USB protocol itself is used.

Table 97. Framing packet format

Byte	Value	Parameter	Description
0	0x5A	Start byte	
1		PacketType	
2		Length_low	Length is a 16-bit field that specifies the entire command or data packet size in bytes.
3		Length_high	
4		Crc16_low	This is a 16-bit field. The CRC16 value covers entire framing packet, including the start byte and command or data packets, but does not include the CRC bytes. See CRC16 algorithm.
5		Crc16_high	
6....n		Command or Data packet payload	

A special framing packet that contains only a start byte and a packet type is used for synchronization between the host and target.

Table 98. Special framing packet format

Byte	Value	Parameter
0	0x5A	Start byte
1	0xA*n*	packetType

The Packet Type field specifies the type of the packet from one of the defined types (below):

Table 99. Packet type field

Packet type	Name	Description
0xA1	kFramingPacketType_Ack	The previous packet was received successfully; the sending of more packets is allowed.
0xA2	kFramingPacketType_Nak	The previous packet was corrupted and must be re-sent.
0xA3	kFramingPacketType_AckAbort	Data phase is being aborted.

Table 100. Packet type field

Packet type	Name	Description
0xA4	kFramingPacketType_Command	The framing packet contains a command packet payload.
0xA5	kFramingPacketType_Data	The framing packet contains a data packet payload.

Table continues on the next page...

Table 100. Packet type field (continued)

Packet type	Name	Description
0xA6	kFramingPacketType_Ping	Sent to verify the other side is alive. Also used for UART autobaud.
0xA7	kFramingPacketType_PingResponse	A response to Ping. It contains the framing protocol version number and options.

11.4.5 CRC16 algorithm

The CRC is computed over each byte in the framing packet header, excluding the CRC16 field itself, and all of the payload bytes. The CRC algorithm is the XMODEM variant of CRC16.

The characteristics of the XMODEM variants are:

Table 101. CRC16 algorithm

Width	16
Polynomial	0x1021
Init value	0x0000
Reflect in	False
Reflect out	False
Xor out	0x0000
Check result	0x31c3

The check result is computed by running the ASCII character sequence "123456789" through the algorithm.

```
uint16_t crc16_update(const uint8_t * src, uint32_t lengthInBytes)
{
    uint32_t crc = 0;
    uint32_t j;
    for (j=0; j < lengthInBytes; ++j)
        {
        uint32_t i;
        uint32_t byte = src[j];
        crc ^= byte << 8;
        for (i = 0; i < 8; ++i)
        {
                    uint32_t temp = crc << 1;
            if (crc & 0x8000)
            {
                                temp ^= 0x1021;
            }
                        crc = temp;
        }
    }
    return crc;
}
```

11.4.6 Command packet

The command packet carries a 32-bit command header and a list of 32-bit parameters.

Table 102. Command packet format

Command Packet Format (32 bytes)										
Command Header (4 bytes)				28 bytes for Parameters (Max 7 parameters)						
Tag	Flags	Rsvd	Param Count	Param 1 (32-bit)	Param 2 (32-bit)	Param 3 (32-bit)	Param 4 (32-bit)	Param 5 (32-bit)	Param 6 (32-bit)	Param 7 (32-bit)

Table 103. Command header format

Byte #	Command header field	Description
0	Command or Response tag	The command header is 4 bytes long with these fields.
1	Flags	
2	Reserved. Should be 0x00.	
3	ParameterCount	

The header is followed by 32-bit parameters up to the value of the ParameterCount field specified in the header. Because a command packet is 32 bytes long, only seven parameters can fit into the command packet.

- **Flags:** Each command packet contains a flag byte. Only bit 0 of the flag byte is used. If bit 0 of the flag byte is set to 1, then data packets follow the command sequence. The number of bytes that are transferred in the data phase is determined by a command specific parameter in the parameters array.
- **ParameterCount:** The number of parameters included in the command packet.
- **Parameters:** The parameters are word-length (32 bits). With the default maximum packet size of 32 bytes, a command packet can contain up to seven parameters.

Command packets are also used by the target to send responses back to the host. As mentioned earlier, command packets and data packets are embedded into framing packets for all of the transfers.

Table 104. Command tags

Command tag	Name	Description
0x01	FlashEraseAll	The command tag specifies one of the commands supported by the bootloader. The valid command tags for the bootloader are listed here.[1]
0x02	FlashEraseRegion	
0x03	ReadMemory	
0x04	WriteMemory	
0x05	FillMemory	
0x06	Reserved	

Table continues on the next page...

Table 104. Command tags (continued)

Command tag	Name	Description
0x07	GetProperty	
0x08	ReceiveSbFile	
0x09	Execute	
0x0A	Reserved	
0x0B	Reset	
0x0C	SetProperty	
0x0D	Reserved	
0x0E	eFuseProgram/FlashProgramOnce	
0x0F	eFuseRead/FlashReadOnce	
0x10	Reserved	
0x11	ConfigureMemory	
0x12	Reserved	
0x13	Reserved	
0x14	Reserved	
0x15	Reserved	
0x16	TrustProvisioning	

1. The GetProperty, Reset, TrustProvisioning, SetProperty, and ReceiveSbFile are allowed in limited ISP mode.

Table 105. Response tags

Response tag	Name	Description
0xA0	GenericResponse	The response tag specifies one of the responses the bootloader (target) returns to the host. The valid response tags are listed here.
0xA3	ReadMemoryResponse	
0xA7	GetPropertyResponse (used for sending responses to GetProperty command only)	
0xA3	ReadMemoryResponse (used for sending responses to ReadMemory command only)	

Table continues on the next page...

Table 105. Response tags (continued)

Response tag	Name	Description
0xAF	FlashReadOnceResponse (used for sending responses to FlashReadOnce command only)	
0xB6	TrustProvisioningResponse(used for sending response to TrustProvisioning command only)	

11.4.7 Response packet

The responses are carried using the same command packet format wrapped with framing packet data. Types of responses include:

- GenericResponse.
- GetPropertyResponse.
- ReadMemoryResponse.
- FlashReadOnceResponse.
- TrustProvisioningResponse

GenericResponse: After the bootloader has processed a command, the bootloader sends a generic response with status and command tag information to the host. The generic response is the last packet in the command protocol sequence. The generic response packet contains the framing packet data and the command packet data (with generic response tag = 0xA0) and a list of parameters (defined in the next section). The parameter count field in the header is always set to 2, for status code and command tag parameters.

Table 106. GenericResponse parameters

Byte #	Parameter	Description
0 - 3	Status code	Bootloader Status Error Codes are errors encountered during the execution of a command by the target. If a command succeeds, then a kStatus_Success code is returned.
4 - 7	Command tag	The Command tag parameter identifies the response to the command sent by the host.

GetPropertyResponse: The GetPropertyResponse packet is sent by the target in response to the host query that uses the GetProperty command. The GetPropertyResponse packet contains the framing packet data and the command packet data, with the command/response tag set to a GetPropertyResponse tag value (0xA7).

The parameter count field in the header is set to greater than 1, to always include the status code and one or many property values.

Table 107. GetPropertyResponse parameters

Byte #	Value	Parameter
0 - 3		Status code
4 - 7		Property value

Table continues on the next page...

Table 107. GetPropertyResponse parameters (continued)

Byte #	Value	Parameter
. . .		. . .
		Can be up to maximum 6 property values, limited to the size of the 32-bit command packet and property type.

ReadMemoryResponse: The ReadMemoryResponse packet is sent by the target in response to the host sending a ReadMemory command. The ReadMemoryResponse packet contains the framing packet data and the command packet data, with the command/response tag set to a ReadMemoryResponse tag value (0xA3), the flags field set to kCommandFlag_HasDataPhase (1).

The parameter count set to two for the status code and the data byte count parameters shown below.

Table 108. ReadMemoryResponse parameters

Byte #	Parameter	Description
0 - 3	Status code	The status of the associated Read Memory command.
4 - 7	Data byte count	The number of bytes sent in the data phase.

FlashReadOnceResponse: The FlashReadOnceResponse packet is sent by the target in response to the host sending a FlashReadOnce command. The FlashReadOnceResponse packet contains the framing packet data and the command packet data, with the command/response tag set to a FlashReadOnceResponse tag value (0xAF), and the flags field set to 0. The parameter count is set to 2 plus *the number of words* requested to be read in the FlashReadOnceCommand.

Table 109. FlashReadOnceResponse parameters

Byte #	Value	Parameter
0 - 3		Status code
4 - 7		Byte count to read
. . .		. . .
		Can be up to 20 bytes of requested read data.

TrustProvisioningResponse: The TrustProvisioningResponse packet is sent by the target in response to the host sending a TrustProvisioning command. The TrustProvisioningResponse packet contains the framing packet data and command packet data, with the command/response tag set to a TrustProvisioningResponse tag value (0xB6), and the flags field set to 0. The parameter count various for different operations.

11.5 Bootloader command set

11.5.1 Introduction

All bootloader commands follow the command packet format wrapped by the framing packet as explained in previous sections.

For a list of status codes returned by bootloader see Bootloader Status Error Codes.

11.5.2 GetProperty command

The GetProperty command is used to query the bootloader about various properties and settings. Each supported property has a unique 32-bit tag associated with it. The tag occupies the first parameter of the command packet. The target returns a

GetPropertyResponse packet with the property values for the property identified with the tag in the GetProperty command.

Properties are the defined units of data that can be accessed with the GetProperty or SetProperty commands. Properties may be read-only or read-write. All read-write properties are 32-bit integers, so they can easily be carried in a command parameter.

The 32-bit property tag is the only parameter required for GetProperty command.

Table 110. Parameters for GetProperty Command

Byte #	Parameter
0 - 3	Property tag (which can be get from the get-property 0 command)
4 - 7	External Memory Identifier (only applies to get property for external memory, or status identifier if the property tag is equal to 8).

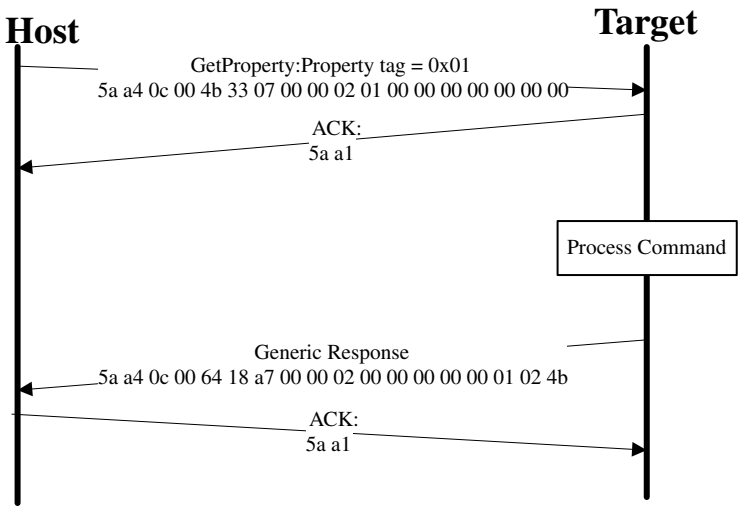

Figure 23. Protocol sequence for GetProperty command

Table 111. GetProperty command packet format (example)

GetProperty	Parameter	Value
Framing packet	Start byte	0x5A
	PacketType	0xA4, kFramingPacketType_Command
	Length	0x0C 0x00
	Crc16	0x4B 0x33

Table 112. GetProperty command packet format (example)

GetProperty	Parameter	Value
Command packet	CommandTag	0x07 – GetProperty
	Flags	0x00
	Reserved	0x00
	ParameterCount	0x02
	PropertyTag	0x00000001 - CurrentVersion
	Memory ID	0x00000000 - Internal Flash

The GetProperty command has no data phase.

Response: In response to a GetProperty command, the target sends a

GetPropertyResponse packet with the response tag set to 0xA7. The parameter count indicates the number of parameters sent for the property values, with the first parameter showing status code 0, followed by the property value(s). Table 113 shows an example of a GetProperty response packet.

Table 113. GetProperty response packet format (example)

GetPropertyResponse	Parameter	Value
Framing packet	Start byte	0x5A
	PacketType	0xA4, kFramingPacketType_Command
	Length	0x0c 0x00 (12 bytes)
	Crc16	0x07 0x7a
Command packet	ResponseTag	0xA7
	Flags	0x00
	Reserved	0x00
	ParameterCount	0x02
	Status	0x00000000
	PropertyValue	0x0000014b - CurrentVersion

11.5.3 SetProperty command

The SetProperty command is used to change or alter the values of the properties or options of the bootloader. The command accepts the same property tags used with the GetProperty command. However, only some properties are writable. If an attempt to write a read-only property is made, an error is returned indicating the property is read-only and cannot be changed.

The property tag and the new value to set are the two parameters required for the SetProperty command.

Table 114. Parameters for SetProperty command

Byte #	Command
0 - 3	Property tag
4 - 7	Property value

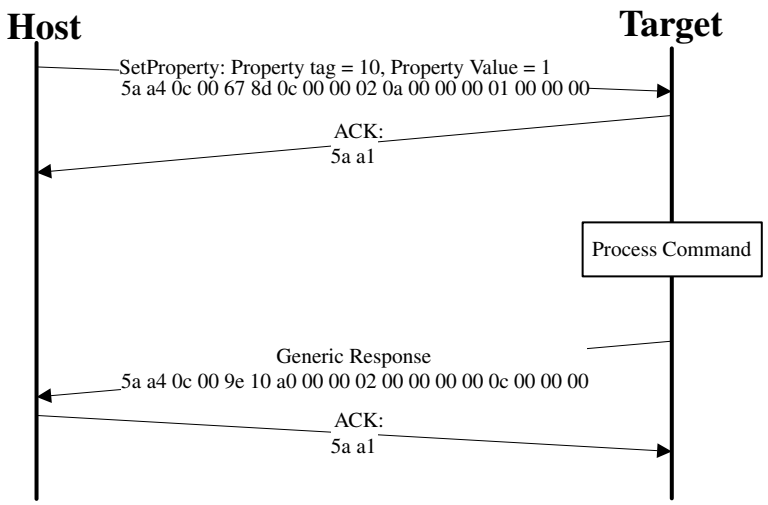

Figure 24. Protocol sequence for SetProperty Command

Table 115. SetProperty command packet format (example)

SetProperty	Parameter	Value
Framing packet	Start byte	0x5A
	PacketType	0xA4, kFramingPacketType_Command
	Length	0x0C 0x00
	Crc16	0x67 0x8D
Command packet	CommandTag	0x0C – SetProperty with property tag 10
	Flags	0x00
	Reserved	0x00
	ParameterCount	0x02
	PropertyTag	0x0000000A - VerifyWrites
	PropertyValue	0x00000001

The SetProperty command has no data phase.

Response: The target returns a GenericResponse packet with one of following status codes:

Table 116. SetProperty response status codes

Status code
kStatus_Success
kStatus_ReadOnly
kStatus_UnknownProperty
kStatus_InvalidArgument

11.5.4 FlashEraseAll command

The FlashEraseAll command performs an erase of the entire flash memory. If any flash regions are protected, then the FlashEraseAll command fails and returns an error status code. The Command tag for FlashEraseAll command is 0x01 set in the commandTag field of the command packet.

The FlashEraseAll command requires memory ID. If memory ID is not specified, the internal flash (memory ID =0) will be selected as default.

Table 117. Parameter for FlashEraseAll command

Byte #	Parameter	
0-3	Memory ID	
	0x000	Internal Flash
	0x09	XSPI NOR
	0x110	Serial NOR/EEPROM through SPI

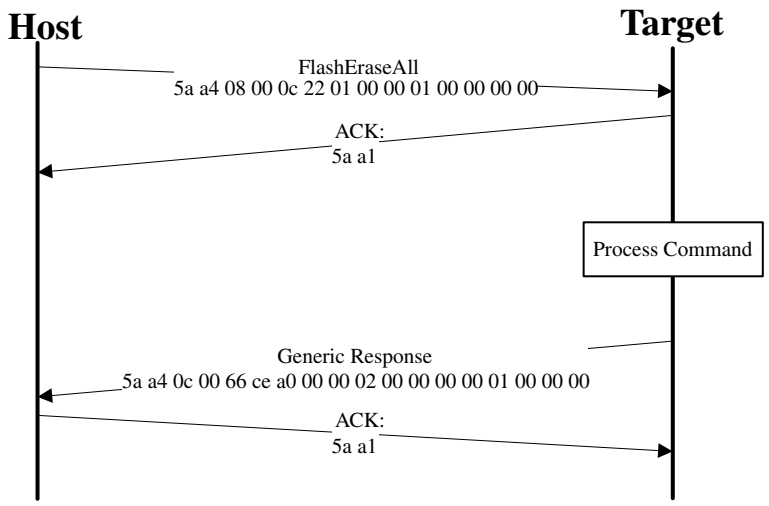

Figure 25. FlashEraseAll command

Table 118. FlashEraseAll command packet format (example)

FlashEraseAll	Parameter	Value
Framing packet	Start byte	0x5A
	PacketType	0xA4, kFramingPacketType_Command
	Length	0x08 0x00
	Crc16	0x0C 0x22
Command packet	CommandTag	0x01 - FlashEraseAll
	Flags	0x00
	Reserved	0x00
	ParameterCount	0x01
	Memory ID	Refer the above table

The FlashEraseAll command has no data phase.

Response: The target returns a GenericResponse packet with status code either set to kStatus_Success for successful execution of the command or set to an appropriate error status code.

11.5.5 FlashEraseRegion command

The FlashEraseRegion command performs an erase of one or more sectors of the flash memory.

The start address, and number of bytes are the two parameters required for the FlashEraseRegion command. The start and byte count parameters must be 4-byte aligned ([1:0] = 00), or the FlashEraseRegion command fails and returns kStatus_FlashAlignmentError (101). If the region specified does not fit in the flash memory space, the FlashEraseRegion command fails and returns kStatus_FlashAddressError (102). If any part of the region specified is protected, the FlashEraseRegion command fails and returns kStatus_MemoryRangeInvalid (10200).

Table 119. Parameter for FlashEraseRegion command

Byte #	Parameter
0-3	Start address
4 - 7	Byte count
8 - 11	Memory ID

The FlashEraseRegion command has no data phase.

Response: The target returns a GenericResponse packet with one of the following error status codes.

Table 120. FlashEraseRegion response status codes

Status code
kStatus_Success (0).

Table continues on the next page...

Table 120. FlashEraseRegion response status codes (continued)

Status code
kStatus_MemoryRangeInvalid (10200).
kStatus_FlashAlignmentError (101).
kStatus_IFlashAddressError (102).

Table 121. FlashEraseRegion response status codes

Status code
kStatus_FlashAccessError (103).
kStatus_FlashProtectionViolation (104).
kStatus_FlashCommandFailure (105).

11.5.6 ReadMemory command

The ReadMemory command returns the contents of memory at the given address, for a specified number of bytes. This command can read any region of memory accessible by the CPU and not protected by security.

The start address, and number of bytes are the two parameters required for ReadMemory command. The memory ID is optional. Internal memory will be selected as default if memory ID is not specified.

Table 122. Parameter for read memory command

Byte #	Parameter	Description
0-3	Start address	Start address of memory to read from.
4-7	Byte count	Number of bytes to read and return to caller.
8-11	Memory ID	Internal or external memory Identifier.

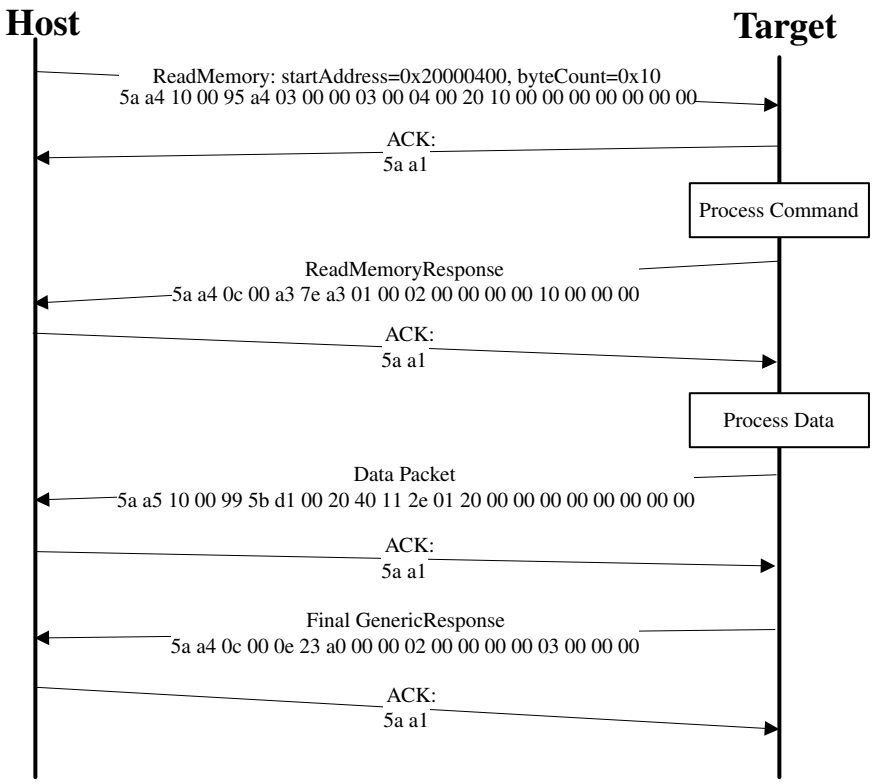

Figure 26. Command sequence for ReadMemory

Table 123. ReadMemory command packet format (example)

ReadMemory	Parameter	Value
Framing packet	Start byte	0x5A
	PacketType	0xA4, kFramingPacketType_Command
	Length	0x10 0x00
	Crc16	0xF4 0x1B
Command packet	CommandTag	0x03 - ReadMemory
	Flags	0x00
	Reserved	0x00
	ParameterCount	0x03
	StartAddress	0x20000400
	ByteCount	0x00000064
	Memory ID	0x0

Data Phase: The ReadMemory command has a data phase. The host needs to pull data packets until the number of bytes of data specified in the byteCount parameter of ReadMemory command are received by host.

Response: The target returns a GenericResponse packet with a status code either set to kStatus_Success upon successful execution of the command or set to an appropriate error status code

11.5.7 WriteMemory command

The WriteMemory command writes data provided in the data phase to a specified range of bytes in memory (flash or RAM). However, if flash protection is enabled, then writes to protected sectors fail.

Special care must be taken when writing to flash.

- First, any flash sector written to must have been previously erased with a FlashEraseAll or FlashEraseRegion command.
- Writing to flash requires the start address to be page aligned.
- The byte count is rounded up to a page size, and trailing bytes are filled with the flash erase pattern (0xff).
- If the VerifyWrites property is set to true, then writes to flash also performs a flash verify program operation.

When writing to RAM, the start address does not need to be aligned, and the data is not padded.

The start address and number of bytes are the two parameters required for WriteMemory command. The memory ID is optional. Internal memory will be selected as default if memory ID is not specified.

Table 124. Parameters for WriteMemory command

Byte #	Command
0-3	Start address
4-7	Byte count
8-11	Memory ID

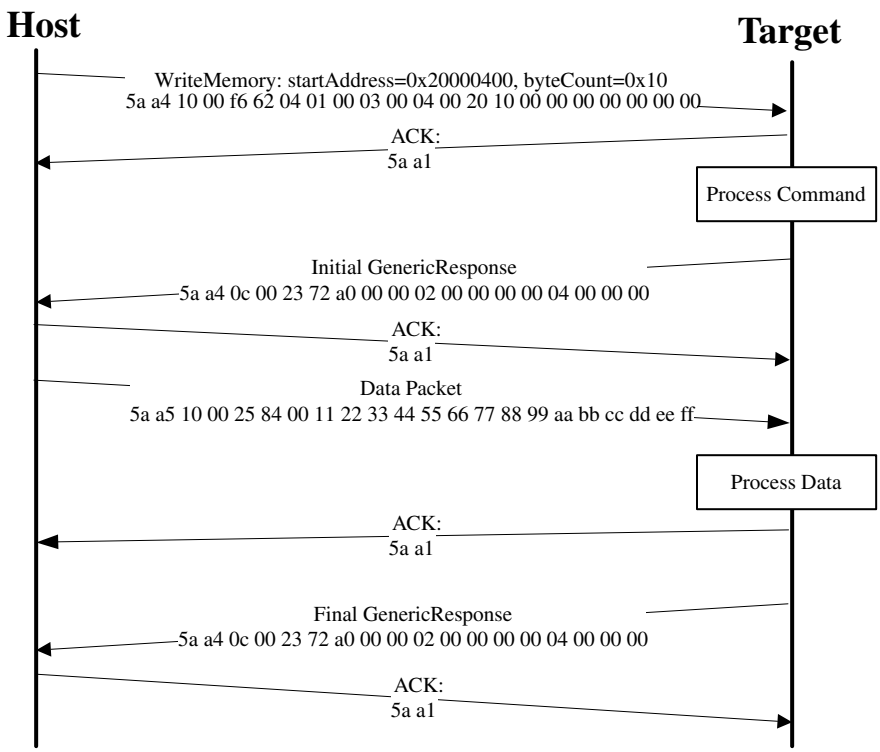

Figure 27. Protocol sequence for WriteMemory command

Table 125. WriteMemory command packet format (example)

WriteMemory	Parameter	Value
Framing packet	Start byte	0x5A
	PacketType	0xA4, kFramingPacketType_Command
	Length	0x10 0x00
	Crc16	0x97 0xDD
Command packet	CommandTag	0x04 - WriteMemory
	Flags	0x01
	Reserved	0x00
	ParameterCount	0x03
	StartAddress	0x20000400
	ByteCount	0x00000064
	Memory ID	0x0

Data Phase: The WriteMemory command has a data phase; the host sends data packets until the number of bytes of data specified in the byteCount parameter of the WriteMemory command are received by the target.

Response: The target returns a GenericResponse packet with a status code set to kStatus_Success upon successful execution of the command, or to an appropriate error status code.

11.5.8 FillMemory command

The FillMemory command fills a range of bytes in memory with a data pattern. It follows the same rules as the WriteMemory command. The difference between FillMemory and WriteMemory is that a data pattern is included in FillMemory command parameter, and there is no data phase for the FillMemory command, while WriteMemory does have a data phase.

Table 126. Parameters for FillMemory command

Byte #	Command
0-3	Start address of memory to fill.
4-7	• Number of bytes to write with the pattern. • The start address should be 32-bit aligned. • The number of bytes must be evenly divisible by 4.
8-11	32-bit pattern.

- To fill with a byte pattern (8-bit), the byte must be replicated four times in the 32-bit pattern.
- To fill with a short pattern (16-bit), the short value must be replicated two times in the 32-bit pattern.

For example, to fill a byte value with 0xFE, the word pattern is 0xFEFEFEFE; to fill a short value 0x5AFE, the word pattern is 0x5AFE5AFE.

Special care must be taken while writing to flash.

- First, any flash sector written to must have been previously erased with a FlashEraseAll, or FlashEraseRegion command.
- Writing to flash requires the start address to be 4-byte aligned ([1:0] = 00).
- If the VerifyWrites property is set to true, then writes to flash also performs a flash verify program operation.

When writing to RAM, the start address does not need to be aligned, and the data is not padded.

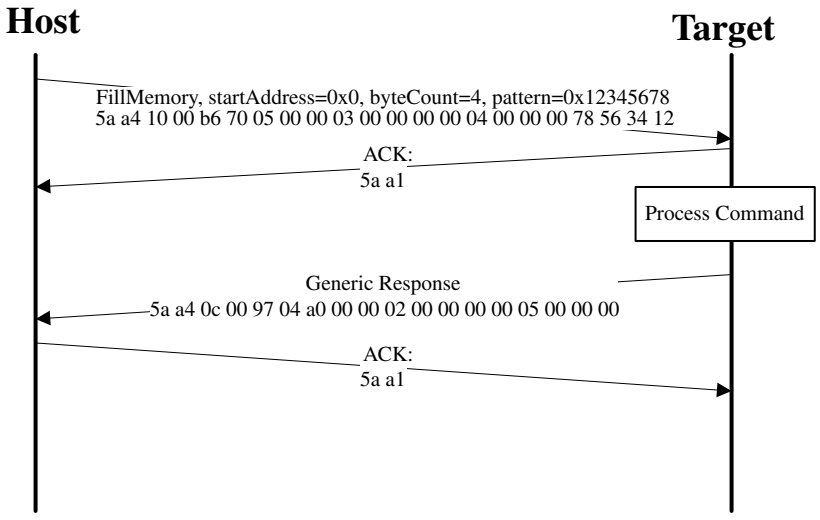

Figure 28. Protocol sequence for FillMemory command

Table 127. FillMemory command packet format (example)

FillMemory	Parameter	Value
Framing packet	Start byte	0x5A
	PacketType	0xA4, kFramingPacketType_Command
	Length	0x10 0x00
	Crc16	0xE4 0x57
Command packet	CommandTag	0x05 – FillMemory
	Flags	0x01
	Reserved	0x00
	ParameterCount	0x03
	StartAddress	0x00007000
	ByteCount	0x00000800
	PatternWord	0x12345678

The FillMemory command has no data phase.

Response: upon successful execution of the command, the target (bootloader) returns a GenericResponse packet with a status code set to kStatus_Success, or to an appropriate error status code.

11.5.9 Execute command

The Execute command results in the bootloader setting the program counter to the code at the provided jump address, R0 to the provided argument, and a Stack pointer to the provided stack pointer address. Prior to the jump, the system is returned to the reset state.

The Jump address, function argument pointer, and stack pointer are the parameters required for the Execute command. If the stack pointer is set to zero, the called code is responsible for setting the processor stack pointer before using the stack.

Table 128. Parameters for Execute command

Byte #	Command
0-3	Jump address.
4-7	Argument word.
8-11	Stack pointer address.

The Execute command has no data phase.

Response: Before executing the Execute command, the target validates the parameters and return a GenericResponse packet with a status code either set to kStatus_Success or an appropriate error status code.

11.5.10 Reset command

The Reset command results in the bootloader resetting the chip.

The Reset command requires no parameters.

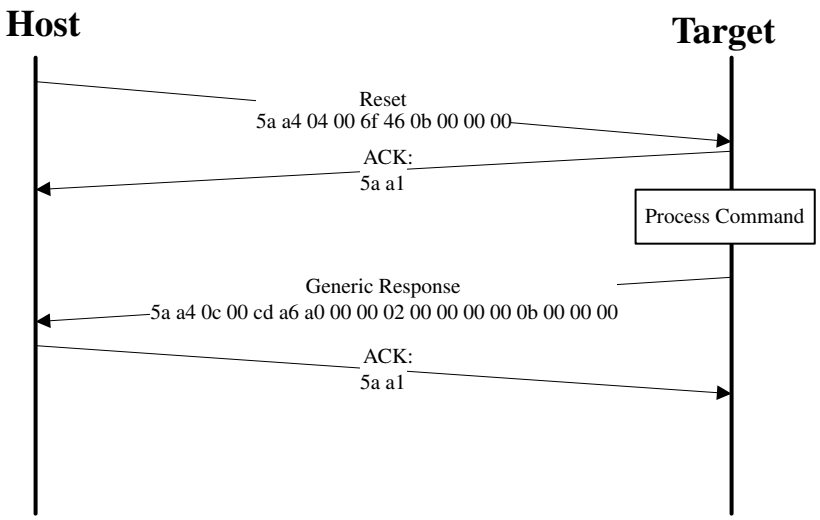

Figure 29. Protocol sequence for Reset command

Table 129. Reset command packet format (example)

Reset	Parameter	Value
Framing packet	Start byte	0x5A
	PacketType	0xA4, kFramingPacketType_Command
	Length	0x04 0x00
	Crc16	0x6F 0x46
Command packet	CommandTag	0x0B - reset
	Flags	0x00
	Reserved	0x00
	ParameterCount	0x03

The Reset command has no data phase.

Response: The target returns a GenericResponse packet with status code set to kStatus_Success, before resetting the chip.

The reset command can also be used to switch boot from flash after successful flash image provisioning via ROM bootloader. After issuing the reset command, allow five seconds for the user application to start running from Flash.

11.5.11 eFuseProgramOnce/FlashProgramOnce command

The FlashProgramOnce command writes data (that is provided in a command packet) to a specified range of bytes in the program once field. Special care must be taken when writing to the program once field.

• The program once field only supports programming once, so any attempted to reprogram a program-once field gets an error response.

• Writing to the program once field requires the byte count to be 4-byte aligned or 8-byte aligned. The FlashProgramOnce command uses three parameters: index 2, byteCount, data.

Table 130. Parameters for FlashProgramOnce Command

Byte #	Command
0 - 3	Index of program once field
4 - 7	Byte count (must be evenly divisible by 4)
8 - 11	Data

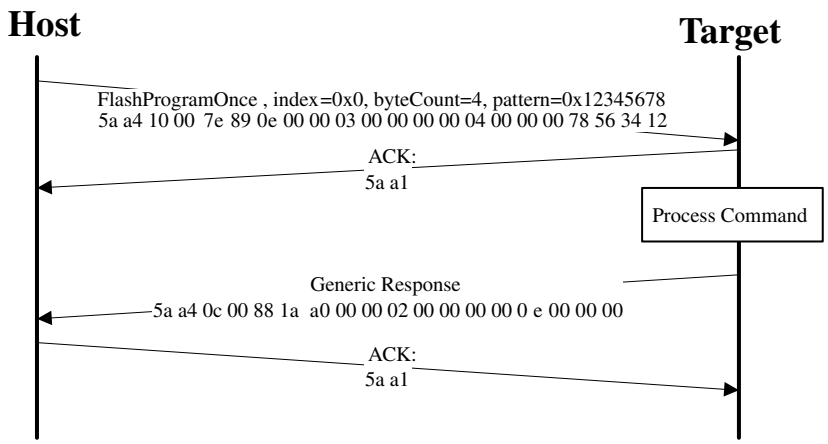

Figure 30. Protocol Sequence for FlashProgramOnce Command

Table 131. FlashProgramOnce Command Packet Format

FlashProgramOnce	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4, kFramingPacketType_Command
	length	0x10 0x00
	crc16	0x7E4 0x89
Command packet	commandTag	0x0E – FlashProgramOnce
	flags	0
	reserved	0
	parameterCount	3

Table continues on the next page...

Table 131. FlashProgramOnce Command Packet Format (continued)

FlashProgramOnce	Parameter	Value
	index	0x0000_0051 (the customer last efuse index)
	byteCount	0x0000_0004
	Data	0x1234_5678

Response: upon successful execution of the command, the target (Kinetis bootloader) returns a GenericResponse packet with a status code set to kStatus_Success, or to an appropriate error status code.

11.5.12 eFuseReadOnce / FlashReadOnce command

The FlashReadOnce command returns the contents of the program once field by given index and byte count. The FlashReadOnce command uses 2 parameters: index and byteCount. eFuseReadOnce command uses only one parameter index.

Table 132. Parameters for FlashReadOnce Command

Byte #	Parameter	Description
0 - 3	Index	Index of the program once field (to read from)
4 - 7	byteCount	Number of bytes to read and return to the caller

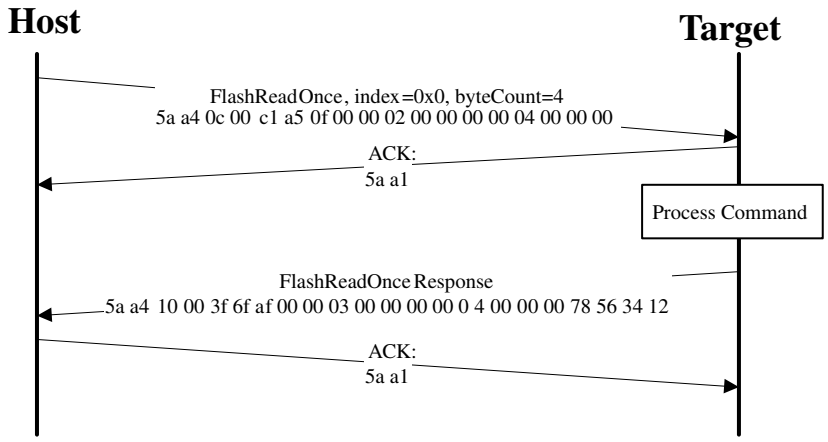

Figure 31. Protocol Sequence for FlashReadOnce Command

Table 133. FlashReadOnce Command Packet Format

FlashReadOnce	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4
	Length	0x0C 0x00

Table continues on the next page...

Table 133. FlashReadOnce Command Packet Format (continued)

FlashReadOnce	Parameter	Value
	Crc	0xC1 0xA5
Command packet	commandTag	0x0F – FlashReadOnce
	Flags	0x00
	Reserved	0x00
	parameterCount	0x02
	Index	0x0000_0000
	byteCount	0x0000_0004

Table 134. FlashReadOnce Response Format

FlashReadOnce Response	Parameter	Value
Framing packet	start byte	0x5A
	packetType	0xA4
	Length	0x10 0x00
	Crc	0x3F 0x6F
Command packet	commandTag	0xAF
	Flags	0x00
	Reserved	0x00
	parameterCount	0x03
	Status	0x0000_0000
	byteCount	0x0000_0004
	Data	0x1234_5678

Response: upon successful execution of the command, the target returns a FlashReadOnceResponse packet with a status code set to kStatus_Success, a byte count and corresponding data read from Program Once Field upon successful execution of the command or returns with a status code set to an appropriate error status code and a byte count set to 0.

11.5.13 ConfigureMemory command

The ConfigureMemory command configures the internal/external memory device using a pre-programmed configuration block. The parameters passed in the command are the memory ID, and then the memory address from which the configuration data can be loaded from. Options for loading the data can be a scenario where the configuration data is written to a RAM or flash location and then this command directs the bootloader to use the data at that location to configure the external memory devices.

Table 135. Parameters for ConfigureMemory command

Byte #	Command
0-3	Memory ID.
4-7	Configuration block address.

Response: The target (Bootloader) returns a GenericResponse packet with a status code either set to kStatus_Success upon successful execution of the command or set to an appropriate error code.

The following table shows the supported memory IDs.

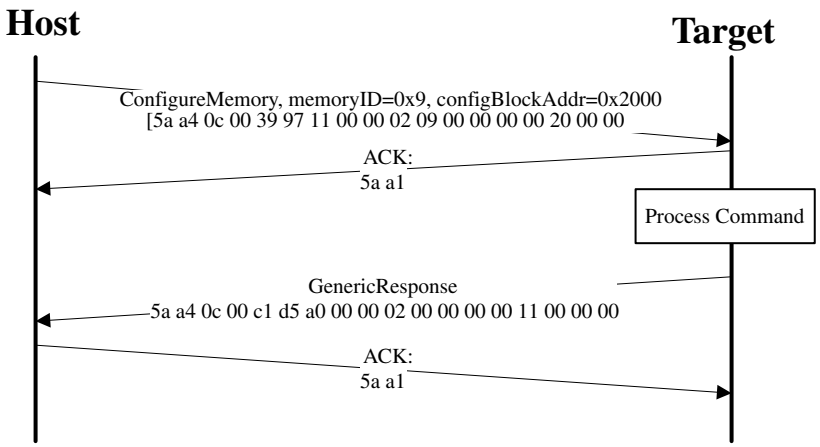

Figure 32. Protocol sequence for ConfigureMemory command

Table 136. Supported memory IDs

Memory ID	Description
0	Internal RAM/FLASH (Used for the PRINCE configuration).
0x9	External XSPI device. See Serial NOR Flash through XSPI.
0x110	External 1-bit SPI NOR FLASH device. See 1-bit Serial NOR flash through SPI.

11.5.14 ReceiveSBFile command

The Receive SB File command (ReceiveSbFile) starts the transfer of an SB file to the target. The command only specifies the size in bytes of the SB file that is sent in the data phase. The SB file is processed as it is received by the bootloader.

Table 137. Parameters for Receive SB File command

Byte #	Command
0-3	Byte count

Data Phase: The Receive SB file command has a data phase; the host sends data packets until the number of bytes of data specified in the byteCount parameter of the Receive SB File command are received by the target.

Response: The target returns a GenericResponse packet with a status code set to the kStatus_Success upon successful execution of the command or set to an appropriate error code.

NOTE

Only the byte address mode is supported in sbloder for NAND device.

11.5.15 Get/SetProperty command properties

This section lists the properties of the GetProperty and SetProperty commands.

Table 138. Properties used by Get/SetProperty commands, sorted by values

Property	Writable	Tag value	Size (byte)	Description
CurrentVersion	No	01h	4	Current bootloader version.
AvailablePeripherals	No	02h	4	The set of peripherals supported on this chip.
AvailableCommands	No	07h	4	The set of commands supported by the bootloader
Check Status	No	08h	4	32-bit return value for CRC Check 10401 - Application CRC check failed 10402 - Application CRC check is inactive 10403 - Application CRC check is invalid
MaxPacketSize	No	0Bh	4	Maximum supported packet size for the currently active peripheral interface.
ReservedRegions	No	0Ch	8*n	List of memory regions reserved by the bootloader. Returned as value pairs (<start-address-of-region>, <end-address-of-region>). If HasDataPhase flag is not set, then the Response packet parameter count indicates the number of pairs. If HasDataPhase flag is set, then the second parameter is the number of bytes in the data phase. "n" indicates number of memory region pairs
RAMStartAddress [<memoryID>]	No	0Eh	4	Start address of on-chip SRAM memoryID 0 (default) - Start address of SRAM partitions located in Common domain 1 - Start address of SRAM partitions located in Sense domain
RAMSizeInBytes [<memoryID>]	No	0Fh	4	On-chip SRAM size in bytes memoryID 0 (default) - Size of SRAM partitions located in Common domain 1 - Size of SRAM partitions located in Sense domain
SystemDeviceId	No	10h	4	Value of the DEVICD_ID and DIEID
LifeCycleState	No	11h	8	The life cycle of the device.

Table continues on the next page...

Table 138. Properties used by Get/SetProperty commands, sorted by values (continued)

Property	Writable	Tag value	Size (byte)	Description
				5aa5_5aa5h - Device is in development life cycle. c33c_c33ch - Device is in deployment life cycle.
UniqueDevice/UUID	No	12h	16	Unique device identification
Target ROM Version	No	18h	4	The target build version number
ExternalMemoryAttributes	No	19h	24	List of attributes supported by the specified memory Id (110h=SPI NOR FLASH).
IrqNotifierPin	Yes	1Ch	4	IRQ notifier pin setting bit[7:0] - GPIO pin, range: 0-31 bit[15:8] - GPIO port, range: 0-7 bit[16] - active polarity: 0 - active low, 1 - active high bit [30:17] - reserved bit [31] - enable flag: 0 - disable, 1 - enable **NOTE** You must not configure the IRQ notifier pin the same as that used as the boot pin, boot interface pin or ISP interface pin.

11.5.15.1 Property definitions

Get/Set property definitions are provided in this section.

11.5.15.1.1 CurrentVersion property

The value of this property is a 4-byte structure containing the current version of the bootloader.

Table 139. CurrentVersion property fields

Bit	[31:24]	[23:16]	[15:8]	[7:0]
Field	Name = 'K' (0x4B)	Major version	Major version	Bugfix version

11.5.15.1.2 AvailablePeripherals property

The value of this property is a bitfield that lists the peripherals supported by the bootloader and the hardware on which it is running.

Table 140. Peripheral bits

Bit	[31:7]	[6]	[5]	[4]	[3]	[2]	[1]	[0]
Field	Reserved	Reserved	Reserved	USB HID	CAN	SPI target	I2C target	LPUART

If the peripheral is available, then the corresponding bit will be set in the property value. All reserved bits must be set to 0.

11.5.15.1.3 AvailableCommands property

This property value is a bitfield with set bits indicating the commands enabled in the bootloader. Only commands that can be sent from the host to the target are listed in the bitfield. Response commands such as GenericResponse are excluded.

The bit number that identifies whether a command is present is the command's tag value minus 1. 1 is subtracted from the command tag because the lowest command tag value is 0x01. To get the bit mask for a given command, use this expression: mask = 1 << (tag - 1).

Table 141. Command bits

Bit	Command
[Others]	Reserved
[21]	TrustProvisioning
[20:17]	Reserved
[16]	ConfigureMemory
[15]	Reserved
[14]	eFuseRead/FlashReadOnce
[13]	eFuseProgram/FlashProgramOnce
[12]	Reserved
[11]	SetProperty
[10]	Reset
[9]	Reserved
[8]	Execute
[7]	ReceiveSbFile
[6]	GetProperty
[5]	Reserved
[4]	FillMemory
[3]	WriteMemory
[2]	ReadMemory
[1]	FlashEraseRegion
[0]	FlashEraseAll

11.5.15.1.4 ExternalMemoryAttributes property

The value returned by this property is a 24-byte data structure containing available external memory attributes: start address, total size in KB, page size, sector size, and block size. Below is the breakdown of 24-byte structure.

Table 142. Fields of ExternalMemoryAttributes property

Field offset	Field Description
0 - 3	The value returned is a bitmap showing the supported attributes for the external memory, with the corresponding bitfield set. 0x00000001 - start address

Table continues on the next page...

Table 142. Fields of ExternalMemoryAttributes property (continued)

Field offset	Field Description
	0x00000002 - total size 0x00000004 - page size 0x00000008 - sector size 0x00000010 - block size
4 - 7	Start address of external memory.
8 - 11	Total size of external memory in kilobytes.
12 - 15	Page size of external memory in bytes.
16 - 19	Sector size of external memory in bytes.
20 - 23	Block size of external memory in bytes.

11.6 Bootloader Status Error Codes

This section describes the status error codes that the Bootloader returns to the host.

Table 143. Bootloader status error codes, sorted by value

Error Code	Value	Description
kStatus_Success	0	Operation succeeded without error.
kStatus_Fail	1	The operation failed with a generic error.
kStatus_ReadOnly	2	Requested value cannot be changed because it is read-only.
kStatus_OutOfRange	3	Requested value is out of range.
kStatus_InvalidArgument	4	The requested command's argument is undefined.
kStatus_Timeout	5	A timeout occurred.
kStatus_NoTransferInProgress	6	No send in progress
kStatus_UnknownCommand	10000	This command is not recognized.
kStatus_SecurityViolation	10001	Security violation happened when receiving disallowed commands.
kStatus_AbortDataPhase	10002	Sender requested data phase abort.
kStatus_Ping	10003	Ping command received from the host.
kStatus_NoResponse	10004	No Response from the host.

Table continues on the next page...

Table 143. Bootloader status error codes, sorted by value (continued)

Error Code	Value	Description
kStatus_NoResponseExpected	10005	Expected No Response from the host.
kStatus_CommandUnsupported	10006	Unsupported command was received.
kStatusRomLdrSectionOverrun	10100	Means reached the end of the sb file processing.
kStatusRomLdrSignature	10101	The signature or version are incorrect.
kStatusRomLdrSectionLength	10102	The bootOffset/ new section count is out of range.
kStatusRomLdrUnencryptedOnly	10103	The unencrypted image is disabled.
kStatusRomLdrEOFReached	10104	The end of the image file is reached.
kStatusRomLdrChecksum	10105	The checksum of a command tag block is invalid.
kStatusRomLdrCrc32Error	10106	The CRC-32 of the data for a load command is incorrect.
kStatusRomLdrUnknownCommand	10107	An unknown command was found in the SB file.
kStatusRomLdrIdNotFound	10108	There was no bootable section found in the SB file.
kStatusRomLdrDataUnderrun	10109	The SB state machine is waiting for more data.
kStatusRomLdrJumpReturned	10110	The function that was jumped to by the SB file has returned.
kStatusRomLdrCallFailed	10111	The call command in the SB file failed.
kStatusRomLdrKeyNotFound	10112	A matching key was not found in the SB file's key dictionary to unencrypt the section.
kStatusRomLdrSecureOnly	10113	The SB file sent is unencrypted, and security on the target is enabled.
kStatusRomLdrResetReturned	10114	The SB file reset operation has unexpectedly returned.
kStatusRomLdrRollbackBlocked	10115	An Image version rollback event detected.
kStatusRomLdrInvalidSectionMacCount	10116	Invalid Section MAC count detected in the SB file.
kStatusRomLdrUnexpectedCommand	10117	The command tag in the sb-file is unexpected.
kStatusRomLdrBadSBKEK	10118	Bad SBKEK detected.
kStatusRomLdrPendingJumpCommand	10119	Represents that the jump command is pending and the actual jump is implemented in sbloader_finalize().

Table continues on the next page...

Table 143. Bootloader status error codes, sorted by value (continued)

Error Code	Value	Description
kStatusMemoryRangeInvalid	10200	The requested address range does not match an entry, or the length extends past the matching entry's end address.
kStatusMemoryReadFailed	10201	Memory Read failed.
kStatusMemoryWriteFailed	10202	Memory Write failed.
kStatusMemoryCumulativeWrite	10203	Cumulative write occurred due to a write to an unerased flash memory region
kStatusMemoryNotConfigured	10205	Memory was not configured before access
kStatusMemoryAlignmentError	10206	Alignment error during memory access
kStatusMemoryVerifyFailed	10207	Verifying operation failed after erasing or programming flash memory
kStatusMemoryWriteProtected	10208	Memory to be written is protected
kStatusMemoryAddressError	10209	Memory address is invalid or wrong
kStatusMemoryUnsupportedCommand	10214	The memory command is not supported.
kStatus_UnknownProperty	10300	The requested property value is undefined.
kStatus_ReadOnlyProperty	10301	The requested property value cannot be written.
kStatus_InvalidPropertyValue	10302	The specified property value is invalid.
kStatus_AppCrcCheckPassed	10400	CRC check is valid and passed.
kStatus_AppCrcCheckFailed	10401	CRC check is valid but failed.
kStatus_AppCrcCheckInactive	10402	CRC check is inactive.
kStatus_AppCrcCheckInvalid	10403	CRC check is invalid because the BCA is invalid, or the CRC parameters are unset (all 0xFF bytes).
kStatus_AppCrcCheckOutOfRange	10404	CRC check is valid, but addresses are out of range.
kStatus_RomApiExecuteCompleted	0	ROM successfully process the whole sb file/ boot image.
kStatus_RomApiNeedMoreData	10801	ROM needs more data to continue processing the boot image.
kStatus_RomApiBufferSizeNotEnough	10802	The user buffer is not enough for use by Kboot during execution of the operation.
kStatus_RomApiInvalidBuffer	10803	The user buffer is not ok for sbloader or authentication.

Table continues on the next page...

Table 143. Bootloader status error codes, sorted by value (continued)

Error Code	Value	Description
kStatus_XSPI_SequenceExecutionTimeout	15300	The XSPI sequence execution timeout.
kStatus_XSPI_InvalidSequence	15301	The XSPI LUT sequence invalid.
kStatus_XSPI_DeviceTimeout	15302	The XSPI device timeout.
kStatus_xSpiNAND_ReadPageFail	20800	XSPI NAND read page failure
kStatus_xSpiNAND_ReadCacheFail	20801	XSPI NAND read cache failure
kStatus_xSpiNAND_EccCheckFail	20802	XSPI NAND ECC cehck failure
kStatus_xSpiNAND_PageLoadFail	20803	XSPI NAND page load failure
kStatus_xSpiNAND_PageExecuteFail	20804	XSPI NAND page execute failure
kStatus_xSpiNAND_EraseBlockFail	20805	XSPI NAND erase block failure
kStatus_xSpiNAND_FcbUpdateFail	20808	XSPI NAND FCB update failure
kStatus_xSpiNAND_DbbtUpdateFail	20809	XSPI NAND DBBT update failure
kStatus_xSpiNAND_WriteAlignmentError	20810	XSPI NAND write address is not aligned
kStatus_xSpiNAND_NotFound	20811	XSPI NAND is not found
kStatus_XSPINOR_ProgramFail	20900	Page programming failure.
kStatus_XSPINOR_EraseSectorFail	20901	Sector Erase failure.
kStatus_XSPINOR_EraseAllFail	20902	Chip Erase failure.
kStatus_XSPINOR_WaitTimeout	20903	The execution time out.
kStatus_XSPINOR_NotSupported	20904	Page size overflow.
kStatus_XSPINOR_WriteAlignmentError	20905	Address alignment error.
kStatus_XSPINOR_CommandFailure	20906	Erase/Program verify error.
kStatus_XSPINOR_SFDP_NotFound	20907	Timeout occurs during the API. call
kStatus_XSPINOR_Unsupported_SFDP_Version	20908	Unrecognized SFDP version.
kStatus_XSPINOR_FLASH_NotFound	20909	Flash detection failure.
kStatus_XSPINOR_DTRRead_DummyProbeFailed	20910	DDR Read dummy probe failure.
kStatus_IAP_Success	0	IAP API execution succeeded.
kStatus_IAP_Fail	1	IAP API execution failed.
kStatus_IAP_InvalidArgument	100001	Invalid argument detected during API execution.

Table continues on the next page...

Table 143. Bootloader status error codes, sorted by value (continued)

Error Code	Value	Description
kStatus_IAP_OutOfMemory	100002	The Heap size is not enough during API execution.
kStatus_IAP_ReadDisallowed	100003	The read memory operation is disallowed during API execution.
kStatus_IAP_CumulativeWrite	100004	The FLASH region to be programmed is not empty.
kStatus_IAP_EraseFailuire	100005	Erase operation failed.
kStatus_IAP_CommandNotSupported	100006	The specific command is not supported.
kStatus_IAP_MemoryAccessDisabled	100007	Memory access is disabled, typically occurred on the XSPI NOR if it is not configured properly.
kStatus_NBOOT_Success	0x5A5A5A5Au	Operation completed successfully in NBOOT functions.
kStatus_NBOOT_Fail	0x5A5AA5A5u	Operation failed in NBOOT functions.
kStatus_NBOOT_InvalidArgument	0x5A5AA5F0u	Invalid argument passed to the function in NBOOT functions.
kStatus_NBOOT_RequestTimeout	0x5A5AA5E1u	Operation timed out in NBOOT functions.
kStatus_NBOOT_KeyNotLoaded	0x5A5AA5E2u	The requested key is not loaded in NBOOT functions.
kStatus_NBOOT_AuthFail	0x5A5AA5E4u	Authentication failed in NBOOT functions.
kStatus_NBOOT_OperationNotAvaialable	0x5A5AA5E5u	Operation not available on this HW in NBOOT functions.
kStatus_NBOOT_KeyNotAvailable	0x5A5AA5E6u	Key is not available in NBOOT functions.
kStatus_NBOOT_IvCounterOverflow	0x5A5AA5E7u	Overflow of IV counter (PRINCE/IPED) in NBOOT functions.
kStatus_NBOOT_SelftestFail	0x5A5AA5E8u	FIPS self-test failure in NBOOT functions.
kStatus_NBOOT_InvalidDataFormat	0x5A5AA5E9u	Invalid data format for example antipole in NBOOT functions.
kStatus_NBOOT_IskCertUserDataTooBig	0x5A5AA5EAu	Size of User data in ISK certificate is greater than 96 bytes in NBOOT functions.
kStatus_NBOOT_IskCertSignatureOffsetTooSmall	0x5A5AA5EBu	Signature offset in ISK certificate is smaller than expected in NBOOT functions.
kStatus_NBOOT_MemcpyFail	0x5A5A845Au	Unexpected error detected during nboot_memcpy()in NBOOT functions.

Table continues on the next page...

Table 143. Bootloader status error codes, sorted by value (continued)

Error Code	Value	Description
kStatus_SKBOOT_Success	0x5ac3c35au	Operation completed successfully in SKBOOT functions.
kStatus_SKBOOT_Fail	0xc35ac35au	Operation failed in SKBOOT functions.
kStatus_SKBOOT_InvalidArgument	0xc35a5ac3u	Return Invalid argument status in SKBOOT functions.
kStatus_MKBOOT_Success	0x0000c35au	Operation completed successfully in Prime KBOOT.
kStatus_MKBOOT_Fail	0x0000c3c3u	Operation failed in Prime KBOOT.
kStatus_MKBOOT_InvalidArgument	0x00005ac3u	Return Invalid argument status in Prime KBOOT.

NOTE

In UART, I2C, CAN and SPI ISP modes, the ROM expects posted responses to be read by the host within 20ms*number of bytes, otherwise the ROM reports the abort command. Considering an ACK from the ROM is only two bytes, the host must read those bytes within 40ms of the ROM posting.

11.7 UART ISP

11.7.1 Introduction

The bootloader integrates an autobaud detection algorithm for the UART peripheral, thereby providing flexible baud rate choices.

Autobaud feature: If UART*n* is used to connect to the bootloader, then the UART*n*_RX pin must be kept high and not left floating during the detection phase in order to comply with the autobaud detection algorithm. After the bootloader detects the Ping packet (0x5A 0xA6) on UART*n*_RX, the bootloader firmware executes the autobaud sequence.

If the baudrate is successfully detected, then the bootloader sends a Ping packet response [(0x5A 0xA7), protocol version (4 bytes), protocol version options (2 bytes) and crc16 (2 bytes)] at the detected baudrate. The bootloader then enters a loop, waiting for bootloader commands via the UART peripheral.

NOTE: The data bytes of the ping packet must be sent continuously (with no more than 80 ms between bytes) in a fixed UART transmission mode (8-bit data, no parity bit and 1 stop bit). If the bytes of the ping packet are sent one-by-one with more than 80 ms delay between them, then the autobaud detection algorithm may calculate an incorrect baud rate. In this instance, the autobaud detection state machine should be reset.

Supported baud rates: The baud rate is closely related to the MCU core and system clock frequencies. Typical baud rates supported are 9600, 19200, 38400, 57600, 115200 ,230400, 460800 and 1000000.

Packet transfer: After autobaud detection succeeds, bootloader communications can take place over the UART peripheral. The following flow charts show:

- How the host detects an ACK from the target.
- How the host detects a ping response from the target.
- How the host detects a command response from the target.

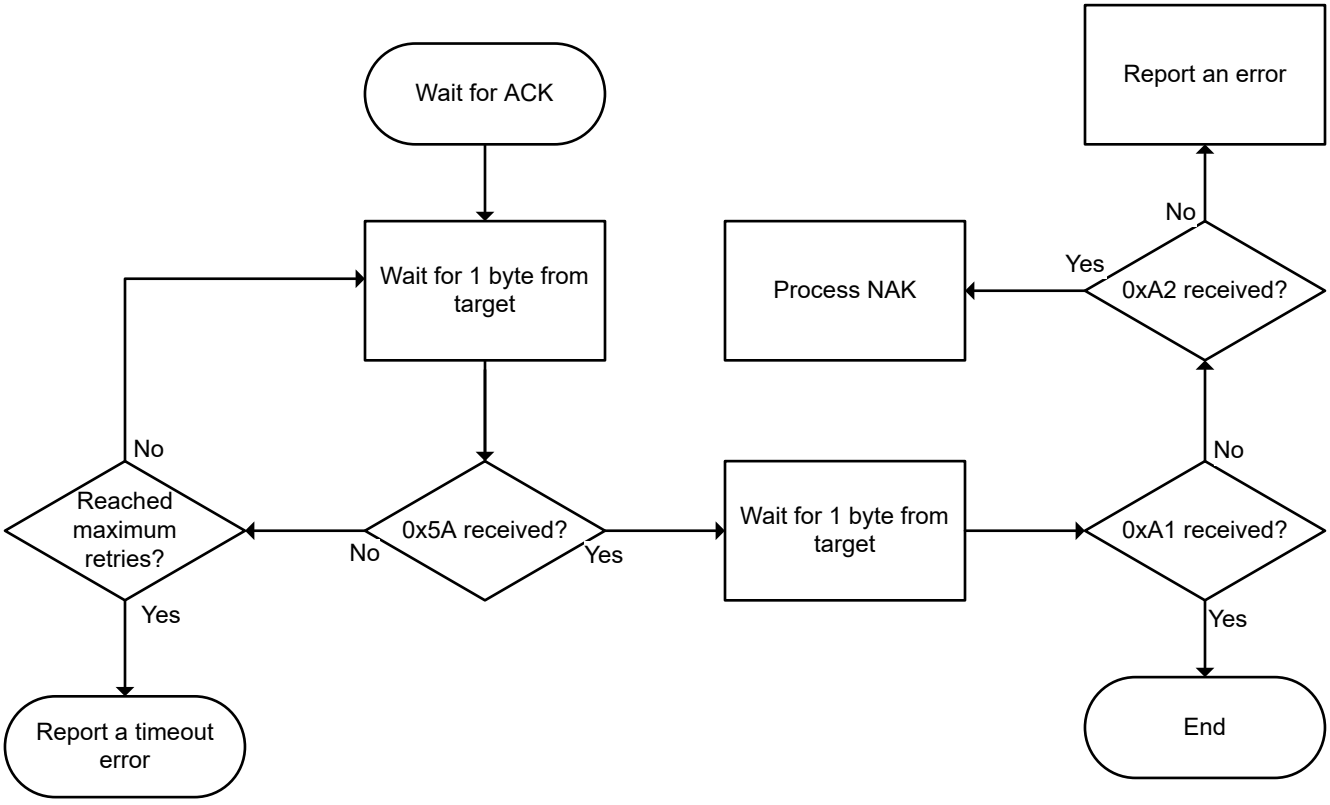

Figure 33. Host reads an ACK from target via UART

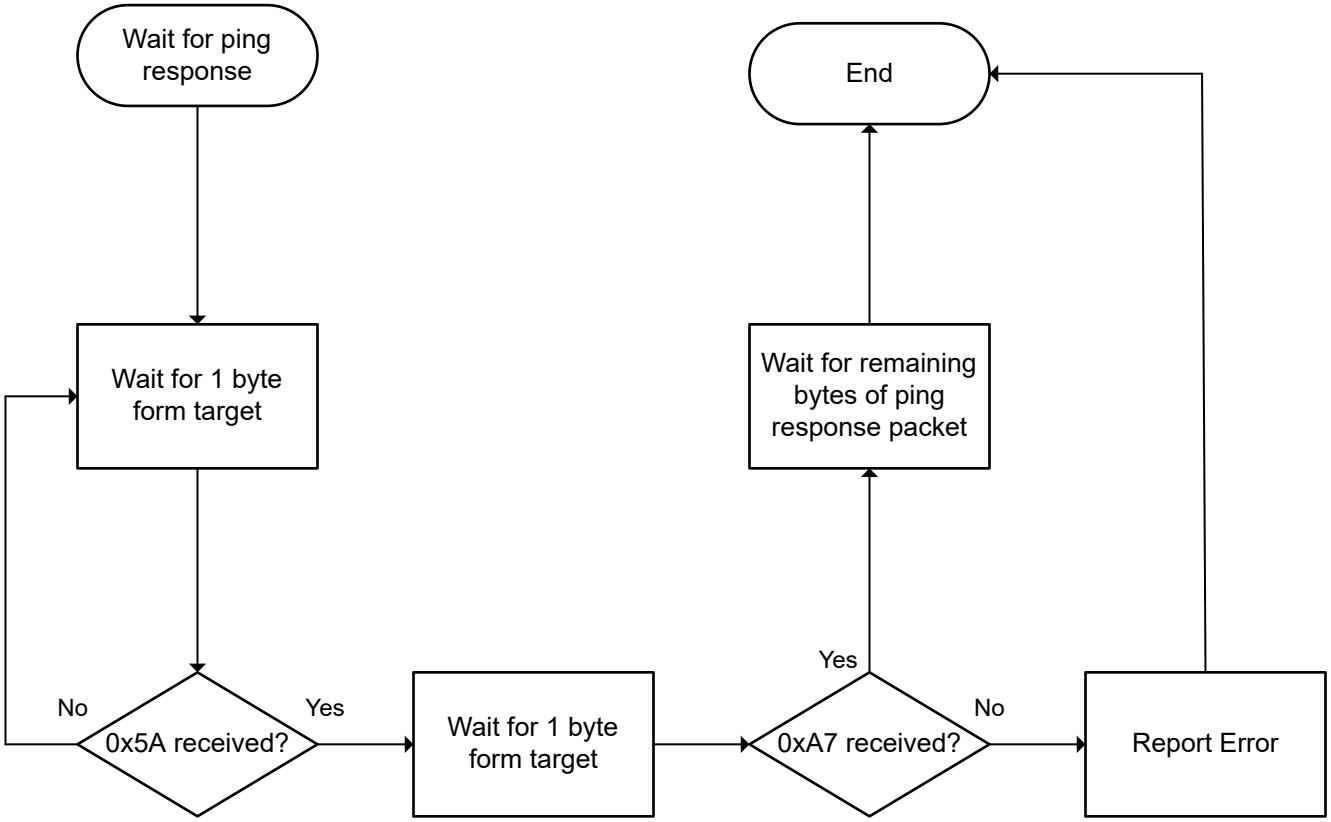

Figure 34. Host reads a ping response from target via UART

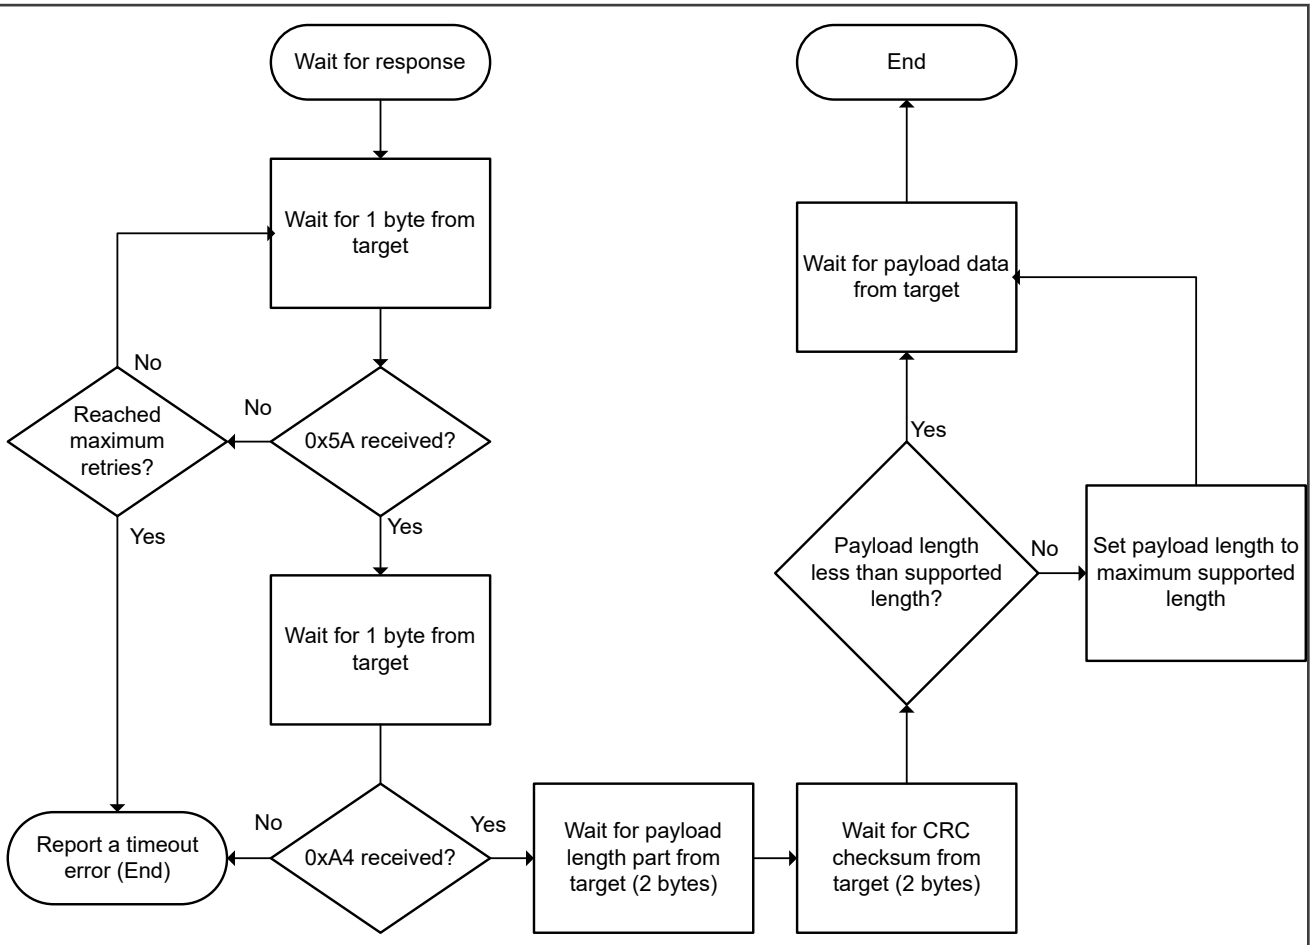

Figure 35. Host reads a command response from target via UART

See Bootloader packet types for more details on UART ISP command format, UART ISP response format, UART ISP data format, and UART ISP commands.

11.8 I2C In-System Programming

11.8.1 Introduction

The bootloader supports loading data into flash via the I2C peripheral, where the I2C peripheral serves as the I2C target. A 7-bit target address is used during the transfer. The bootloader uses 0x10 as the I2C target address and supports up to 400 kbit/s as the I2C baud rate.

The maximum supported I2C baud rate depends on the core clock frequency when the bootloader is running. The typical baud rate is 400 kbit/s with factory settings.

Because the I2C peripheral serves as an I2C target device, each transfer should be started by the host, and each outgoing packet should be fetched by the host.

- An incoming packet is sent by the host with a selected I2C target address and the direction bit is set to write.
- An outgoing packet is read by the host with a selected I2C target address and the direction bit is set as read.
- 0x00 is sent as the response to host if the target is busy with processing or preparing data.

The following charts show the communication flow of the host reading the ping and ACK packets, and the corresponding responses from the target.

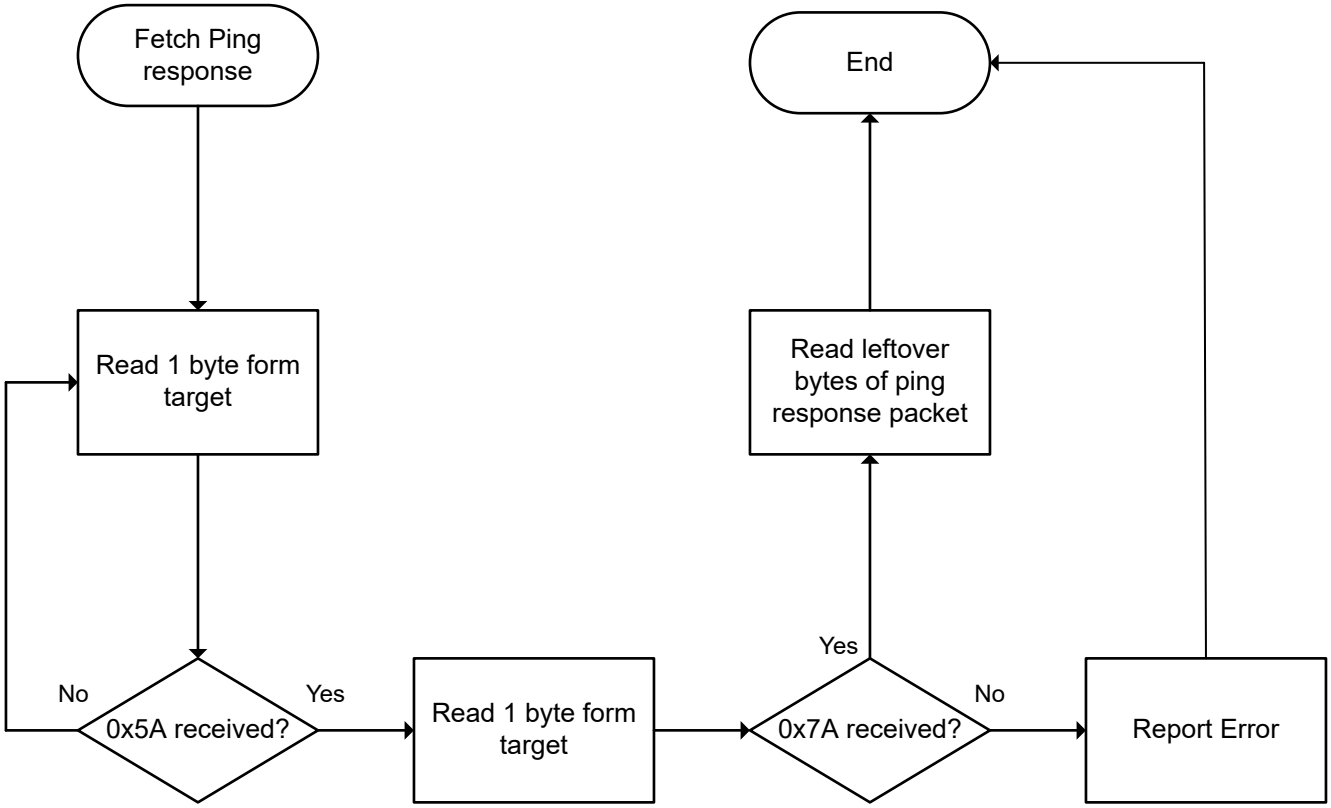

Figure 36. Host reads ping response from target via I2C

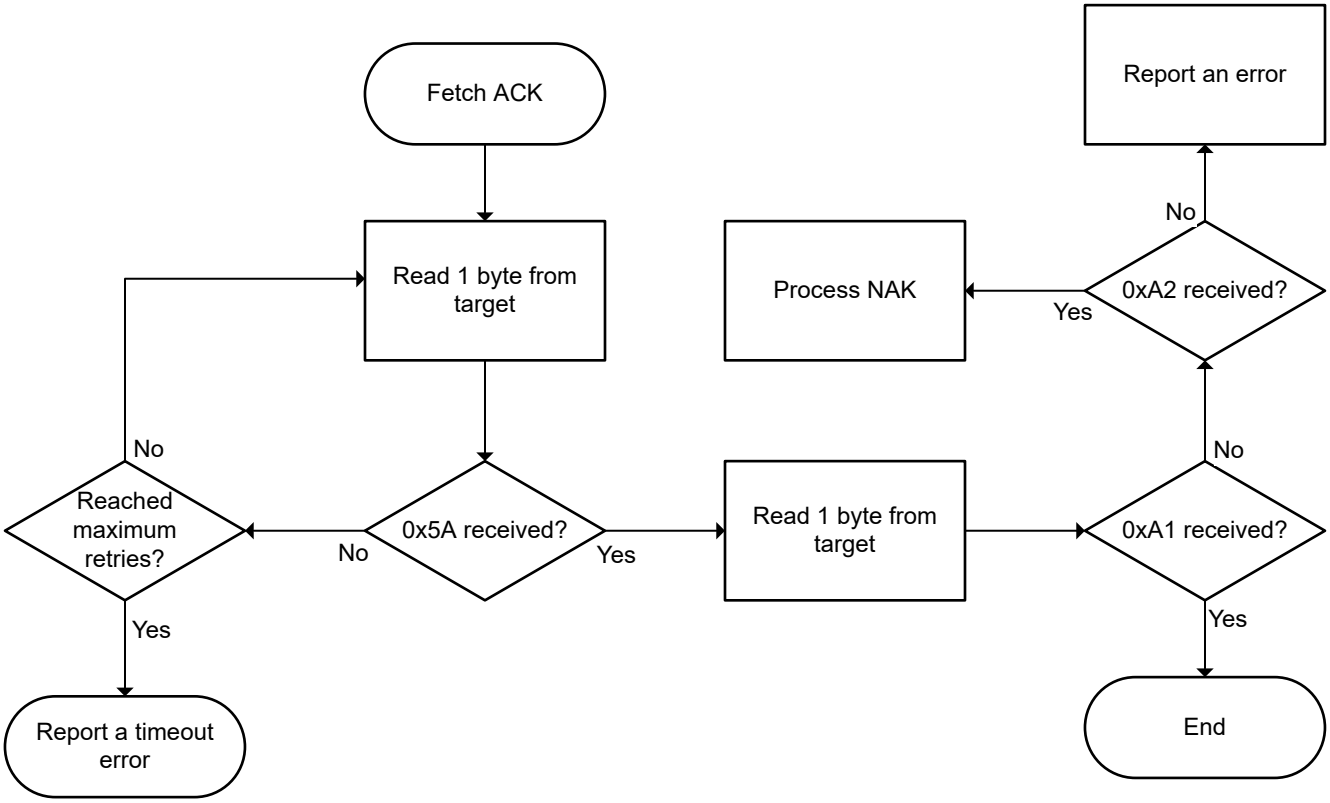

Figure 37. Host reads ACK packet from target via I2C

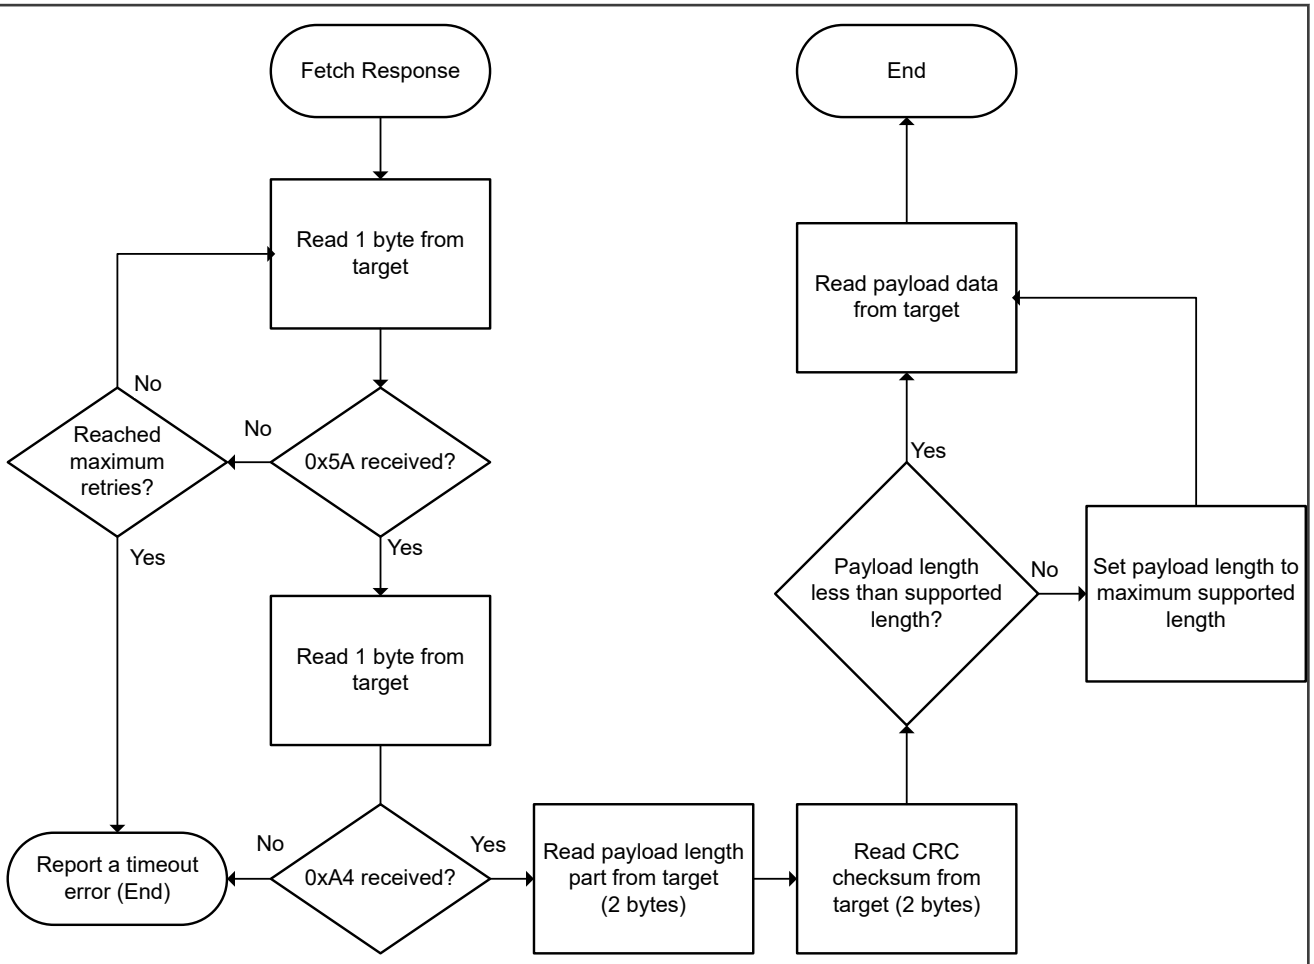

Figure 38. Host reads response from target via I2C

See Bootloader packet types for more details on I2C ISP command format, I2C ISP response format, and I2C ISP data format.

See Bootloader command set for more details on I2C ISP commands.

The bootloader also supports the active notification pin (nIRQ pin) to notify the host processor it is busy or ready for new commands/data.

To accelerate the I2C transfer between the host and the bootloader, the bootloader provides an active notification pin known as the nIRQ pin, it can be enabled by the SetProperty command. In SetProperty command, an active polarity field in defined.

- If the active polarity is set as default 0, then the host needs to wait until it sees a negative edge on the nIRQ pin before reading any data from the bootloader, and it needs to wait until the nIRQ pin is high before sending any data to the bootloader.
- If the active polarity is set as 1, then the host needs to wait until it sees a positive edge on the nIRQ pin before reading any data from the bootloader, and it needs to wait until the nIRQ pin is low before sending any data to the bootloader.

See Table 138 for more details.

11.9 SPI In-System programming

11.9.1 Introduction

The bootloader supports loading data into flash via the SPI peripheral, where the SPI peripheral serves as an SPI target. The SPI transfer should be SPI Mode 3 with 8 data bits.

The maximum supported baud rate of the SPI depends on the core clock frequency when the bootloader is running. The typical baud rate is 2000 kbit/s with the factory settings. The actual baud rate is lower or higher than 2000 kbit/s, depending on the actual value of the core clock.

Because the SPI peripheral serves as an SPI target device, each transfer should be started by the host, and each outgoing packet should be fetched by the host.

- The transfer on SPI is slightly different from I^2C:
- The host receives 1 byte after it sends out any byte.
- Received bytes should be ignored when the host is sending out bytes to the target
- The host starts reading bytes by sending 0x00s to target

The byte 0x00 is sent as a response to host if the target is under the following conditions:

- Processing incoming packet.
- Preparing outgoing data.
- Received invalid data.

The bootloader also supports the active notification pin (nIRQ pin) to notify the host processor it is busy or ready for new commands/data.

To accelerate the SPI transfer between the host and the bootloader, the bootloader provides an active notification pin known as the nIRQ pin, it can be enabled by the SetProperty command. In SetProperty command, an active polarity field in defined.

- If the active polarity is set as default 0, then the host needs to wait until it sees a negative edge on the nIRQ pin before reading any data from the bootloader, and it needs to wait until the nIRQ pin is high before sending any data to the bootloader.
- If the active polarity is set as 1, then the host needs to wait until it sees a positive edge on the nIRQ pin before reading any data from the bootloader, and it needs to wait until the nIRQ pin is low before sending any data to the bootloader.

See Table 138 for more details.

See below figure for the typical physical connection between the host and the bootloader device.

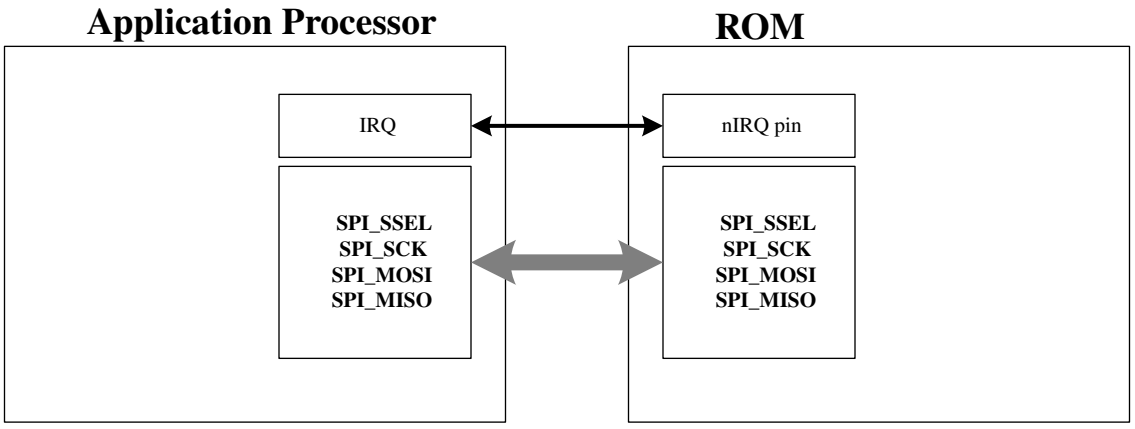

Figure 39. Physical interface for SPI ISP

The following flowcharts show how the host reads a ping response, an ACK and a command response from target via SPI without the nIRQ pin enabled.

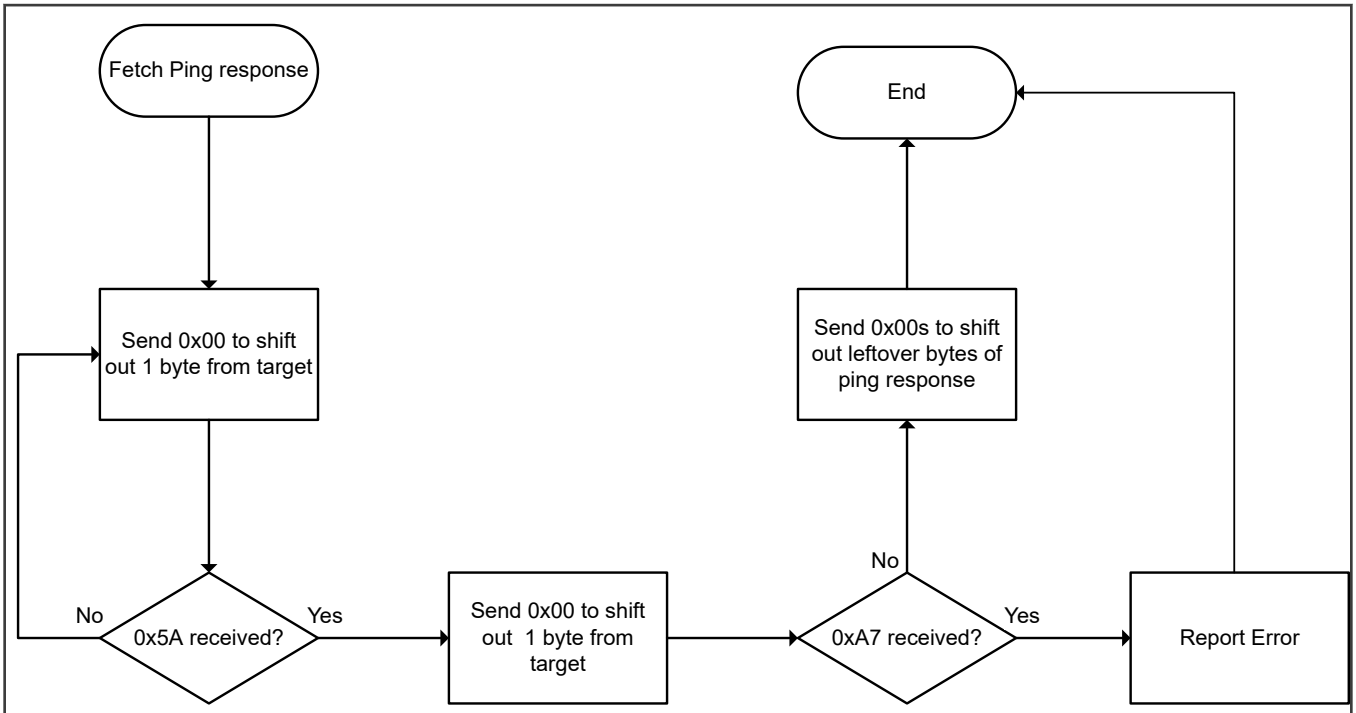

Figure 40. Host reads ping packet from target via SPI

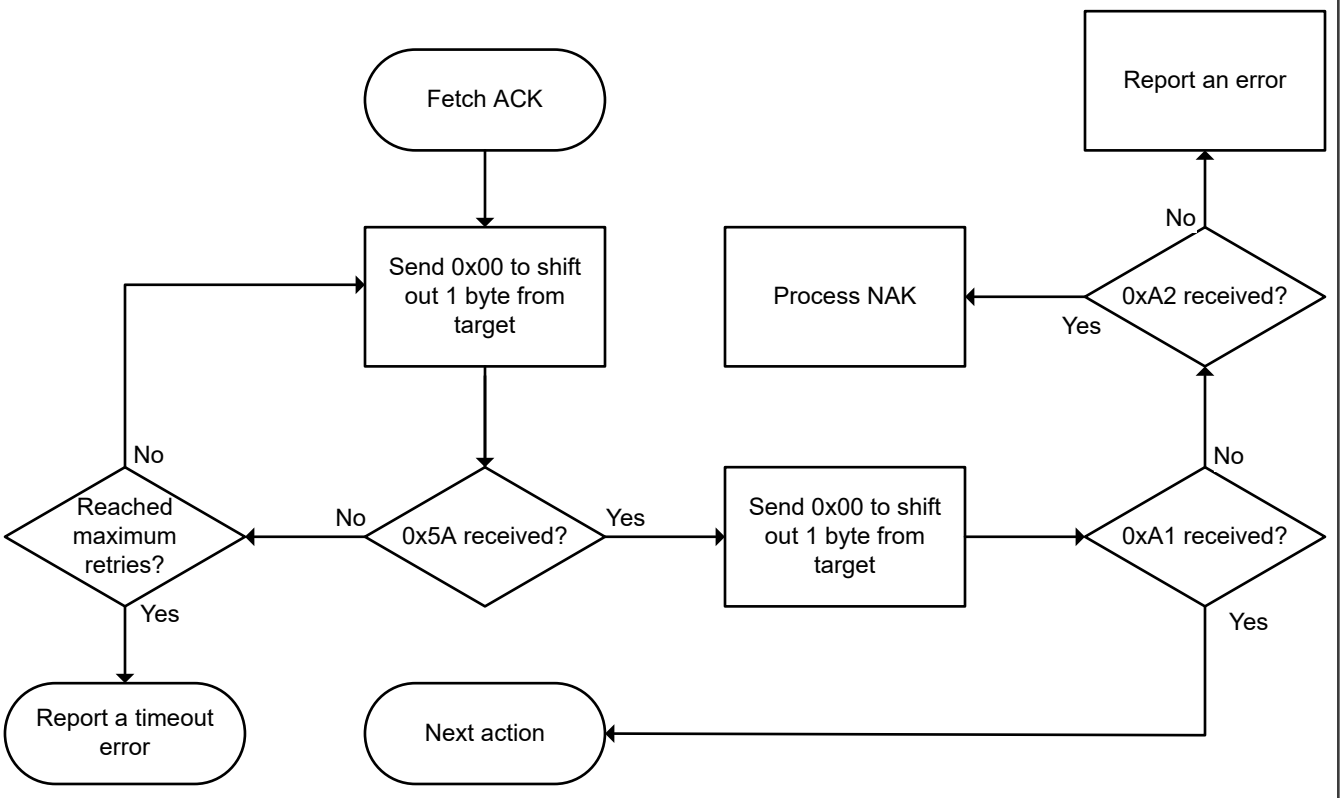

Figure 41. Host reads ACK from target via SPI

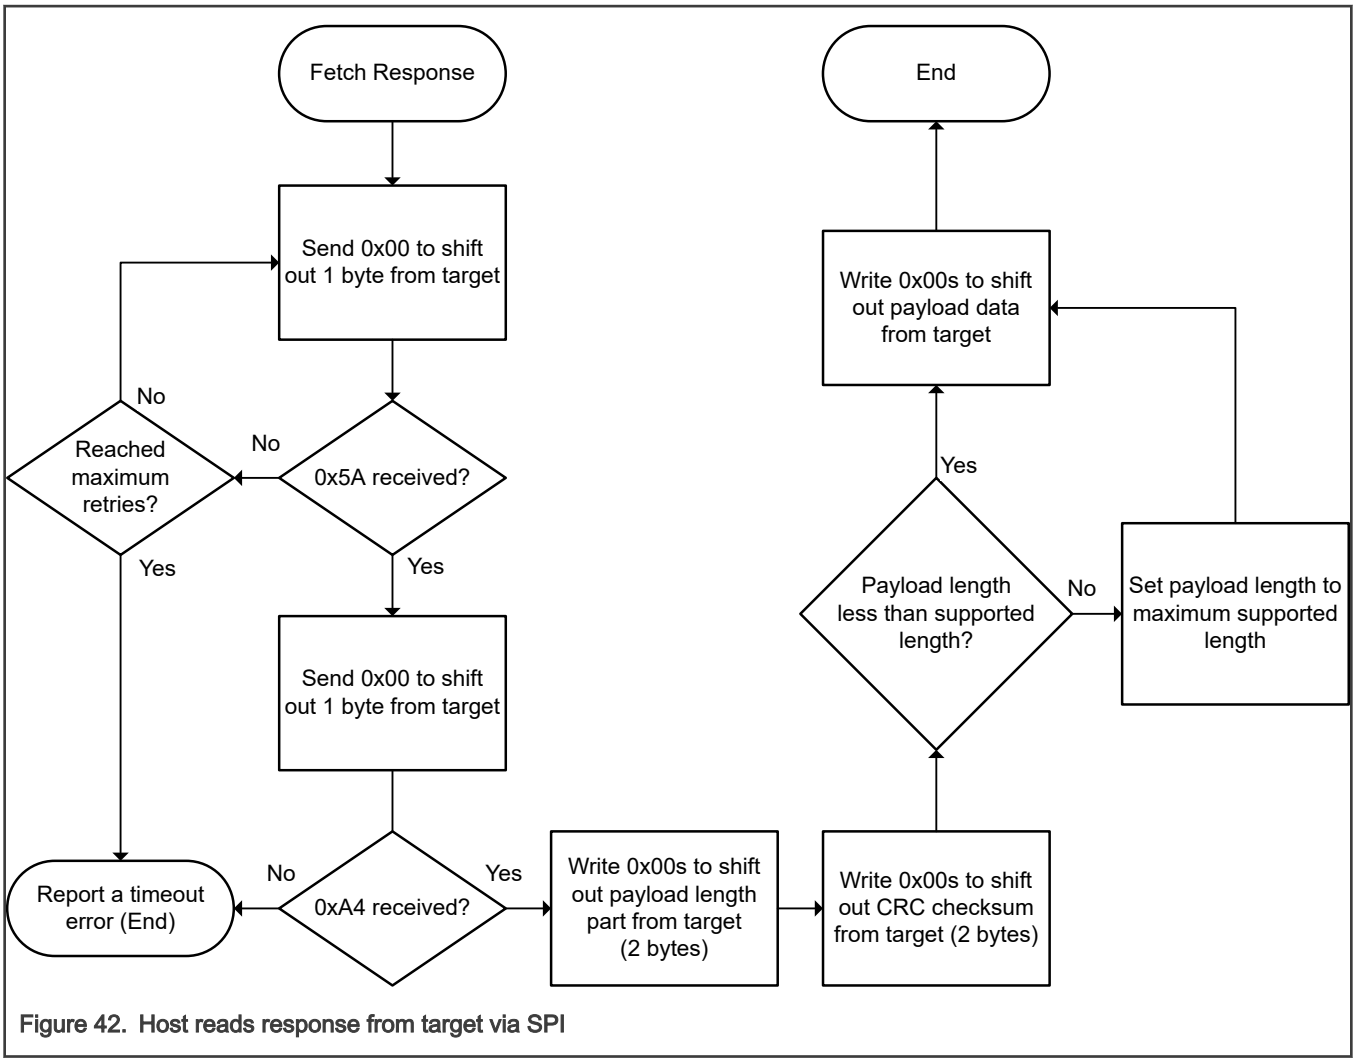

Figure 42. Host reads response from target via SPI

See Bootloader packet types for more details on SPI ISP command format, SPI ISP response format, and SPI ISP data format.

See Bootloader command set for more details on SPI ISP commands.

11.9.2 Host read ACK(5a,a1) packet timing restriction

If IRQ pin is not used for the In-System Programming protocol, the host needs to follow the below data fetching timing for ACK from the device as the below figures shows.

- After sending out the command, the host should wait for at least 100 us before polling the start byte 0x5A of the ACK packet sent out by the device; If fetching data is not 0x5A, delay 100us, and do polling to reread 0x5A.
- For the ACK packet 0x5A, 0xA1, after the host receives the 0x5A, a 50us delay must add before fetching the 0xA1 from the device.

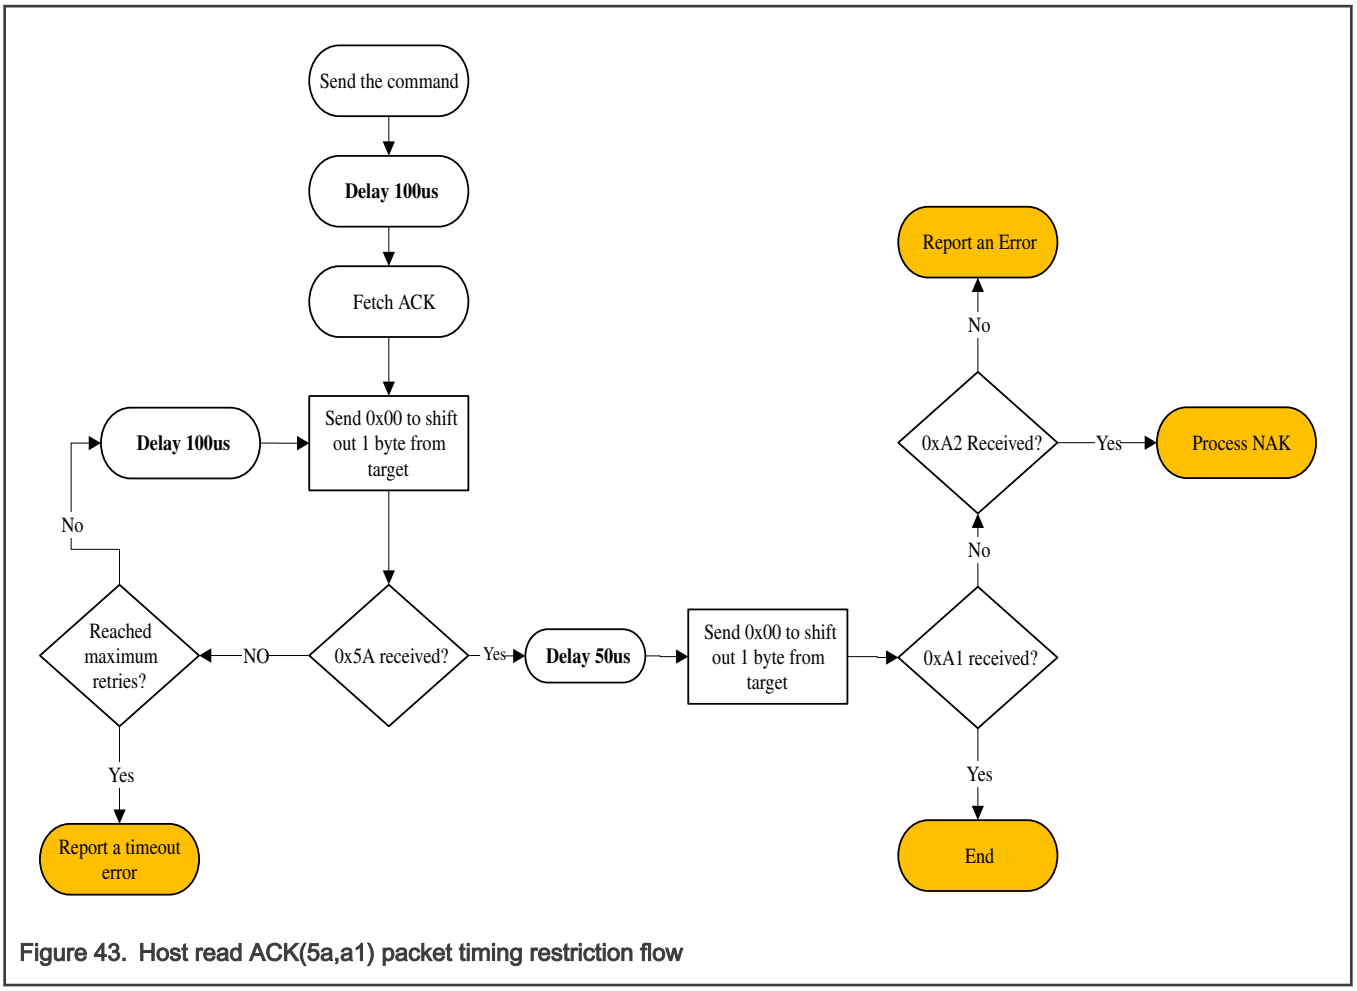

Figure 43. Host read ACK(5a,a1) packet timing restriction flow

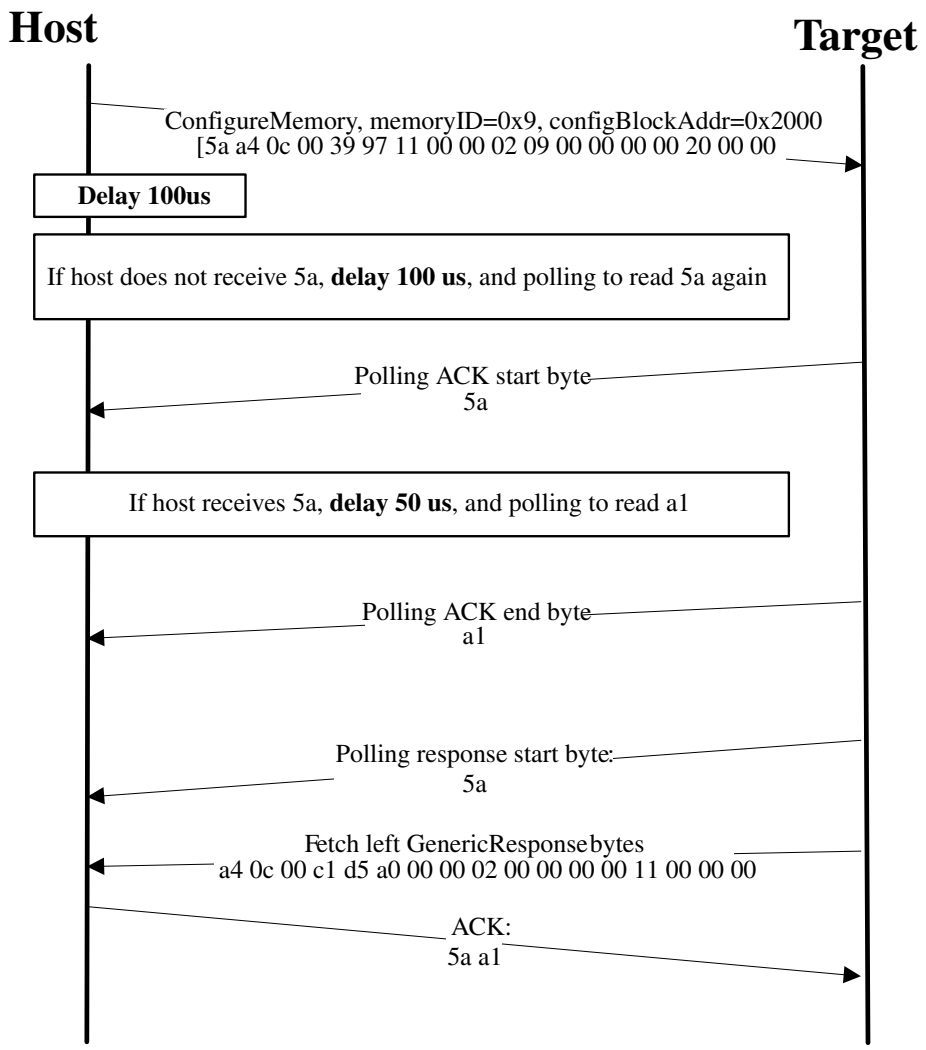

Figure 44. Host read ACK(5a,a1) packet timing restriction

11.10 USB In-System Programming

11.10.1 Introduction

The bootloader supports In-System Programming using the USB (USB0 and USB1) peripheral. The target is implemented as USB-HID device classes.

When transfer data through USB device class, USB does not use framing packets. Instead, the packetization, inherent in the USB protocol itself is used. The ability for the device to NAK out transfers (until they can be received) provides the required flow control. The built-in CRC of each USB packet provides the required error detection.

NOTE

USB interface needs an external XTAL supply, and thus you need to configure XTAL_FREQ within fuse BOOT_CFG5 correctly to match the actual frequency of XTAL for the use case. ROM assumes that a 24 MHz XTAL is used by default if this fuse region is not configured. Also, you need to configure OSC_HIGH_GAIN_MODE fuse bit according to the actual working mode of external XTAL. ROM assumes that you use XTAL in low power mode by default.

11.10.1.1 Device descriptor

The bootloader configures the default USB(USB0 and USB1) VID/PID/Strings as below:

Default VID/PID:

- VID = 0x1FC9
- PID = 0x0026

Default Strings:

- Manufacturer [1] = "NXP SEMICONDUCTOR INC".
- Product [2] = "USB HID DEVICE".

The USB (USB0 and USB1) VID, PID can be customized using the fuse BOOT_CFG6. For example, the USB VID and PID can be customized by writing the new VID to the USB_VID[15:0] in the fuse and the new PID to the USB_PID[15:0] in the fuse.

11.10.1.2 Endpoints

The HID peripheral uses three endpoints:

- Control (0).
- Interrupt IN (1).
- Interrupt OUT (2).

The Interrupt OUT endpoint is optional for HID class devices, but the MCU bootloader uses it as a pipe, where the firmware can NAK send requests from the USB host.

11.10.1.3 HID Reports

There are four HID reports defined and used by the bootloader USB HID peripheral. The report ID determines the direction and type of packet sent in the report; otherwise, the contents of all reports are the same.

Table 144. HID reports assigned for the bootloader

Report ID	Packet Type	Direction
1	Command	OUT
2	Data	OUT
3	Command	IN
4	Data	IN

Each report has a maximum size of 60 bytes. The maximum payload size is 56 bytes. In addition, there is a 4-byte report header that indicates the length (in bytes) of the payload and report id sent the packet.

The actual data sent in all of the reports looks like:

Table 145. Data format sent in USB HID packet

Report ID	Data
0	Report ID
1	Padding

Table continues on the next page...

Table 145. Data format sent in USB HID packet (continued)

2	Packet Length LSB
3	Packet Length MSB
4	Packet[0]
5	Packet[1]
6	Packet[2]
	...
N+4-1	Packet[N-1]

This data includes the Report ID, which is required if more than one report is defined in the HID report descriptor. The actual data sent and received has a maximum length of 35 bytes. The Packet Length header is written in little-endian format, and it is set to the size (in bytes) of the packet sent in the report. This size does not include the Report ID or the Packet Length header itself. During a data phase, a packet size of 0 indicates a data phase abort request from the receiver.

See Command packet for more details on USB ISP command format, and USB ISP response format.

See Response packet for more details on USB ISP data format.

See Bootloader command set for more details on USB ISP commands.

Chapter 12
Power Overview

12.1 Introduction

Power Management Controller (PMC) and Sleep Controller (SLEEPCON) handle the distribution, control and management of power throughout the chip.

- PMC controls power mode transitions, power domain power switching (on or off), and the main and peripheral memory power switching.
- SLEEPCON controls main clock gating per domain in low power modes and clock sources in power down modes.

12.2 Power architecture

The chip has nine separate power domains and multiple distinct power rails. At any given time, domains can be active or placed in a lower-power state to meet the performance requirements of a system application. This power architecture allows for a more granular distribution of power where and when needed.

The chip includes separate Compute and Sense processing domains that can independently enter or exit Sleep and Deep Sleep modes. In addition, separate Media and Common domains on power rail VDDN contain modules that need a higher voltage to operate, while other domains can operate at a lower voltage.

12.2.1 Power domains

A power domain is a collection of circuits that can be powered off even when a voltage source is still supplied. The table below summarizes the power domains within the chip, and the following figure shows the placement of modules within these domains.

Table 146. Power domain summary

Power domain	Modules
VDD2_COMP	CPU0, NPU, and Compute Domain modules
VDD2_DSP	HiFi4 DSP
VDD2_MEDIA	Media Domain modules on the VDD2 power rail
VDD2_COM	Common Domain modules on the VDD2 power rail
VDD1_SENSE	CPU1, Sense Domain (private region) modules, and Common Domain modules
VDDN_MEDIA	Media Domain modules on the VDDN power rail
VDDN_COM	Common Domain modules on the VDDN power rail
VDD1V8_AON	Always-on modules, also includes RESETN, PMIC_MODE0, PMIC_MODE1, PMIC_IRQN, XTALIN32KHZ, and XTALOUT32KHZ pins
VDD1V8_PMC	PMC

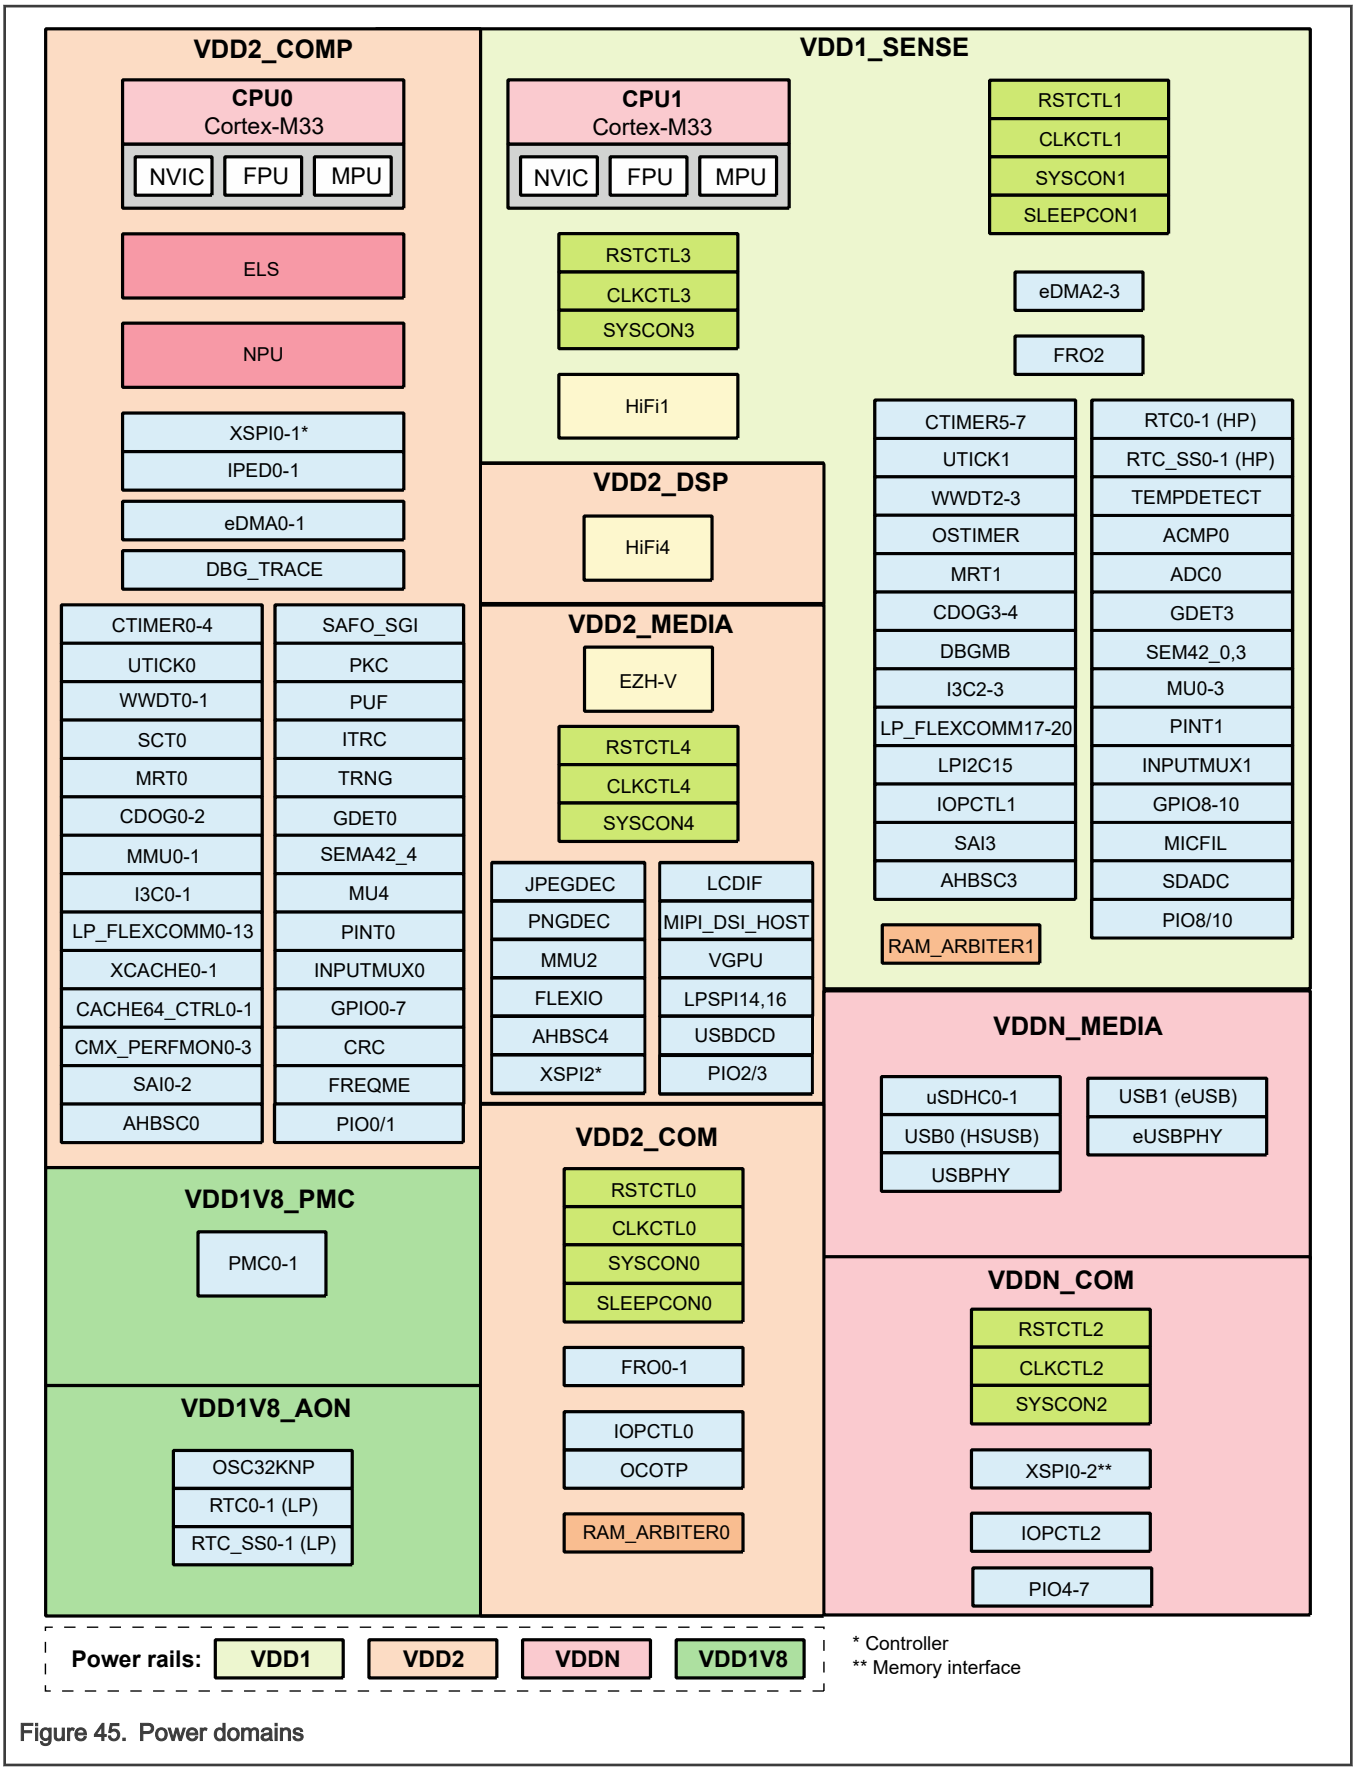

Figure 45. Power domains

Below is a complete list of modules within their respective power domains.

Table 147. Power domains

VDD1_SENSE	VDD2_COMP	VDD2_MEDIA	VDDN_MEDIA
CPU1	CPU0	EZH-V	uSDHC0-1
RSTCTL1,3	ELS	RSTCTL4	USB0-1
CLKCTL1,3	NPU	CLKCTL4	USBPHY
SYSCON1,3	XSPI0-1 (Controller)	SYSCON4	eUSBPHY

Table continues on the next page...

Table 147. Power domains (continued)

SDADC RAM_ARBITER1 PIO8/10	FREQME PIO0/1		

12.2.2 Power supplies

The chip has separate power supplies for the digital logic: VDD1, VDD2, VDDN, VDD1V8, and VDD1V8_AO. In addition, independent power supplies are available for the IO port pins.

Table 148. Power supply summary

Power supplies	Description
VDD1	For VDD1_SENSE domain
VDD2	For VDD2_COMP, VDD2_DSP, VDD2_MEDIA, and VDD2_COM domains
VDDN	For high-speed logic in VDDN_MEDIA domain, analog interfaces, and VDDN_COM domain
VDD1V8	For 1.8 V logic
VDD1V8_AO	For Always-on logic, such as power management

12.2.2.1 Main power from on-chip PMC

The on-chip PMC can supply power to the main power rails, as shown below.

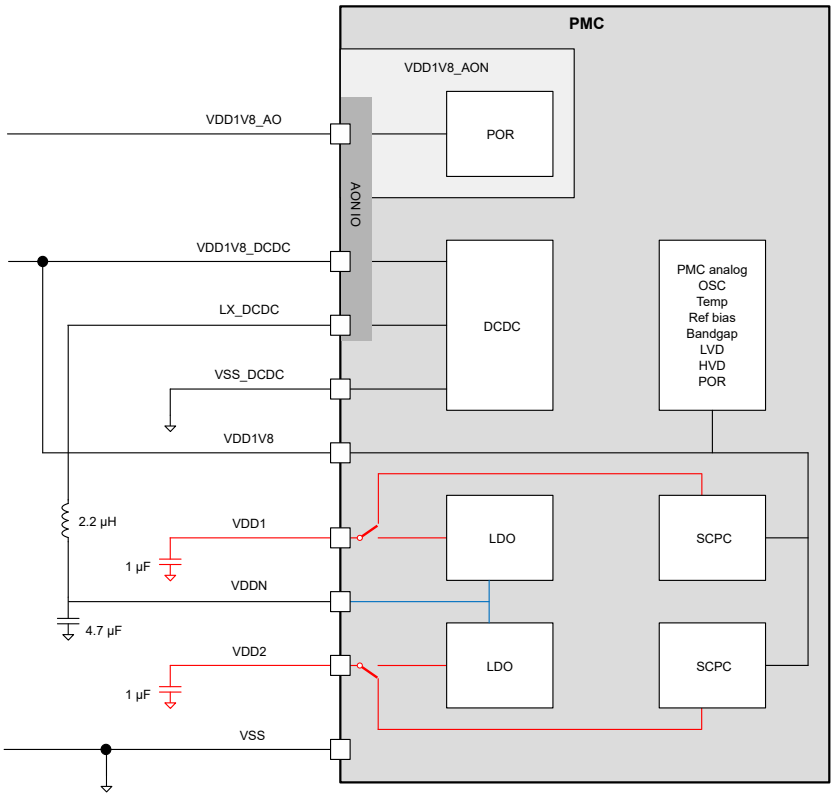

Figure 46. Main power connections from on-chip PMC

12.2.2.2 Main power from external PMIC

An optional external PMIC can supply power to the main power rails, as shown below.

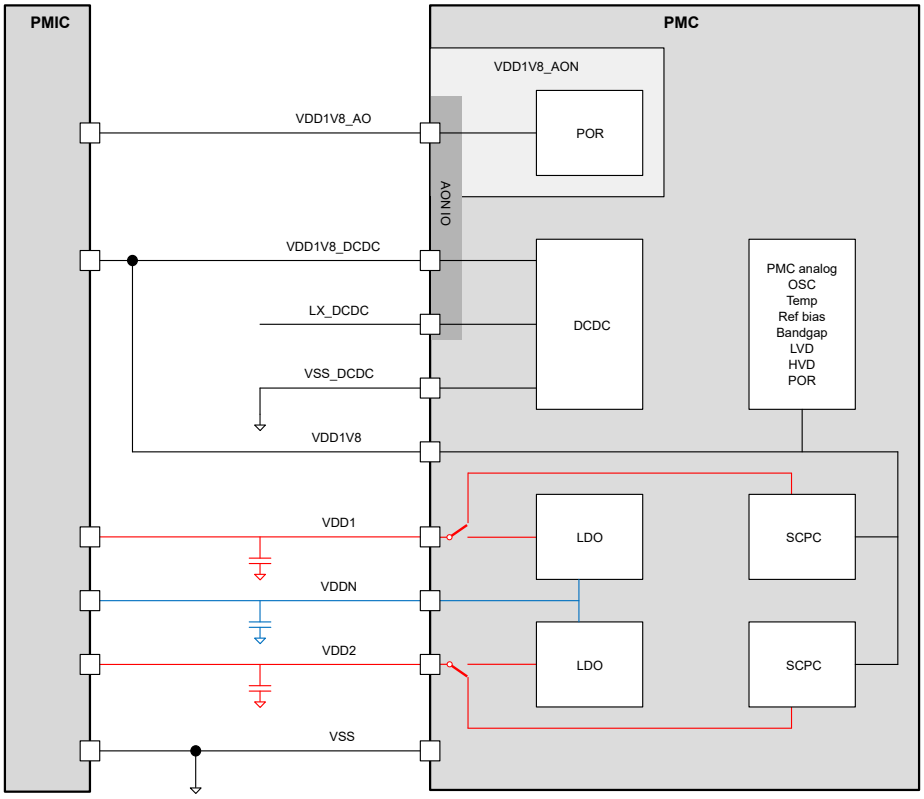

Figure 47. Main power connections from external PMIC

12.2.3 Power switches

Below shows the power switch architecture for each of the domains. The VDD1V8_AON and VDD1V8_PMC domains are not included because they are not switchable.

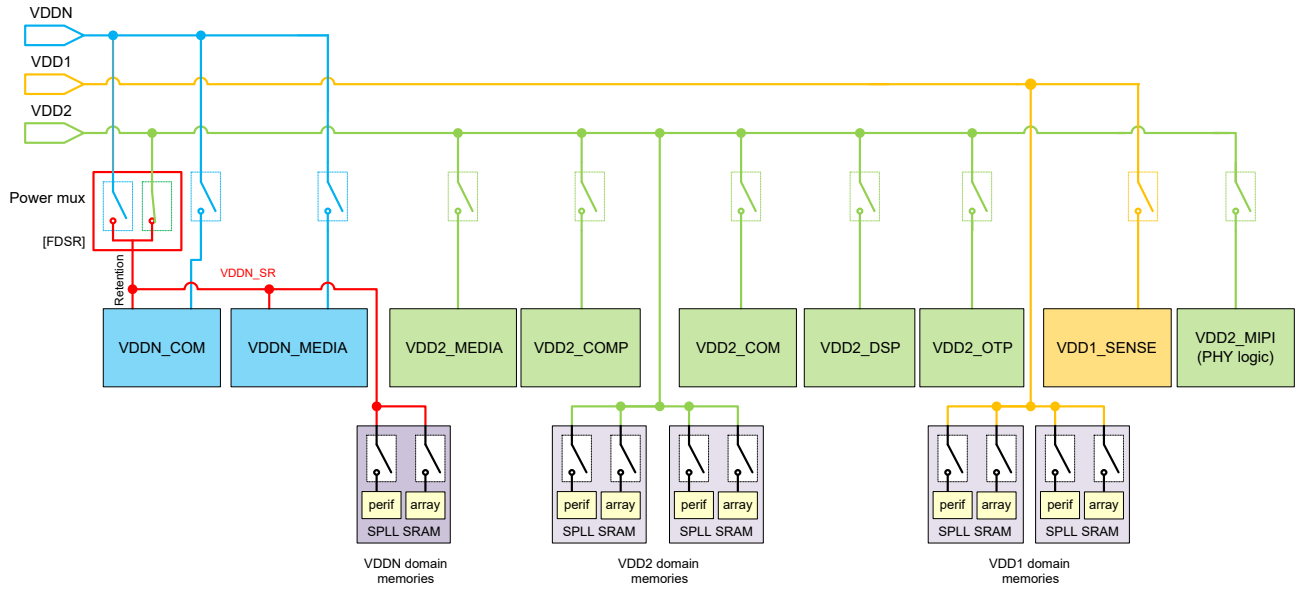

Figure 48. Power switch architecture

The VDDN domains (VDDN_COM and VDDN_MEDIA) have a power mux to save the uSDHC/XSPI content. The power mux switches from VDDN during Active mode to VDD2 during DSR mode. The power mux supplies VDDN_SR for retention logic in VDDN_MEDIA and VDDN_COM.

The power switch architecture establishes certain state dependencies and requirements between each of the power domains. For example, if VDD1_SENSE is off, all other domains (except VDD1V8_AON and VDD1V8_PMC) must be off. Below shows the possible states of other domains when each one of them is off.

Table 149. Power switch dependencies

When a power domain below is off...	These power domains must be...								
	VDD1_SENSE	VDD2_COM	VDD2_COMP	VDD2_DSP	VDD2_MEDIA	VDDN_MEDIA	VDDN_COM	VDD1V8_PMC	VDD1V8_AON
VDD1_SENSE	-	Off	Off	Off	Off	Off	Off	On or off	On
VDD2_COM	On or off	-	Off	Off	Off	Off	Off	On or off	On
VDD2_COMP	On or off	On or off	-	Off	On or off	On or off	On or off	On or off	On
VDD2_DSP	On or off	On or off	On or off	-	On or off	On or off	On or off	On or off	On
VDD2_MEDIA	On or off	On or off	On or off	On or off	-	Off	On or off	On or off	On
VDDN_MEDIA	On or off	On or off	On or off	On or off	Off	-	On or off	On or off	On
VDDN_COM	On or off	On or off	On or off	On or off	Off	Off	-	On or off	On
VDD1V8_PMC	Off	Off	Off	Off	Off	Off	Off	-	On or off
VDD1V8_AON	Off	Off	Off	Off	Off	Off	Off	Off	-

NOTE

Software must maintain the power domain state relationships shown in the table above. Hardware does not prevent illegal power switch configurations.

The power state dependencies between each of the power domains are also listed below:

- VDD1V8_AON, VDD1_SENSE, VDD2_COMP and VDD2_COM are default on after VDD1V8_PMC is powered on. All other domains are default off after initial power up.
- VDD2_DSP depends on VDD2_COMP. If VDD2_COMP is off, VDD2_DSP also must be off.
- VDD2_MEDIA and VDDN_MEDIA share one power switch control, so they both must be on or off together.
- VDDN_COM can be off only when both VDD2_MEDIA and VDDN_MEDIA are off.
- VDD2_COM can be off only when VDD2_COMP, VDD2_DSP, VDD2_MEDIA, VDDN_MEDIA and VDDN_COM are all off.
- VDD1_SENSE can be off only when VDD2_COM, VDD2_COMP, VDD2_DSP, VDD2_MEDIA, VDDN_MEDIA and VDDN_COM are all off.
- VDD1V8_PMC can be off only when VDD1_SENSE, VDD2_COM, VDD2_COMP, VDD2_DSP, VDD2_MEDIA, VDDN_MEDIA and VDDN_COM are all off. This is FDPD mode. In this mode, all other domains are powered off automatically, so no software enforcement is needed after entering that mode (and turning off the external power).

12.3 Power modes

The chip supports different power modes that moderate power consumption to match the performance requirements of the system applications active at any given time.

12.3.1 Active mode

In Active mode, clocks to a CPU, memories and modules are enabled. VDD2_COMP domain is active after reset, and the boot values of PMC.PDRUNCFG*n*, SLEEPCON.RUNCFG, and CLKCTL.PSCCTL*n* determine the power configuration requested by the domain. Runtime software can change the power configuration, programming modules to be in a normal power, low power, or off state.

12.3.1.1 Power optimization in Active mode

To achieve the performance requirements of a given system application while minimizing power consumption, Active mode permits the following power-saving options when possible:

- Configure CLKCTL.PSCCTL registers to control which memories and modules are running. To save power, turn off functional clocks that are not needed by the application. Clocks can be dynamically turned off and on as needed.
- For analog modules such as FRO, LPOSC, and PLL, configure SLEEPCON.RUNCFG to control the power. As with clock controls, turn off analog modules that are not needed by the application to save power. Note: If powered off, these analog modules require additional set up time for stabilization, whereas FRO outputs can be gated to save dynamic power without additional set up time.

  NOTE

  We recommend to power down FRO without clock gating by configuring SLEEPCON.RUNCFG[FRO*n*_PD] and [FRO*n*_GATE] bits.

- For RAM, configure PMC.PDRUNCFG2-5 to control the power. Use SLEEPCON.RUNCFG to control the RAM Arbiter clocks.
- In general, a lower clock frequency means lower power consumption. So running a CPU and other system functions at a frequency just sufficient for the application (plus some margin) saves power. Select the best-suited clock sources for system functions from among the several options in the CLKCTL registers. Also, running PLLs at a lower VCO frequency saves power. Configure CLKCTL2.MAINPLL0PFD[PFD*n*_CLKGATE] and AUDIOPLL0PFD[PFD*n*_CLKGATE] bits to gate off unused PLL PFDs.
- Many modules use individual functional clocks with their own local clock dividers. Use these clock divider or gating registers to shut down individual module clocks if another system function still requires an upstream shared clock source.

12.3.2 Sleep mode

In Sleep mode, power domains remain powered, but the CPU clock is gated off via a WFI/WFE instruction. Execution of instructions is suspended until either a reset or an interrupt occurs. Module functions, if selected to be clocked in CLKCTL.PSCCTL registers, continue operation and may generate interrupts to cause the processor to resume execution.

Sleep mode eliminates dynamic power used by the processor itself. Memory systems, related controllers, and internal buses continue to operate. The processor state and registers, module registers, and internal SRAM values are maintained. The logic levels of pins remain static unless affected by modules that remain in operation.

In Sleep mode, the configuration programmed into PMC.PDRUNCFG*n* and SLEEPCON.RUNCFG remain in effect.

12.3.2.1 Entering Sleep mode

CPU0 and CPU1 software can independently initiate Sleep mode. To enter Sleep mode, follow these steps:

1. In the NVIC, enable all interrupts that are needed to wake up the domain.
2. Configure PMC.PDRUNCFG*n* and SLEEPCON.RUNCFG to reflect any functions that need to be on or off during Sleep mode.
3. If you modify a PMC.PDRUNCFG*n* register, set PMC.CTRL[APPLYCFG] for the changes to take effect.
4. Execute a WFI/WFE instruction to enter Sleep mode.

12.3.2.2 Exiting Sleep mode

Sleep mode is exited automatically when an interrupt arrives at a CPU, or when a reset occurs. After a wake-up caused by an interrupt, CPU clocking resumes and the domain enters Active mode. Changes to PMC.PDRUNCFG*n* or SLEEPCON.RUNCFG done during the Sleep mode entry sequence can be undone to return to the previous Active condition. If a reset occurs, the domain enters the default configuration in Active mode.

12.3.2.3 Power optimization in Sleep mode

Power optimization in Sleep mode is similar to optimizing in Active mode:

- Select modules that are to remain powered during Sleep through PMC.PDRUNCFG*n* and SLEEPCON.RUNCFG.
- Enabled clocks remain running, so disable any clocks not needed.

12.3.3 Deep Sleep mode

In Deep Sleep mode, SLEEPCON.SLEEPCFG and PMC.PDSLEEPCFG*n* take effect. You should shut off specific bus clocks and power down unused clock sources, ADC0, the main domain and module clocks. You can also switch off unused power domains; however, the power domain containing the controlling SLEEPCON instance must remain powered to handle a wake-up event. For example, VDD2_COM must be powered to allow SLEEPCON0 to wake VDD2_COMP.

GPIO Pin Interrupts, GPIO Group Interrupts, and selected modules (such as USB, MICFIL, LP_FLEXCOMM, WWDT, RTC, and UTICK) and primary clock sources (such as FRO), the RTC oscillator, and the LPOSC can be left running in Deep Sleep mode. For supporting modules, DMA can operate in Deep Sleep mode; see Temporary wakeup for DMA.

12.3.3.1 Entering Deep Sleep mode

CPU0 and CPU1 software can independently initiate Deep Sleep mode. To enter Deep Sleep mode, follow these steps:

1. Configure PMC.PDSLEEPCFG*n* and SLEEPCON.SLEEPCFG to reflect any functions that need to be on or off.
2. For unused modules, use SLEEPCON to perform the low-power request-and-acknowledge handshake before gating a module's clock in its associated CLKCTL.PSCCTL register.
3. Configure SLEEPCON.WAKEUPEN*n* registers to enable the desired wakeup sources.
4. Configure SLEEPCON.HW_WAKE registers to enable the desired DMA wakeup sources.
5. For modules selected as wakeup sources, configure the appropriate wakeup conditions to generate interrupts.

6. In the associated NVIC, enable all interrupts that are needed to wake up the domain.
7. Configure the CPU's SCR register to enable SLEEPDEEP.
8. Execute a WFI/WFE instruction.

12.3.3.2 Exiting Deep Sleep mode

A domain can wake from Deep Sleep mode using many options, such as:

- A watchdog interrupt or RTC interrupt
- A reset from RESETN (RESETN pin assertion also resets the system.)
- A reset from the WWDT
- A wake-up signal from a module that is operating in Deep Sleep mode and capable of an asynchronous interrupt
- GPIO interrupts
- PINT pin interrupts
- PMIC_IRQN pin through PMC0 interrupt

See Wake-up sources for a complete list of wake-up sources in Deep Sleep mode.

NOTE

An interrupt used as a wake-up source must also be enabled in NVIC and in SLEEPCON.WAKEUPEN*n*.

12.3.3.3 Configuring MIPI_DSI_HOST for Deep Sleep entry and exit

For applications using MIPI_DSI_HOST connected to an external display, include the steps below before entering Deep Sleep:

1. Configure the display for Deep Sleep mode.
2. Disable MIPI_DSI_HOST (Power Down Register MIPI_DSI_HOST.PD_DPHY[PD_DPHY]).
3. Configure PMC.PDSLEEPCFG0[V2MIPI_PD].

After exiting Deep Sleep, follow the steps below:

1. Enable MIPI_DSI_HOST.
2. Configure the display to exit from Deep Sleep mode.

12.3.3.4 Temporary wakeup for DMA

Some modules support the option to send a DMA request in Deep Sleep mode. In this case, the domain wakes up just enough to perform the requested DMA before returning to Deep Sleep mode without waking the CPU. Follow the general enablement procedure below for the modules that support temporary DMA wake-up before entering Deep Sleep mode.

1. Configure the required module operation for normal DMA activity, including FIFO transfer threshold watermarks if available.
2. Configure the DMA controller, including a transfer complete interrupt.
3. Enable the DMA interrupt in the NVIC.
4. Enable DMA wakeup for the module by writing 1 to the related HW_WAKE[HWWK_SRC*n*] bit in SLEEPCON0 or SLEEPCON1.

NOTE

If a DMA transaction hangs, the chip remains in a higher power state until an interrupt or other wakeup source can wakeup the core.

An interrupt that occurs during a DMA wakeup causes an exit from Deep Sleep mode without affecting the DMA transfer.

12.3.3.4.1 Modules supporting DMA wakeup

The modules that support temporary DMA wakeup are listed below.

Table 150. Modules supporting temporary DMA wakeup

Module	DMA wakeup enable bit
FLEXIO	SLEEPCON0.HW_WAKE[HWWK_SRC1] or SLEEPCON1.HW_WAKE[HWWK_SRC1]
LP_FLEXCOMM0-13	SLEEPCON0.HW_WAKE[HWWK_SRC2]
LP_FLEXCOMM17-20	SLEEPCON1.HW_WAKE[HWWK_SRC2]
LPSPI14, LPSPI16	SLEEPCON0.HW_WAKE[HWWK_SRC3]
SAI0-2	SLEEPCON0.HW_WAKE[HWWK_SRC4]
SAI3	SLEEPCON1.HW_WAKE[HWWK_SRC4]

12.3.3.4.2 DMA wakeup considerations for communications modules

When configuring a serial communications module for DMA wakeup, you might need to enable both interrupts and DMA requests. For example, FIFO servicing requires enabling the relevant DMA request, but errors are generally handled only through interrupts. Errors include both FIFO underflow and overflow, and also could include protocol errors, such as parity errors or NACKs.

12.3.3.5 Double wakeup considerations

If the wakeup is due to a HW_WAKE event and an overlapping normal wakeup event occurs, the CPU starts executing software immediately. If software subsequently attempts to access memories that are in the process of being powered back on, a memory fault can occur. Avoid configuring a module to trigger both types of wakeup simultaneously.

12.3.3.6 Power optimization in Deep Sleep mode

Deep Sleep mode is configurable, supporting the option to turn off nearly all power consumption on a domain power supply at the cost of a longer wake-up time. Compute/Sense domain supply voltage can also be reduced to the minimum retention level in this mode.

NOTE

When lowering supply voltages connected to clocks, reduce their frequencies according to the specifications provided in the data sheet as needed.

Power consumption in Deep Sleep mode is determined primarily by which wake-up sources remain enabled. Dynamic power used by the processor itself, memory systems and related controllers, and internal buses (other than those specifically designated to remain functional) is eliminated. Serial peripherals and pin interrupts configured as wake-up sources contribute to the power consumption only to the extent that they are clocked.

12.3.3.7 Deep Sleep Async mode

Deep Sleep Async mode is a special sub-mode of Deep Sleep. Generally the operation is the same as Deep Sleep (SLEEPCON.SLEEPCFG and PMC.PDSLEEPCFGn take effect), but to enter Deep Sleep Async:

- The compute domain can enter Deep Sleep Async while the sense domain stays active, or both compute and sense domains can enter Deep Sleep Async.
- Clock sources within the domain(s), bus clocks, and peripheral clocks within the domain(s) must be disabled. If both domains are in Deep Sleep Async, then the only allowed clock is the RTC oscillator in the VDD1V8_AON domain.

Disabling all of the clocks allows for decreasing the voltage even lower than regular Deep Sleep. See the i.MX RT700 Crossover Microcontroller Data Sheet.

Only modules that can support asynchronous operation, such as GPIO, can be used to wakeup from Deep Sleep Async.

12.3.3.7.1 Entering Deep Sleep Async mode

To enter Deep Sleep Async mode, follow these steps:

1. Configure PMC.PDSLEEPCFGn and SLEEPCON.SLEEPCFG to reflect any functions that need to be on or off. Clock sources within the domain(s) must be configured to power down. If both compute and sense are entering Deep Sleep Async, then PLLs must be powered down.
2. For unused modules, use SLEEPCON to perform the low-power request-and-acknowledge handshake before gating a module's clock in its associated CLKCTL.PSCCTL register.
3. Configure SLEEPCON.WAKEUPENn registers to enable the desired wakeup sources.
4. For modules selected as wakeup sources, configure the appropriate wakeup conditions to generate interrupts.
5. In the associated NVICs, enable all interrupts that are needed to wake up each domain.
6. Configure CPU's SCR register to enable SLEEPDEEP.
7. Execute a WFI/WFE instructions.
8. After the domain has gone to Deep Sleep Async mode, then the voltage can be decreased.

12.3.3.7.2 Exiting Deep Sleep Async mode

A domain can wake from Deep Sleep Async using interrupts from modules that support asynchronous operations such as GPIOs. See Table 164 for a complete list of wake-up sources in Deep Sleep Async mode.

On wakeup from Deep Sleep Async, the VDD1/VDD2 voltages must be raised back to active levels corresponding to the frequency used by each domain.

NOTE

An interrupt used as a wake-up source must also be enabled in NVIC and in SLEEPCON.WAKEUPn.

12.3.4 Deep Sleep Retention (DSR)

Deep Sleep Retention (DSR) mode allows significant portions of the chip to be powered-down while maintaining some level of state retention, particularly the state of CPU0 and other system-critical functions. Depending on which portions of the chip are to be retained and power-gated, power management hardware automatically ensures that no operations are ongoing and that clocks are parked properly before entering DSR.

You can switch off unused power domains; however, the power domain containing the controlling SLEEPCON instance must remain powered to handle a wake-up event. For example, VDD2_COM must be powered to allow SLEEPCON0 to wake VDD2_COMP.

DSR is a deeper low-power state than Deep Sleep mode. Unlike Deep Sleep mode, DSR does not provide the option to keep selected module clocks on for wake-up. For example, if the Compute, Media, and Common domains are placed in DSR, the modules supporting DSR would have their states retained and all modules within those domains would not operate.

Below shows a complete list of modules that support DSR.

Table 151. Modules supporting DSR

VDD1_SENSE	VDD2_COMP	VDD2_MEDIA	VDD2_COM	VDDN_COM
CPU1	CPU0	EZH-V	RSTCTL0	RSTCTL2
CLKCTL1,3	ELS	RSTCTL4	CLKCTL0	CLKCTL2
FRO2	XSPI0-1 (Controller)	CLKCTL4	SYSCON0	SYSCON2
RSTCTL1,3	IPED0-1	SYSCON4	SLEEPCON0	XSPI0-2 (Memory interface)
SYSCON1,3	CDOG0-2	MMU2	FRO0-1	

Table continues on the next page...

Table 151. Modules supporting DSR (continued)

SLEEPCON1 AHBSC3 IOPCTL1 (GPIO8-10) GDET3 CDOG3-4 LPI2C15	MMU0-1 CACHE64_CTRL0-1 AHBSC0 ITRC GDET0	AHBSC4 XSPI2 (Controller) LCDIF MIPI_DSI_HOST -	IOPCTL0 (GPIO0-3) OCOTP	IOPCTL2 (GPIO4-7)
			VDD2_DSP	**VDDN_MEDIA**
			-	uSDHC0-1
			VDD1V8_AON	**VDD1V8_PMC**
			-	-

12.3.4.1 Sense domain entering DSR

The Sense domain can enter DSR mode only when all other domains are in DSR mode. CPU1 software must first check that all other domains are in DSR before entering DSR. If the condition is true, CPU1 can program the RTC timer to schedule a wake-up and enter DSR mode. If the condition is false, CPU1 software might choose to go into a shallower low power mode (Sleep or Deep Sleep mode) because the Sense domain cannot enter DSR mode in this case.

NOTE

When both the Compute and Sense domains are in DSR, a wake-up event for Compute requires both domains to exit DSR because part of the Sense domain needs to be active for Compute to operate.

12.3.4.2 DSR combinations

Only certain combinations of logic being place in DSR mode are valid. Because DSR involves power gating, the rules are the same as for power gating of domains. See Table 149 for a full list of rules.

The following sections present example valid combinations and their wake-up sources.

12.3.4.2.1 Compute, Media, Sense, and Common in DSR (Full DSR)

The following table summarizes the power domain states when the Compute, Media, Sense, and Common processing domains are in DSR.

Table 152. Compute, Media, Sense, and Common in DSR

Power domain	Power switched
VDD2_COMP	Off
VDD2_DSP	Off
VDD1_SENSE	Off
VDD2_MEDIA	Off
VDDN_MEDIA	Off
VDD2_COM	Off
VDDN_COM	Off
VDD1V8_PMC	Powered by VDD1V8
VDD1V8_AON	Powered by VDD1V8_AO

Full DSR (FDSR) is a chip level mode. To enter FDSR both CPUs must execute WFI/WFE with their corresponding FDSR bit set.

Because Compute, Media and Sense are all in DSR mode, the only source of the wake-ups can be the external wake-ups similar to DPD and FDPD.

Table 153. Wake-up sources for FDSR

Source	Configuration
PMIC_IRQN, RTC_ALARM, RTC_WAKE	Enable the related function in SLEEPCON.WAKEUPEN*n*.
RESETN	Configuration is not needed. **NOTE** Asserting RESETN wakes the chip but also causes the whole chip to reset.

12.3.4.2.2 Compute, Media, and Common in DSR (Hub mode)

The following table summarizes the power domain states when the Compute, Media, and Common processing domains are in DSR.

Table 154. Compute, Media, and Common in DSR

Power domain	Power switched
VDD2_COMP	Off
VDD2_DSP	Off
VDD1_SENSE	Powered by VDD1
VDD2_MEDIA	Off
VDDN_MEDIA	Off
VDD2_COM	Off
VDDN_COM	Off
VDD1V8_PMC	Powered by VDD1V8
VDD1V8_AON	Powered by VDD1V8_AO

This low-power combination with Compute, Media, and Common in DSR is known as Hub mode. In Hub mode, the chip can collect and process data at low power. Use Hub mode for applications that only need the Sense domain functions until some condition requires activating other chip resources.

Because the Sense domain remains active in Hub mode, you have more options for waking the chip. You can program timers to wake the Compute domain. Alternatively, CPU1 can communicate a wake-up event through the messaging unit to interrupt CPU0, causing it to wake.

Table 155. Wake-up sources for Compute domain (Hub mode)

Source	Configuration
Interrupts from VDD1_SENSE modules that remain active	Enable the interrupt in both the module itself and the associated interrupt controller.
OSTIMER interrupt	Enable the interrupt in both the module itself and the associated interrupt controller.
MU interrupt	Enable the interrupt in both the module itself and the associated interrupt controller.

Table continues on the next page...

Table 155. Wake-up sources for Compute domain (Hub mode) (continued)

Source	Configuration
ADC0, ACMP, MICFIL, PMIC_IRQN, RTC_ALARM, RTC_WAKE	Enable the related function in SLEEPCON.WAKEUPEN*n*.
RESETN	Configuration is not needed. **NOTE** Asserting RESETN wakes the chip but also causes the whole chip to reset.

12.3.4.2.3 Compute and Media in DSR

The following table summarizes the power domain states when the Compute and Media processing domains are in DSR.

Table 156. Compute and Media in DSR

Power domain	Power switched
VDD2_COMP	Off
VDD2_DSP	Off
VDD1_SENSE	Powered by VDD1
VDD2_MEDIA	Off
VDDN_MEDIA	Off
VDD2_COM	Powered by VDD2
VDDN_COM	Off
VDD1V8_PMC	Powered by VDD1V8
VDD1V8_AON	Powered by VDD1V8_AO

Because both the Sense and Common domains remain active in this scenario, you have more options for waking the chip. You can program timers to wake the Compute domain. Alternatively, CPU1 can communicate a wake-up event through the messaging unit to interrupt CPU0, causing it to wake.

Table 157. Wake-up sources for Compute domain (Compute and Media in DSR)

Source	Configuration
Interrupts from VDD2_COM modules that remain active	Enable the interrupt in both the module itself and the associated interrupt controller.
Interrupts from VDD1_SENSE modules that remain active	Enable the interrupt in both the module itself and the associated interrupt controller.
OSTIMER interrupt	Enable the interrupt in both the module itself and the associated interrupt controller.
MU interrupt	Enable the interrupt in both the module itself and the associated interrupt controller.
ADC0, ACMP, MICFIL, PMIC_IRQN, RTC_ALARM, RTC_WAKE	Enable the related function in SLEEPCON.WAKEUPEN*n*.

Table continues on the next page...

Table 157. Wake-up sources for Compute domain (Compute and Media in DSR) (continued)

Source	Configuration
RESETN	Configuration is not needed. **NOTE** Asserting RESETN wakes the chip but also causes the whole chip to reset.

12.3.4.2.4 Compute in DSR

The following table summarizes the power domain states when the Compute processing domain is in DSR.

Table 158. Compute in DSR

Power domain	Power switched
VDD2_COMP	Off
VDD2_DSP	Off
VDD1_SENSE	Powered by VDD1
VDD2_MEDIA	Powered by VDD2
VDDN_MEDIA	Powered by VDDN
VDD2_COM	Powered by VDD2
VDDN_COM	Powered by VDDN
VDD1V8_PMC	Powered by VDD1V8
VDD1V8_AON	Powered by VDD1V8_AO

Because the Sense, Media, and Common domains all remain active in this scenario, you have more options for waking the chip. You can program timers to wake the Compute domain. Alternatively, CPU1 can communicate a wake-up event through the messaging unit to interrupt CPU0, causing it to wake.

Table 159. Wake-up sources for Compute domain (Compute in DSR)

Source	Configuration
Interrupts from VDDN_COM modules that remain active	Enable the interrupt in both the module itself and the associated interrupt controller.
Interrupts from VDDN_MEDIA modules that remain active	Enable the interrupt in both the module itself and the associated interrupt controller.
Interrupts from VDD2_MEDIA modules that remain active	Enable the interrupt in both the module itself and the associated interrupt controller.
Interrupts from VDD2_COM modules that remain active	Enable the interrupt in both the module itself and the associated interrupt controller.
Interrupts from VDD1_SENSE modules that remain active	Enable the interrupt in both the module itself and the associated interrupt controller.
OSTIMER interrupt	Enable the interrupt in both the module itself and the associated interrupt controller.

Table continues on the next page...

Table 159. Wake-up sources for Compute domain (Compute in DSR) (continued)

Source	Configuration
MU interrupt	Enable the interrupt in both the module itself and the associated interrupt controller.
ADC0, ACMP, MICFIL, PMIC_IRQN, RTC_ALARM, RTC_WAKE	Enable the related function in SLEEPCON.WAKEUPEN*n*.
RESETN	Configuration is not needed. **NOTE** Asserting RESETN wakes the chip but also causes the whole chip to reset.

12.3.5 Deep Power Down (DPD) mode

In DPD mode, power and clocks are shut off to the entire chip with the exception of the RTC. SRAM content and module registers (other than those in the RTC) are not retained. All functional pins are tristated as long as VDDIO power rails are supplied externally. On-chip regulators are off. VDD1V8 and VDD1V8_AO remain on. PMC retains state. VDD1V8 monitors stay on. Voltage rail definitions are retained. TRIM is maintained allowing for less voltage margins needed on wake-up.

DPD is a chip level mode. To enter DPD both CPUs must execute WFI/WFE with their corresponding DPD bit set.

The following table summarizes the power domain states in DPD mode.

Table 160. Power domain states in DPD mode

Power domain	Power switched
VDD2_COMP	Off
VDD2_DSP	Off
VDD1_SENSE	Off
VDD2_MEDIA	Off
VDDN_MEDIA	Off
VDD2_COM	Off
VDDN_COM	Off
VDD1V8_PMC	Powered by VDD1V8
VDD1V8_AON	Powered by VDD1V8_AO

12.3.5.1 Entering DPD mode

DPD mode has no configuration options. All clocks, the core, and all peripherals are powered down. Only the RTC is powered, as long as power is supplied to VDD1V8_AO.

To enter DPD mode when using the RTC for waking up, follow these steps:

1. Set up the RTC high resolution timer. Write to the VAL bits in WAKE register. [Write to the RTC VAL register.] This starts the high resolution timer if enabled. Alternatively, another option is to use the 1-Hz alarm timer.
2. Set the associated PMC PDSLEEPCFG0[DPD] bit.
3. Configure the CPU's SCR register to enable SLEEPDEEP.
4. Execute a WFI/WFE instruction.

12.3.5.2 Exiting DPD mode

A wake-up event triggers exit from DPD mode. The chip undergoes a power-on-reset and system boot. After boot, all registers are in their reset states except those retained by the VDD1V8_AO supply, such as the RTC registers.

Table 161. Wake-up sources for DPD

Source	Configuration
PMIC_IRQN, RTC_ALARM, RTC_WAKE	Enable the related function in SLEEPCON.WAKEUPEN*n*.
RESETN	Not needed.

12.3.6 Full Deep Power Down (FDPD) mode

Similar to DPD mode, FDPD mode is the chip's lowest power mode option where only VDD1V8_AO is powered. An RTC event, an external interrupt, or an external reset can trigger wake-up. The PMIC mode control pins remain powered to enable an optional external PMIC upon a wake-up event.

FDPD is a chip level mode. To enter FDPD both CPUs must execute WFI/WFE with their corresponding FDPD bit set.

The following table summarizes the power domain states in FDPD mode.

Table 162. Power domain states in FDPD mode

Power domain	Power switched
VDD2_COMP	Off
VDD2_DSP	Off
VDD1_SENSE	Off
VDD2_MEDIA	Off
VDDN_MEDIA	Off
VDD2_COM	Off
VDDN_COM	Off
VDD1V8_PMC	Off
VDD1V8_AON	Powered by VDD1V8_AO

12.4 Power mode transitions

The VDD2_COMP and VDD1_SENSE domains can move from Active to Sleep or Deep Sleep from the Active mode of operation. VDD2_COMP can further move to DSR from Active mode, but VDD1_SENSE cannot independently move to DSR before VDD2_COMP has entered DSR. The deeper low-power modes (DPD and FDPD) can occur only when both domains signal their intent to enter these lower power modes. The valid combinations of power modes are shown below:

Table 163. Valid power mode combinations of the VDD2_COMP and VDD1_SENSE domains

		VDD2_COMP power modes					
		Active	Sleep	Deep Sleep	DSR	DPD	FDPD
VDD1_SENSE power modes	Active	Valid	Valid	Valid	Valid	—	—
	Sleep	Valid	Valid	Valid	Valid	—	—
	Deep Sleep	Valid	Valid	Valid	Valid	—	—
	DSR	—	—	—	Valid	—	—
	DPD	—	—	—	—	Valid	—
	FDPD	—	—	—	—	—	Valid

Below is the overall state diagram of power mode transitions:

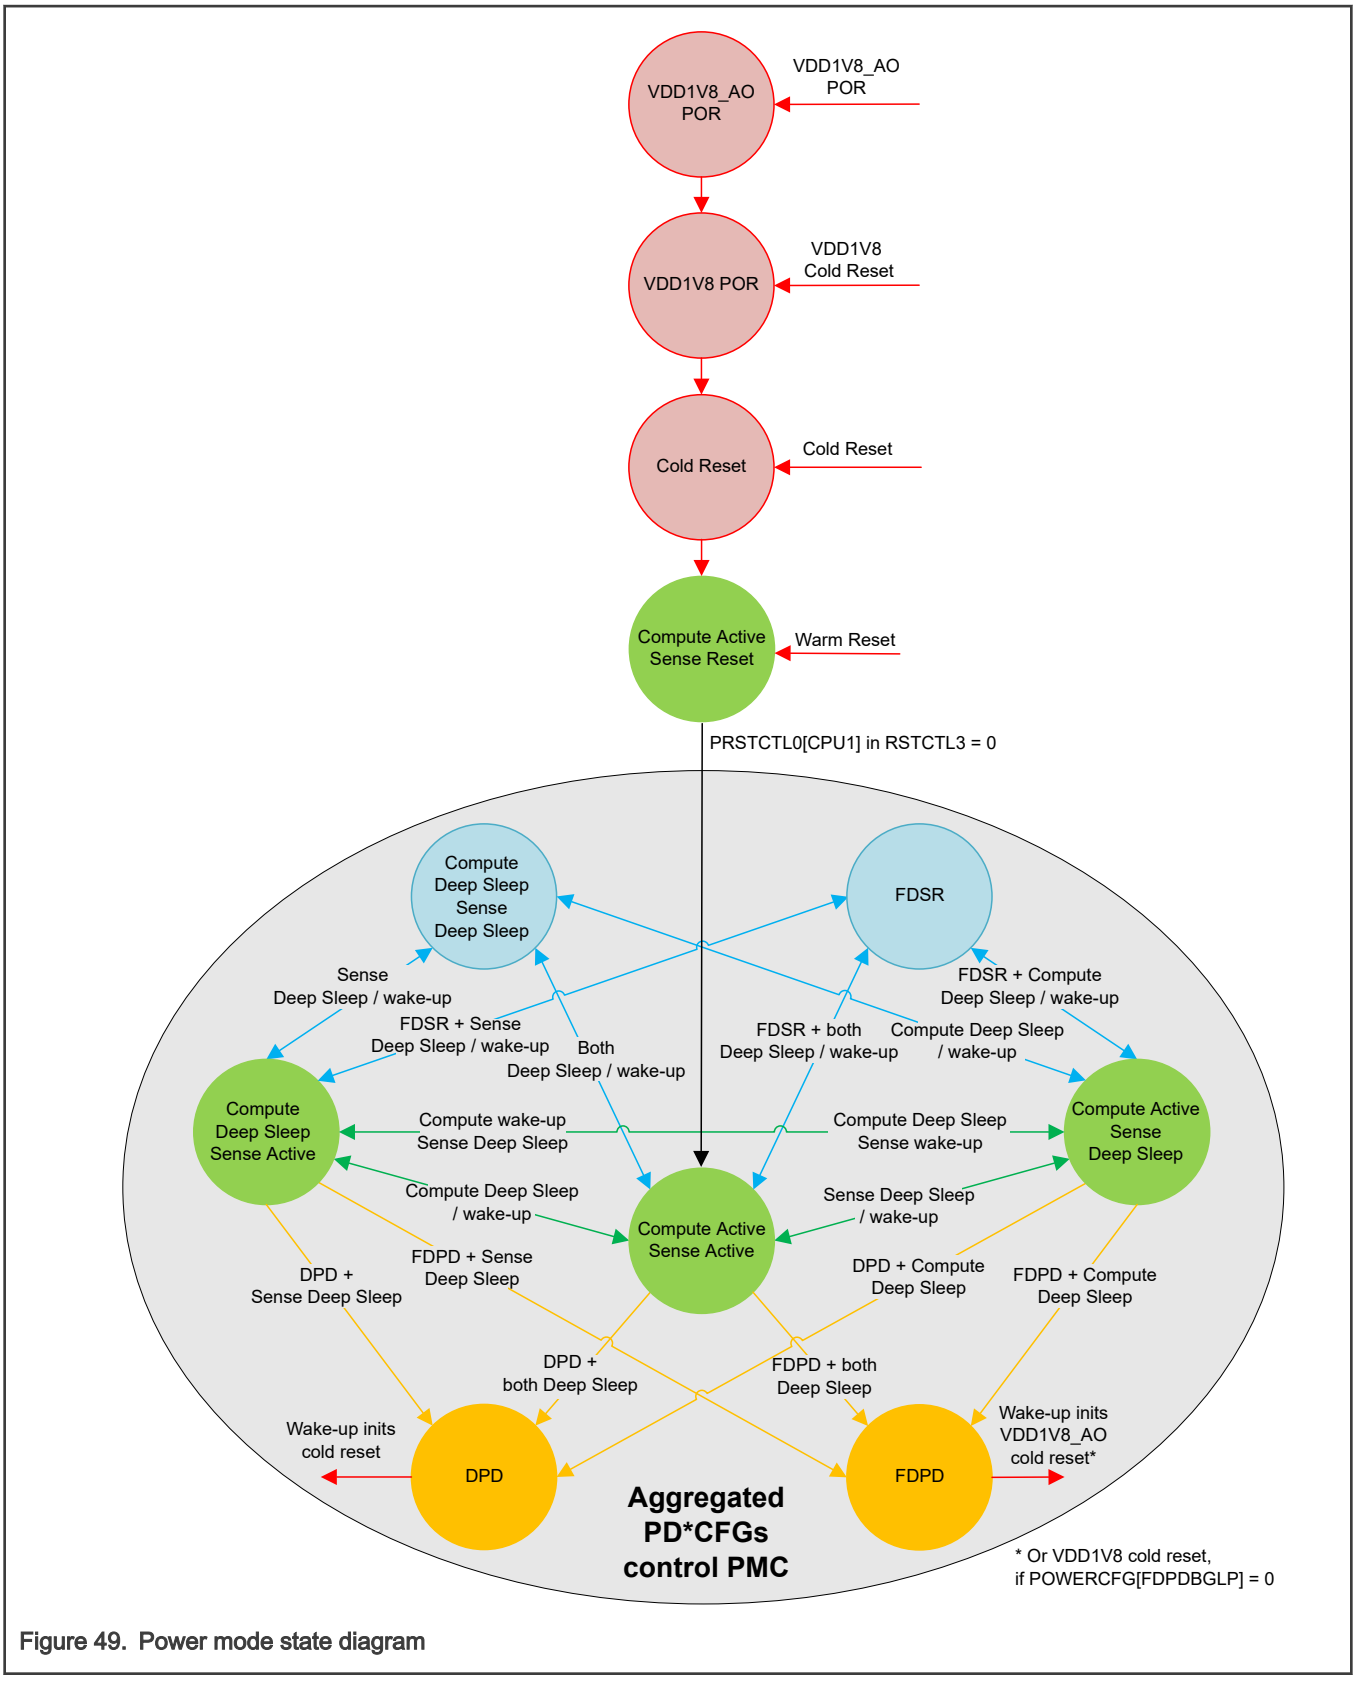

Figure 49. Power mode state diagram

12.4.1 Wake-up sources

The tables below list all wake-up sources for CPU0 and CPU1 in the different power modes. In the “Async Interrupt” column:

- “Y” means the source is asynchronous and can be asserted without a bus clock.
- “Available” means the source interrupt can be either synchronous or asynchronous. When the bus clock is gated off, an asynchronous interrupt can still be trigged by the module’s functional clock.

In the “CPU0” and “CPU1” columns, “Y” means the source can wake up the CPU if:

- For Sleep mode, the module must be clocked, and the module’s power domain must be powered. The corresponding NVIC channel must also be enabled.
- For Deep Sleep mode, the bus clock is off, so only modules capable of asynchronous interrupts can be wake up sources. The module’s functional clock must not be gated, and the corresponding SLEEPCON must be powered.

Table 164. Wake-up sources for different power mode

Source	Async interrupt	Sleep		Deep Sleep		Deep Sleep Async		FDSR	
		CPU0	CPU1	CPU0	CPU1	CPU0	CPU1	CPU0	CPU1

		CPU0	CPU1	CPU0	CPU1	CPU0	CPU1	CPU0	CPU1
PMC1: Sense Domain interrupt			Y		Y		Y		
PMC0: Compute Domain interrupt		Y		Y		Y			

1. Filters and window mode must be disabled for Deep Sleep Async, because these functions require a clock.
2. Only pin interrupts (PSF) can be used for Deep Sleep Async wakeup.

12.5 SLEEPCON and PMC

The two SLEEPCON instances, SLEEPCON0 and SLEEPCON1, initiate clock gating with CLKCTL and control which clock sources to power down. Each SLEEPCON contains two register banks: SLEEPCFG and RUNCFG. The power status of the associated CPU determines which register bank controls the power state of the modules:

- When CPU is in Deep Sleep or a deeper low-power mode, SLEEPCFG applies.
- When CPU is in Active or Sleep mode, RUNCFG applies.

Software needs to configure the SLEEPCON registers before entering Deep Sleep. After SLEEPCON has completed its tasks, it automatically transfers control to PMC to start taking action.

PMC controls power mode transitions. Like SLEEPCON, PMC also has two register banks: PDSLEEPCFG and PDRUNCFG. PMC uses the power status from SLEEPCON to select which register bank takes effect. Because the two configuration values coming from the Compute and Sense domains may be different, PMC aggregation ensures the higher power mode always wins.

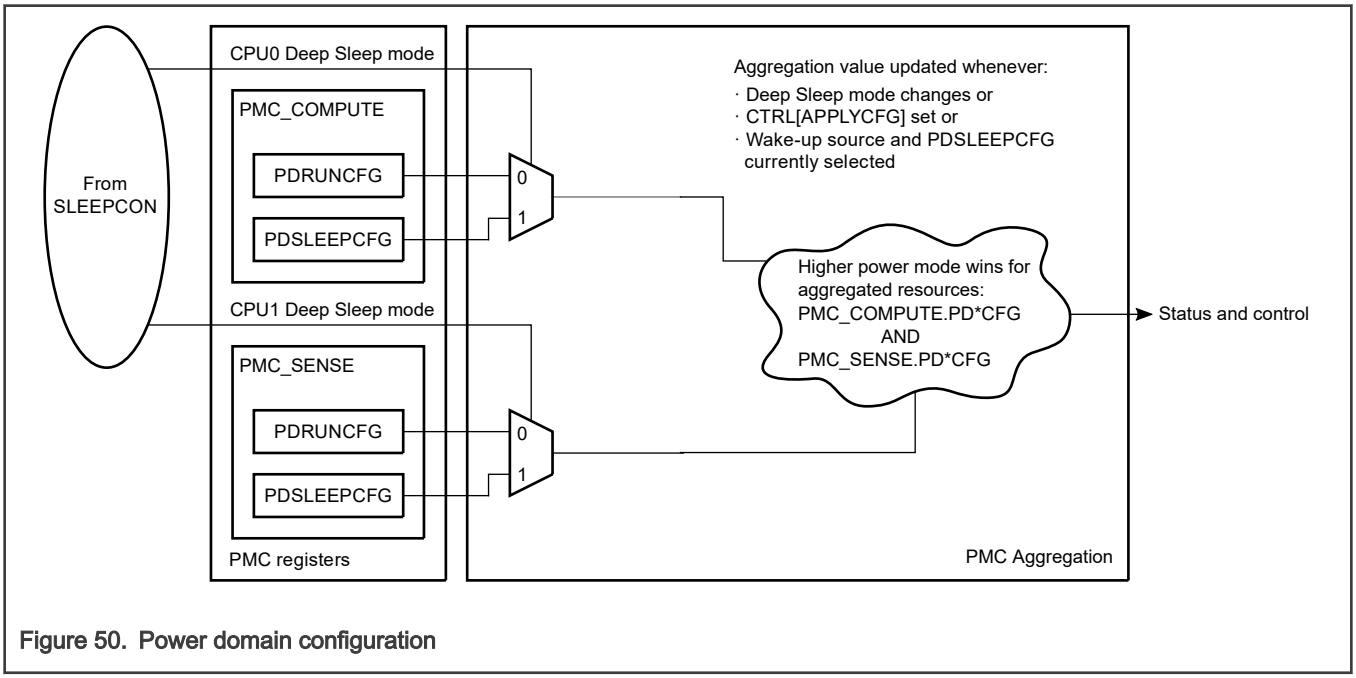

Figure 50. Power domain configuration

12.5.1 SLEEPCON dependencies

SLEEPCON0 and SLEEPCON1 are both sleep configuration modules but have the following differences and dependencies:

- CPU0 can access SLEEPCON0.
- CPU1 can access SLEEPCON1.

- SLEEPCON1 controls the modules in the VDD1_SENSE domain (default state is all off), clock source PLL and OSC in VDDN_COM, and the RAM_ARBITER0 main clock in VDD2_COM and VDD2/VDDN_MEDIA. SLEEPCON0 cannot control private modules in the VDD1_SENSE domain.
  - This means before VDD2 goes off, CPU0 software must appropriately configure modules outside the VDD1_SENSE domain. CPU1 software has no control over the power states of modules connected to VDD2 or VDDN.
  - For example, if a VDD2_MEDIA module needs to remain active, VDD2 must remain on.
- Because shared modules in VDD1_SENSE have duplicated controls in SLEEPCON1 and SLEEPCON0, if either SLEEPCON configures a shared module to be on, it remains on. Both SLEEPCONs must program a shared module to be off for it to be off.

12.5.2 Analog module power control in SLEEPCON

For analog modules such as FRO, LPOSC, PLL, the power control is in SLEEPCON:

- In Active mode and in Sleep mode, RUNCFG0 controls the power.
- In Deep Sleep mode and in DSR mode, SLEEPCFG0 controls the power.

The table below shows the module control fields and their bit numbers in the SLEEPCON0 and SLEEPCON1 configuration registers.

Table 165. SLEEPCON power control fields

Field	Description	SLEEPCON0		SLEEPCON1	
		SLEEPCFG0	RUNCFG0	SLEEPCFG0	RUNCFG0
FRO2_GATE	FRO2 Gating	[31]	[31]	[31]	[31]
FRO0_GATE	FRO0 Gating	[29]	[29]	-	-
ADC0_PD	ADC0 Power Down	[16]	[16]	[16]	[16]
AUDPLLLDO_PD	Audio PLL Internal Regulator Power Down	[15]	[15]	[15]	[15]
AUDPLLANA_PD	Audio PLL Analog Function Power Down	[14]	[14]	[14]	[14]
PLLLDO_PD	Main PLL Internal Regulator Power Down	[13]	[13]	[13]	[13]
PLLANA_PD	Main PLL Analog Function Power Down	[12]	[12]	[12]	[12]
LPOSC_PD	LPOSC Power Down	[11]	[11]	[11]	[11]
FRO2_PD	FRO2 Power Down	[10]	[10]	[10]	[10]
FRO1_PD	FRO1 Power Down	[9]	[9]	-	-
FRO0_PD	FRO0 Power Down	[8]	[8]	-	-
XTAL_PD	Xtal Oscillator Power Down	[7]	[7]	[7]	[7]

To reduce the amount of inter-processor communication required to manage common resources controlled by both CPU0 and CPU1, power-control fields are available in the registers of both SLEEPCON0 and SLEEPCON1. AND logic determines what power state takes effect. For example, FR02 is powered down only if (SLEEPCON0[FRO2_PD] = 1) AND (SLEEPCON1[FRO2_PD] = 1) is true. If a CPU does not use a common resource, that CPU must put that resource in a power-down state.

12.6 RAM Arbiter and shared memory power considerations

The RAM Arbiter modules manage access to the on-chip shared RAM memory partitions. RAM_ARBITER0 in the VDD2_COM power domain manages accesses to the VDD2 shared memories. RAM_ARBITER1 in the VDD1_SENSE power domain manages accesses to the VDD1 shared memories.

This section describes power saving options and considerations for the RAM Arbiter modules.

12.6.1 Memory power switches

Each shared memory partition has two power switches that can independently turn off power to their periphery (address decoding and IOs) and array (memory content). If software does not need to access the memory partition, turn off the periphery power. If software does not need to retain the partition's memory content, turn off the array power also.

For active (run) mode, the PMC PDRUNCFG registers control these switches. For low-power modes, the PMC PDSLEEPCFG registers control these switches.

12.6.2 RAM Arbiter clocking

The RAM Arbiter modules do not have their own dedicated clocks. Instead, they use the clocks of the transaction initiators accessing the shared memory. These clocks, listed below, should be turned off whenever possible to maximize power saving.

Table 166. RAM_ARBITER0 clocks

Clock	Power control
CPU0 bus clock (COMPUTE_MAIN_CLK)	Automatically gated when no access
VDD1_SENSE Access RAM_ARBITER0 Clock (COMMON_RAM_CLK)	CLKCTL1.PSCCTL1[SENSE_ACCESS_RAM_ARBITER0]
HiFi4 clock	Clock off HiFi4 to turn it off
NPU clock	Clock off NPU to turn it off
VDD2_MEDIA Access RAM_ARBITER0 Clock (MEDIA_MAIN_CLK)	CLKCTL0.PSCCTL5[MEDIA_ACCESS_RAM_ARBITER0]

Table 167. RAM_ARBITER1 clocks

Clock	Power control
CPU1 bus clock (SENSE_MAIN_CLK)	Automatically gated when no access
VDD2_COMP Access RAM_ARBITER1 Clock (SENSE_RAM_CLK)	CLKCTL0.PSCCTL5[COMP_ACCESS_RAM_ARBITER1]
HiFi4 Access RAM_ARBITER1 Clock (SENSE_RAM_CLK)	CLKCTL0.PSCCTL5[HiFi4_ACCESS_RAM_ARBITER1]
HiFi1 clock	Clock off HiFi1 to turn it off
Media Access RAM_ARBITER1 Clock (SENSE_RAM_CLK)	CLKCTL3.PSCCTL0_COMP[MEDIA_ACCESS_RAM_ARBITER1] or CLKCTL3.PSCCTL0_SENS[MEDIA_ACCESS_RAM_ARBITER1]

12.6.3 Clock switching

Because a shared RAM partition being accessed connects to and remains parked on the last initiator's clock, a new access from another initiator with a different clock triggers clock switching inside the RAM Arbiter. This clock switching requires that both the last clock and the new clock are available, so prematurely turning off the last access clock prevents the clock switching and blocks any new access to that partition.

12.6.4 RAM auto clock gating when using CPU bus clock

When a RAM partition's clock is parked on the associated CPU bus clock, the partition is clocked only when accessed. That is, hardware automatically gates the CPU bus clock connection whenever possible to save power.

12.6.5 Safely turning off an initiator's clock using CPU dummy reads

In a power-sensitive system with multiple initiators sharing RAM partitions, system applications must know when initiators would use partitions and manage the initiators' clocks accordingly. If an initiator that does not use the CPU bus clock shares a RAM partition with others, the associated CPU (CPU0 for RAM_ARBITER0, CPU1 for RAM_ARBITER1) should first perform a dummy read to that partition before turning off that initiator's clock.

The CPU dummy read triggers the RAM Arbiter to switch the partition's clock to the CPU bus clock, so the clock turns on only during transactions to save power. See RAM auto clock gating when using CPU bus clock.

12.6.5.1 Cache considerations for CPU0 dummy reads

The CPU0 dummy reads must miss the cache to be effective. To ensure a RAM Arbiter is physically accessed, use one of the following methods:

- Access a non-cacheable region if available per the MPU configuration.
- Disable the cache, perform the dummy read, then re-enable the cache.
- Invalidate the cache line with a line command to the target address before performing the dummy read.

12.6.6 Accessing RAM_ARBITER0 with Compute in Deep Sleep

If a system application requires CPU1 or EZH-V to access RAM_ARBITER0 partitions while the Compute domain is in Deep Sleep mode with COMPUTE_MAIN_CLK off, CPU1 or EZH-V must perform a dummy read first before turning off the Compute domain bus clock.

12.6.7 Power saving options in SYSCON

In addition to the power switches, the shared memories have power saving options controlled by SYSCON registers:

- When no processor core or other memory transaction initiator requires a shared memory partition, gate the partition's input clock to save power as follows:
  1. Perform a dummy read to the target partition to establish the CM33 bus clock connection.
  2. Clear the corresponding SRAM_CLKGATE_CTRL[PARTITIONn] bit to gate the clock.

12.7 Chip operation in low-power modes

Chip components can operate differently depending on the power mode.

12.7.1 Module operation in low-power modes

The following table shows the functional states of the modules in low-power modes.

Table 168. Module states in low-power modes

Module or clock name	Main controlling entity	Active	Sleep	Deep Sleep	DSR	DPD	FDPD
FRO2 (325 MHz)	CPU1	On	Software-configured	Software-configured	Off with state retained	Off	Off

Table continues on the next page...

Table 168. Module states in low-power modes (continued)

Module or clock name	Main controlling entity	Active	Sleep	Deep Sleep	DSR	DPD	FDPD
LPOSC (1M_LPOSC)	CPU1	On	Software-configured	Software-configured	Off with state retained	Off	Off
FRO0 (325 MHz)	CPU0	On	Software-configured	Software-configured	Off with state retained	Off	Off
FRO1 (192 MHz)	CPU0	On	Software-configured	Software-configured	Off with state retained	Off	Off
Main crystal oscillator (MHz OSC)	CPU0	Software-configured[1]	Software-configured	Software-configured	Off	Off	Off
System PLL and Audio PLL (528 MHz)	CPU0	Software-configured	Software-configured	Software-configured	Off	Off	Off
OSC32KNP (RTC and RTC oscillator)	CPU0	Software-configured	Software-configured	Software-configured	Software-configured	Software-configured	Software-configured
SRAM memory arrays and peripheries	Controlled by both based on ownership	Software-configured	Software-configured	Software-configured	Software-configured	Off	Off
Boot ROM	CPU0	On	On	Off	Off	Off	Off
Other digital modules	Some controls are with CPU0, others with CPU1, rarely shared except few like OSTIMER etc.						
ADC	Shared between CPU0 and CPU1	Software-configured	Software-configured	Software-configured	Off	Off	Off
MIPI_DSI_HOST	CPU0	Software-configured	Software-configured	Software-configured	Off	Off	Off
DSP	Both CPU0 and CPU1 have their own DSPs	Software-configured	Software-configured	Software-configured	Off	Off	Off
OCOTP	CPU0	Software-configured	Software-configured	Software-configured	Off	Off	Off

1. Software-configured = On or off, clock-gated, or power-gated

12.7.2 Power switches in low-power modes

The following table shows the states of the power switches in low-power modes.

Table 169. Power switch states in low-power modes

Power switch	Controlling logic	Compute Domain power modes					
		Active	Sleep	Deep Sleep	DSR	DPD	FDPD
PS0_VDD2	VDDC switch for VDD2_COMP	Optional	Dep[1]	Dep	Dep	Dep	Dep
PS1_VDD2	VDD switch for VDD2_COMP	Ena[2]	Ena	Ena	Dis[3]	Dis	Dis
PS2_VDD2	VDDC switch for VDD2_MEDIA	Optional	Dep	Dep	Dep	Dep	Dep
PS3_VDD2	VDD switch for VDD2_MEDIA	Ena	Ena	Ena	Dis	Dis	Dis
PS4_VDD2	VDDC switch for VDD2_COM	Optional	Dep	Dep	Dep	Dep	Dep
PS5_VDD2	VDD2_COM	Ena	Ena	Ena	Dis	Dis	Dis
PS6_VDD2	VDD2_DSP	Prog[4]	Prog	Ena	Dis	Dis	Dis
PS7_VDD2	Memory periphery	Ena	Ena	Ena	Dis	Dis	Dis
PS8_VDD2	Memory array	Ena	Ena	Ena	Ena	Dis	Dis
PS0_VDDN	VDDN_MEDIA for DSR Power mux for retained logic	Ena	Ena	Ena	Dis	Dis	Dis
PS1_VDDN	VDDN_MEDIA for DSR Power mux for retained logic	Ena	Ena	Ena	Ena	Dis	Dis
PS2_VDDN	VDDN_MEDIA for non-retained logic	Ena	Ena	Ena	Dis	Dis	Dis
PS3_VDDN	VDDN_COM	Ena	Ena	Ena	Dis	Dis	Dis

1. Dep = Depends. State of power switch depends on domain controlling the logic
2. Ena = Enabled. Power switch closed
3. Dis = Disabled. Power switch open
4. Prog = Programmable. Power switch is programmable based on specific application use-case

Chapter 13
Clock Overview

13.1 Overview

The chip supports domain-specific clock controllers (CLKCTL) to generate the peripheral clock sources. The domain-specific clocking approach helps reduce power needs through the following methods:

- Better clock control by utilizing divided clock sources to each power domain
- Local clock generation logic (muxing, dividers, gates) for each power domain
- Local peripheral clock and reset control for each power domain

13.1.1 System diagram

The chip's clock overview diagram is shown below:

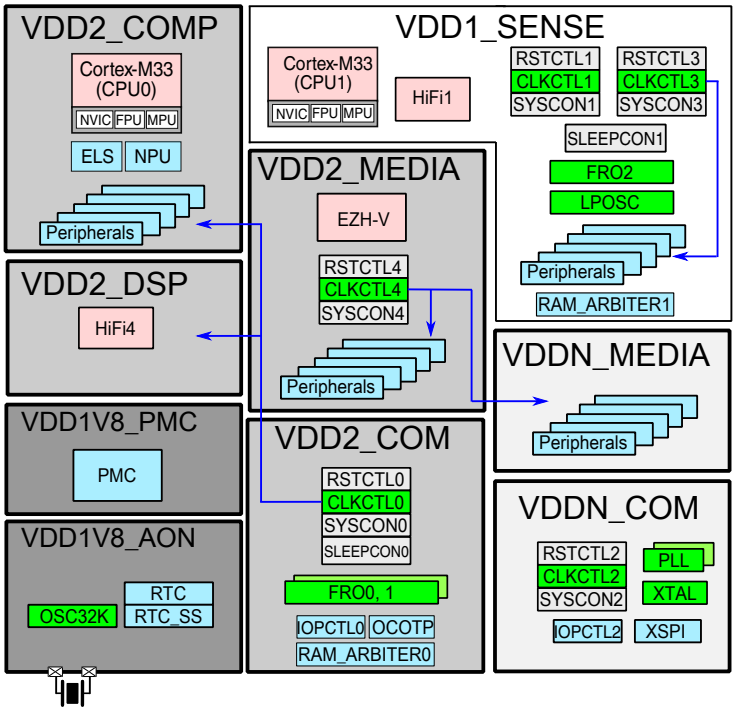

Figure 51. Clock overview

13.1.2 Clocking modules and components

The clock generation and distribution are implemented by the following blocks:

Table 170. Clocking components

IP module	Description
Clock controller (CLKCTL)	The CLKCTL module provides control for clock generation, division, distribution, and coarse-level gating. See Clock Controller (CLKCTL) for information on the CLKCTL architecture, functional description and programming model.
FRO Clock Generator(FRO)	The FRO is the free-running oscillators. The FROs are used to work as the primary clocking sources for the Compute and Sense Domains.
Nano Power 32 kHz Oscillator (OSC32KNP)	The OSC32KNP interfaces the external 32 kHz crystal oscillator.

13.2 Clocking considerations

There are 2 processors in the Compute (CPU0) and Sense (CPU1) domains respectively which follow semi-autonomous execution environments. During boot, the CPU0 boots first. Subsequently the CPU1 comes up, if CPU0 boots it. Overall, the architecture supports multiple schemes of handling shared resources – however in the context of clocking control in active mode inter-CPU messaging mechanism is used to ensure only one execution entity has control of the resource at any one point of time. The inter-CPU mailbox mechanism has the following features:

- Provide means for Inter-processor communication allowing multiple CPUs to share resources and communicate with each other in a simple manner
- Each CPU can claim a shared resource if it is available
- Provides a mutual exclusion configuration for the communication handshake

13.3 Clock sources

Table 171. Clock sources

Clock source	Description	Source at boot?
FRO	FROs are tunable, and are used to work as the primary clocking sources for the Compute and Sense Domains. FRO0 and FRO2 support configurable frequencies from 150 MHz to 325 MHz. FRO1 supports a fixed frequency of 192 MHz, and is used for bootup.	FRO0 - no FRO1 - yes FRO2 - no
Main PLL (528 MHz)	The main PLL is used when high frequencies (> 300 MHz) are required, as well as when strict clocking specifications such as jitter and duty cycle are needed. The PLL sources the main-compute domain and has individual outputs for the HiFi4. Input frequencies supported are 16, 19.2, 24, 26, 30 or 32 MHz	no
Audio PLL (528 MHz)	The audio PLL is used for audio purposes with strict jitter requirements. The clock inputs and acceptable input frequencies are the same as with the main PLL.	no
External clock (clkin)	The external clock brings in the possibility to bring in an external clock source	yes
XTAL oscillator (osc_out)	The Xtal oscillator brings in the possibility to bring in an external clock source.	yes

Table continues on the next page...

Table 171. Clock sources (continued)

Clock source	Description	Source at boot?
1 MHz Low-Power Oscillator (1m_lposc)	One of the main uses of the 1 MHz low power oscillator is to boot up the chip. The output of the 1 MHz oscillator 1m_lposc also goes through a divider to generate a 32 kHz low frequency clock source which is widely used throughout chip. The sense domain is alive in the active mode of the chip – therefore the wake32k_clk can be used for the SIO, USB etc.	yes
Nano Power 32 kHz Oscillator (for RTC)	Supports RTC clocking by supplying the 32 kHz source clock. The 32 kHz crystal oscillator is external. The 32 kHz clock may not be available for Cold Boot, but it will be available for low-power wakeup and reset	yes

See Clock Controller (CLKCTL) for more information.

13.4 Generated clock sources

In addition to the clock sources described in Clock sources section, there are also generated clock sources.

The clock sources and generated clock sources are inputs to the clock slice multiplexers. Clock source selection for generated clock sources and clock slice multiplexers are all done in the CLKCTL registers.

13.5 Clock root generation

Clock generation in the CLKCTL creates clock roots for on-chip peripherals. Each clock root has a dedicated clock slice. Each clock slice takes the clock source input and generates the clock root with the required frequency.

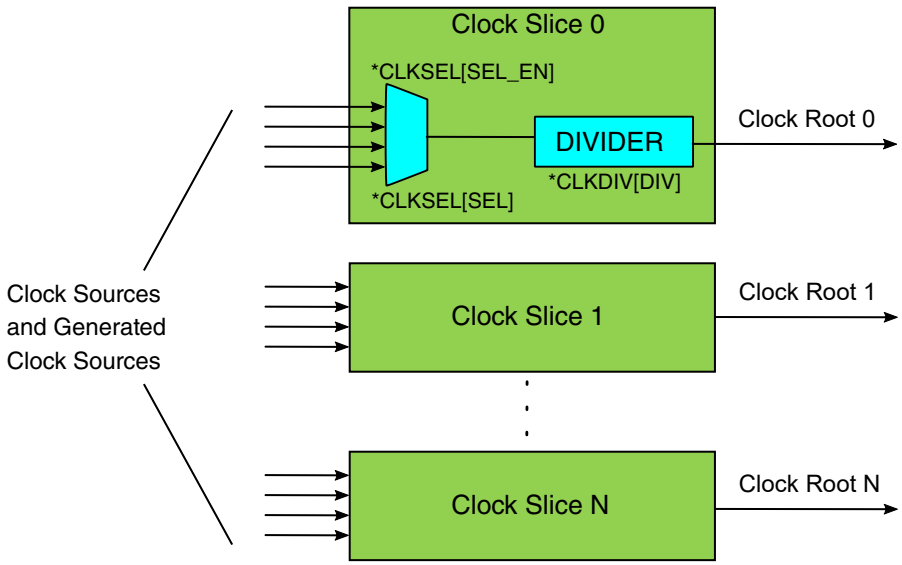

Figure 52. Clock root generation from clock slice

Clock source selection is in the CLKCTL functional clock select registers (SEL bitfield). Downstream from the clock source mux is the clock slice divider, which is controlled by the divider registers (DIV bitfield).

Each clock slice has a gate on the output of the functional clock select mux. The enable for these gates are also in the functional clock select registers (SEL_EN bitfield).

See Clock Controller (CLKCTL) for more information about clock generation and the clocking block diagrams.

13.6 Clock Gating

There are two levels of clock gating supported on the chip. An entire clock slice can be gated and all the downstream peripheral clocks connected to the slice by configuring the *CLKSRC[SEL_EN] field. This should only be done when all related peripherals connected to the clock slice are not in use. Peripheral clock gating is also supported. The peripheral clock gates are a distributed network of clock enables configured by the CLKCTL PSCCTL registers. For more information, please see the Clock Controller (CLKCTL) chapter.

Chapter 14
Graphics Overview

14.1 Overview

The graphics and display components on the chip are coupled together, and interface with on-chip memories (RAM_ARBITER) and external memory interfaces (XSPI) for efficient low-power performance.

14.1.1 Block diagram

The system diagram for the graphics, display, and camera modules is shown below:

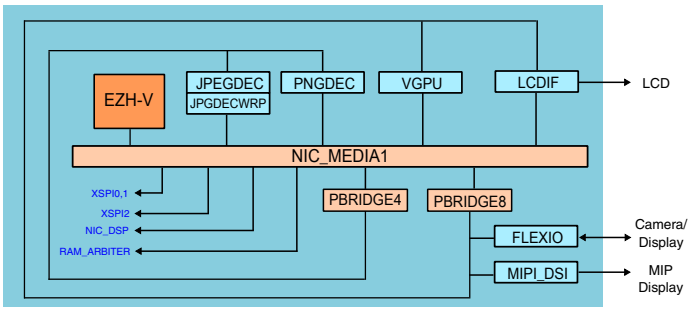

Figure 53. System diagram

14.1.2 Modules

The following table describes the graphics related modules in the chip.

Modules	Instances	Description	Main Features
EZH-V	1	The EZH-V is primarily implemented to provide a smart DMA engine for post-processing graphics data assembled by either or both the GPU and CPU, and then passing it to the FLEXIO for output. Processing operations may include data packing and endianness adjustment. The EZH-V is available for any other general-purpose handling that may be required and supports an extensive selection of trigger inputs from GPIOs and most on-chip peripherals.	• EZH-V Event / Algorithm Handler with 32 KB EZH code RAM and 64-bit I/D TCM.
VGPU	1	The VGPU provides a high-performance UI-based	• Open VG 1.1 • Linear paint

Table continues on the next page...

Table continued from the previous page...

Modules	Instances	Description	Main Features
		graphic core to enable hardware acceleration of the OpenVG API and display vector graphics. The DECNano (Decoder/ Encoder Core) series pixel compression and decompression fabric provides a unified lossy pixel compression and decompression infrastructure and support for pixel processing pipelines.	• Pixel input format • YUY2 input • INDEX 1/2/4/8 • DECNano compression / decompression • ETC2 decompression • Transformation support
JPEGDEC	1	High-performance JPEG decoder for still image and video decompression applications. JPEGDEC is a submodule of JPGDECWRAP.	• Decoding standard-compliant baseline and extended JPEG streams • Decompress video payload of several standard motion JPEG container formats.
JPGDECWRP	1	JPGDECWRP is a high-performance JPEG decoder for still image and video decompression applications. Contains DMA channels for bit stream fetching and decoded pixel data storing, as well as a register interface and chained descriptors for frame or bit stream buffer switching. There are two submodules, JPEG decoder wrapper and JPEG decoder core.	• Baseline and extended ISO/IEC 10918-1 JPEG compliance • Conversion of the pixel MBT format to linear format • Multi-bit-stream context switch based on frame • YUV444, YUV420, YUV422, RGB, ARGB, and Gray formats are supported • 8-bit and 12-bit pixels precision
PNGDEC	1	PNGDEC decodes pictures in the PNG source format. PNGDEC includes a DMA engine	• 64-bit DMA engines used to fetch PNG bitstreams from the system memory and feed them into PNGDEC, and store decoded RGB-A raw pixel data and ancillary data • Huffman encoded data (both static and dynamic) • Gray scale, RGB (8- or 16-bit depth) and indexed color (8-bit depth) with and without alpha channel
LCDIF	1	LCDIF is a high-performance, low-power display processor unit (DPU). It outputs video and graphic streams from a single output panel. The single output panel can	• Provides DPI or DBI for display output. • LCDIF uses the DBI interface by default. The supported DBI types include: - Type A (Fixed E mode or Clocked E mode) - Type B

Table continues on the next page...

Table continued from the previous page...

Modules	Instances	Description	Main Features
		connect to either a display pixel interface (DPI) device or a display bus interface (DBI) device to support RGB output.	• Provides post-processing computing functions, including: - Alpha blending - Gamma - Dither
MIPI_DSI	1	MIPI DSI controller interface for serial graphics display output that implements all protocol functions defined in the MIPI_DSI_HOST Specification. The MIPI_DSI_HOST controller provides an interface that allows communication with MIPI_DSI_HOST-compliant peripherals.	• Implements all three DSI Layers (Pixel to Byte packing, Low Level Protocol, Lane Management) • Support for Command and Video Modes • Supports virtual channels (dual display) • Host Version • Supports PHY Protocol: - 1 Clock lane - 2 data lanes - Supports MIPI Standard for D-PHY - High Speed Serializers and Deserializers - MIPI Alliance Specification for Display Serial Interface Version 1.1 compliant • Support for all three Video Mode packet sequences — Non-Burst Mode with Sync Pulses — Non-Burst Mode with Sync Events — Burst mode
NIC_MEDIA1	1	Bus interconnect for the graphics and media modules. AXI_SWITCH is an Arm CoreLink Network Interconnect component (NIC) that switches any initiator access to the target memory or peripheral. It has multiple target interfaces and initiator interfaces. It supports Arm CoreLink QoS-400 Network Interconnect Advanced Quality of Service (QoS) to arbitrate and regulate the transactions from various SoC initiators.	• Programmable maximum for outstanding transactions to include: — Separate maximum for read and write requests. — Combined maximum for all requests. — Fractional value to provide finer control. • Regulation of read and write request issuing rates to meet programmed traffic
XSPI	3	XSPI provides an interface to a single external SFM device.	• Programmable sequence engine for memory device commands and operations

Table continues on the next page...

Table continued from the previous page...

Modules	Instances	Description	Main Features
		This device can have up to 16 bidirectional data lines. Three XSPI Flash Interface modules support Octal and Quad SPI memory devices. Two of them (XSPI0 and XSPI1) are supported with a policy selector (CACHE64_POLSEL). The first XSPI instance (XSPI0) is primarily for code execution from off-chip SPI flash memory. It supports execute-in-place (XIP) and on-the-fly (OTF) decryption using the PRINCE module. It also provides a mechanism to shift a designated range of addresses to a different region of off-chip memory to support dual-image boot. The second XSPI instance (XSPI1) is primarily to access data from SDRAM (particularly for graphics). The XSPI1 is accessible by the HiFi4 DSP as well as the CPU0. Both XSPI0 and XSPI1 Interfaces will include a 32 KB cache with an CACHE64 cache controller.	• Single, dual, and quad modes of operation supported for Quad flash memories • Octal and single IO operation supported for Octal flash memories • Double Data Rate (DDR)/Double Transfer Rate (DTR) mode that generates data on every edge of the memory clock • Flash memory data strobe signal to support data sampling in DDR and Single Data Rate (SDR) mode • HyperRAM support • Direct memory mapping of all AHB memory accesses to the chip system memory space. • SNAND device support for NOR-compatible command through the IPS interface • X16 operation for PSRAM with EIGHT PAD support (similar to X8 mode). • Programmable bit skewing adjustment for dual DQS.
RAM_ARBITER	2	Internal SRAM interface	• 7.5 MB of system SRAM accessible by the VDD2_COMP and • VDD1_SENSE processing domain, DMA engines, and bus initiators
FLEXIO	1	Flexible IO controller can emulate a variety of serial and parallel communication protocol. FlexIO can be configured to provide a parallel interface to an LCD.	• Flexible 16-bit timers with support for a variety of trigger, reset, enable, and disable conditions.

14.2 Functional description

14.2.1 Application information

The chip has devoted pads to driving a memory-in-pixel (MIP) display. This typical application, supports 2-bit color, 6 data lines, horizontal sync and vertical sync. In addition, the chip can provide the panel back plane signals that are driven from the 32 kHz RTC clock. See NXP site for additional graphics support resources, including support from the SDK and GUI guider.

Applications

- Battery powered devices
- Multiple display options (ex. OLED 24-bit color display)
- Augmented reality glasses

Primary supported use cases - 500x500 display size

- 24-bit color graphics from internal and external memory using JPEG and PNG images at 70 fps.
- 888 color depth supporting full motion JPEG at 30 fps
- LCDIF supporting DPI and DBI mode, fetch decoded data from SRAM
- LCDIF display in VG layer
- LCDIF fetch vGPU render data from SRAM and display in overlayer0
- Use XPSI2 (PSRAM), XSPI0 (Flash), and RAM_ARBITER (SRAM) memories

14.2.2 MIPI display interface

The chip supports a MIPI panel display through the MIPI DSI interface. The MIPI DSI interfaces the LCDIF to provide packet support to the DPI and DBI interfaces. The DSI then interfaces the DPHY, which connects to the panel display pins.

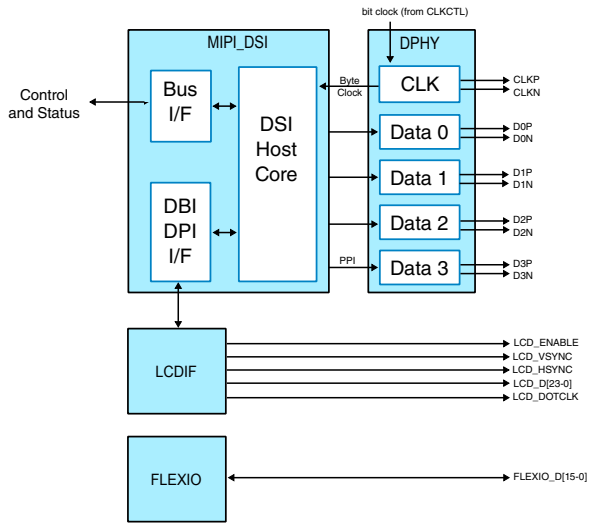

Figure 54. Display interface

14.2.3 FLEXIO interface

The FLEXIO can support a camera and display interface. The camera interface can couple with the DSI for an integrated camera and display solution. See the FLEXIO chapter for more information, including the pinmux sections for the associated pinout details.

- FLEXIO_D[7-0] – Samples data 0 to data 7
- FLEXIO_D8 – PCLK as internal shift clock, timer 0 decrements on PCLK
- FLEXIO_D9 – HREF as trigger to enable 16-bit counter (timer 0)

Chapter 15
Timers Overview

15.1 Introduction

The timer modules provide timers to support many different functions throughout the device. This chapter does not cover timers that are exclusive to particular domains and have no user interface.

15.1.1 Block diagram

The block diagram for the system level timer architecture is provided below.

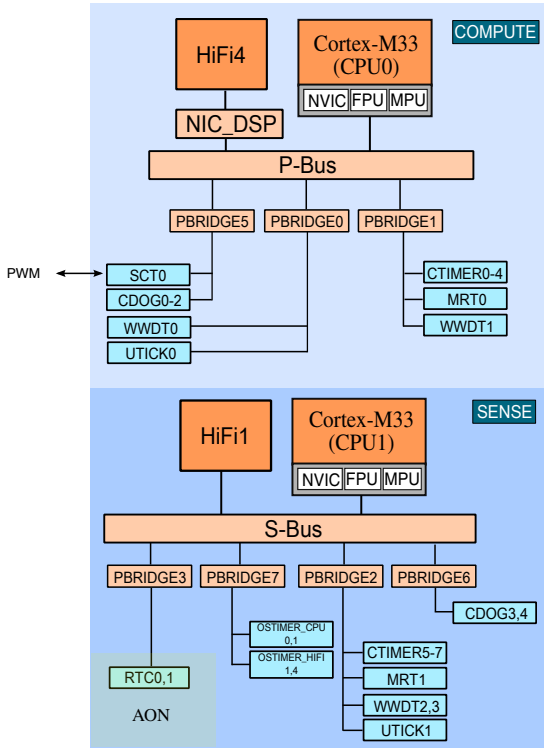

Figure 55. System timer block diagram

15.1.2 Modules

This chip includes the following timer modules.

Table 172. Timer modules

Modules	Instances	Description	Main feature
Real Time Clock (RTC)	RTC0,1 (HP) - Sense (VDD1) RTC0,1 (LP)- AON (VDD1V8)	RTC provides time keeping and calendaring functions. It also provides protection against external or internal tampering, protection against spurious memory or register updates, and battery operation.	• Basic clock functions — Separate counters for days, hour, minutes, and seconds

Table continues on the next page...

Table 172. Timer modules (continued)

Modules	Instances	Description	Main feature
			— Calendaring support—Separate counters for year, month, and day of the week ◦ Automatic adjustment for daylight saving with user-defined parameters ◦ Automatic adjustment for month and leap year — External clock support • Time zone offset • Programmable alarm with interrupt • Periodic interrupts • Hardware compensation to frequency and temperature changes For detailed information, see Real Time Clock (RTC).
Micro-Tick Timer (UTICK)	UTICK0 - Compute (VDD2) UTICK1 - Sense (VDD1)	UTICK is a 31-bit timer that counts down to 0 and then generates an interrupt. Therefore, it provides a fixed time interval between interrupts. It is a simple, ultra-low-power timer that can run and wake up the chip in reduced-power mode, including sleep and deep sleep modes.	• Wakes up the chip from Low-power mode. • Operates using interrupt or software polling mode. • Includes Capture registers that use external pin transitions as a trigger. For detailed information, see Micro-Tick Timer (UTICK).
Standard Counter and Timers (CTIMER)	CTIMER0 - Compute (VDD2) CTIMER1 - Compute (VDD2) CTIMER2 - Compute (VDD2) CTIMER3 - Compute (VDD2) CTIMER4 - Compute (VDD2) CTIMER5 - Sense (VDD1) CTIMER6 - Sense (VDD1)	CTIMER contains multiple timers each of which can generate interrupts or perform other actions at specified timer values a configured in four match registers. Each timer can also capture the timer value when an input signal transitions and optionally generate an interrupt at that transition. Using the match registers, you can configure a timer to output PWM pulses.	• Contains a 32-bit CTIMER with a programmable 32-bit prescaler • Contains Timer Control (TCR) and External trigger enable • Performs counter or timer operations • Selects the function clocks that may be asynchronous to other system clocks • Includes up to four 32-bit captures For detailed information, see Standard/Counter Timers (CTIMER).

Table continues on the next page...

Table 172. Timer modules (continued)

Modules	Instances	Description	Main feature
	CTIMER7 - Sense (VDD1)		
OS Event Timer (OSTIMER)	OSTIMER (OSTIMER_CPU0,1 and OSTIMER_HiFi1,4) - Sense (VDD1)	OSTIMER includes a shared timer and separate match and capture functions for CPU0, CPU1, HiFi1 and HiFi4.	• Provides a 64-bit Gray code counter • Supports separate functions for each CPU: — A capture register can copy the main counter value when triggered by a CPU request. — A match register can be compared to the main counter and can optionally generate an interrupt or wake-up event. For detailed information, see OS Event Timer (OSTIMER).
SCTimer (SCT)	SCT0 - Compute (VDD2)	SCT is a flexible timer module capable of creating complex PWM waveforms and performing advanced timing and control operations with minimal or no CPU intervention. It can operate as a single 32-bit counter or as two independent, 16-bit counters in Unidirectional or Bidirectional modes.	• Configurable as two 16-bit counters or one 32-bit counter • Configurable as up counters or up-down counters • Configurable number of match and capture registers • Ability to create time-proportioned PWM signals • Up to eight single-edge or four dual-edge PWM outputs For detailed information, see SCTimer (SCT).
Multi-Rate Timer (MRT)	MRT0 - Compute (VDD2) MRT1 - Sense (VDD1)	MRT provides a repetitive interrupt timer with 4 channels. MRT provides a repetitive interrupt timer with 4 channels.	• 24-bit interrupt timer. • 4 channels independently counting down from individually set values. • Repeat Interrupt, One-Shot Interrupt, and One-Shot Stall modes. • Programmable individual time intervals for each channel. For detailed information, see Multi-Rate Timer (MRT).
Windowed Watchdog Timer (WWDT)	WWDT0 - Compute (VDD2) WWDT1 - Compute (VDD2) WWDT2 - Sense (VDD1)	WWDT helps you reset or interrupt a microcontroller or core that is stuck in an infinite loop or is executing unintended code. If an application fails to reload or feed a watchdog (WDOG) timer within the predefined duration of time (the window), WWDT can generate a watchdog reset.	• Can reset or interrupt the chip within a programmable time • Watchdog reset indication flag • Clocking features: — Programmable 24-bit timer with an internal fixed (divided by 4) prescaler

Table continues on the next page...

Table 172. Timer modules (continued)

Modules	Instances	Description	Main feature
	WWDT3 - Sense (VDD1)		— Selectable time period in increments of four watchdog clocks — Watchdog clock (WDCLK) source having a selectable frequency • Can be configured to run in Low-Power mode For detailed information, see Windowed Watchdog Timer (WWDT).
Code Watchdog Timer (CDOG)	CDOG0 - Compute (VDD2) CDOG1 - Compute (VDD2) CDOG2 - Sense (VDD1) CDOG3 - Sense (VDD1) CDOG4 - Sense (VDD1)	CDOG provides mechanisms for detecting side-channel attacks and the execution of unexpected instruction sequences	• Secure Counter (SEC_CNT) detects altered software in the execution flow. • Instruction Timer (INST_TIMER) places a hard upper-limit on the interval between checks of the secure counter. For detailed information, see the I.MX RT700 Security Reference Manual.

Chapter 16
System Debug

16.1 Overview

It is necessary to be able to debug SoC and to ensure that access is properly controlled. Within the chip there are multiple objects which need to be debugged and an overall infrastructure to enable that to occur. The chip debug architecture is based on Arm CoreSight technology, with support for the Cortex-M33 cores.

16.1.1 Block diagram

The block diagram for the system level debug architecture is provided below.

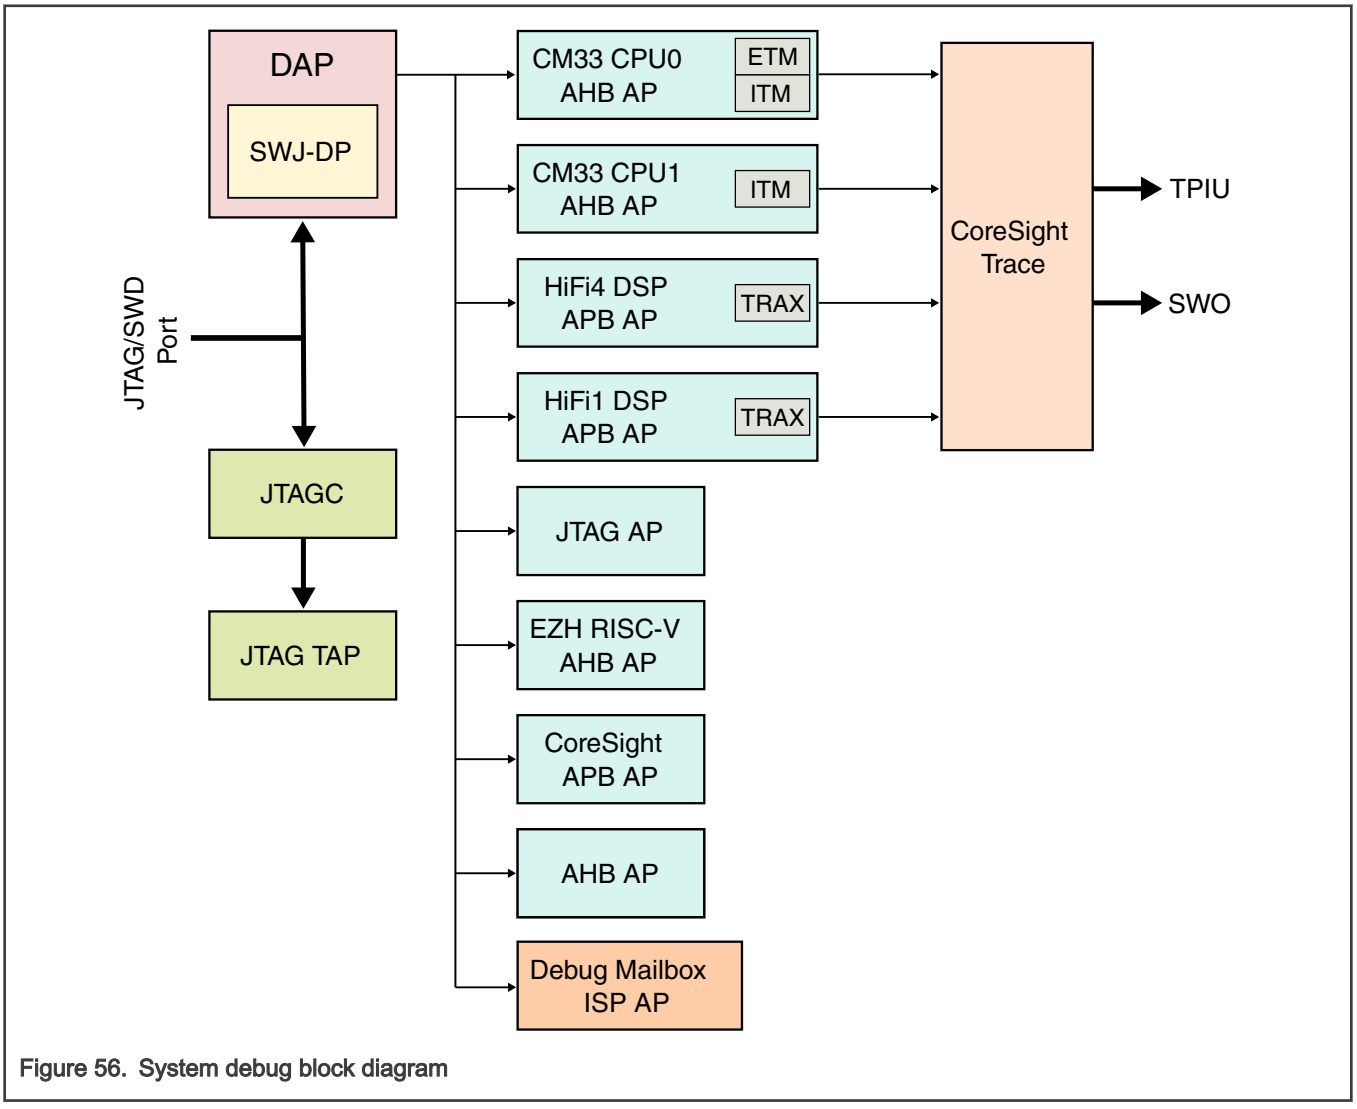

Figure 56. System debug block diagram

16.2 Functional description

16.2.1 Features

The debug infrastructure provides support for debug and trace of core and trace of chip modules. Some of the features that debug infrastructure provides are:

- Debug access control
- Debug Access Port (DAP)
- Run control
- CPU and interconnect traces
- Trace data export to system memory and off-chip
- Global trace Timestamp
- Embedded Cross Triggering (ECT)

The key features of the debug system include:

- Support the following cores and IP
  - 2x Cortex-M33 cores
  - HiFi4 DSP core
  - HiFi1 DSP core
  - EZH RISC-V core
- Support 1149.1 (JTAG) 5-pin interface
- Support Arm Serial Wire Debug (SWD) 2-pin interfaces. Through sequence recognized by the Arm DAP IP, the JTAG signals can change to SWD mode
- Support both non-intrusive trace and halt-mode debug options
- Support the combination of trace streams from cores and modules that support trace
- Support capture of trace using the Arm Trace Memory Controller (TMC). Trace can be captured into:
  - A 16 KB Embedded Trace FIFO (ETF) in chip trace block
  - System memory using the Arm Embedded Trace Router (ETR)
  - CoreSight Serial Wire Output (SWO)
- The SWJ-DP interprets the data coming in and routes to appropriate Access Port (AP).
- Timestamp distribution and the closely related system timer distribution in the chip

16.2.2 Debug Access Port (DAP)

DAP is a standard Arm component, comprising of several components. These components are used to access the DAP from an external debugger, and Access Ports to access on-chip debug system resources. The DAP supports 1149.1/Arm SW-DP interface, which means that the JTAG interface can be operated in either standard 5-pin JTAG-DP interface or in 2-pin SW-DP interface.

Serial Wire port (SWJ-DP) consists of a wrapper around the JTAG-DP and SW-DP. It selects JTAG or SWD as the connection mechanism and enables either JTAG-DP or SW-DP as the interface to the various on-chip debug/trace components.

16.2.3 AP Select Decoding

The recommendation for AP selects decoding is provided in the following table.

The selection of different access ports in the DAP is done based on the APSEL value set in the SELECT register of SWJ-DP. APSEL is 31:24 bit field of the DAP SELECT register. The APSEL will be decoded as given in the following table.

Table 173. Address Decoding for DAPBUSIC

Destination	DAPBUSIC_AP_SEL[31:24]
AHB-AP to CPU0 M33	00h (M0)
AHB-AP to CPU1 M33	01h (M1)
Debug Mailbox ISP-AP	02h (M2)
APB-AP0 to Advanced Peripheral Bus Interconnect (APBIC)	03h (M3) Refer to Decoding for APBIC
AHB-AP to system bus	04h (M4)
Reserved (Default AP response)	05h - FFh

Table 174. Decoding for APBIC

Destination	Identification Register (IDR)
HiFi4 DSP	5477_0002h
HiFi1 DSP	5477_0002h
EZH RISC-V Core	5477_0002h

From the interface of the debugger, serially feeding the “address” into a TAP controller via TDI, and once acknowledged, the associated data register is either streamed out on TDO or into on TDI. See the Arm Debug Interface Architecture Specification ADIv5.2 for more information about selecting and accessing Access Ports.

16.2.4 JTAGC and TLM

A TAP Linking Module (TLM) module is used to select the different JTAG TAPs inside the device.

- Port 0: JTAG (default port)
- Port 1: USB2.0 PHY

The selection between JTAG and SWD is performed by the SWJ-DP in the DAP. This is done by recognizing a sequence on the JTAG pins and therefore no additional switching of the JTAG scan chain is needed to support this Arm feature.

The JTAG command length is 4-bits. All JTAG TAPs operating in unison have the same Instruction Register (IR) width. This includes the Arm DAP’s TAP.

JTAGC and SWJ-DP share the same 5-pin JTAG interface from the PAD I/O pad of chip.

The JTAGC TAP follows the DAP TAP. If a the JTAGC TAP leaves the TAP Link Reset (TLR) state, then it is known that some activity is being performed on the JTAG port.

NOTE

IEEE 1149.7 interface is not supported.

16.2.4.1 JTAG IR Commands

Selection is based on the following table of decodes.

Table 175. Instruction Register

Instruction	Value	Module
EXTEST	0000b	JTAGC
SAMPLE	0001b	JTAGC
PRELOAD/SAMPLE	0001b	JTAGC
HIGHZ	0010b	JTAGC
CLAMP	0011b	JTAGC
IDCODE (JTAGC)	0100b	JTAGC
TEST_CTRL_REG	0111b	JTAGC
ABORT	1000b	Arm
DPACC	1010b	Arm
APACC	1011b	Arm
TEST_LEAKAGE	1100b	JTAGC
IDCODE (Arm)	1110b	Arm
BYPASS	1111b	JTAGC

16.2.4.2 JTAG and SWD

A special sequence on the JTAG state machine changes the DAP operation from the JTAG to SWD. This sequence is specified by Arm Ltd and fully recognized within the SWJ-DP's JTAG-DP.

SW-DP pins (TCK,TMS) are connected directly from and to chip pins.

When SW-DP is enabled, both JTAGC and JTAG-DP are disabled.

When SW-DP is disabled, the output to TDO from JTAGC and JTAG-DP are selected by a mux that is controlled by decode of the IR inside the JTAGC, and then connected to chip pins for debug and/or test purposes.

NOTE

By default, PIO0_0 must be externally pulled high to enable debug over SWD pins.

16.2.5 Debug over USB pins

This chip supports to debug over USB0 pins.

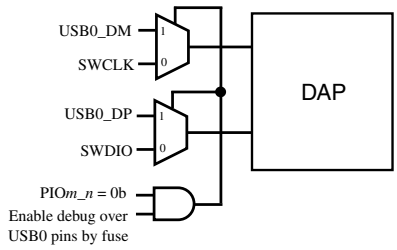

Figure 57. Debug over USB0 pins

In order to debug over USB0 pins, you need to:

1. Configure fuse to support debug over USB0 pins:

- Write 0b to BOOT_CFG8[DBG_OVER_USB_DIS] to enable debug over USB0 pin feature.
- Assign the port pin PIO*m_n* that will be used to enable debug over USB0 pins by BOOT_CFG8[DBG_OVER_USB_SEL_PORT] (*m*) and BOOT_CFG8[DBG_OVER_USB_SEL_GPIO] (*n*)

NOTE

PIO*m_n* must be an existent pin. PIO0_0 is the default pin to select debug over SWD or USB0. By default, PIO0_0 must be externally pulled high or low to enable debug over SWD or USB0. You can assign another existent port pin besides PIO0_0 to enable debug over SWD or USB0,

2. Configure the pin PIO*m_n* = 0b (low) to enable debug over USB0 pins.

NOTE

If BOOT_CFG8[DBG_OVER_USB_DIS] = 1b or PIO*m_n* = 1b (high), SWCLK and SWDIO are used as debug pins.

16.2.6 Trace

16.2.6.1 Trace Export

16.2.6.1.1 Embedded Trace Router (ETR)

The Embedded Trace Router converts ATB to AXI protocol so that trace data can be stored in chip addressable memory.

16.2.6.1.2 Arm CoreSight Trace Port interface (TPIU)

The TPIU is one of the targets for forwarded trace data from the Instruction Trace Macrocell (ITM). The TPIU is used to transfer trace information to the physical trace port of the device.

16.2.6.1.3 Serial Wire Output (SWO)

The device supports a serial wire output mechanism for trace. The output is muxed onto the TDO pin.

16.2.6.2 Trace Data Bus

The AMBA Trace Bus (ATB) is used to transport trace data from the trace source to the system memory or off-chip. ATB traces are routed in the chip through CoreSight SoC-400 ATB Funnel and ATB replicators.

16.2.7 Cross Triggering

Cross-triggering allows a condition recognized by one debug or trace block to be reacted to in another debug or trace block. Examples of this include multi-core halting, or having a core halt due to chip condition.

Cross-triggering is required between all major subsystems of the chip (those which have a core-like structure, or trace function STM, ETM, etc.) for debug purposes.

NOTE

SoC-400 CoreSight cross-triggering components are used, which require provided Cross Trigger Interface/Matrix (CTI/CTM) adapters to interface with compliant Arm cores and debug components.

The debug enable on the CTM and CTI blocks is connected to a chip wide debug enable. The effect is that selectively controlling cross-trigger only between two components is not supported. It is enabled or not-enabled globally.

The Cross-Triggering matrix include connections to:

- Cortex-M33 CPU cores
- HiFi4
- HiFi1

- EZH RISC-V
- ETR
- ETF
- Trigger connections to system interrupts

16.2.7.1 Embedded Cross Trigger (ECT)

Embedded Cross Trigger (ECT) comprises a set of CoreSight Cross Trigger Interface (CTI) and Cross Trigger Matrix (CTM) components connected together. The main function of the ECT is to pass debug events from one core to another. For example, the ECT can communicate debug state information from one core to another, so that program execution on both cores can be stopped at the same time if required.

The diagram below shows the structure of the ECT.

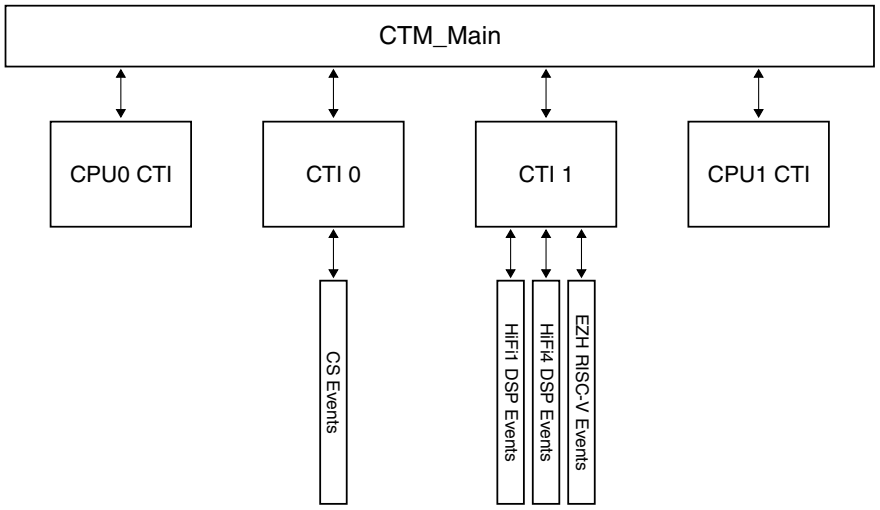

Figure 58. Embedded Cross Trigger Diagram

16.2.8 Timestamp

Timestamping on the device is performed with the use of several CoreSight components.

The Arm CoreSight Timestamp Generator is implemented in the system to provide a consistent view of time for the multiple blocks in the device. The 64-bit counter works in the Compute CPU0 CM33 clock domain and is the source of the time used by the following components:

- Cortex-M33 CPU0
- Cortex-M33 CPU1
- HiFi4
- HiFi1

16.2.9 JTAG IDCODE

The JTAG_IDCODE (JTAG ID) is a 32-bit identifier that identifies the chip silicon for the purpose of both debug and boundary scan access.

Table 176. JTAG_IDCODE

Device	JTAG_IDCODE
I.MXRT700	288C_C01Dh

Chapter 17
Audio Overview

17.1 Audio overview

The audio subsystem consists of an 8-channel MICFIL, which supports PDM input, hardware based voice activation detection (HWVAD), and decimation functions.. Some decimator outputs can be streamed to SAI module through a DMA operation. The subsystem also includes a Sigma-delta ADC (SDADC), which supports both line input mode and analog microphone input mode.

17.1.1 Block diagram

The audio block diagram is shown below:

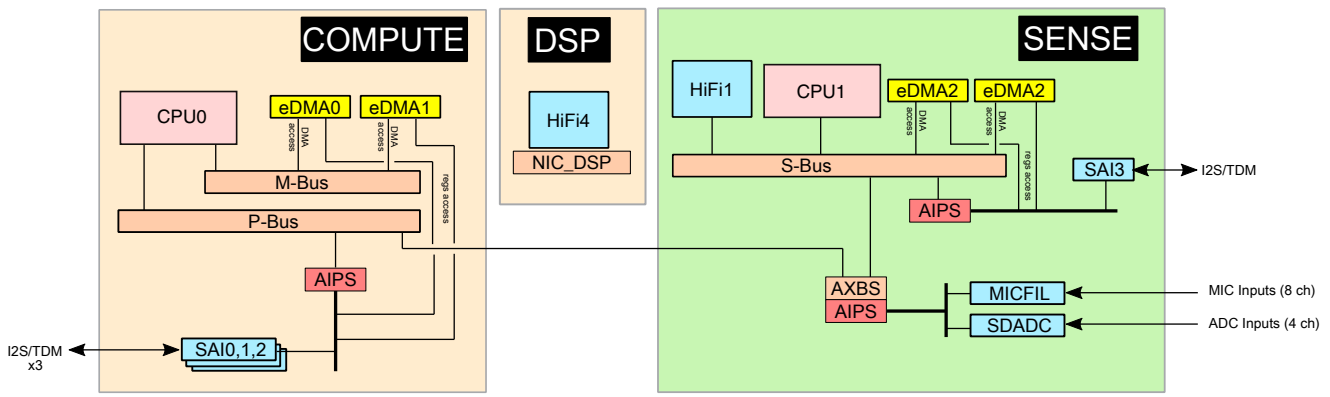

Figure 59. Audio block diagram

17.1.2 Modules

The following audio peripherals are part of this subsystem.

Table 177. Audio Modules

Modules	Instances	Description	Main Features
PDM Microphone Interface (MICFIL)	MICFIL	The PDM Microphone Interface (MICFIL) is used to receive audio from microphone. It supports 8-microphones (4 lanes) input and support for frame synchronization feature and Acoustic Overload Point (AOP) microphones for high quality audio applications. The MICFIL can support an ultrasonic channel on the same MICFIL input. There is a separate high frequency band pass filter that will route the ultrasonic channel data to a separate buffer.	• Decimation filters • FIFOs with interrupt and DMA capability • Hardware Voice Activity Detection (HWVAD) • Programmable PDM clock generator • MICFIL is in the Sense domain

Table continues on the next page...

Table 177. Audio Modules (continued)

Modules	Instances	Description	Main Features
Synchronous Audio Interface (SAI)	SAI0 SAI1 SAI2 SAI3	The SAI are synchronous serial interfaces used to transfer audio data.	• The microphone channel pair 0, 1 can be streamed to SAI0 through a DMA operation. • Transmitter and receiver with independent Bit Clock and Frame Sync • Asynchronous FIFO for each Transmit and Receive data line • SAI0 - SAI2 are in the Compute domain • SAI3 is in the Sense domain
Sigma Delta Analog-to-Digital Converter (SDADC)	SDADC	This ADC is a high dynamic range audio Analog-to-Digital Converter. It supports both line input mode and microphone input mode. It provides low latency decimation to enable Acoustic Noise Cancellation and Acoustic Echo Cancellation. It has a high input impedance to reduce its loading to input sources and to improve its robustness to interference. The DAC inside the SDADC can be used as a stand-alone DAC to provide a low-impedance voltage output.	• Low noise, high linearity ADC • Support single-ended and differential inputs • Support analog microphones: MEMS and JFET • SDADC is in the Sense domain
HiFi 1 DSP	HiFi1	This DSP resides in the Sense domain and is primarily intended for Always-On Applications, Bluetooth LE audio, and Sensor fusion.	• 2-slot machine with up to 64-bit load or storage bandwidth • Two-way SIMD ALU or MAC operations • Supports quad 16 x 16, dual 32 x 16-bit MACs, and single 32-bit MACs • HiFi1 is in the Sense domain
HiFi 4 DSP	HiFi4	This DSP is intended for efficient execution of audio and voice codecs, and pre- and post-processing modules.	• Support for four 32 x 32-bit MACs • Limited support for 72-bit accumulators • Support eight 32 x 16-bit MACs • Ability to issue two 64-bit loads per cycle. • Floating point unit included • HiFi4 is in the DSP domain
Enhanced Direct Memory Access (eDMA)	eDMA0 eDMA1 eDMA2 eDMA3	The eDMAs perform complex data transfers with minimal processor intervention. See Audio modules access to CPUs, DSPs and DMAs for specific information regarding audio module access to the eDMAs.	• eDMA0 and eDMA1 are 16-channel eDMAs. These reside in the Compute domain • eDMA2 and eDMA3 are 8-channel eDMAs. These reside in the Sense domain

17.2 Functional description

17.2.1 Audio modules access to CPUs, DSPs and DMAs

The following table shows which CPUs, DSPs and DMAs can access the audio modules.

Table 178. Audio modules access to CPUs, DSPs and DMAs

Module	CPU0 access?	HIFI4 access?	CPU1 access?	HIFI1 access?	eDMA0/ eDMA1 access?	eDMA2/ eDMA3 access?
MICFIL	yes	yes	yes	yes	yes	yes
SAI0-2	yes	yes	no	no	yes	no
SAI3	no	no	yes	yes	no	yes
SDADC	yes	yes	yes	yes	yes	yes

17.2.2 SAI module clocking

The following figure shows a detailed SAI clock multiplexing scheme.

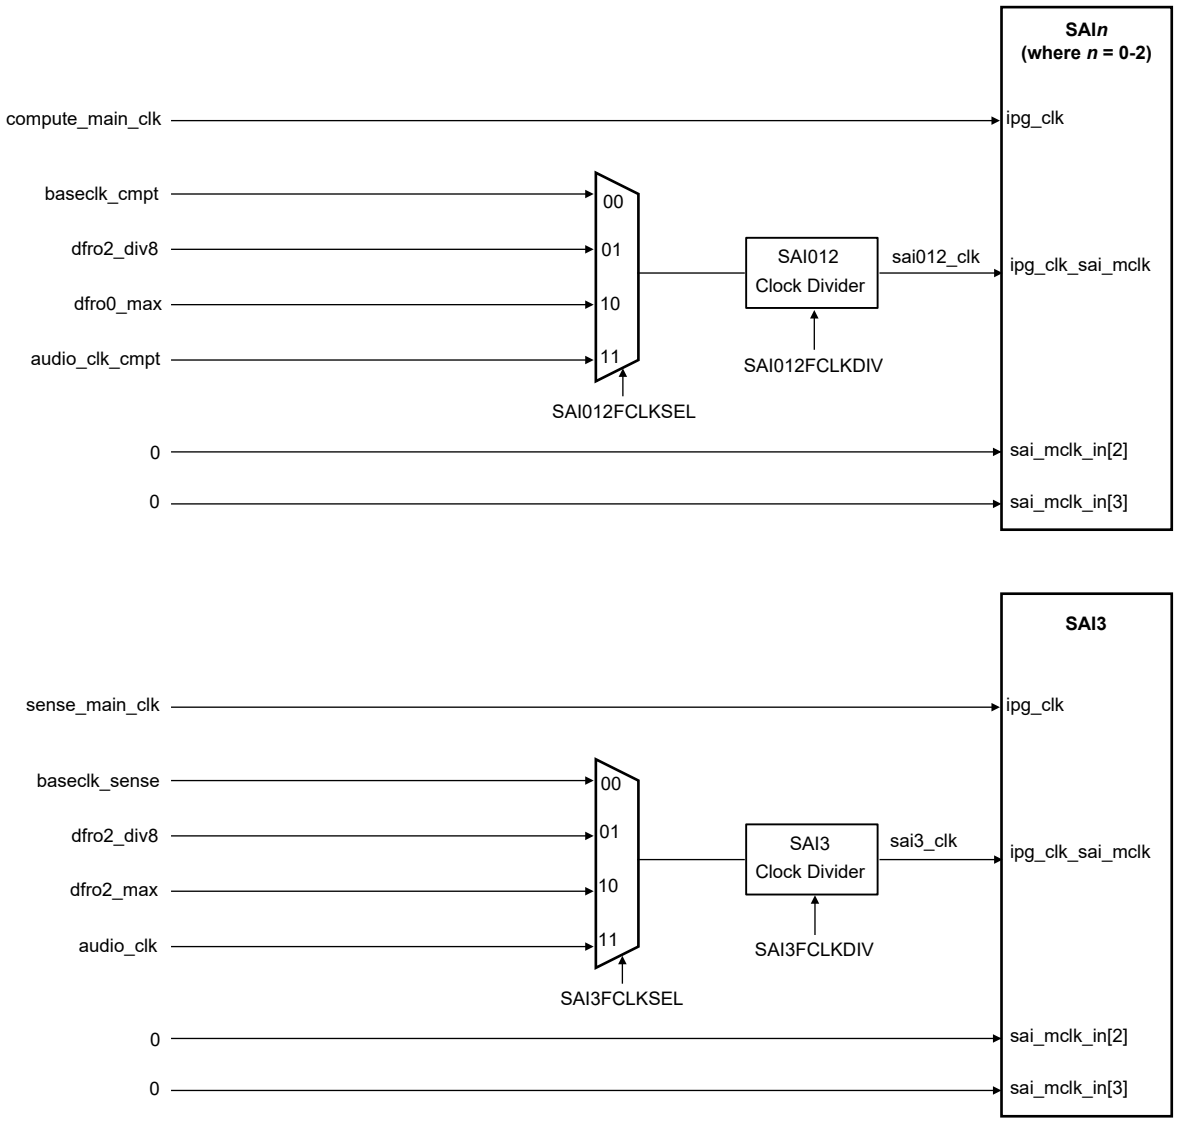

Figure 60. SAI clock multiplexing

NOTE

SAI012FCLKSEL, SAI012CLKDIV, SAI3FCLKSEL, and SAI3CLKDIV are CLKCTL registers.

The following figure shows muxing details for audio_clk and audio_clk_cmpt.

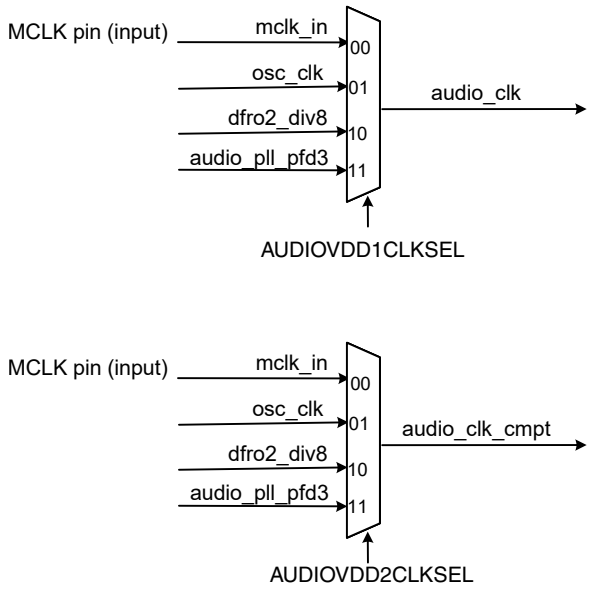

Figure 61. audio_clk and audio_clk_cmpt details

NOTE

AUDIOVDD1CLKSEL and AUDIOVDD2CLKSEL are CLKCTL registers.

See CLKCTL chapter for more clocking details. See SAI chapter for more SAI configuration information.

Chapter 18
Analog Overview

18.1 Analog Overview

This chapter covers the analog modules on this chip.

18.1.1 Block diagram

The analog block diagram is shown below:

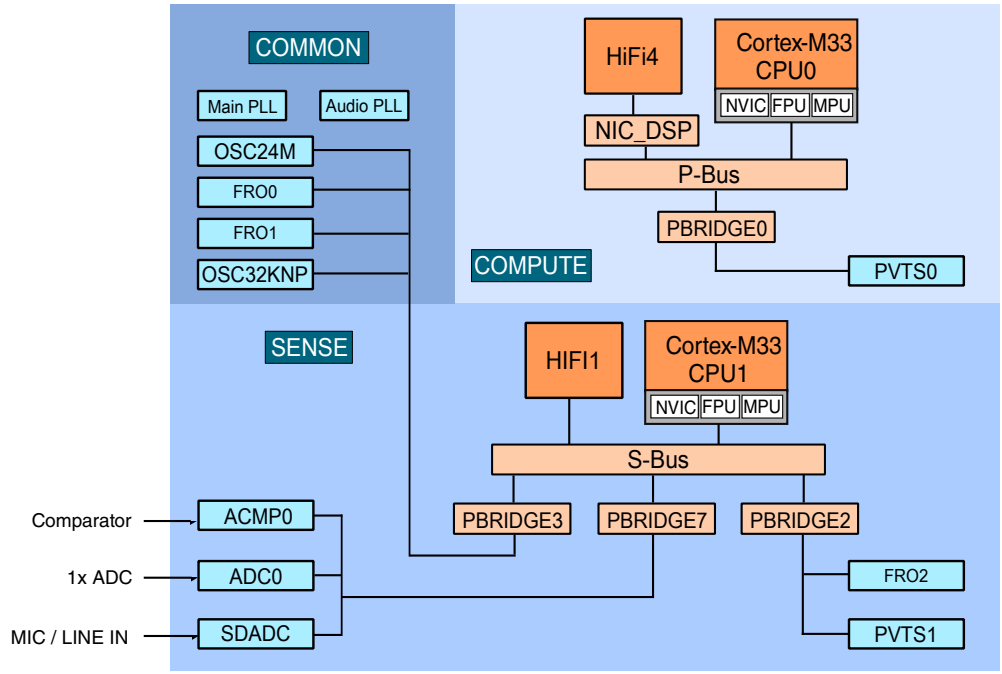

Figure 62. Analog block diagram

18.1.2 Modules

The following analog modules are part of this subsystem.

Table 179. Analog modules

Modules	Instances	Description	Main features
Analog-to-Digital Converter (ADC)	1	ADC is a dual successive approximation ADC designed for operation within an integrated microcontroller system-on-chip. ADC is in the VDD1_SENSE power domain.	• Linear successive approximation algorithm: differential operation with 16-bit or 13-bit resolution, single-ended operation with 16-bit or 12-bit resolution

Table continues on the next page...

Table 179. Analog modules (continued)

Modules	Instances	Description	Main features
			• One ADC supports for two simultaneous single ended conversions • Channel support for up to 64 analog input channels for conversion of external pins and from internal sources
Sigma Delta Analog-to-Digital Converter (SDADC)	1	SDADC is a low-power high-performance audio ADC system. It mainly targets battery- powered, hearable and wearable audio devices. It supports analog microphone and line inputs. Decimation filter is also part of this system. The decimation filter has low latency to enable acoustic noise and echo cancellation. SDADC is in the VDD1_SENSE power domain.	• Low noise, high linearity ADC • Low power modulator • Supports sampling frequencies of 16kHz, 32kHz, and 48kHz • Support single-ended and differential inputs • Support analog microphones: MEMS and JFET
Comparator (ACMP)	1	ACMP includes high-speed Comparator, DAC, and ANMUX modules. The high speed comparator (CMP) module provides a circuit for comparing two analog input voltages. The comparator circuit operates across the full range of the supply voltage, known as rail-to-rail operation. The Analog MUX (ANMUX) module provides a circuit for selecting an analog input signal from eight channels. One signal is provided by the 8-bit digital-to-analog converter (DAC). The mux circuit is designed to operate across the full range of the supply voltage. The DAC module is a 256-tap resistor ladder network that provides a selectable voltage	• CMP features: — Operational over the entire supply range — Rail to rail inputs — Programmable hysteresis control • DAC features: — 8-bit resolution — Selectable supply reference source — Configurable low power mode or high speed mode • ANMUX features: — Two 8-to-1 channel MUXes for selection of the source for comparator input

Table continues on the next page...

Table 179. Analog modules (continued)

Modules	Instances	Description	Main features
		reference for applications requiring a voltage reference. The 256-tap resistor ladder network divides the supply reference Vin into 256 voltage levels. A 8-bit digital register input selects the output voltage level, which varies from Vin to Vin/256. Vin can be selected from two voltage sources, Vin1 or Vin2. ACMP is in the VDD1_SENSE power domain.	— Operational over the entire supply range
Process, Voltage, and Temperature Sensor (PVTS)	2	PVTS delivers a digital output that indicates if junction temperature is above or below a given temperature threshold. PVTS0 is in the VDD2_COM power domain, and PVTS1 is in the VDD1_SENSE power domain.	• Programmable threshold value from -45 °C to 130 °C with better than 1.5 °C resolution • Configurable to continuously monitor a specific temperature threshold
Nano Power 32 kHz Oscillator (OSC32KNP)	1	OSC32KNP contains AIP and DIP. The AIP is an analog IP designed to provide 32.768 kHz clock to SoC with an external. The DIP is used to configure AIP and monitor the stability of clock. OSC32KNP is in the VDD1V8_AON power domain.	• Supports 32.768 kHz clock to SoC • Configurable clock accuracy • Capability to support clock in high power mode and low power mode
FRO Clock Generator (FRO_TUNER)	3	FRO_TUNER module provides a trimmable system clock. FRO_TUNER0 and FRO_TUNER1 are in the VDD2_COM power domain, and FRO_TUNER2 is in the VDD1_SENSE power domain. FRO_TUNER0 and FRO_TUNER1 are part of the memory slot of CLKCTL0, and FRO_TUNER2 is part of the memory slot of CLKCTL3.	• Trimmable FRO output • Programmable FRO post divider • Loss of trimmed lock Interrupt request

Table continues on the next page...

Table 179. Analog modules (continued)

Modules	Instances	Description	Main features
XTAL Oscillator (OSC24M)	1	OSC24M module provides the main crystal oscillator that can be used as an internal clock source. OSC24M is in the VDDN_COM power domain. OSC24M is part of the memory slot of CLKCTL2.	See CLKCTL section for information on OSC24M.
PLL	2	PLL contains a Main System PLL and an Audio PLL	See Clocking section for information on PLLs.

Chapter 19
Security Overview

19.1 Overview

This chapter provides an overview of the following chip security components, explaining the purpose and features of each of them.

More information can be found in the Security Reference Manual for this chip.

19.1.1 System diagram

The following shows a simplified security system diagram.

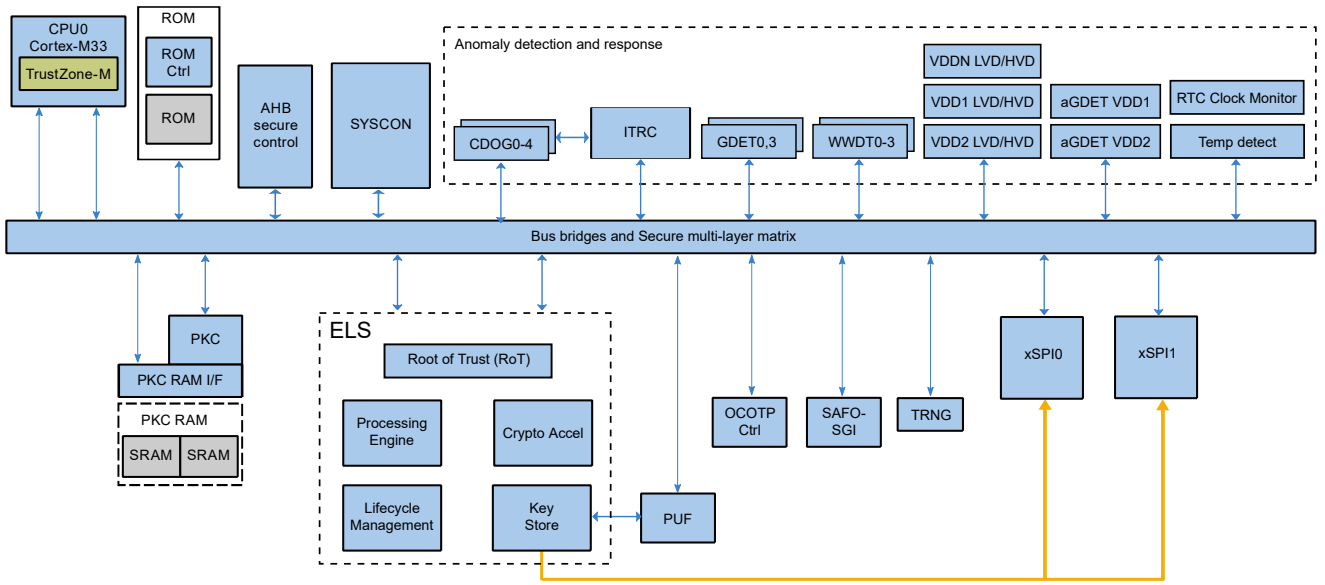

Figure 63. Security system diagram

NOTE

The High Voltage Detectors (HVD), Low Voltage Detectors (LVD), Analog Glitch Detectors (aGDET), and Temperature Detector are part of the Power Management Controller (PMC). See the PMC chapter for more information on these detectors.

19.1.2 Modules

The following modules are security components of the chip:

Table 180. Security subsystems and modules

Modules	Description
Secure Isolation components	
Arm TrustZone	Arm's TrustZone for Armv8-M architecture included as part of the Cortex-M33 complexes
Secure bus control	NXP's Secure AHB Bus Controller

Table continues on the next page...

Table 180. Security subsystems and modules (continued)

Modules	Description
Cryptographic Accelerators	
ELS	EdgeLock Secure Subsystem
PKC	Public Key Crypto Co-processor
SAFO_SGI	Symmetric Cryptographic Accelerator
Key Management	
ELS	Part of ELS provides this function
SRAM-PUF	Physical Unclonable Function to create device unique Root of Trust (RoT) key
Security Configuration Storage	
OCOTP Control	OTP controller to store security configuration
Anomaly Detection and Response	
aGDET	Two Analog glitch sensors - one for each security-sensitive voltage rail
GDET	Two Digital Glitch Detectors connected to voltage rails
ITRC	Intrusion and Tamper Response controller to configure response sequence to detected security events
LVD/HVD	Low-Voltage (LVD) and High-voltage (HVD) Detectors per voltage rail
RTC Clock Monitor	Clock frequency monitor for 32KHz RTC crystal oscillator and main oscillator
CDOG	Five Code Watchdog controllers (3x Compute domain, 2x Sense domain)
Boot ROM	
Boot ROM Security Features	• Secure boot providing ECDSA signature verification as per NIST P-256 and P-384 curves • Secure update using SB3.1 file format. Supports firmware update mechanism with authenticity (ECDSA P-256/P-384 signed) and confidentiality (AES-CBC encrypted and SHA256 chained) protection • Secure Debug: Certificate based debug authentication mechanism using ECDSA P-256 and P-384 keys • Secure Provisioning • Secure Identity solutions
Secure Storage	
ELS key store	Support for OTP-based device unique key as well as SRAM-PUF device unique key **Note:** ELS key store generated from SRAM-PUF based device unique key supported only when external non-volatile memory is available
IPED	Inline Prince Encryption and Decryption engine (IPED) for off-chip flash with option to select regular counter mode (CTR) or Galois Counter mode (GCM) per region for code storage and data

19.2 Functional description

19.2.1 Root of Trust (RoT)

The Root of Trust (RoT) consists of truly immutable hardware logic, including analog and digital logic, read-only memory and one-time programmable memory. Immutable RoT is essential for guaranteeing any security feature, including Secure Boot, Secure Debug, Life-cycle Management, and a number of others. In this device, Immutable RoT is embedded in the Boot ROM (immutable bootloader). It uses the device hardware cryptographic functionality for its function.

19.2.2 Life-cycle management

During its lifespan, a typical device finds itself in various places around the world. It is manufactured in a semiconductor factory, tested and packaged in silicon manufacturer facilities, sold to various distributors, sold further to the Original Equipment Manufacturer (OEM), assembled, tested and provisioned by their Contract Manufacturers and, finally, delivered to the end customer. In the case of failure, a device is returned to OEM or even back to the silicon manufacturer for further failure analysis.

Device life-cycle state is used to reflect the actual state of the device, which is further used to instruct the device on how exactly to protect the assets a device hosts during specific time. For example, when a device is being tested at a silicon manufacturer facility and no OEM or end-customer assets have been provisioned on it, then access to the device, in terms of debug or test, is less restrictive than when a device is with the end-customer.

Life-cycle state is monotonic, meaning it can only be increased. Transition between different life-cycle states is an irreversible process. Immutable RoT is in charge of life-cycle management and it enforces device access policies accordingly.

19.2.3 Secure boot

Secure Boot ensures authenticity, integrity and confidentiality of the device bootloader, firmware, and other software during the boot process and ensures that the intended secure life-cycle state is reached. ECDSA P-256 with SHA-256 or ECDSA P-384 with SHA-384 are there to guarantee authenticity and integrity of the firmware image. Immutable RoT is in charge of enforcing Secure Boot and it does so according to the policies defined by the life-cycle state.

19.2.4 Secure update

Secure Update is the process used to securely update the firmware image in the field. On this chip, the ROM supports secure update using SB3.1 file format. The SB3.1 file is encrypted usingAES-128 or AES-256 and signed using ECDSA P-256 or ECDSA P-384.

Secure Update provides authenticity and confidentiality of the new image. It can also include image rollback protection.

19.2.5 Secure debug

Secure Debug is the process used to securely access debug, following the policy defined by the life-cycle state.

See the Security Reference Manual for more information.

19.2.6 IP protection

IP Protection is a set of mechanisms used to protect confidentiality and integrity of valuable code and data stored on the device.

PRINCE-based memory encryption can be used to provide confidentiality for code/data stored in external flash. Up to 16 independent memory regions/context are supported for XSPI0 and XSPI1.

19.2.7 Secure isolation

The chip has multiple functional domains and power domains with bus architecture partitioned for a balance of optimal performance and power efficiency based on target applications. The chip uses the following components to provide secure isolation:

- ELS with dedicated processing engine and cryptographic accelerators providing fully isolated security functions

- Additional isolation is provided using ARM TrustZone for Armv8-M architectures
  - Memory Protection Unit (MPU) inside Cortex-M33 core. Both CPU0 and CPU1 have 8 MPU regions
  - Security Attribute Unit (SAU) inside Cortex-M33 core. Both CPU0 and CPU1 have 8 SAU regions
- Secure AHB Bus Controller (AHBSC) module provides register to define which domains can access shared SRAM and peripherals present in common and sense domains. See the Security Reference Manual for more information

19.2.8 Secure attestation

Secure Attestation is a set of mechanisms used to provide evidence to a remote party on the device's genuine identity, its software and firmware versions, as well as its integrity and life-cycle state. Runtime Fingerprint (RTF) is the NXP-proprietary attestation mechanism, which measures the device's state during boot-time and run-time as well.

19.2.9 Secure storage

ELS Key store with the following two key hierarchies are supported on this chip:

- SRAM-PUF generated Device Unique Key (DUK)
- OTP-based DUK

NOTE

SRAM-PUF generated DUK is only supported in the case where external non-volatile memory is available.

In the case that the ELS key store is generated from SRAM-PUF-based device unique key, Inline Prince Encryption and Decryption engine (IPED) is used for off-chip flash with option to select regular counter mode (CTR) or Galois Counter mode (GCM) per region for code storage and data.

In the case of the OTP-based DUK hierarchy, the DUK is derived from OTP seed and ELS commands. This key is then used to derive memory encryption (PRINCE) keys. For more information, see the Security Reference Manual for this chip.

19.2.10 Trust provisioning

Trust provisioning is a process used for creation of initial Device Identity keys. Its major objective is to provide a cryptographic proof of the device's origin and to offer a set of tools to OEM for secure provisioning of their own assets. A device-unique private-public key pair is created on every device, the public portion of which is collected and signed by NXP. That signed public key is installed back onto every device in a form of a device-unique certificate, which serves as the actual proof of the device's origin. The corresponding private key, together with other pre-installed key, is then used for authentication and secure connection to the device, enabling secure provisioning of OEM assets.

19.2.11 Secure key management

Secure key management is a process of securing valuable keys and various key material which are essential in maintaining security of the end-user, OEM, and NXP assets. The process strongly relies on the Immutable RoT consisting of ELS Key store, hardware logic, and ROM. A device-unique master key is provided and only used for further key derivation. Part of the derivation data is supplied by the Immutable RoT, accurately reflecting the device's state, making sure different keys are derived in different states. For example, different life-cycle state will often yield a different derived key. Similarly, when the debug port is open a different key will be derived than when the debug port is closed. All the platform keys reside within a security subsystem, hidden from the application core at all times.

See Secure storage and the chip's Security Reference Manual for more information.

19.2.12 Anomaly Detection and Reaction

Anomaly Detection and Reaction describes the processes or algorithms that analyze the device input and output such as sensor data, as well as the software integrity and application operation for abnormal events and, if required, trigger and execute a user-defined security application (e.g. logging the anomaly, issuing a message to the cloud backend, resetting the device, and changing the life-cycle state).

Chapter 20
IO PAD Controller (IOPCTL)

20.1 Chip-specific IOPCTL information

Table 181. Reference links to related information

Topic	Related module	Reference
Full description	IOPCTL	IOPCTL
Peripheral memory map		Memory map overview
Clocking		Clock overview Clock controller
Power management	PMC	Power overview PMC
Signal multiplexing		External signals and pin multiplexing
General-purpose input and output	GPIO	General-purpose input and output

20.1.1 Module instances

This device has 3 instances of the IOPCTL module: IOPCTL0, IOPCTL1 and IOPCTL2.

Each IOPCTL supports to configure each pad (bond wired to pin) including function selection (IO muxing) for the corresponding pad. The function 0 (0000b) of IOPCTL.PIO*x_y*[FSEL] is for GPIO.

Table 182. IOPCTL instances

	IOPCTL0	IOPCTL1	IOPCTL2
Control pins in	GPIO0-GPIO3	GPIO8-GPIO10, PMIC_I2C	GPIO4-GPIO7
Control pins[1]	PIO0_0-31, PIO1_0-19, PIO2_0-15, PIO3_0-14	PIO8_0-1, PIO9_0-2, PIO10_0-17, PMIC_I2C_SDA/SCL	PIO4_0-20, PIO5_0-20, PIO6_0-12, PIO7_0-25
Located in	VDD2_COM	VDD1_SENSE	VDDN_COM
Access	CPU0, HiFi4, EZH-V, eDMA0, eDMA1	CPU0, CPU1, HiFi4, HiFi1, EZH-V, eDMA0, eDMA1, eDMA2, eDMA3	CPU0, CPU1, HiFi4, EZH-V, eDMA0, eDMA1, eDMA2, eDMA3
ipg_clk_s clock source	COMPUTE_MAIN_CLK	SENSE_MAIN_CLK_1	COMMON_VDDN_CLK

1. Not all the pins are available for each package, see Pin assignments for more details.

20.2 Overview

IOPCTL provides IO pad control functions. Each port pin PIOm_n has one IOPCTL register assigned to control the characteristics of the pin.

20.2.1 Block diagram

Figure 64 is the block diagram for PIO0, PIO1 and PIO3-PIO7.

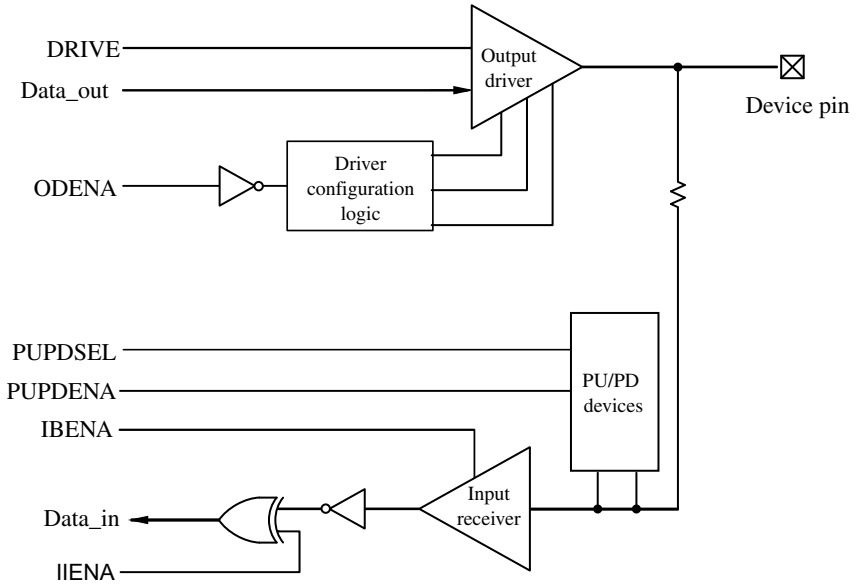

Figure 64. IO cell block diagram 1

Figure 65 is the block diagram for PIO2, PIO8-PIO10, and PMIC_I2C. PMIC_I2C has no DRIVE.

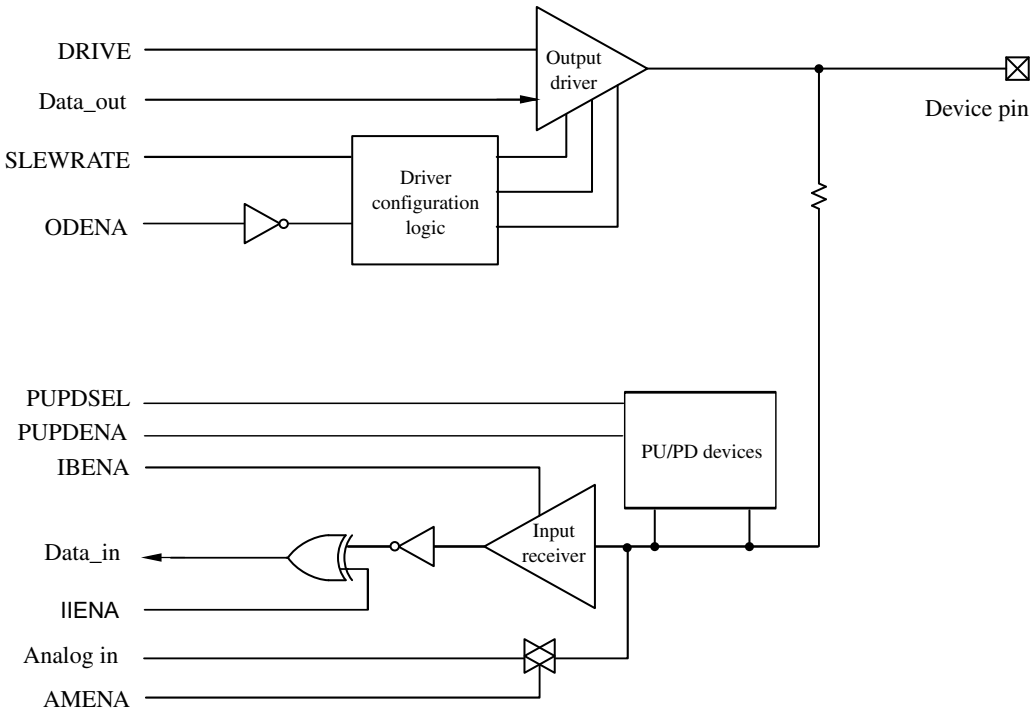

Figure 65. IO cell block diagram 2

Figure 66 shows the Data_out and Data_in in the above two figures.

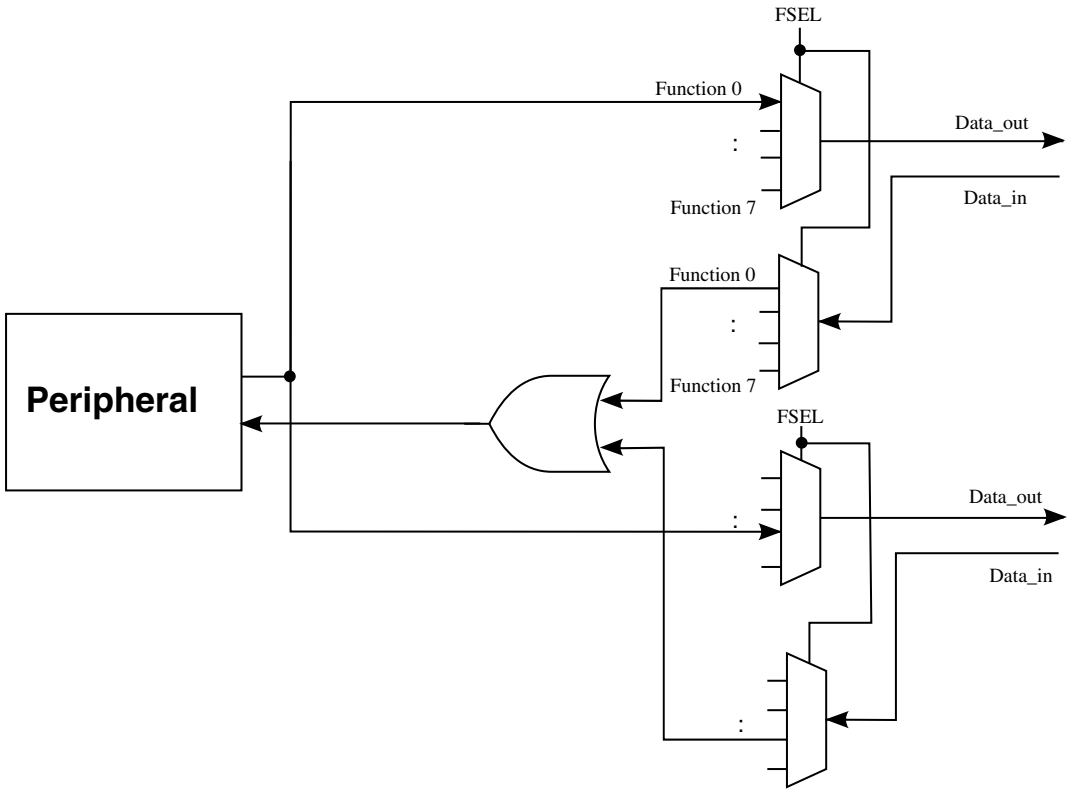

Figure 66. Function selector block diagram

20.2.2 Features

- Function selection from among the available functions for each pin.
- Pull-up resistor, pull-down resistor, or neither.
- Input buffer enable/disable.
- Slew rate.
- Drive strength.
- Analog multiplexor enable for pins that include an analog function.
- Simulated open-drain mode.
- Inverted input function.

20.3 Functional description

20.3.1 Clocking

Table 183. IOPCTL clock

Type of clock	Description
Module clock (ipg_clk_s)	Functions the module and controls the access to the registers.

See the chip-specific information for more details.

20.4 Signals

See External Signals and Pin Multiplexing for details on the available port pins and functions supported.

20.5 Initialization

This module has no initialization considerations.

20.6 Memory map and register definition

This section includes the IOPCTL module memory map and detailed descriptions of all registers.

The IOPCTL registers control the functions of device pins. Each GPIO pin has a dedicated control register to select its function and characteristics. Each pin has a unique set of functional capabilities. Not all pin characteristics are selectable on all pins. For instance, pins that have an I^2C function can be configured for different I^2C-bus modes, while pins that have an analog alternate function have an analog mode can be selected.

Since a particular peripheral function may be allowed on more than one pin, it is possible to configure more than one pin to perform the same function. If a peripheral output function is configured to appear on more than one pin, it will in fact be routed to those pins. If a peripheral input function is defined as coming from more than one source, the values will be logically combined, possibly resulting in incorrect peripheral operation. Therefore care should be taken to avoid this situation.

The IOPCTL registers support only the 32-bit accesses.

20.6.1.2 IOPCTL Configuration (PIO0_0 - PIO3_14)

Offset

Registers in this array exist only for the following combinations of index values.

Index *y*	Index *x*
0	0–31
1	0–19
2	0–15
3	0–14

Register	Offset
PIOy_x	0h + (y × 80h) + (x × 4h)

Function

Each port pin PIO has one IOPCTL register assigned to control the characteristics of the pin.

Field	Function
AMENA	Enables analog multiplexor. 0b - Disables for digital pin function 1b - Enables for analog pin function
8 —	Reserved
7 SLEWRATE	Slew Rate Control Enables the output slew rate control to limit the output rate change and maximum toggle frequency. This effect is voltage and load dependent, see datasheet for details. 0b - Disables. Standard mode. 1b - Enables. Slow mode.
6 IBENA	Input Buffer Enable Enables the input buffer for digital functions. It can be disabled when not needed and must be disabled when the pin is used for an analog function. Input buffer is not needed for a GPIO that is used as an output and is never read back by software. Peripheral functions that are generally outputs do need the input buffer enabled because the peripheral uses it to sense the situation on the pin as part of its function. If there is any doubt, it is best to leave the input buffer enabled 0b - Disables 1b - Enables
5 PUPDSEL	Pullup or Pulldown Selector Enables the internal pull-up or pull-down resistor when PMIC_I2C_SDA[PUPDENA]=1. 0b - Enables the internal pull-down resistor. 1b - Enables the internal pull-up resistor.
4 PUPDENA	Pullup / Pulldown Enable Enables internal pull resistor on the pin. 0b - Disables 1b - Enables
3-0 —	Reserved

20.6.3.2 IOPCTL Configuration (PIO4_0 - PIO7_25)

Offset

Registers in this array exist only for the following combinations of index values.

Index *y*	Index *x*
4–5	0–20
6	0–12
7	0–25

Register	Offset
PIOy_x	-200h + (y × 80h) + (x × 4h)

Function

Each port pin PIO has one IOPCTL register assigned to control the characteristics of the pin.

Chapter 21
Pin Interrupt and Pattern Match (PINT)

21.1 Chip-specific PINT information

Table 184. Reference links to related information

Topic	Related module	Reference
Full description	PINT	PINT
Peripheral memory map		Memory map overview
Clocking		Clock overview Clock controller
Signal multiplexing	IOPCTL	External signals and pin multiplexing IO PAD controller
Input multiplexing	INPUTMUX	See PINT0_TRIG0 - PINT0_TRIG7 registers in INPUTMUX0 and PINT1_TRIG0 - PINT1_TRIG3 registers in INPUTMUX1.

21.1.1 Module instances

This device has two instances of the PINT module, PINT0 and PINT1.

PINT0 interrupt 0-7 are used to interrupt CPU0 and PINT1 interrupt 0-3 are for CPU1 interrupt. The edge and level interrupts are supported even as a wake-up source of the sleep and deep-sleep modes.

Table 185. PINT instances

21.1.2 PMCFG[CFGy] configuration for LPUART

When an LP_FLEXCOMM is used as LPUART, and the related LP_FLEXCOMMx_TRIG[TRIGIN] in INPUTMUX is configured as 1100b to select PINT Boolean pattern-match output as input trigger , the related PMCFG[CFGy] must not be configured as 111b (Event).

21.1.3 Initialization

- Select up to eight external interrupt pins from all available digital port pins on ports 0 and 1 in INPUTMUX. The pin selection process is the same for pin interrupts and the pattern match engine. The two features are mutually exclusive.
- Enable the clock to the PINT0 module via CLKCTL0_PSCCTL3[PINT0] and enable the clock to the PINT1 module via CLKCTL1_PSCCTL1[PINT1].

- Clear the PINT0 peripheral reset via RSTCTL0_PRSTCTL4[PINT0] or RSTCTL0_PRSTCTL4_CLR[PINT0] and clear the PINT1 peripheral reset via RSTCTL1_PRSTCTL0[PINT1] or RSTCTL1_PRSTCTL0_CLR[PINT1].

21.1.3.1 Pin interrupts initialization

In addition to the initialization steps described above, for Pin Interrupts initialization do the following:

- Each selected pin interrupt is assigned to one interrupt in the INPUTMUX. Note that 8 are available for PINT0 and 4 are available for PINT1.

21.1.3.2 Pattern Match Initialization

In addition to the initialization steps described above, for Pattern match engine initialization do the following:

- Each bit slice of the pattern match engine is assigned to one interrupt (see INPUTMUX). Note that 8 are available for PINT0 and 4 are available for PINT1.

21.1.3.3 Configure pins as pin interrupts or as inputs to the pattern match engine

1. Determine the pins that you want to serve as pin interrupts or pattern match inputs. See the data sheet for determining the GPIO port pin number associated with the package pin.
2. For each pin selected, program the GPIO port pin number from port 0 into one of the eight PINT0_TRIG registers and port 1 into one of the four PINT1_TRIG registers in the INPUTMUX module.

   NOTE

   The port pin number serves to identify the pin to the PINT_TRIG register. Any function, including GPIO, can be assigned to this pin via IOPCTL.

3. Enable each pin interrupt in the PINT.

Once the pin interrupts or pattern match inputs are configured, the pin interrupt detection levels or the pattern match boolean expression can be set up.

NOTE

The inputs to the Pin interrupt select registers bypass the IOPCTL function selection. They do not have to be selected as GPIO in IOPCTL. Make sure that no analog function is selected on pins that are input to the pin interrupts.

21.2 Overview

The Pin Interrupt and Pattern Match (PINT) IP provides interrupt functionality for a selected set of GPIO pins. Per-pin edge- or level-sensitive interrupts can be generated. This IP also includes a pattern match engine that uses the selected GPIO pins as inputs to a Boolean expression. When the expression is satisfied, an interrupt is generated.

21.2.1 Block diagram

From all available GPIO pins, select up to 8 pins in the INPUTMUX module to serve as external interrupt pins (see the "INPUTMUX" chapter for more details). Each external interrupt pins connect to eight individual interrupts in the NVIC. It is possible to create external interrupt pins based either on rising or falling edges or on the input level.

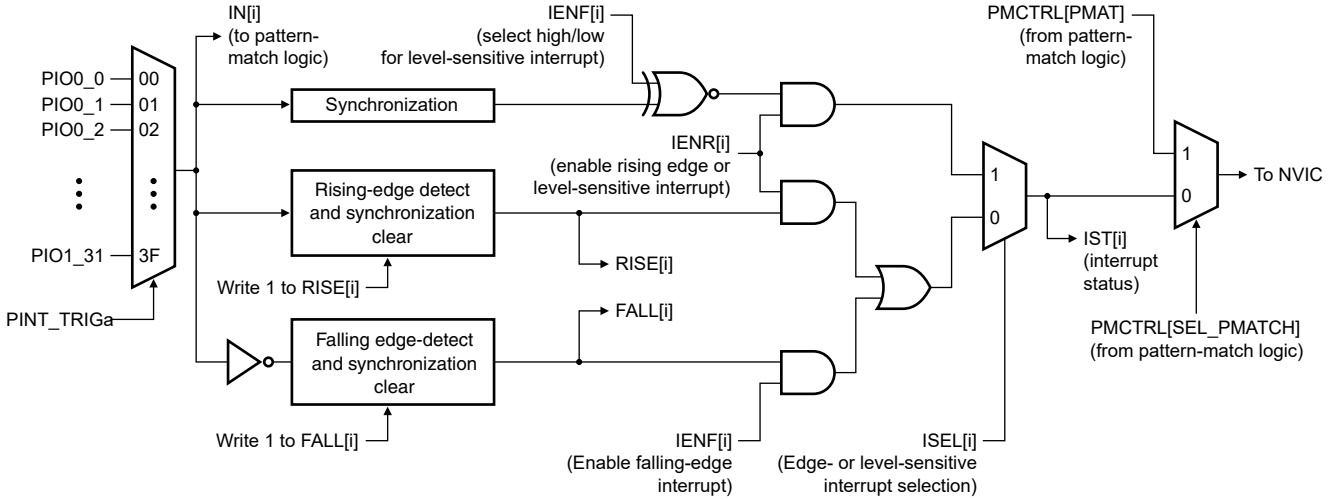

Figure 67. Pin Interrupt diagram

21.2.2 Features

- Pin interrupts
  - Select up to 8 pins from all GPIO pins on ports 0 and 1 as edge- or level-sensitive interrupt requests. Each request creates a separate interrupt in the NVIC.
  - Edge-sensitive interrupt pins interrupt on rising or falling edges or both.
  - Level-sensitive interrupt pins are high- or low-active.
- Pattern-match engine
  - Select up to 8 pins from all digital pins on ports 0 and 1 to contribute to a Boolean expression. The Boolean expression consists of specified levels and/or transitions on various combinations of these pins.
  - Each bit slice minterm (product term) consisting of the specified Boolean expression can generate its own, dedicated interrupt request.
  - You can program any occurrence of a pattern match to generate a Receive Event (RXEV) notification to the CPU.
  - Use pattern match, in conjunction with software, to create complex state machines based on pin inputs.

21.3 Functional description

21.3.1 Pattern-match engine

With pattern matching, you can construct complex Boolean expressions using the same set of 8 GPIO pins you selected for interrupts. Implement each term in the Boolean expression as one slice of the pattern-match engine. A slice consists of an input selector and detection logic that continuously monitors the selected input and creates a HIGH output (true). If the input qualifies as detected, several terms combine to a minterm. Assertion of a pin interrupt occurs when the minterm evaluates as true.

The detection logic of each slice can detect the following events on the selected input:

- Edge with memory (sticky): A rising edge, a falling edge, or a rising or falling edge that is detected at any time after the edge-detection mechanism has been cleared. The input qualifies as detected (the detection logic output remains high) until the pattern-match engine detect logic is cleared again.
- Event (nonsticky): Every time an edge (rising or falling) is detected, the detection logic output goes HIGH. After one clock cycle, writing 1 to this bit enables the detection logic to detect another edge.
- Level: A high or low level on the selected input.

The following figure shows the details of the edge-detection logic for each slice.

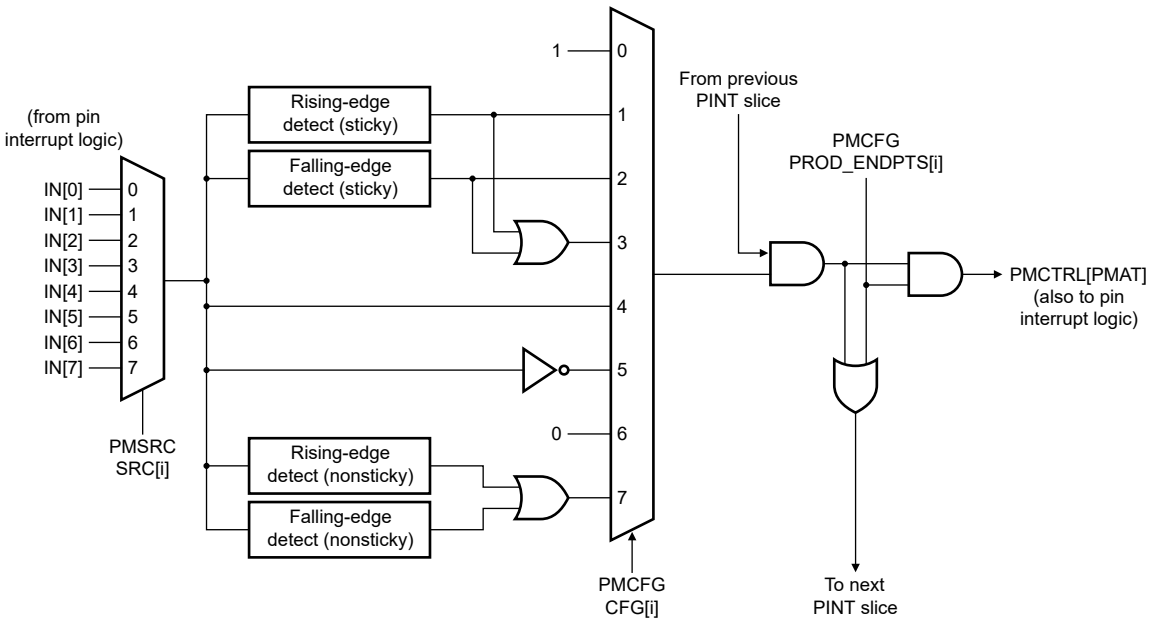

Figure 68. Pattern-match bit slice

Combined sticky and nonsticky events form a pin interrupt whenever a rising or falling edge occurs after a qualifying edge event.

Combining a level detect with an event detect can create a time window during which rising or falling edges will create a pin interrupt. See Pattern-match engine edge-detect examples for details.

The following figure shows connections between the pins and the pattern-match engine. The INPUTMUX block selects all pins that are inputs to the pattern-match engine and can be GPIO port pins or other pin functions depending on the configuration.

NOTE

The pattern-match feature requires clocks in order to operate. It cannot generate an interrupt or wake the chip during reduced power modes below sleep mode.

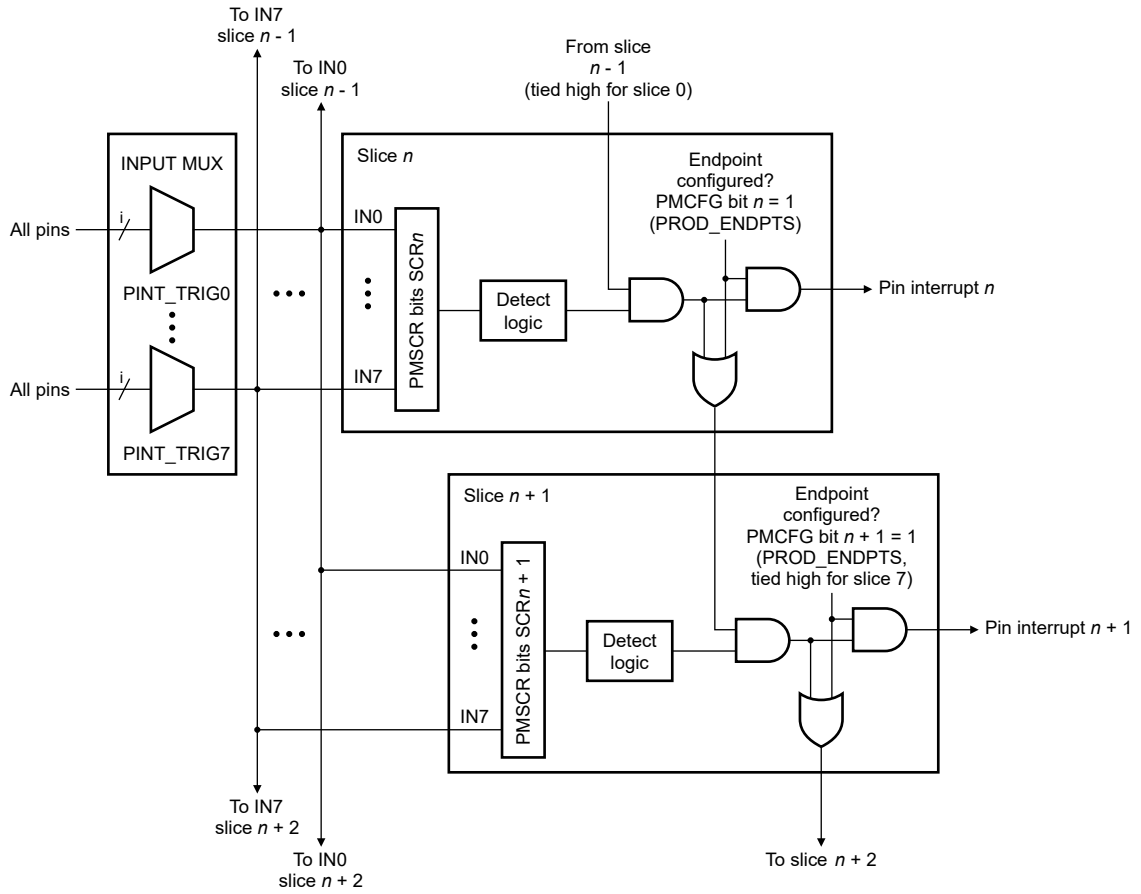

Figure 69. Pattern-match engine connections

The pattern-match logic continuously monitors the 8 inputs and generates interrupts when any one or more minterms (product terms) of the specified Boolean expression match. Each individual minterm generates a separate interrupt request.

It is also possible to enable the pattern-match module to generate RXEV output if any minterm in the Boolean expression matches.

The pattern-match function uses the same 8 interrupt request lines as the pin interrupts. Therefore, in terms of interrupt generation, these two features are mutually exclusive. Control bit generates interrupt requests based on standard pin interrupts or pattern matches. When selecting the pin interrupts, enable the RXEV request to the CPU for pattern matches.

NOTE

Do not use pattern matching to wake the part from deep-sleep mode. Pin interrupts must be selected in order to use the GPIO for wake-up.

8 bit-slice elements make up the pattern-match module. Each bit slice represents a single component in a minterm (product term) within the Boolean expression. Every time the last bit slice for a particular minterm matches, an interrupt request is asserted.

Use the pattern-match capability to create complex software state machines. Each minterm (and its corresponding individual interrupt) represents a different transition event to a new state. Then establish the new set of conditions (that is a new Boolean expression) to make a transition out of the current state.

21.3.2 Clocking

The PINT module has a single clock input, the APB PCLK.

This clock is used for its APB interface, as well as all other peripheral functionality. It must be enabled by the system for register accesses and pattern matching.

21.3.3 Interrupts

The PINT module has 8 interrupt channels, which can be configured by its registers. Each channel has its own interrupt output. Depending on how this IP is integrated, the interrupt outputs can be ORed together to use a single system-level interrupt.

21.4 External signals

PINT_TRIGa determines the inputs to the pin interrupt and pattern-match and engines. See the "INPUTMUX" chapter for more details.

21.5 Initialization

For initialization steps, see chip-specific section.

21.6 Application information

Pattern-Match Interrupt Bit-Slice Source (PMSRC) and Pattern-Match Interrupt Bit Slice Configuration (PMCFG) specify the following expression:

```
IN0 AND NOT IN1 AND IN3 rising edge OR IN1 AND IN2 OR IN0 AND NOT IN3 AND NOT IN4
```

Each term in the Boolean expression, IN0, NOT IN1, IN3 rising edge, and so on, represents one bit slice of the pattern-match engine.

- In the first AND function IN0 AND NOT IN1 AND IN3 rising edge, bit slice 0 monitors for a high level on input IN0, bit slice 1 monitors for a low level on input IN1, and bit slice 2 monitors for a rising edge on input IN3. Detecting this combination of features (all three terms are true) asserts the interrupt associated with bit slice 2.
- In the second AND function IN1 AND IN2, bit slice 3 monitors input IN1 for a high level and bit slice 4 monitors input IN2 for a high level. Detecting this combination asserts the interrupt associated with bit slice 4.
- In the third AND function IN0 AND NOT IN3 AND NOT IN4, bit slice 5 monitors input IN0 for a high level, bit slice 6 monitors input IN3 for a low level, and bit slice 7 monitors input IN4 for a low level. Detecting this combination asserts the interrupt associated with bit slice 7.
- The ORed result of all three AND functions asserts the RXEV request to the CPU. That is, any of the three terms that are true will assert the output.

21.6.1 Pattern-match engine example

Suppose you want to match the Boolean pattern

(IN1) + (IN1 * IN2) + (~IN2 * ~IN3 * IN6fe) + (IN5 * IN7ev)

with:

IN6fe = (sticky) falling edge on input 6

IN7ev = (nonsticky) event (rising or falling edge) on input 7

Each individual term in the above expression is controlled by one bit slice. To specify this expression, program the pattern-match bit slice source and configuration register fields as follows:

- Pattern-Match Interrupt Bit-Slice Source (PMSRC)
  - Because bit slice 5 is used to detect a sticky event on input 6, you can write 1 to SRC5 to clear any preexisting edge detects on bit slice 5.
  - SRC0: 001 - select input 1 for bit slice 0
  - SRC1: 001 - select input 1 for bit slice 1
  - SRC2: 010 - select input 2 for bit slice 2

- SRC3: 010 - select input 2 for bit slice 3
- SRC4: 011 - select input 3 for bit slice 4
- SRC5: 110 - select input 6 for bit slice 5
- SRC6: 101 - select input 5 for bit slice 6
- SRC7: 111 - select input 7 for bit slice 7

- Pattern-Match Interrupt Bit Slice Configuration (PMCFG)
  - PROD_ENDPTS0 = 1
  - PROD_ENDPTS2 = 1
  - PROD_ENDPTS5 = 1
  - All other slices are not product term endpoints and their PMCFG[PROD_ENDPTSn] are 0. Slice 7 is always a product term endpoint and does not have a register bit associated with it.
  - PROD_ENDPTS= 0100101 - bit slices 0, 2, 5, and 7 are product-term endpoints. (Bit slice 7 is an endpoint by default - no associated register bit).
  - CFG0: 000 - high level on the selected input (input 1) for bit slice 0
  - CFG1: 000 - high level on the selected input (input 1) for bit slice 1
  - CFG2: 000 - high level on the selected input (input 2) for bit slice 2
  - CFG3: 101 - low level on the selected input (input 2) for bit slice 3
  - CFG4: 101 - low level on the selected input (input 3) for bit slice 4
  - CFG5: 010 - (sticky) falling edge on the selected input (input 6) for bit slice 5
  - CFG6: 000 - high level on the selected input (input 5) for bit slice 6
  - CFG7: 111 - event (any edge, nonsticky) on the selected input (input 7) for bit slice 7
- Pattern-Match Interrupt Control (PMCTRL)
  - Bit0: Writing this bit selects pattern matches to generate the pin interrupts in place of the standard pin interrupt mechanism.

    For this example, detecting a match on the first product term asserts pin interrupt 0 (which, in this case, is just a high level on input 1).

    Pin interrupt 2 is asserted in response to a match on the second product term.

    Pin interrupt 5 is asserted when there is a match on the third product term.

    Pin interrupt 7 is asserted on a match on the last term.
  - Bit1: Writing this bit causes the RXEV signal to the CPU getting asserted whenever a match occurs on any of the product terms in the expression. Otherwise, the RXEV line does not get used.
  - Bit31:24: At any given time, bits 0, 2, 5, and 7 may be high if the corresponding product terms are currently matching.
  - The remaining bits are low.

21.6.2 Pattern-match engine edge-detect examples

The following figures show only pattern-match functionality in which accurate timing is not implied. Inputs (INn) are shown synchronized to the system clock for simplicity.

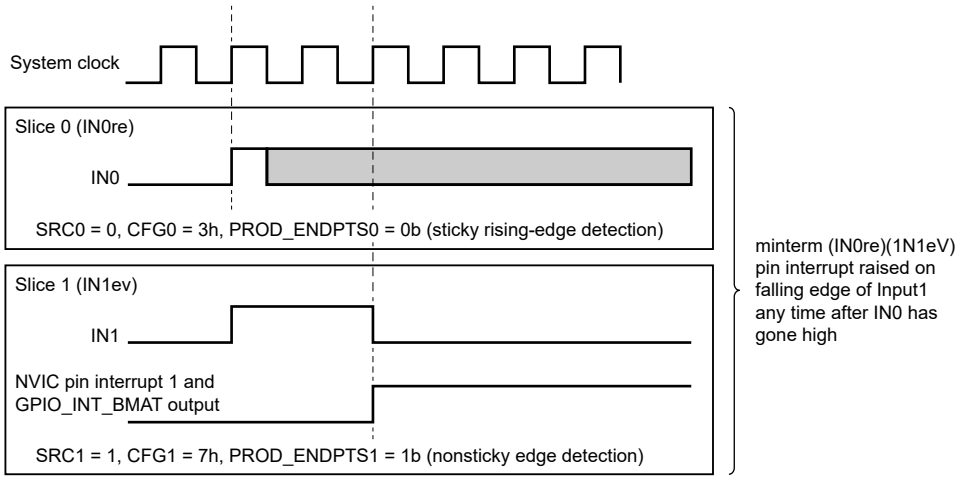

Figure 70. Pattern-match engine examples: sticky edge detect

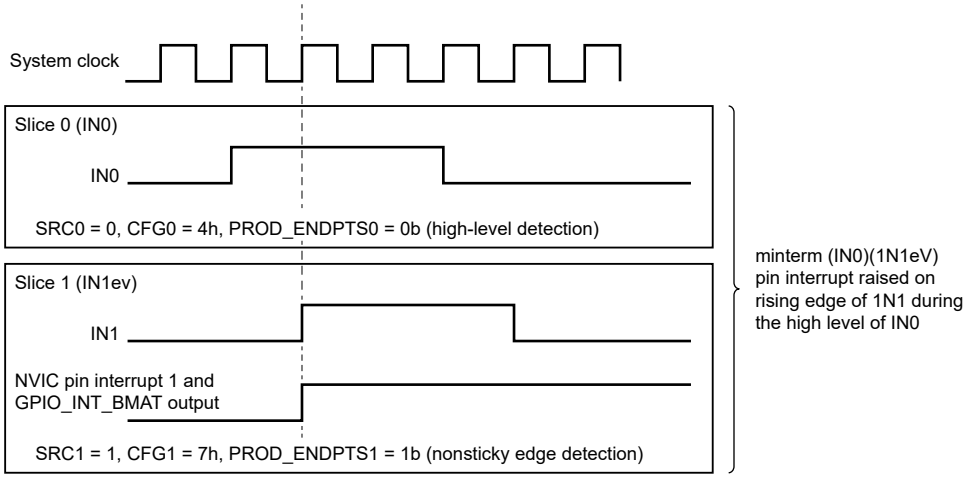

Figure 71. Pattern-match engine examples: Windowed nonsticky edge-detect evaluates as true

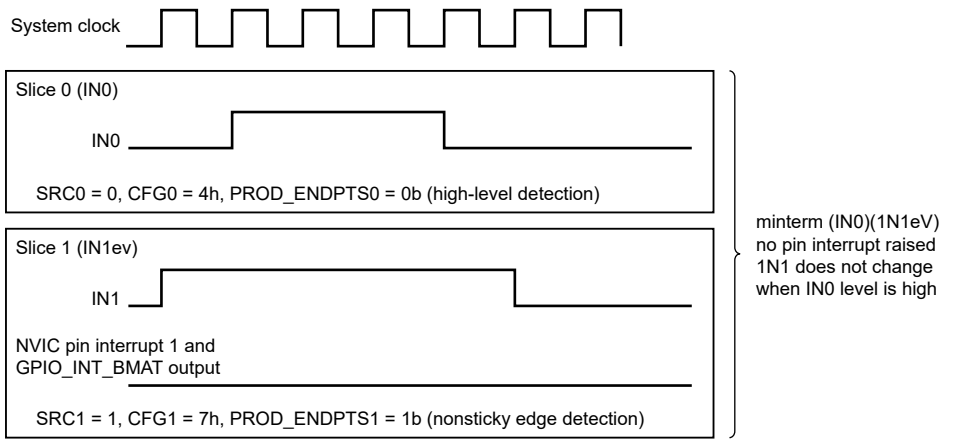

Figure 72. Pattern-match engine examples: Windowed nonsticky edge-detect evaluates as false

21.7 Memory map and register definition

This section includes the PINT memory map and detailed descriptions of all registers.

The chip includes up to 8 pins identified as interrupt sources by Pin Interrupt Select (PINT_TRIGa). The registers have 8 fields that correspond to the pins called out by PINT_TRIG.

Table 186. Pin interrupt registers for edge- and level-sensitive pins

Name	Edge-sensitive function	Level-sensitive function
IENR	Enables rising-edge interrupts.	Enables level interrupts.
SIENR	Write to enable rising-edge interrupts.	Write to enable level interrupts.
CIENR	Write to disable rising-edge interrupts.	Write to disable level interrupts.
IENF	Enables falling-edge interrupts.	Selects active level.
SIENF	Write to enable falling-edge interrupts.	Write to select high active.
CIENF	Write to disable falling-edge interrupts.	Write to select low active.

21.7.1 PINT register descriptions

21.7.1.1 PINT memory map

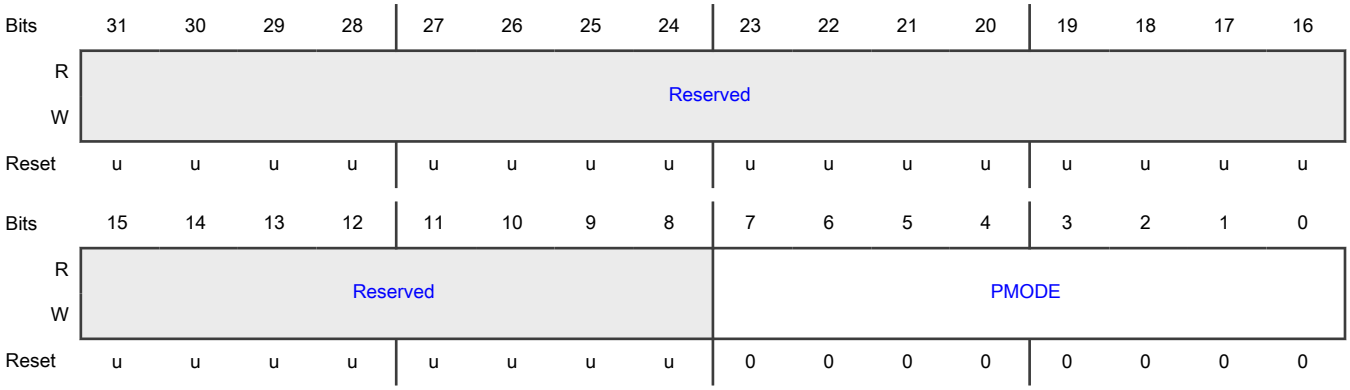
21.7.1.2 Pin Interrupt Mode (ISEL)

Offset

Register	Offset
ISEL	0h

Function
Determines whether an interrupt is edge- or level-sensitive.

Diagram



Fields

Field	Function
31-8 —	Read value is undefined; write only 0.
7-0 PMODE	Interrupt mode Selects the interrupt mode for each pin interrupt. Bit *n* configures the pin interrupt selected in PINT_TRIG in INPUTMUX. **NOTE** This field is not supported in every instance. The following table includes only supported registers.

Instance	Field supported in	Field not supported in
PINT0	ISEL	—
PINT1	ISEL[3–0]	ISEL[7–4]

NOTE
The descriptions of the field settings vary by module instance.

Table continued from the previous page...

Field	Function

Instance	Field value and description
PINT0	0000_0000b - In bit n configures the interrupt to be edge-sensitive 0000_0001b - In bit n configures the interrupt to be level-sensitive
PINT1	0000b - In bit n configures the interrupt to be edge-sensitive 0001b - In bit n configures the interrupt to be level-sensitive

21.7.1.3 Pin Interrupt Level or Rising-Edge Interrupt Enable (IENR)

Offset

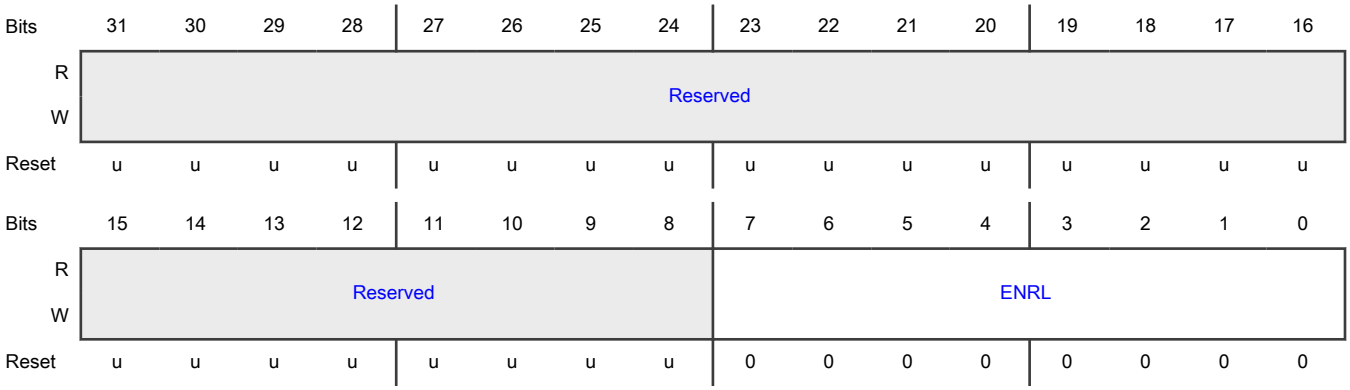
Register	Offset
IENR	4h

Function

Enables the interrupt by each field in Pin Interrupt Level or Rising-Edge Interrupt Enable (IENR), depending on the ISEL[PMODE] configured in Pin Interrupt Mode (ISEL).

- If the PMODE is edge sensitive (PMODE = 0), the rising-edge interrupt is enabled.
- If the PMODE is level sensitive (PMODE = 1), the level interrupt is enabled. Pin Interrupt Active Level or Falling-Edge Interrupt Enable (IENF) configures the active level (HIGH or LOW) for this interrupt.

Diagram



Fields

Field	Function
31-8 —	Read value is undefined; write only 0.
7-0 ENRL	Enables Interrupt Enables the rising edge or level interrupt for each pin interrupt corresponding to the bit index. Bit *n* configures the pin interrupt selected in PINT_TRIGa. **NOTE** This field is not supported in every instance. The following table includes only supported registers.

Instance	Field supported in	Field not supported in
PINT0	IENR	—
PINT1	IENR[3–0]	IENR[7–4]

NOTE
The descriptions of the field settings vary by module instance.

Instance	Field value and description
PINT0	0000_0000b - In bit n disables the corresponding interrupt 0000_0001b - In bit n enables the corresponding interrupt
PINT1	0000b - In bit n disables the corresponding interrupt 0001b - In bit n enables the corresponding interrupt

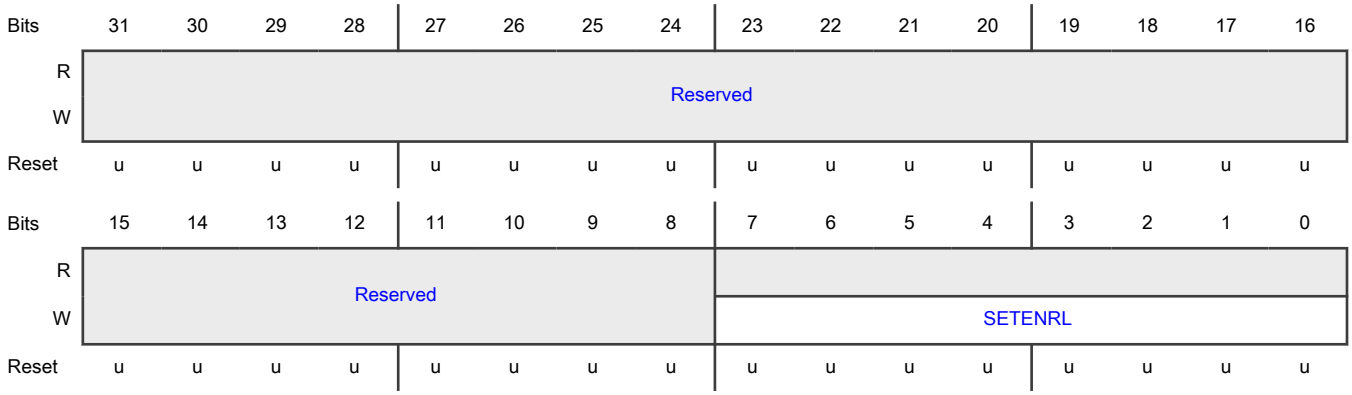
21.7.1.4 Pin Interrupt Level or Rising-Edge Interrupt Set (SIENR)

Offset

Register	Offset
SIENR	8h

Function
Configures the corresponding field in Pin Interrupt Level or Rising-Edge Interrupt Enable (IENR) by each field in Pin Interrupt Level or Rising-Edge Interrupt Set (SIENR), depending on the ISEL[PMODE] configured in Pin Interrupt Mode (ISEL).

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SETENRL	Configures IENR Configures IENR by writing 1s to this address. Bit *n* configures the corresponding bit in IENR. **NOTE** This field is not supported in every instance. The following table includes only supported registers.

Instance	Field supported in	Field not supported in
PINT0	SIENR	—
PINT1	SIENR[3–0]	SIENR[7–4]

NOTE

The descriptions of the field settings vary by module instance.

Instance	Field value and description
PINT0	0000_0000b - No operation for interrupt n 0000_0001b - Enable rising edge or level interrupt for interrupt n
PINT1	0000b - No operation for interrupt n 0001b - Enable rising edge or level interrupt for interrupt n

21.7.1.5 Pin Interrupt Level (Rising-Edge Interrupt) Clear (CIENR)

Offset

Register	Offset
CIENR	Ch

Function

Writing 0 to each bit in Pin Interrupt Level (Rising-Edge Interrupt) Clear (CIENR) adjusts the corresponding bit in Pin Interrupt Level or Rising-Edge Interrupt Enable (IENR) depending on the ISEL[PMODE] configured in Pin Interrupt Mode (ISEL). Writing 0 to this address configures bits in Pin Interrupt Level or Rising-Edge Interrupt Enable (IENR), effectively disabling interrupts. Writing 0 to bit *a* configures bit *n* in Pin Interrupt Level or Rising-Edge Interrupt Enable (IENR).

Diagram

21.7.1.6 Pin Interrupt Active Level or Falling-Edge Interrupt Enable (IENF)

Offset

Register	Offset
IENF	10h

Function

Enables the falling-edge interrupt or configures the level sensitivity depending on the ISEL[PMODE] configured in Pin Interrupt Mode (ISEL).

- If the PMODE is edge sensitive (PMODE = 0), the falling-edge interrupt is enabled.
- If the PMODE is level sensitive (PMODE = 1), the active level of the level interrupt (HIGH or LOW) is configured.

21.7.1.7 Pin Interrupt Active Level or Falling-Edge Interrupt Set (SIENF)

Offset

Register	Offset
SIENF	14h

Function

Sets the corresponding bit in Pin Interrupt Active Level or Falling-Edge Interrupt Enable (IENF) (by each bit of SIENF), depending on the PMODE configured in Pin Interrupt Mode (ISEL).

- If the PMODE is edge sensitive (PMODE = 0), the falling-edge interrupt becomes 1.
- If the PMODE is level sensitive (PMODE = 1), the HIGH-active interrupt is selected.

Diagram

21.7.1.9 Pin Interrupt Rising Edge (RISE)

Offset

Register	Offset
RISE	1Ch

Function

Contains 1s for pin interrupts selected in PINT_TRIGa (see the "INPUTMUX" chapter for more details) on which a rising edge has been detected. Writing 1s to this register clears rising-edge detection. Ones in this register assert an interrupt request for pins that are enabled for rising-edge interrupts. All edges are detected for all pins selected by PINT_TRIG, regardless of whether they are interrupt-enabled.

</table>

21.7.1.10 Pin Interrupt Falling Edge (FALL)

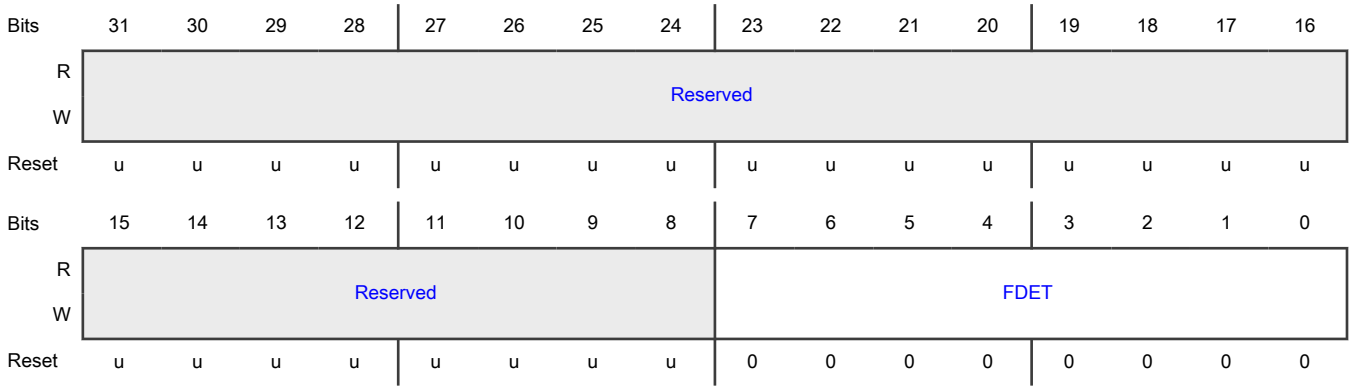
Offset

Register	Offset
FALL	20h

Function

Contains 1s for pin interrupts selected in PINT_TRIGa on which a falling edge has been detected. Writing 1s to this register clears falling-edge detection. The values (1s) in this register assert interrupt requests for pins with falling-edge interrupt capabilities. PINT_TRIGa detects all edges for all pins, regardless of whether they are interrupt-enabled.

Diagram



Fields

Field	Function
31-8 —	Reserved

21.7.1.11 Pin Interrupt Status (IST)

Offset

Register	Offset
IST	24h

Function

Returns 1s for pin interrupts that are currently requesting an interrupt. For edge-sensitive pins in Interrupt Select, writing 1s to this register clears both rising- and falling-edge detection for the pin. For level-sensitive pins, writing 1s inverts the corresponding bit in the active-level register, thus switching the active level on the pin.

21.7.1.12 Pattern-Match Interrupt Control (PMCTRL)

Offset

Register	Offset
PMCTRL	28h

Function

Contains a field to select pattern-match interrupt generation (as opposed to pin interrupts which share the same interrupt request lines), and another to enable the RXEV output to the CPU. Read the current state of the pattern match in this register. If the pattern-match feature is not used (either for interrupt generation or for RXEV assertion), write 0 to PMCTRL[SEL_PMATCH] and PMCTRL[ENA_RXEV] of this register to conserve power.

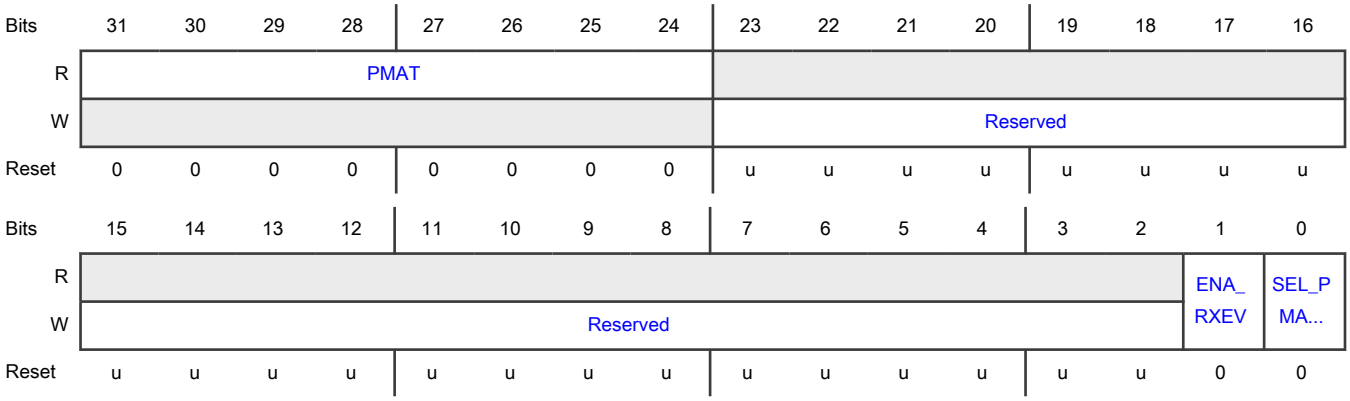
NOTE

Set up the pattern-match configuration in Pattern-Match Interrupt Bit-Slice Source (PMSRC) and Pattern-Match Interrupt Bit Slice Configuration (PMCFG) before writing to this register to enable (or reenable) the pattern-match functionality. This prevents spurious interrupts from occurring during the feature"s activation.

NOTE

The pattern-match feature requires clocks to operate and thus not generate an interrupt or wake the chip during reduced power modes below sleep mode.

Diagram



Fields

Field	Function
31-24 PMAT	Pattern Matches Displays the current state of pattern matches. 0000_0001b - The corresponding product term is matched by the current state of the appropriate inputs
23-2 —	Reserved, will read 0"s
1 ENA_RXEV	Enables the RXEV output to the CPU and/or to a GPIO output, when the specified Boolean expression evaluates to true. If this value is 0b, RXEV output to the CPU is disabled. If this value is 1b, RXEV output to the CPU is enabled. 0b - Disabled 1b - Enabled
0 SEL_PMATCH	Specifies whether the pin interrupts are controlled by the pin interrupt function or by the pattern-match function. If this value is 0b, interrupts are driven in response to the standard pin interrupt function. If this value is 1b, interrupts are driven in response to pattern matches. 0b - Pin interrupt 1b - Pattern match

21.7.1.13 Pattern-Match Interrupt Bit-Slice Source (PMSRC)

Offset

Register	Offset
PMSRC	2Ch

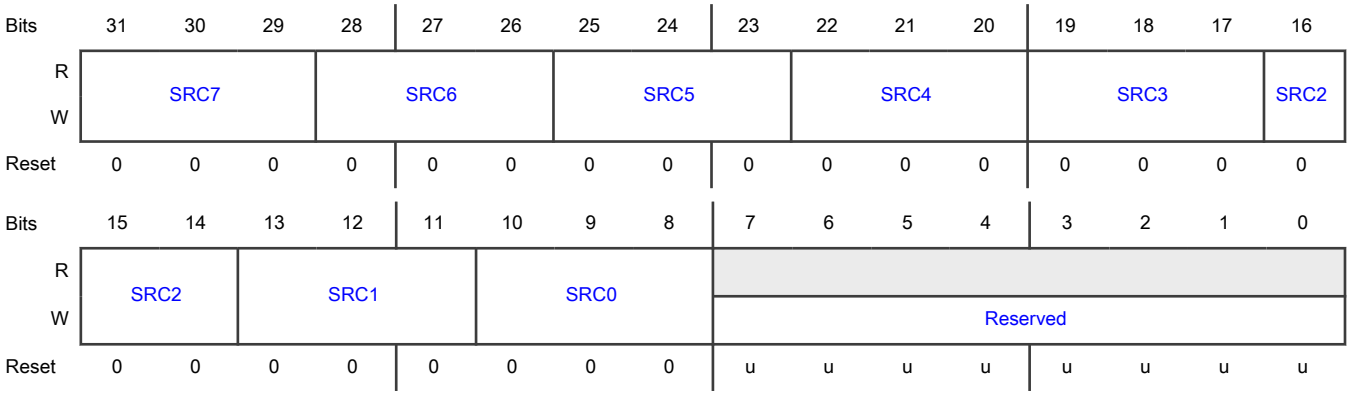
Function

Specifies the input source for each of the pattern-match bit slices. Each of the possible 8 inputs is selected in the pin interrupt select registers in INPUTMUX. Input 0 corresponds to the pin selected in PINT_TRIG0, input 1 corresponds to the pin selected in PINT_TRIG1, and so on.

NOTE

Writing any value to either Pattern-Match Interrupt Bit Slice Configuration (PMCFG) or Pattern-Match Interrupt Bit-Slice Source (PMSRC), or disabling the pattern-match feature by clearing both the PMCTRL[SEL_PMATCH] and PMCTRL[ENA_RXEV] bits in Pattern-Match Interrupt Control (PMCTRL) to zeros will erase all edge-detect history.

Diagram



Fields

Field	Function
31-29: SRC7 28-26: SRC6 25-23: SRC5 22-20: SRC4 19-17: SRC3 16-14: SRC2 13-11: SRC1 10-8: SRC0	Selects the input source for bit slice n 000b - Input 0 (selects the pin identified in PINT_TRIG0) 001b - Input 1 (selects the pin identified in PINT_TRIG1) 010b - Input 2 (selects the pin identified in PINT_TRIG2) 011b - Input 3 (selects the pin identified in PINT_TRIG3) 100b - Input 4 (selects the pin identified in PINT_TRIG4) 101b - Input 5 (selects the pin identified in PINT_TRIG5) 110b - Input 6 (selects the pin identified in PINT_TRIG6) 111b - Input 7 (selects the pin identified in PINT_TRIG7)
7-0 —	Reserved, will read 0's

21.7.1.14 Pattern-Match Interrupt Bit Slice Configuration (PMCFG)

Offset

Register	Offset
PMCFG	30h

Function

Configures the detect logic and contains bits to select from among eight alternative conditions for each bit slice that cause that bit slice to contribute to a pattern match. The seven LSBs of this register specify which bit slices are the end-points of product terms in the Boolean expression (where OR terms are to be inserted in the expression).

Two types of edge detection on each input are possible:

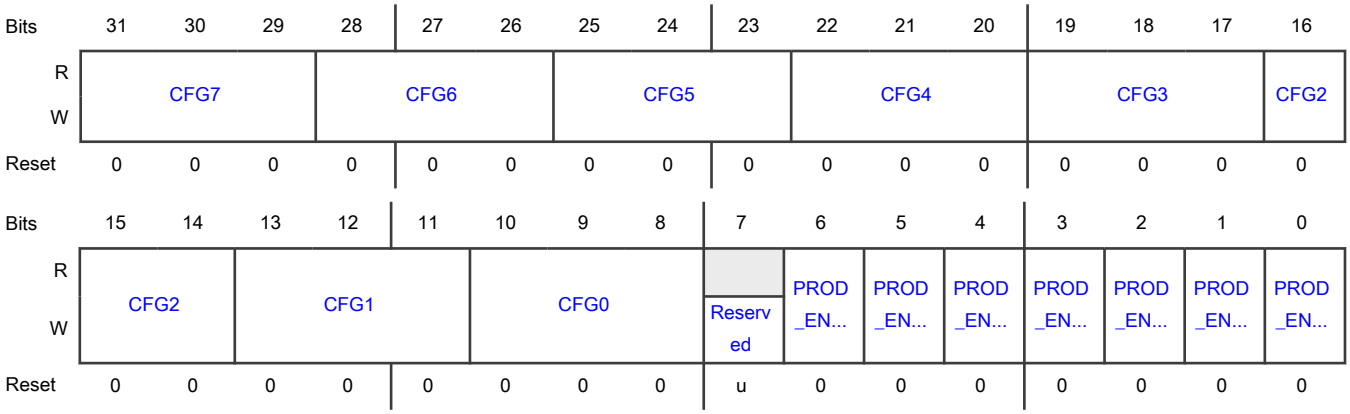
- Sticky: A rising edge, a falling edge, or a rising or falling edge that is detected at any time after the edge-detection mechanism becomes 0. The input qualifies as detected (the detect logic output remains HIGH) until the pattern-match engine detect logic becomes 0 again.
- Nonsticky: In the event of an edge (rise or fall), the detect logic output for this pin goes HIGH. One clock cycle clears this bit, allowing the edge detector to detect a second edge.

To clear the pattern-match engine detect logic, write any value to either Pattern-Match Interrupt Bit Slice Configuration (PMCFG) or Pattern-Match Interrupt Bit-Slice Source (PMSRC), or disable the pattern-match feature by changing both PMCTRL[SEL_PMATCH] and PMCTRL[ENA_RXEV] to 0 by writing 1 to Pattern-Match Interrupt Control (PMCTRL). This will erase all edge-detect history.

To select whether a slice marks the final component in a minterm of the Boolean expression, write a 1 in the corresponding PROD_ENDPTSa bit. Setting a term as the final component has two effects:

1. Anytime a match to that product term occurs, this leads to an assertion of interrupt request associated with this bit slice.
2. The next bit slice will start a new, independent product term in the Boolean expression. The Boolean expression will include an OR following the element controlled by this bit slice.

Diagram



Fields

Field	Function
31-29: CFG7 28-26: CFG6 25-23: CFG5 22-20: CFG4 19-17: CFG3 16-14: CFG2 13-11: CFG1	Match Configuration Specifies the match contribution condition for bit slice n: • If the value is 000b, this bit slice always contributes to a product term match. • If the value is 001b, edge detection for this bit slice is clear when there has been a rising edge on the specified input since last clearing. In order to clear this match condition, you must write to Pattern-Match Interrupt Bit Slice Configuration (PMCFG) or Pattern-Match Interrupt Bit-Slice Source (PMSRC).

Table continues on the next page...

Table continued from the previous page...

Field	Function
10-8: CFG0	• If the value is 010b, edge detection for this bit slice is clear when there has been a falling edge on the specified input since last clearing. In order to clear this match condition, you must write to Pattern-Match Interrupt Bit Slice Configuration (PMCFG) or Pattern-Match Interrupt Bit-Slice Source (PMSRC). • If the value is 011b, edge detection for this bit slice is clear when there has been either a rising or a falling edge on the specified input since last clearing. In order to clear this match condition, you must write to Pattern-Match Interrupt Bit Slice Configuration (PMCFG) or Pattern-Match Interrupt Bit-Slice Source (PMSRC). • If the value is 100b, match for this bit slice occurs when there is a high level on the input specified for this bit slice in Pattern-Match Interrupt Bit-Slice Source (PMSRC). • If the value is 101b, match occurs when there is a low level on the specified input. • If the value is 110b, it never contributes to a match and must be used to disable any unused bit slices. • If the value is 111b, a match occurs when the specified input first detects a rising or falling edge. This is a nonsticky version of value 0 x 3. Write 0 to this field after one clock cycle. 000b - Constant HIGH 001b - Sticky rising edge 010b - Sticky falling edge 011b - Sticky rising or falling edge 100b - High level 101b - Low level 110b - Constant 0 111b - Event (Nonsticky rising or falling edge)
7 ——	Bit slice 7 is automatically considered a product endpoint.
6-0 PROD_ENDPTSn	Determines whether slice n is an endpoint. Slice n is not an endpoint. Slice n is the endpoint of a product term (minterm). Pin interrupt n in the NVIC is raised if the minterm evaluates as true. 0b - No effect 1b - Endpoint

Chapter 22
General-Purpose Input/Output (GPIO)

22.1 Chip-specific GPIO information

Table 187. Reference links to related information

Topic	Related module	Reference
Full description	GPIO	GPIO

Clocking		Clock overview Clock controller
Power management	PMC	Power overview PMC
Signal multiplexing	IOPCTL	External signals and pin multiplexing IO PAD controller

22.1.1 Module instances

This device has 11 instances of the GPIO module: GPIO0 to GPIO10.

Table 188. GPIO instances

	GPIO0-GPIO7	GPIO8-GPIO10
Located in	VDD2_COMP	VDD1_SENSE
Access	CPU0, HiFi4, EZH-V, eDMA0, eDMA1	CPU1, HiFi1, eDMA2, eDMA3

22.1.2 GPIO pins and interrupts

Each GPIO instance supports GPIO configuration of 32 pins. Each GPIO function is connected to the pin via IOPCTL. Not all the GPIO pins are available, see Pin assignments for GPIO pins available for each package.

GPIO0-7 are used to interrupt CPU0 and GPIO8-10 are for CPU1 interrupt. The edge and level interrupts are supported even as a wake-up source of the sleep and deep-sleep modes. Each GPIO interrupt can be configured to channel 0 or 1.

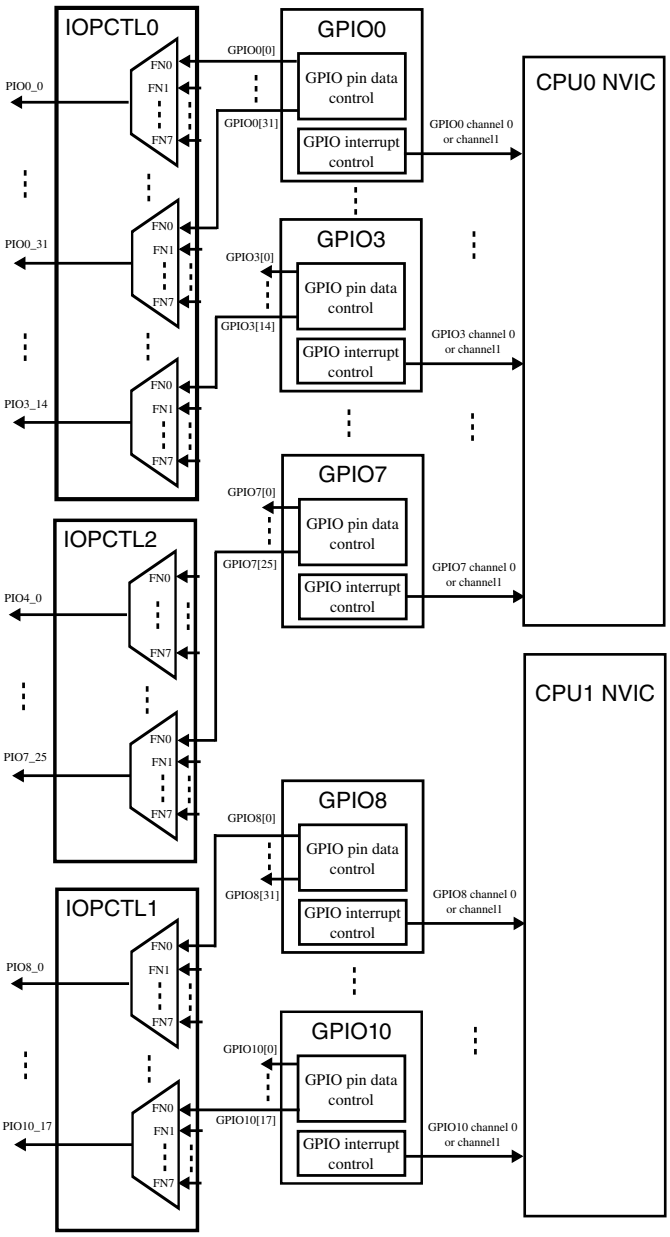

Figure 73. GPIO pins and interrupts

22.1.3 Security considerations

The GPIO module implements Access protection that can be used to configure secure/non-secure and privileged/non-privileged access on a per pin basis. The interrupt, DMA, or trigger functionality for each pin can also be configured for secure/non-secure and privileged/non-privileged access.

Each GPIO module is also instantiated to use two module slots (for example, GPIO0 and GPIO0_alias). At the Secure AHB controller, one slot can be configured for secure access while the other is configured for non-secure access. This allows each GPIO module to be accessed by both secure and non-secure masters using the appropriate slot. While the Secure AHB controller's MISC_CTRL_REG[DISABLE_STRICT] option is configured for strict mode. Each GPIO module's pin and interrupt, DMA, or trigger secure/non-secure access protections are then used to restrict access according to the level used by that particular GPIO slot.

22.2 Overview

GPIO communicates to the processor core via a zero wait-state interface for maximum pin performance.

22.2.1 Block diagram

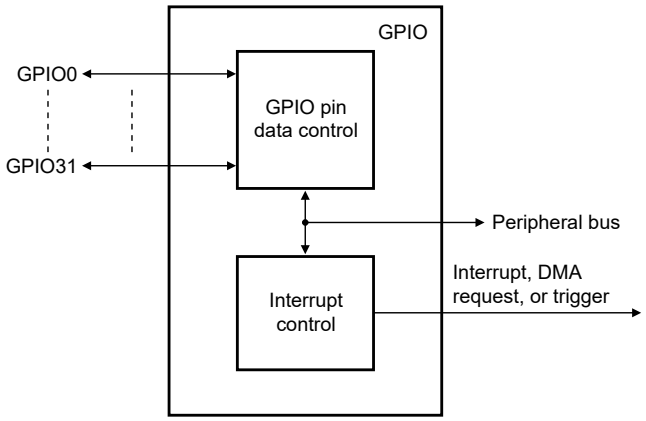

Figure 74. Block diagram

22.2.2 Features

- Port Data Input (PDIR) displays the logic value on each pin when the pin is configured for any digital function, provided the corresponding Port Control and Interrupt modules for that pin are enabled.
- Port Data Output (PDOR), with corresponding set, clear, and toggle registers, controls the output data of each pin when the pin is configured for the GPIO function.
- Port Data Direction (PDDR) controls the direction of each pin when the pin is configured for the GPIO function.
- Port Input Disable (PIDR) controls disabling of the input for each general-purpose pin.
- Pin interrupts:
  - Interrupt flags and enable registers for each pin are functional in all digital pin muxing modes.
  - Support for interrupt, peripheral trigger, or DMA request is configured for each pin.
  - Support for edge-sensitive (rising, falling, or both) or level-sensitive (low, high) interrupts is configured for each pin.
  - Asynchronous wake-up in Low-Power mode.
  - GPIO generates a total of 2 interrupts, 2 output triggers, and 2 DMA requests.
  - Each pin can be used to generate a single interrupt, output trigger, or DMA request.
- Protection registers:
  - Each pin is configured for secure or nonsecure and privileged or nonprivileged access.
  - Each interrupt, trigger, and DMA request domain is configured for secure or nonsecure and privileged or nonprivileged access.

22.3 Functional description

22.3.1 Low-Power mode

You can configure GPIO to exit Low-Power mode via an asynchronous wake-up signal if an enabled interrupt is detected.

22.3.2 Debug mode

GPIO remains functional in Debug mode.

22.3.3 General-purpose input

The logic state of each pin is available via Port Data Input (PDIR) if:

- The corresponding field in Port Input Disable (PIDR) is 0.
- The pin is configured for a digital function.

22.3.4 General-purpose output

The logic state of each pin is controlled via Port Data Output (PDOR) and Port Data Direction (PDDR), provided the pin is configured for the GPIO function. The following table depicts the conditions for a pin to be configured as input or output.

Table 189. General-purpose output

If	Then
A pin is configured for the GPIO function and the corresponding PDDR field is 0	The pin is configured as an input.
A pin is configured for the GPIO function and the corresponding PDDR field is 1	The pin is configured as an output and the logic state of the pin is equal to the corresponding PDOR field.

For efficient bit manipulation on the general-purpose outputs, pin data set, pin data clear, and pin data toggle registers allow one or more outputs within one port to be set, cleared, or toggled from a single register write, eliminating the need for a read-modify-write operation to prevent changing pins accidentally.

22.3.5 Clocking

GPIO receives a single clock, which is used for register access and synchronization with external pin inputs. There are no special considerations.

22.3.6 Reset

GPIO receives a single reset, which resets the peripheral. There are no special considerations.

22.3.7 External interrupts

The external interrupt capability of GPIO is available in all digital pin muxing modes.

GPIO generates a total of 2 interrupts, 2 output triggers, and 2 DMA requests. You can configure each pin individually for interrupt, output trigger, or DMA requests:

- Each output implements a separate interrupt status flag (ISF) register for that domain.
- Each output generates a single interrupt.
- Each output generates a single DMA request.
- Each output generates a single peripheral trigger output.

You can configure each pin individually for any of the external interrupt modes shown in the following table.

Table 190. Available pin configurations for external interrupts

Signal conditions	Software polling using flags	Peripheral triggers	Interrupts	DMA requests
Rising-edge	Yes	—	Yes	Yes
Falling-edge	Yes	—	Yes	Yes
Rising- and falling-edge	Yes	—	Yes	Yes
High-level	—	Yes	Yes	—
Low-level	—	Yes	Yes	—

The interrupt status flag is set when the configured edge or level is detected on the pin. Unless GPIO is in Low-Power mode, the input is first synchronized to the system clock to detect the configured level or edge transition.

GPIO generates a pin interrupt that asserts when the interrupt status flag is set for any enabled interrupt for that output. The interrupt negates after the interrupt status flags for all enabled interrupts are cleared by writing a logic 1 to either ISFR0[ISF*n*] or ICR0[ISF].

GPIO generates a DMA request that asserts when the interrupt status flag is set for any enabled DMA request in that output. The DMA request negates after the DMA transfer is completed because that clears the interrupt status flags for all enabled DMA requests.

In Low-Power mode, the interrupt status flag for any enabled interrupt is asynchronously set if the required level or edge is detected. This also generates an asynchronous wake-up signal to exit Low-Power mode.

GPIO generates a peripheral trigger output that asserts if any pin configured for the active-high trigger is logic 1, or any pin triggered for the active-low trigger is logic 0. The peripheral trigger output asynchronously updates from the value on the configured pins.

22.3.8 Global interrupt control

The two global interrupt control registers (Global Interrupt Control Low (GICLR) and Global Interrupt Control High (GICHR)) allow a single register write to update the upper 16 bits of Interrupt Control a (ICR0 - ICR31) for up to 16 pins, all with the same value.

These global interrupt control registers allow you to quickly configure multiple pins within the same port with the same interrupt configuration.

The global interrupt control registers are write-only registers and always read 0.

22.3.9 DMA

GPIO generates 2 requests. For each pin, you can configure DMA requests to assert for either rising, falling, or both edge detection. See External interrupts for more information.

22.3.10 Access protection

GPIO implements access protection registers (PCNS and PCNP) for each pin, as shown in Table 191.

Table 191. PCNS and PCNP register access protection implementation

Access	Description
Secure	You can write to or read the pins configured for secure access only in the Secure state.
Nonsecure	You can write to or read the pins configured for nonsecure access only in the Nonsecure state.

Table continues on the next page...

Table 191. PCNS and PCNP register access protection implementation (continued)

Access	Description
Privilege	You can write to the pins configured for privilege access only in the Privilege state.
Nonprivilege	You can write to the pins configured for nonprivilege access in both the Privilege and Nonprivilege states.

GPIO implements access protection registers (ICNS and ICNP) for each interrupt, trigger output, and DMA request as shown in Table 192.

Table 192. ICNS and ICNP register access protection implementation

Access	Description
Secure	You can configure the outputs programmed for secure access only in the Secure state.
Nonsecure	You can configure the outputs programmed for nonsecure access only in the Nonsecure state.
Privilege	You can configure the outputs programmed for privilege access only in the Privilege state.
Nonprivilege	You can configure the outputs programmed for nonprivilege access in both the Privilege and Nonprivilege states.

You can write to the access protection registers (PCNS, PCNP, ICNS, and ICNP) only in the Secure-Privilege state; you can optionally lock these registers until the next reset.

Configuring a pin interrupt, trigger output, or DMA request requires the following access permissions:

- Access permission to configure the pin.
- Access permission to either configure to the desired interrupt, trigger output, or DMA request, or writing 0 to ICR*n*[IRQC].
- Access permission to either configure with the existing interrupt, trigger output, or DMA request, or if the current value of ICR*n*[IRQC] is 0.
- The interrupt configuration is not locked.

22.4 External signals

Table 193. External signals

Signal	Description		Direction
GPIO31–GPIO0	General-purpose input/output		I/O
	State meaning	Asserted: The pin is logic 1. Deasserted: The pin is logic 0.	
	Timing	Assertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock. Deassertion: When output, this signal occurs on the rising-edge of the system clock. For input, it may occur at any time and input may be asserted asynchronously to the system clock.	

NOTE

Not all pins within each GPIO are implemented on each chip. See the "Signal Multiplexing" chapter for the number of GPIO pins within each port available on this chip.

22.5 Initialization

To initialize GPIO:

1. Initialize the GPIO pins for the output function:
    a. Configure the output logic value for each pin by using Port Data Output (PDOR).
    b. Configure the direction for each pin by using Port Data Direction (PDDR).
2. Initialize the interrupt function by writing to Interrupt Control a (ICR0 - ICR31) for the corresponding pins and desired configuration. If the pin is previously used for a different function, first write 0100_0000h to Interrupt Control a (ICR0 - ICR31) to disable the previous function and clear the flag.

22.6 Application information

GPIO includes the following applications:

- Reading the state of a single pin by performing a byte read of Pin Data (P0DR - P31DR).
- Updating the state of a single pin by performing a byte write to Pin Data (P0DR - P31DR).
- Reading the state of multiple pins by reading Port Data Input (PDIR).
- Updating the state of multiple pins by using the following ways:
    — Writing to Port Data Output (PDOR).
    — Writing to Port Set Output (PSOR) to write 1 to Port Data Output (PDOR).
    — Writing to Port Clear Output (PCOR) to write 0 to Port Data Output (PDOR).
    — Writing to Port Toggle Output (PTOR) to toggle Port Data Output (PDOR).

22.7 Memory map and register definition

The GPIO registers support 8-bit, 16-bit, or 32-bit accesses. Any read or write access to the GPIO memory space that is outside the valid memory map results in a bus error.

NOTE

For simplicity, each GPIO port's register appears with the same width of 32 bits, corresponding to 32 pins. The actual number of pins per port (and therefore the number of usable control bits per port register) is chip-specific. See the "Signal Multiplexing" chapter for the exact control bits of each port.

22.7.1 GPIO register descriptions

22.7.1.1 GPIO memory map

GPIO0 base address: 4010_0000h

3-0 IRQNUM	Interrupt Number Indicates the number of interrupt, trigger, or DMA request domains.

22.7.1.4 Lock (LOCK)

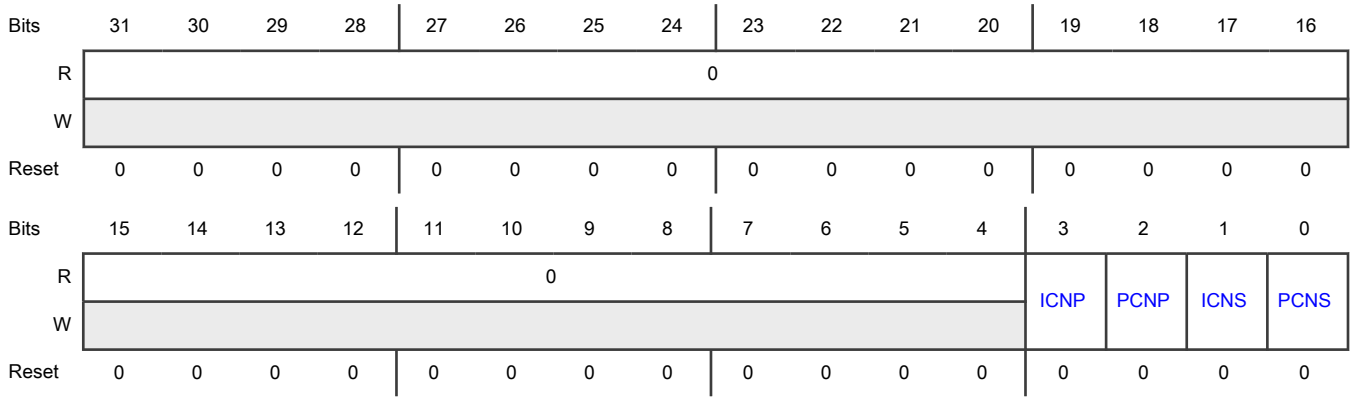
Offset

Register	Offset
LOCK	Ch

Function

Locks the nonsecure and nonprivilege access protection registers. You can write to this register only in the Secure-Privilege state.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 ICNP	Lock ICNP Locks Interrupt Control Nonprivilege (ICNP). If this field is 0, you can write to ICNP in the Secure-Privilege state. If this field is 1, you cannot write to ICNP until the next reset. 0b - Writable in Secure-Privilege state 1b - Not writable until the next reset
2 PCNP	Lock PCNP Locks Pin Control Nonprivilege (PCNP). If this field is 0, you can write to PCNP in the Secure-Privilege state. If this field is 1, you cannot write to PCNP until the next reset. 0b - Writable in Secure-Privilege state 1b - Not writable until the next reset
1 ICNS	Lock ICNS Locks Interrupt Control Nonsecure (ICNS). If this field is 0, you can write to ICNS in the Secure-Privilege state. If this field is 1, you cannot write to ICNS until the next reset. 0b - Writable in Secure-Privilege state 1b - Not writable until the next reset
0 PCNS	Lock PCNS Locks Pin Control Nonsecure (PCNS). If this field is 0, you can write to PCNS in the Secure-Privilege state. If this field is 1, you cannot write to PCNS until the next reset. 0b - Writable in Secure-Privilege state 1b - Not writable until the next reset

22.7.1.5 Pin Control Nonsecure (PCNS)

Offset

Register	Offset
PCNS	10h

Function

Configures secure or nonsecure access protection for each pin. You can write to this register only in the Secure-Privilege state if it is not locked (LOCK[PCNS] = 0).

Diagram

Fields

Field	Function
31-0 NSEn	Nonsecure Enable Configures secure or nonsecure access protection for each pin. If this field is 0, the pin is configured for secure access. You can read or write to the corresponding pin's registers and fields only in the Secure state. When you access the corresponding pin's registers in the Nonsecure state, all fields in the registers related to that pin are read zero (with writes ignored). If this field is 1, the pin is configured for nonsecure access. You can read or write to the corresponding pin's registers and fields only in the Nonsecure state. When you access the corresponding pin's registers in the Secure state, all fields in the registers related to that pin are read zero (with writes ignored). 0b - Secure access 1b - Nonsecure access

22.7.1.6 Interrupt Control Nonsecure (ICNS)

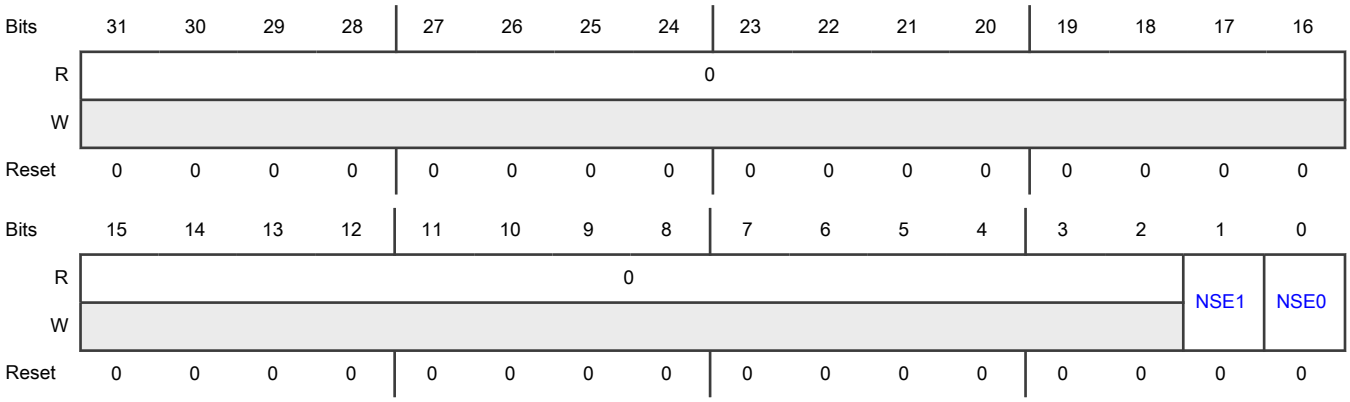
Offset

Register	Offset
ICNS	14h

Function

Configures secure and nonsecure access protection for each interrupt, output trigger, or DMA request. You can update this register only in the Secure-Privilege state if it is not locked (LOCK[ICNS] = 0).

Diagram



Fields

Field	Function
31-2 —	Reserved
1-0 NSEn	Nonsecure Enable Configures secure or nonsecure access protection for each interrupt, output trigger, or DMA request. If this field is 0, the interrupt, output trigger, or DMA request is configured for secure access. You can configure a pin to use the corresponding interrupt, output trigger, or DMA request, or reconfigure a pin that is already configured to use the corresponding interrupt, output trigger, or DMA request only in the Secure state. If this field is 1, the interrupt, output trigger, or DMA request is configured for nonsecure access. You can configure a pin to use the corresponding interrupt, output trigger, or DMA request, or reconfigure a pin that is already configured to use the corresponding interrupt, output trigger, or DMA request only in the Nonsecure state. **NOTE** See the GPIO chip-specific information to determine which GPIO instances support interrupt, DMA request, or trigger capabilities. 0b - Secure access 1b - Nonsecure access

22.7.1.7 Pin Control Nonprivilege (PCNP)

Offset

Register	Offset
PCNP	18h

Function

Configures access protection on each pin either for privilege or for both privilege and nonprivilege accesses. You can update this register only in the Secure-Privilege state if it is not locked (LOCK[PCNP] = 0).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 NPEn	Nonprivilege Enable Configures privilege or nonprivilege access protection for each pin. If this field is 0, the pin is configured for privilege access. Write access to the corresponding pin's registers and fields is allowed only in the Privilege state. When you access the corresponding pin's registers and fields in the Nonprivilege state, all fields related to that pin in this GPIO are readable (with writes ignored). If this field is 1, the pin is configured for nonprivilege access; read or write access to the corresponding pin's registers is allowed in both Privilege and Nonprivilege states. 0b - Privilege access 1b - Nonprivilege access

22.7.1.8 Interrupt Control Nonprivilege (ICNP)

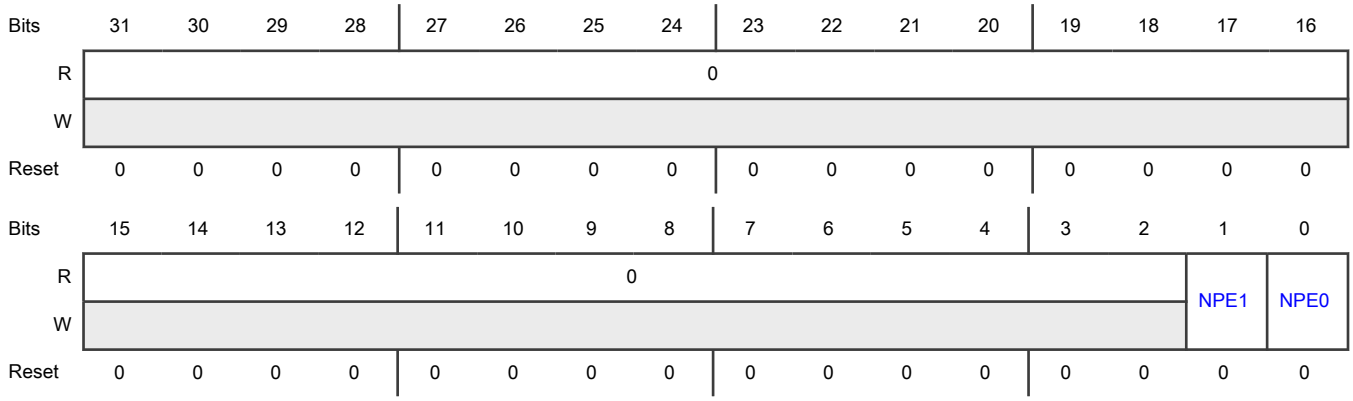
Offset

Register	Offset
ICNP	1Ch

Function

Configures privilege and nonprivilege access protection for each interrupt, trigger output, or DMA request. You can update this register only in the Secure-Privilege state if it is not locked (LOCK[ICNP] = 0).

Diagram



Fields

Field	Function
31-2 —	Reserved
1-0 NPEn	Nonprivilege Enable Configures privilege or nonprivilege access protection for each interrupt, trigger output, or DMA request. If this field is 0, the pin is configured for privilege access. You can configure a pin to use the corresponding interrupt, trigger output, or DMA request, or reconfigure a pin that is already configured to use the corresponding interrupt, trigger output, or DMA request only in the Privilege state. If this field is 1, the pin is configured for nonprivilege access. In either Privilege or Nonprivilege state, you can configure a pin to use the corresponding interrupt, trigger output, or DMA request, or reconfigure a pin that is already configured to use the corresponding interrupt, trigger output, or DMA request. **NOTE** See the GPIO chip-specific information to determine which GPIO instances support interrupt, DMA request, or trigger capabilities. 0b - Privilege access 1b - Nonprivilege access

22.7.1.9 Port Data Output (PDOR)

Offset

Register	Offset
PDOR	40h

Function

Configures the logic levels that are driven on each general-purpose output pin.

NOTE

Do not modify the pin configuration registers associated with pins that are not available in your selected package. By default, these unbonded pins are set to the Disable state for lowest power consumption.

Diagram

22.7.1.20 Interrupt Status Flag (ISFR0 - ISFR1)

Offset

Register	Offset
ISFR0	120h
ISFR1	124h

Function

Indicates whether the related configured interrupt is detected on each pin. The pin interrupt configuration is valid in all digital pin muxing modes. The ISF for each pin is also visible in the corresponding Interrupt Control register, and each flag can be cleared in either location.

There is a separate ISF register for each interrupt, trigger, or DMA request domain. Each status flag is only visible in the register that corresponds to that flag's domain, as configured in ICR*n*[IRQS].

101_1000b	cac_wb_push		Cache writeback line pushes
101_1100b	cac_push_stalls		Stalled cache writeback line pushes

23.2 Overview

CMX_PERFMON contains counters that you can configure to count events used to calculate the performance of a CPU, cache, or memory. You can configure CMX_PERFMON to select the events to be counted for each counter. An additional instruction counter is available to count CPU instruction fetches.

Block diagram provides an overview of CMX_PERFMON, which includes three event counters and an instruction counter.

23.2.1 Block diagram

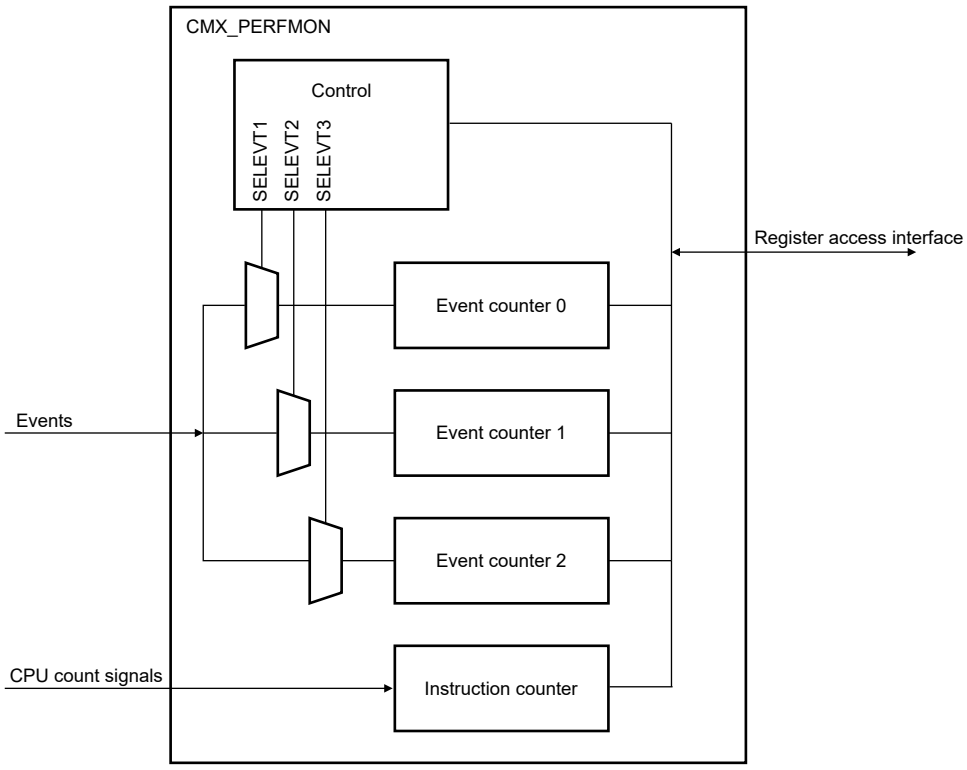

Figure 75. Block diagram

23.2.2 Features

- Three 40-bit event counters
- One 40-bit instruction counter
- Programmable event select
- Countable events that include cache, branch fetches, and stalls
- Memory mapped performance monitor that counts instructions, cache, branch, IPS, and TCM stats
- Count filter based on privilege level

23.3 Functional description

23.3.1 Operations

See the chip-specific CMX_PERFMON information for details about the countable events for the performance counters per CMX_PERFMON instance on this chip.

CMX_PERFMON has 3 programmable counters to count CPU events. The event to be counted is configured using the PMCR0 register.

Each counter is a 40-bit register that tracks the number of occurrences of the selected event.

The counters can be programmed to take one of the 3 states:

- At idle state, the counters are in idle and do not perform any operation.

- At local start state, the counters are actively listening to CPU and cache and start incrementing when the selected events are observed.
- At local stop state, the counters stop listening to all components. The 3 event counter can be independently cleared by writing to PMCR0[RECTR*n*], where *n* denotes the counter instance.

23.3.2 Operating modes

The following table shows:

- The operating modes that you can specify for CMX_PERFMON.
- The PMCR0[CMODE] value that you must specify to count events in each mode.

Table 197. Operating modes

Mode	Description	CMODE value (binary)
Privileged	If supported, only counts events in Privilege mode.	11
User	If supported, only counts events in User mode.	10
Both Privileged and User	Counts events in both Privilege and User mode.	00

Use PMCR0[SSC] to start and stop the counters.

23.3.3 Clocking

Clock name	Direction	Description
CPU clock (hclk)	Input	Configures the counter logic.
Bus clock (ipg_clk)	Input	Controls the access to the registers.

23.3.4 Interrupts

This module has no interrupts.

23.4 External signals

CMX_PERFMON has no external signals.

23.5 Initialization

To initialize CMX_PERFMON:

1. Program PMCR0[SELEVT*n*] to select the specific CPU event to be counted by this counter, where *n* denotes the counter instance.
2. Set PMCR0[CMODE] to filter each counter for the selected event while the CPU is in privilege, user, or either mode.
3. Set PMCR0[SSC] to program the counter to be in one of idle, local start, or local stop states.
4. Set PMCR0[RECTR*n*] to clear the counters independently where *n* denotes the counter instance.

23.6 Memory map and register definition

23.6.1 CMX_PERFMON register descriptions

23.6.1.1 CMX_PERFMON memory map

CMX_PERFMON0 base address: 4018_C000h

CMX_PERFMON1 base address: 4018_D000h

CMX_PERFMON2 base address: 4018_E000h

24.1.2 CSAR register

For this chip, the CSAR[28] must be configured as 0b.

24.2 Overview

XCACHE is a general-purpose AMBA AHB bus protocol cache that provides low-latency access to slower memories.

24.2.1 Block diagram

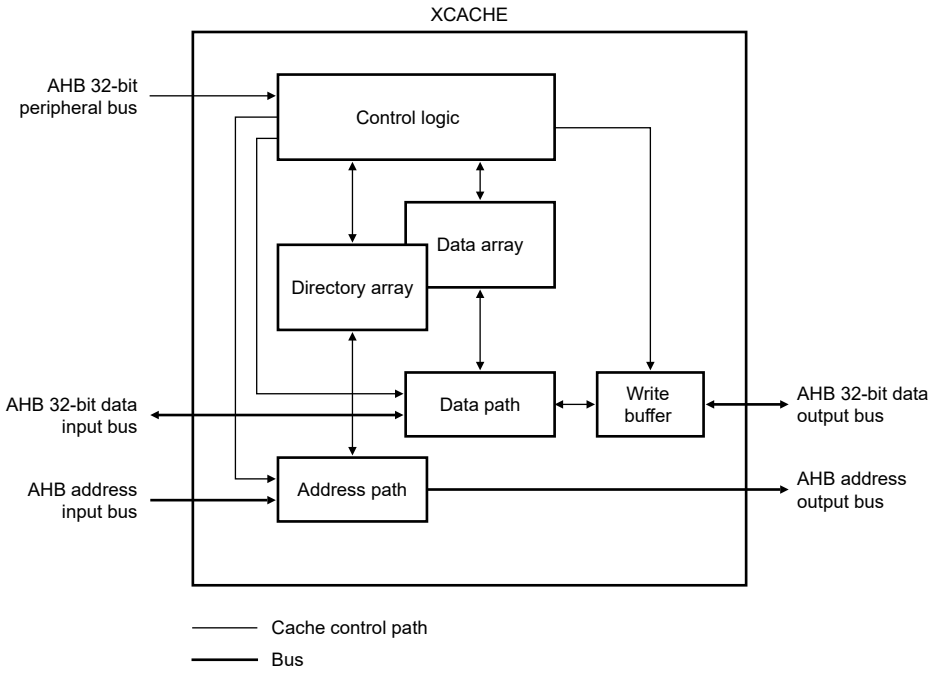

Figure 76. Block diagram

24.2.2 Features

XCACHE is designed to work with AMBA AHB bus systems. It includes:

- An AHB input bus. Accesses have cache mode attributes for cacheable copyback, cacheable write-through, or noncacheable mode operation and for write bufferable mode operation on an access-by-access basis.
- 32-bit data path AHB output bus for downstream cache read miss, cache write-through write, and noncacheable accesses.
- Connections to tag and data RAMs for implementing the cache functions.
- A peripheral interface for accessing the cache's programming model.

XCACHE includes the following AMBA_AHB buses:

- AHB input bus
- AHB output bus

24.3 Functional description

XCACHE is a block of high-speed memory locations that contains address information (commonly known as a tag) and its associated data. It decreases the average time of a memory access.

When data loads into a cache, the access times for subsequent loads and stores are reduced, resulting in overall performance benefits. Access to information already in a cache is known as a cache hit, and other accesses are known as cache misses.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the input bus wants to access a cacheable location, the cache is checked. If the access is a cache hit, the access occurs immediately. Otherwise, a location is allocated and the cache line is loaded from memory. Different cache topologies and access policies are possible. However, they must comply with the memory coherency model of the underlying architecture.

24.3.1 Principles of locality

XCACHE operates using the following two principles of locality.

Table 200. Type of locality

Type of locality	Description	Access
Spatial	Groups several locations together under the same tag to minimize the quantity of control information stored. This logical block is commonly known as a cache line.	Access to one location is possibly followed by accesses from adjacent locations (for example, sequential instruction execution or usage of a data structure).
Temporal	Retains recently accessed lines in the cache.	Access to an area of memory possibly repeats within a short period of time (for example, execution of a code loop).

24.3.2 Modes of operation

Table 201. Modes of operation

Mode	Description
Write-Through	Access to address spaces with this cache mode are cacheable: • If all cacheable spaces are read-only spaces, then cache contains read-only data and all writes to the cache cause a fault. See chip-specific cacheable space information. • A read miss on the input bus causes a line read on the output bus of a 16-byte-aligned memory address that contains the desired address. This missed data is loaded into the cache and is marked as valid and not modified. • A read hit to a valid cache location returns data from the cache with no output bus access. • A write miss bypasses the cache and writes to the output bus (no allocation on write-miss policy for Write-Through mode spaces). • A write hit updates the cache hit line with the write data and writes to the output bus. • Caches are input-bus-local and do not support hardware cache coherency. If the input bus accesses write-through regions and an external input bus (such as DMA) need to update these regions, you must first perform explicit cache clears to any needed cache memory range. This ensures all modified cache lines update their associated memories before external inputs modify them, and subsequent cache input bus accesses get the updated memory.
Write-back	Access to address spaces with this cache mode are cacheable: • A read miss on the input bus causes a line read on the output bus of a 16-byte-aligned memory address that contains the desired address. This missed data is loaded into the cache and is marked as valid and not modified. • A read hit to a valid cache location returns data from the cache with no output bus access. • A write miss performs a read-to-write (allocate on write miss policy for write-back mode spaces). You perform a line read on the output bus of a

Table continues on the next page...

Table 201. Modes of operation (continued)

Mode	Description
	16-byte-aligned memory address containing the desired write address. This missed data is loaded into the cache and marked as valid and modified. Then the write data updates the appropriate cache data locations. • A write hit updates the cache hit line with the write data and marks the line as modified. • Caches do not support hardware cache coherency. If the cache's input bus has written to write-back regions and another input bus that can access the same target memory without going through the cache needs to see these updates, you must perform explicit cache pushes to any needed cache memory range to ensure all modified cache lines update their associated memories before being read by this input. Likewise, if the cache's input bus has accessed write-back or write-through regions and another input bus that can access the same target memory without going through the cache needs to update these regions, you must first perform explicit cache clears to any needed cache memory range. This ensures all modified cache lines update their associated memories before this input modifies them, and subsequent cache input bus accesses get the updated memory.
Non-cacheable	Access to address spaces with this cache mode are not cacheable. These accesses bypass the cache and access the output bus.

24.3.3 XCACHE function

XCACHE receives bus requests on the input bus.

You can access the programming model for the cache via XCACHE's AMBA APB bus.

XCACHE then processes the cacheable accesses as needed, when bypassing the noncacheable, cache write-through, cache miss, and cache maintenance accesses to its output bus.

The cache on this chip is structured as follows. It has a 2-way set-associative cache structure with a total size of 32 KB for the cache. The caches have 32-bit addresses and data paths and a 16-byte line size. The cache tags and data storage use single-port, synchronous RAMs.

The tag cache contains the required upper address bits, a modify bit, a valid bit, and up to 8 bits of extended address attributes. The extended address attribute field has information such as the supervisor, user, and/or domain ID of the accesses loading this tag. If any extended address attribute bits are provided, for subsequent accesses that hit a valid tag but have different attributes, the cache coherently forces a miss so that the downstream memory protection logic can check the access.

For this 32 KB cache, each cache tag function uses two 1024 x 20-bit RAM arrays or optionally two up to 1024 x 28-bit RAM arrays (if all 8 bits of the extended address attribute are used). The cache data function uses two 4096 x 32-bit RAM arrays. The cache tag entries store 18 bits of upper address as well as a modified and valid bit per cache line, and any optional extended address attribute bits. The cache data entries store four bytes of code or data.

All normal cache accesses use physical addresses. This leads to the use of the following cache address:

CACHE - 32 KB size = (1024 sets) x (16-byte lines) x (2-way set associative)

Table 202. Tag cache address use

Tag cache address use	Cache
Tag hit address range	Address[31:14]

Table continues on the next page...

Table 202. Tag cache address use (continued)

Tag cache address use	Cache
Tag set select address range	Address[13:4] selects 1 of the1024 sets
Not used	Address[3:0]

Table 203. Data cache address use

Data cache address use	System cache
Not used	Address[31:14]
Data set select address range	Address[13:4] used to select one of the 1024 sets
32-bit word select	Address[3:2] used to select one of the four 32-bit words within a set
Byte select	Address[1:0] used to select the byte within the 32-bit word

24.3.4 XCACHE control

The cache is disabled at reset. Cache tag and data arrays are not cleared at reset. Therefore, to enable and configure the cache, you must clear the cache commands and initialize the required tag array.

24.3.4.1 XCACHE set commands

XCACHE set commands may operate on:

- All of way 0
- All of way 1
- All of both ways (complete cache)

You can initiate cache set commands by using the upper bits in Cache Control (CCR). Cache set commands perform their operation on the cache independent of CCR[ENCACHE].

You initiate a cache set command by writing 1 to CCR[GO]. This field also acts as a busy bit for set commands and remains 1 when the command is active. XCACHE writes 0 to it after the completion of the set command.

Table 204 shows a list of supported cache set commands:

- Invalidate − Unconditionally clears valid and modify bits of a cache entry.
- Push − Pushes a cache entry if it is valid and modified, and then clears the modify bit. If the entry is not valid or not modified, leave it as is.
- Clear − Pushes a cache entry if it is valid and modified, and then clears the valid and modify bits. If the entry is not valid or not modified, clear the valid bit.

Table 204. Cache set commands

Cache Control (CCR)[27:24] settings				Command
CCR[PUSHW1]	CCR[INVW1]	CCR[PUSHW0]	CCR[INVW0]	
0	0	0	0	NOP
0	0	0	1	Invalidate all way 0
0	0	1	0	Push all way 0

Table continues on the next page...

Table 204. Cache set commands (continued)

Cache Control (CCR)[27:24] settings				Command
CCR[PUSHW1]	CCR[INVW1]	CCR[PUSHW0]	CCR[INVW0]	
0	0	1	1	Clear all way 0
0	1	0	0	Invalidate all way 1
0	1	0	1	Invalidate all way 1; invalidate all way 0 (invalidate cache)
0	1	1	0	Invalidate all way 1; push all way 0
0	1	1	1	Invalidate all way 1; clear all way 0
1	0	0	0	Push all way 1
1	0	0	1	Push all way 1; invalidate all way 0
1	0	1	0	Push all way 1; push all way 0 (push cache)
1	0	1	1	Push all way 1; clear all way 0
1	1	0	0	Clear all way 1
1	1	0	1	Clear all way 1; invalidate all way 0
1	1	1	0	Clear all way 1; push all way 0
1	1	1	1	Clear all way 1 and way 0 (clear cache)

After a reset, complete an invalidate cache command before using the cache. It is possible to combine the cache invalidate command with the cache enable. That is, writing 8500_0001h to Cache Control (CCR) invalidates the cache and enables the cache.

24.3.4.2 XCACHE line commands

XCACHE line commands operate on a single line in the cache at a time. You can perform cache line commands using a physical or cache address that consists of a set address and a way select. The line command acts on the specified cache line.

Cache line commands with physical addresses first search both ways of the cache set specified by the following physical address bits (see Table 205). If they hit, the commands perform their action on the hit way.

You specify cache line commands using the upper bits in Cache Line Control (CLCR). Cache line commands perform their operation on the cache independent of CCR[ENCACHE]. Using a cache address, the command can be completely specified using Cache Line Control (CLCR). Using a physical address, the command must also use Cache Search Address (CSAR) to specify the physical address.

You can initiate a line cache command by writing 1 to CLCR[LGO] or CSAR[LGO]. These fields also act as busy bits for line commands and remain 1 when the line cache command is active and XCACHE writes 0 to them after the completion of the command.

Table 205. Cache line commands

Cache Line Control (CLCR)[27:24] settings			Command
CLCR[LACC]	CLCR[LADSEL]	CLCR[LCMD]	
0	0	00	Search by cache address and way
0	0	01	Invalidate by cache address and way

Table continues on the next page...

Table 205. Cache line commands (continued)

Cache Line Control (CLCR)[27:24] settings			Command
CLCR[LACC]	CLCR[LADSEL]	CLCR[LCMD]	
0	0	10	Push by cache address and way
0	0	11	Clear by cache address and way
0	1	00	Search by physical address
0	1	01	Invalidate by physical address
0	1	10	Push by physical address
0	1	11	Clear by physical address
1	0	00	Write by cache address and way
1	0	01	Reserved, NOP
1	0	10	Reserved, NOP
1	0	11	Reserved, NOP
1	1	*xx*	Reserved, NOP

24.3.4.2.1 Executing a series of line commands using cache addresses

You can perform a series of line commands with incremental cache addresses by writing to Cache Line Control (CLCR):

1. Place the command in the following fields:
   - CLCR[LACC]
   - CLCR[LADSEL]
   - CLCR[LCMD]
2. Write 1 to CLCR[WSEL] and CLCR[TDSEL] as required.
3. Place the cache address in CLCR[CACHEADDR].
4. Write 1 to CLCR[LGO].

After one line command completes, perform the following procedure to initiate the next command:

1. Increment the cache address (at bit 2 to step through data or at bit 4 to step through lines).
2. Write 1 to CLCR[LGO].

24.3.4.2.2 Executing a series of line commands using physical addresses

You can perform a series of line commands with incremental physical addresses by writing to Cache Line Control (CLCR):

1. Place the command in the following fields:
   - CLCR[LACC]
   - CLCR[LADSEL]
   - CLCR[LCMD]
2. Write 1 to CLCR[TDSEL].
3. Place the physical address in CSAR[PHYADDR] and write 1 to CSAR[LGO].

After one line command completes, perform the following procedure to initiate the next command:

1. Increment the physical address (at bit 2 to step through data or at bit 4 to step through lines).

2. Write 1 to CSAR[LGO].

Cache Line Control (CLCR) and Cache Search Address (CSAR) both contain a field called LGO. Therefore, you can complete the aforementioned steps in a single write to CSAR.

24.3.4.2.3 Line command results

After the completion of a line command, Cache Line Control (CLCR) contains information on the initial state of the line targeted by the command. For line commands with cache addresses, read this information before performing a line command action from the targeted cache line. For line commands with physical addresses, read this information on a hit before performing a line command action from the hit cache line, or, clear the initial valid bit if the command misses. In general, if CLCR[LCIVB] becomes 0, the targeted line is invalid at the start of the line command and no line operation is performed.

Table 206. Line command results

Cache Line Control (CLCR)[22:20] settings			For cache address commands	For physical address commands
CLCR[LCWAY]	CLCR[LCIMB]	CLCR[LCIVB]		
0	0	0	Way 0 line is invalid	No hit
0	0	1	Way 0 valid and not modified	Way 0 valid and not modified
0	1	0	Way 0 line is invalid	No hit
0	1	1	Way 0 valid and modified	Way 0 valid and modified
1	0	0	Way 1 line is invalid	No hit
1	0	1	Way 1 valid and not modified	Way 1 valid and not modified
1	1	0	Way 1 line is invalid	No hit
1	1	1	Way 1 valid and modified	Way 1 valid and modified

After the completion of a line command other than a write, Cache Read/Write Value (CCVR) contains information on the initial state of the line tag or data targeted by the command. For line commands, CLCR[TDSEL] selects between tag and data. If the line command uses a physical address and misses, the data is don't care. For write commands, Cache Read/Write Value (CCVR) holds the write data.

The cache does not have line lock capability.

24.3.5 Clocks

XCACHE uses the AHB input bus clock.

24.3.6 Interrupts

XCACHE has no interrupts.

24.4 External signals

XCACHE has no external signals.

24.5 Initialization

To configure and enable the cache, you must perform XCACHE commands to clear and initialize the required tag array fields.

Table 207. Initialization sequence

Purpose	Programming	Notes
Enable the cache after reset, with the write buffer enabled.	Write 8500_0003h to Cache Control (CCR).	After you write to CCR[GO], it initiates the cache command specified by the following fields: • CCR[INVW1] • CCR[INVW0] The aforementioned fields indicate a command to clear all entries in both cache ways. CCR[ENWRBUF] enables the write buffer and CCR[ENCACHE] enables the cache. See XCACHE control for more information.
Enable the cache after reset, with the write buffer disabled.	Write 8500_0001h to Cache Control (CCR).	After you write to CCR[GO], it initiates the cache command specified by the following fields: • CCR[INVW1] • CCR[INVW0] The aforementioned fields indicate a command to clear all entries in both cache ways, and CCR[ENCACHE] enables the cache. See XCACHE control for more information.

24.6 Application information

XCACHE provides a low-latency access to instructions or data. This decouples processor performance from system memory performance, thereby increasing bus availability for other modules and improving system performance.

24.7 XCACHE register descriptions

The XACHE programming model provides various registers for the following functions:

- Configuring and controlling the cache
- Providing indirect access paths to all cache tag and data storage

NOTE

You can access XCACHE registers only in Supervisor mode.

24.7.1 XCACHE memory map

XCACHE0 base address: 4003_3000h

XCACHE1 base address: 4003_4000h

Field	Function
	1b - Write: initiate command; Read: cache command active
30-28 —	Reserved
27 PUSHW1	Push Way 1 Pushes all modified lines in way 1 when you write 1 to GO. 0b - No operation 1b - Push all modified lines in way 1
26 INVW1	Invalidate Way 1 Invalidates all lines in way 1 when you write 1 to GO. **NOTE** If PUSHW1 and INVW1 are 1, then after you write 1 to GO, this field pushes all modified lines in way 1 and invalidates all lines in way 1 (clear way 1). 0b - No operation 1b - Invalidate all lines in way 1
25 PUSHW0	Push Way 0 Pushes all modified lines in way 0 when you write 1 to GO. 0b - No operation 1b - Pushes all modified lines in way 0
24 INVW0	Invalidate Way 0 Invalidates all lines in way 0 when you write 1 to GO. **NOTE** If PUSHW0 and INVW0 are 1, then after you write 1 to GO, this field pushes all modified lines in way 0 and invalidates all lines in way 0 (clear way 0). 0b - No operation 1b - Invalidate all lines in way 0
23-4 —	Reserved
3 FRCNOALLC	Force No Allocation on Cache Misses Forces no allocation on cache misses when FRCWT is 1. 0b - Allocate on cache misses 1b - Force no allocation on cache misses

Table continues on the next page...

Table continued from the previous page...

Field	Function
2 FRCWT	Force Write Through Mode Specifies whether all cacheable spaces to write through are forced. 0b - Not force 1b - Force
1 —	Reserved You must always write 0 to this field to maintain compatibility.
0 ENCACHE	Cache Enable Enables the cache. 0b - Disable 1b - Enable

24.7.3 Cache Line Control (CLCR)

Offset

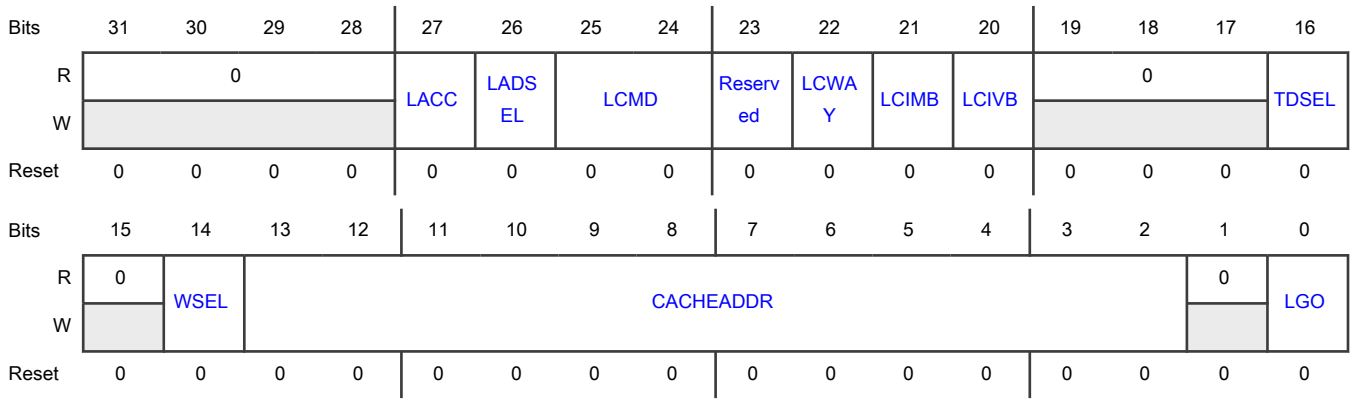
Register	Offset
CLCR	4h

Function

Defines the specific line-sized cache operations that you perform using a specific cache line address or physical address.

If you specify a physical address, both ways of the cache are searched, and the command only performs on the way that hits.

Diagram



Fields

Field	Function
31-28 —	Reserved
27 LACC	Line Access Type Specifies the line access type. 0b - Read 1b - Write
26 LADSEL	Line Address Select Specifies the address (cache or physical). When you use the cache address, you must also specify the way in CLCR[WSEL]. When you use the physical address, both ways are searched and the command performs only if there is a hit. 0b - Cache address 1b - Physical address
25-24 LCMD	Line Command Specifies the line command. 00b - Search and read or write 01b - Invalidate 10b - Push 11b - Clear
23 —	Reserved
22 LCWAY	Line Command Way Indicates the way that the line command uses. Applies only if CLCR[LCIVB] = 1.
21 LCIMB	Line Command Initial Modified Specifies the initial state of the modified bit. If the command uses cache address and way, then this field shows the initial state of the modified bit. If the command uses physical address and a hit, then this field shows the initial state of the modified bit. If the command uses a miss, then this field reads zero.
20 LCIVB	Line Command Initial Valid Specifies the initial state of the valid bit. If the command uses cache address and way, then this field shows the initial state of the valid bit.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If the command uses physical address and a hit, then this field shows the initial state of the valid bit. If the command uses a miss, then this field reads zero.
19-17 —	Reserved
16 TDSEL	Tag or Data Select Selects tag or data for search and read or write commands. 0b - Data 1b - Tag
15 —	Reserved
14 WSEL	Way Select Selects the way for line commands. 0b - Way 0 1b - Way 1
13-2 CACHEADDR	Cache Address Represents bits [13:2] of the cache address: CLCR [13:4] accesses the tag arrays. CLCR [13:2] accesses the data arrays.
1 —	Reserved
0 LGO	Initiate Cache Line Command Initiates the cache command that CLCR[LCMD], CLCR[LADSEL], and CLCR[LACC] indicate if you write 1 to this field. Reading this field indicates whether a line command is active. **NOTE** • This field remains 1 until the command completes. Writing 0 to it has no effect. • This field is shared with CSAR[LGO]. 0b - Write: no effect; Read: no line command active 1b - Write: initiate line command; Read: line command active

24.7.4 Cache Search Address (CSAR)

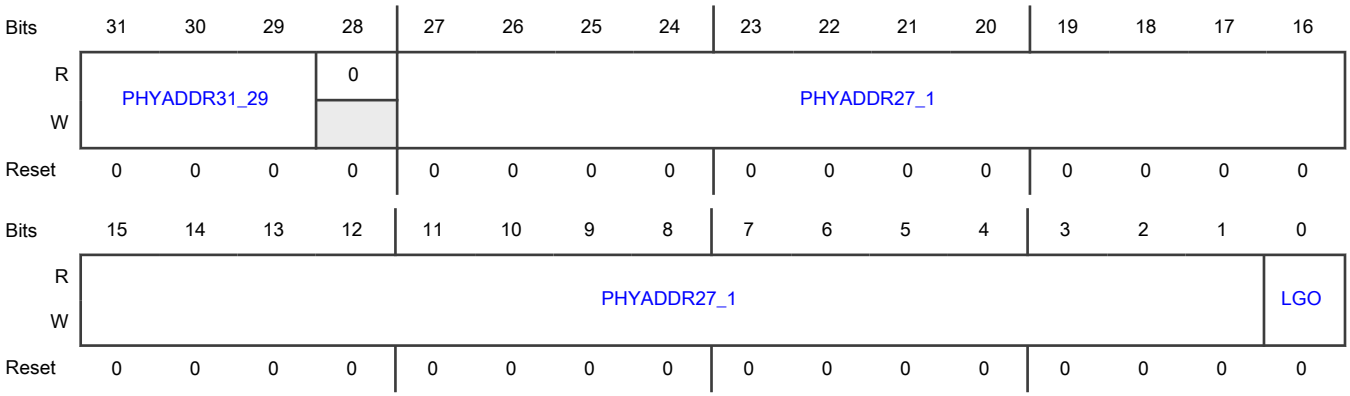
Offset

Register	Offset
CSAR	8h

Function

Defines the explicit cache address or physical address for line-sized commands specified in CLCR[LADSEL].

Diagram



Fields

Field	Function

25.2 Overview

SEMA42 is a memory-mapped module that provides robust hardware support needed in multi-core systems for implementing semaphores and provides a simple mechanism to achieve "lock and unlock" operations via a single - write access. The hardware semaphore module provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.

NOTE

Terminology in this chapter has been updated as follows:

Table 210. Updated terms

Updated term	Deprecated term
Initiator	Master
Target	Slave
Stop	Abort

25.2.1 Block diagram

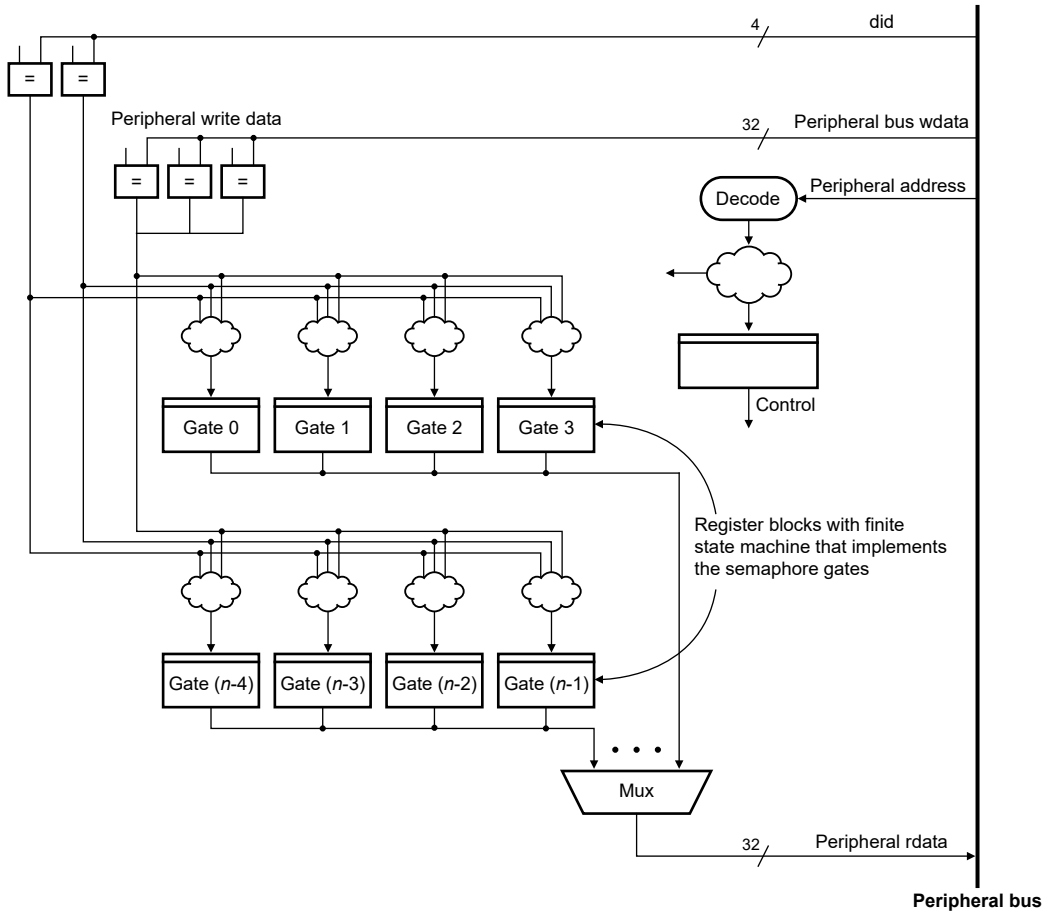

Figure 77. SEMA42 block diagram

25.2.2 Features

SEMA42 implements hardware-enforced semaphores as an IPS-mapped target peripheral device. The feature set includes:

- Support for 64 hardware-enforced gates in a multi-domain configuration that supports up to 15 domains.
- Each hardware gate appears as a 16-state, 4-bit state machine.
- Support for secure reset mechanisms to clear the contents of individual gates, as well as a clear-all capability.
- Memory-mapped target peripheral that offers programming-model accesses.

25.3 Functional description

The intent of the hardware gate implementation is to specify a protocol where the locking domain must unlock the gate. However, some systems may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset. To support this special gate reset requirement, SEMA42 implements a secure reset mechanism that allows you to initialize a hardware gate (or all the gates) by following a specific dual-write access pattern. The secure-gate reset:

- Uses a technique similar to that required for the servicing of a software watchdog timer
- Requires two consecutive writes with pre-defined data patterns from the same domain

You must do this to force the clearing of the specified gate(s). The required access pattern as follows:

1. A domain performs a 16-bit write to the RSTGT memory location. The most significant byte (RSTGT_W[RSTGDP]) must be E2h. The value of least significant byte is irrelevant for this reference and can be anything.
2. The same domain then performs a second 16-bit write to the RSTGT location. For this write, the upper byte (RSTGT_W[RSTGDP]) is the logical complement of the first data pattern (1Dh) and the lower byte (RSTGT_W[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate or all gates to be cleared. If the same domain writes incorrect data on the second access or another domain performs the second write access, SEMA42 stops the special gate reset sequence and does not assert an error signal.
3. Reads of the RSTGT location return information on the 2-bit reset state machine (RSTGT_R[RSTGSM]) that implements these functions:
   - The domain performing the reset (RSTGT_R[RSTGMS])
   - The last-cleared gate number(s) (RSTGT_R[RSTGTN])

   Reads of the RSTGT register do not affect the secure-reset finite state machine in any manner.

25.3.1 Multi-core programming: software gates

Multi-processor systems require a function that can be used to safely and easily provide a locking mechanism for system software to control access to shared data structures, shared hardware resources, and so on. The software uses the gating mechanisms to serialize (and synchronize) accesses to shared data and/or resources to prevent race conditions and preserve memory coherency between different processes and domains.

Consider the following description of a typical use-case: domain*X* enters a section of code, where shared data values are to be updated. The domain must first acquire a semaphore. Think of this as the locking (or closing) of a software gate. After the gate locks, a properly-architected software system does not allow other processes (or domains) to execute the same code segment or modify the shared data structure protected by the gate. In other words, the system locks out other processes/domains. Many software implementations include a spin-wait loop within the lock function until the gate locks. After domain X obtains the lock, domain X continues execution and updates the data values protected by the particular lock. After domain X completes the updates, it unlocks (or opens) the software gate, allowing other processes/domains access to the updated data values.

A correctly-implemented system solution must follow these important rules:

- A gate variable must protect all writes to shared data values or shared hardware resources.
- After a domain locks a gate, the system must block other processes/domains from accessing the shared data or resources. Software conventions enforce this.
- The domain that locks a particular gate is the only domain that can open (unlock) that gate.

Information in the hardware gate identifying the locking domain can be extremely useful for system-level debugging.

25.3.2 64 Hardware-enforced gates

Gates appear as a 64-entry byte-size array with read and write accesses.

Domains lock gates by writing "domainID_number+1" to the appropriate gate and must read back the gate value to verify that the lock operation succeeded.

After the gate locks, the locking domain unlocks the gate by writing zeroes.

- 16-state implementation

  If gate = 0h, then state = unlocked

  if gate = 1h, then state = locked by domain (initiator) 0

  if gate = 2h, then state = locked by domain (initiator) 1

  …

  if gate = Fh, then state = locked by domain (initiator) 14

SEMA42 uses the logical domain number and the specified data patterns as reference attributes to validate all write operation.

After a gate locks, the locking domain must unlock the gate by writing zeroes.

25.3.3 State machine of the GATE*n* registers

This section describes more about the SEMA42 functional operation and specific details of the state machines of the GATE*n* registers.

As described previously, each of the GATE*n* registers implements a 4-bit, 16-state machine. The following figure shows a simplified diagram of the state transitions for each gate.

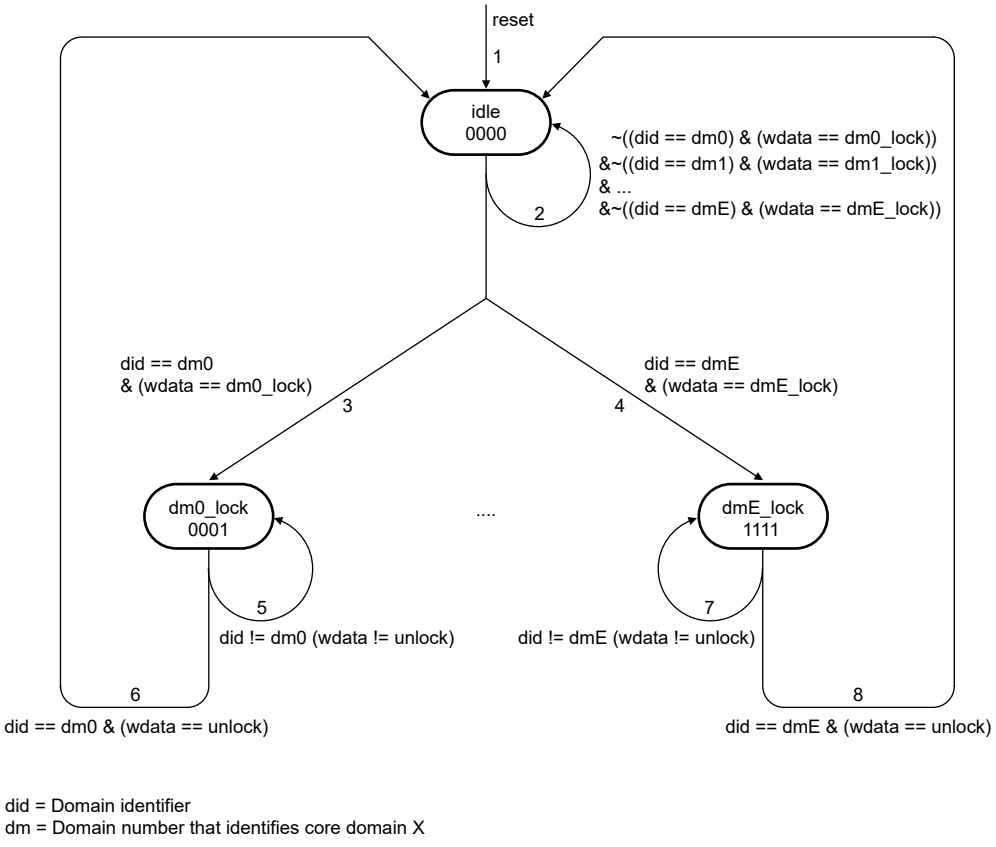

Figure 78. GATE*n* state machine

In the figure above, "dmE" represents domain 14 (E in hexadecimal). The platform passes the domain number to SEMA42.

The following table defines the GATE*n* state transitions.

Table 211. GATE*n* state transitions

Current state	Next state	Transition	Description
–	idle	1	Any reset, whether a system reset or a software-initiated gate reset, unconditionally forces the gate into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding domain occurs, the gate remains in the idle state.
idle	dm0_lock	3	When domain 0h initiates a write of the dm0_lock data value, the gate transitions into the dm0_lock state.
idle	dmE_lock	4	When domain Eh initiates a write of the dmE_lock value, the gate transitions into the dmE_lock state.
dm0_lock	dm0_lock	5	When in this state, the gate remains here if any attempted write is not from domain 0h with the unlock data value.
dm0_lock	idle	6	The gate returns to the idle (unlocked) state after a write from domain 0h with the unlock data value occurs.
dmE_lock	dmE_lock	7	When in this state, the gate remains here if any attempted write is not from domain Eh with the unlock data value.
dmE_lock	idle	8	The gate returns to the idle (unlocked) state after a write from domain Eh with the unlock data value occurs.

SEMA42 uses these gate data values:

- The lock data value is (domain number) + 1.
- The unlock data value is 00h.

25.3.4 Clocking

Type of clock	Description
Module clock (clk)	Functions the module and controls the access to the registers.

25.3.5 Interrupts

This module has no interrupts.

25.4 External signals

This module has no external signals.

25.5 Initialization

This module does not require initialization.

25.6 Memory map/register definition

You can access these registers only in Supervisor mode. User accesses terminate with an error.

25.6.1 SEMA42 register descriptions

25.6.1.1 SEMA42 memory map

SEMA42_0 base address: 4020_6000h

SEMA42_3 base address: 4031_B000h

SEMA42_4 base address: 4018_A000h

Offset	Register	Width (In bits)	Access	Reset value
0h - 3Fh	Gate (GATE0 - GATE63) [1]	8	RW	00h
42h	Reset Gate Read (RSTGT_R)	16	R	0000h
42h	Reset Gate Write (RSTGT_W)	16	W	See section

1. In this array, the index and offset values of the registers do not increment in direct alignment. For details, see the register description.

25.6.1.2 Gate (GATE0 - GATE63)

Offset

For n = 0 to 63:

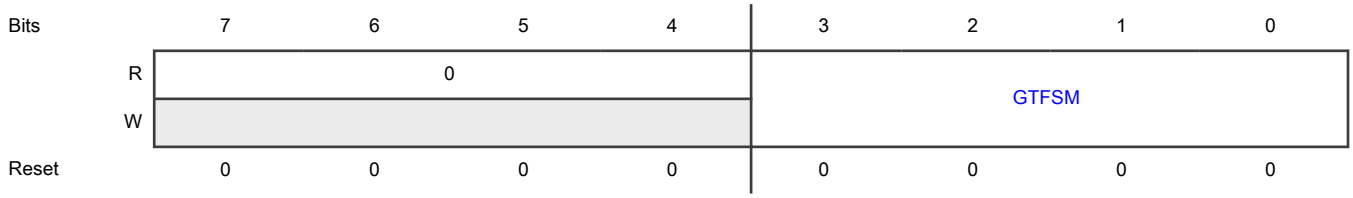
Register	Offset
GATEn	0h + (n + 3 - 2 × (n mod 4))

Function

Implements each semaphore gate in a 4-bit finite state machine, right-justified in a byte data structure. The hardware uses the logical domain-identifier number in conjunction with the data patterns to validate all attempted write operations. Only domain initiators can modify the gate registers. After a gate locks, only the locking domain must open (unlock) the gate.

You can read multiple gate values in a single access. However, you can update only a single gate at a time, via a write operation. If you attempt to write a byte-wide value that is neither the unlock value (00h) nor the appropriate lock value (domainID_number + 1), SEMA42 considers this as "no operation" and does not change any gate state. Attempts to write multiple gates in a single-aligned access with a size larger than 8 bits (byte) generate an error termination and do not allow any gate state changes.

Diagram



Fields

Field	Function
7-4 —	Reserved
3-0 GTFSM	Gate Finite State Machine Indicates the state of the gate for the last domain that locked the gate. This can be useful during system debug. The hardware gate has a 16-state implementation, defined as: 0000b - The gate is unlocked (free). 0001b - Domain 0 locked the gate. 0010b - Domain 1 locked the gate. 0011b - Domain 2 locked the gate. 0100b - Domain 3 locked the gate. 0101b - Domain 4 locked the gate. 0110b - Domain 5 locked the gate. 0111b - Domain 6 locked the gate. 1000b - Domain 7 locked the gate. 1001b - Domain 8 locked the gate. 1010b - Domain 9 locked the gate. 1011b - Domain 10 locked the gate. 1100b - Domain 11 locked the gate. 1101b - Domain 12 locked the gate. 1110b - Domain 13 locked the gate. 1111b - Domain 14 locked the gate.

25.6.1.3 Reset Gate Read (RSTGT_R)

Offset

Register	Offset
RSTGT_R	42h

Function

Describes the specific hardware gate to be reset and records the logic number of domain. Reset Gate Write (RSTGT_W) also describe the same register showing the fields when you write it.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0		RSTGSM		RSTGMS				RSTGTN							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-14 —	Reserved
13-12 RSTGSM	Reset Gate Finite State Machine Indicates the encoded state machine value when you read the register. RSTGSM = 10b is valid for only a single machine cycle, so a read can never return this value. SEMA42 maintains the reset state machine in a 2-bit, 3-state implementation, defined as follows: 00b - Idle, waiting for the first data pattern write. 01b - Waiting for the second data pattern write 10b - The 2-write sequence has completed. Generate the specified gate reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. 11b - This state encoding is never used and therefore reserved.
11-8 RSTGMS	Reset Gate Domain Records the logical number of the domain performing the gate reset function. To succeed, this function requires that the same domain initiate the two consecutive writes to this register. SEMA42 updates the field each time a write to this register occurs.
7-0 RSTGTN	Reset Gate Number Specifies the specific hardware gate to be reset. The second write updates this field. If RSTGTN < 64, SEMA42 resets the single gate defined by RSTGTN. Otherwise, SEMA42 resets all the gates.

25.6.1.4 Reset Gate Write (RSTGT_W)

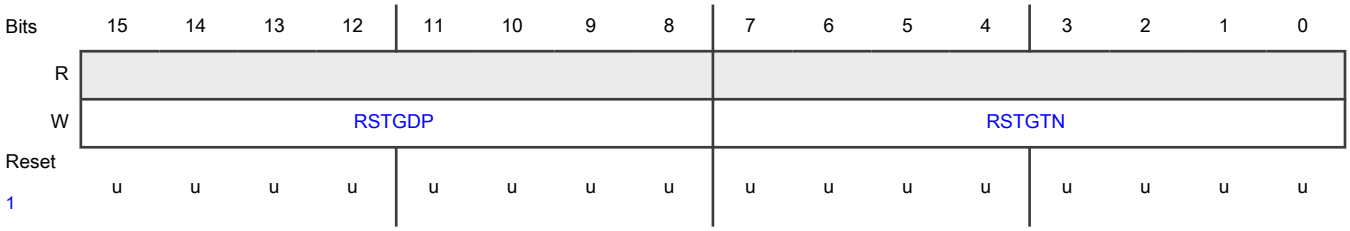
Offset

Register	Offset
RSTGT_W	42h

Function

Specifies the hardware gate to reset when data patterns are specified.

Diagram



1. Reset value is not applicable for writes.

Fields

Field	Function
15-8 RSTGDP	Reset Gate Data Pattern You access this field with the specified data patterns on the two consecutive writes to enable the gate-reset mechanism. For the first write, RSTGDP must be E2h. For the second write, RSTGDP must be 1Dh.
7-0 RSTGTN	Reset Gate Number Specifies the specific hardware gate to be reset. The second write updates this field. If RSTGTN < 64, SEMA42 resets the single gate defined by RSTGTN. Otherwise, SEMA42 resets all the gates.

26.1.3 CCR0[BOOT]

For this chip, the CCR0[BOOT] is reserved for each instance.

26.2 Overview

MU enables two processors on a chip to communicate and coordinate by passing messages (for example, data, status, and control) through the MU interface. MU also allows one processor to signal the other processor using interrupts.

MU must synchronize the accesses from one side to the other because MU can manage messaging between processors using different clocks. MU accomplishes synchronization using two sets of matching registers: processor A-facing and processor B-facing.

26.2.1 Block diagram

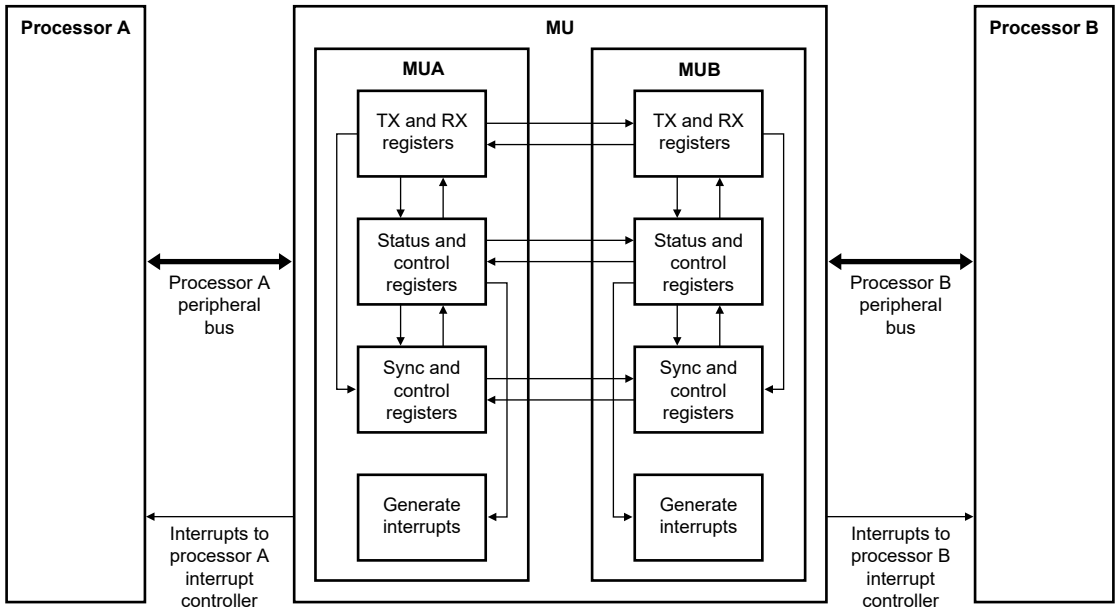

Figure 79. Block diagram

26.2.2 Features

- Memory-mapped registers (MU is connected as a peripheral under the peripheral bus on the processor A-side and processor B-side)
- Synchronized message transfers between cores
  - To send data or messages from one side to the other, messaging unit A (MUA) provides 4 transmit registers and 4 receive registers. Messaging unit B (MUB) provides 4 transmit registers and 4 receive registers.

  - Transmit empty flags (TSR[TEn]) and receive full flags (RSR[RFn]) facilitate the transfer of data or messages between cores on both sides of MU.
  - A synchronization mechanism updates the transmit and the receive flags. There is an inherent latency between updating the flag on one side and reflecting its status on the other side. See Event update timing.
  - MU has a 3-bit flag data register, which you can use to send flag data between the two MU sides.
- Interprocessor interrupts
  - MU has 12 interrupt sources on each side (processor A-side, processor B-side) for signaling the other processor. You can use the interrupts for notification of receive and transmit events and for general-purpose signaling between processors. There are 4 general-purpose interrupt requests available and 8 receive and transmit interrupt sources.
  - Processor A can initiate a non-maskable interrupt (NMI) to processor B.
  - Processor B can initiate a non-maskable interrupt (NMI) to processor A.
- Reset (Each processor can issue a reset to MU via CR[MUR], which is a self-clearing field).

26.3 Functional description

MU enables two cores (processor A and processor B) to communicate with each other:

- By sharing messages and data.
- By enabling one core to wake the other core by using interrupts.

The messaging, control, and status registers of the two cores are mapped to processor A memory and processor B memory as a regular peripheral. The peripheral data bus is 32 bits wide inside MU.

Messaging logic is used with shared memory. Various messaging methods can implement a messaging protocol. For example, a message could mean one of the following:

- A message of *n* words has been written starting at offset *x* in the memory.
- The previous data block that was sent has been read.

The ability to keep messaging logic independent of the shared memory is not restricted to a predefined hardware protocol. The software required to manage the messaging is short and straightforward.

Most of the messaging mechanisms are symmetric. They are duplicated and are available on both the processor A side and processor B side. The messaging mechanisms are:

- 4 32-bit transmit registers, which are each reflected in 4 read-only receive registers on the side of the other processor. These registers can transfer 32-bit word messages or the frame information of the messages written to the shared memory. For example, they can transfer the number of words, initial address, and message type code.
- Writing to a transmitter-side transmit register (TR*n*) clears the Transmitter Empty flag in the transmitter-side Status register (TS*n*[TE*n*]), and sets the Receiver Full flag in the receiver-side Status register (RS*n*[RF*n*]). Setting the flag on the receiver side can trigger an interrupt on the receiver side (a maskable receive interrupt).
- Reading a receiver-side receive register (RR*n*) clears the Receiver Full flag in the receiver-side Status register (RS*n*[RF*n*]), and sets the Transmitter Empty flag in the transmitter-side Status register (TS*n*[TE*n*]). Setting the Transmitter Empty flag can trigger an interrupt on the transmitter side (a maskable transmit interrupt).
- 4 general-purpose interrupt request flags are reflected in General-purpose Status (GSR) on the receiver side.
- 3-bit flag data is transmitted from Flag Control (FCR) to Flag Status (FSR) on the side receiving the flag data. SR[FUP] sets when the flag data is transmitted and clears when the receiving side acknowledges the flag data (the flag is updated).

Writing to a transmit register signals to the receiver side that data is ready for retrieval.

Do not write to the transmit register again without verifying that the data is retrieved. The transmitter side cannot determine the exact time that the receiver attempts to retrieve the data. Before attempting to write to the transmit register again, the transmitter side must wait for the Transmitter Empty interrupt or it must poll TSR[TE*n*].

Reading a receive register signals to the transmitter side that data can be written to that register.

Do not read the receive register again without verifying that the data is written. The receiver side cannot determine the exact time that the transmitter attempts to write the data. Before attempting to read the receive register again, the receiver side must wait for the Receiver Full interrupt or it must poll RSR[RF*n*].

26.3.1 Submodules

26.3.1.1 MUA side

MUA receives its register configuration via the processor A peripheral bus. It sends or receives messages to or from MUB. Processor A can receive messages by reading MUA registers, and MUA can send interrupts to processor A when interrupts are enabled.

NOTE

Processor B should not access MUA registers. Processor C, if exist, should also not access MUA registers. TRDC might be needed to prevent such illegal access of Processor B or C to MUA registers.

26.3.1.2 MUB side

MUB receives its register configuration via the processor B peripheral bus. It sends or receives messages to or from MUA. Processor B can receive messages by reading MUB registers, and MUB can send interrupts to processor B when interrupts are enabled.

NOTE

Processor A should not access MUB registers. Processor C, if exist, should also not access MUB registers. TRDC might be needed to prevent such illegal access of Processor A or C to MUB registers.

26.3.2 Event update timing

The messaging side of each processor has a hardware mechanism to send event update requests to the other processor. An event occurs when the status register of the receiving processor must reflect any information change. The event update latency is the delay between the event being ready at one processor and the resulting update at the status register of the other processor:

- The minimum event latency is (1 clock cycle of the sending side) + (2.5 clock cycles of the receiving side). This minimum case happens when no event is pending when the new event occurs.
- The maximum event latency is (6 clock cycles of the sending side) + (6.5 clock cycles of the receiving side). The maximum case happens when the event occurs just after a previous event is sent to the other side.

The event update latency varies depending on the time at which the subsequent event is triggered.

26.3.3 Clocking

Table 215. MU clocks

Clock name	Description
Bus clock MUA	Used only for bus accesses to MUA control and configuration registers
Bus clock MUB	Used only for bus accesses to MUB control and configuration registers

26.3.4 Resets

The following sections list the reset sources included in MU. Each reset performs a different function for the MU module compared to the function it performs for the system.

26.3.4.1 Asynchronous system reset

When the asynchronous system reset on either side of MU is asserted, SR[MURS] becomes 1 until the asynchronous system reset sequence on both the MUA and MUB sides ends. Verify that SR[MURS] becomes 0 before accessing MU.

The asynchronous system reset on one side of MU resets the other side of MU. The reset forces all control and status registers to return to their default values and clears all internal states. The following table shows the exceptions to this behavior.

Table 216. Exceptions to asynchronous system reset

MUA-side exceptions	MUB-side exceptions
MUB_SR[MURS] MUB_CSSR0/MUB_CSR0	MUA_SR[MURS] MUA_CSSR0/MUA_CSR0

26.3.4.2 MU software reset

Writing 1 to CR[MUR] causes most control and status registers to return to their default values and clears all internal states.

The instruction immediately following the assertion of CR[MUR] must not write to the MU registers. The reset sequence may overwrite such a write, with the register retaining the reset value. To know the end of the reset sequence for both processors, monitor the value of SR[MURS]. After the reset sequence on both processors has ended, a write to the MU registers can be attempted.

NOTE

The process of CR[MUR] becoming 1 is delicate because it asynchronously affects the registers on the other side. CR[MUR] becoming 1 may cause unpredictable behavior if, for example, the other processor is concurrently testing an MU register field (TSR[TE*n*] in the other processor). Before writing 1 to CR[MUR], verify that the other processor is not engaged in an MU signaling activity.

26.3.5 Interrupts

MU controls interrupt requests that one processor makes to the other processor. This section describes all the interrupts that the module generates.

MU can generate these interrupt sources individually to send to the processors:

- 4 receive interrupts (asserted when the Receive Full flags are set in Receive Status (RSR) and enabled in Receive Control (RCR)) for each receive register
- 4 transmit interrupts (asserted when the Transmit Empty flags are set in Transmit Status (TSR) and enabled in Transmit Control (TCR)) for each transmit register
- 4 general-purpose interrupts (asserted when the GIP flags are set in General-Purpose Interrupt Enable (GIER) and enabled in General-Purpose Interrupt Enable (GIER))
- One non-maskable interrupt (NMI) flag (asserted when the NMI flag is set in Core Control 0 (CCR0))

All interrupts except NMI are maskable in the processor control registers: TCR, RCR, GIER, and CR. MU does not assume any internal priority of these interrupts. Multiple interrupts (for example, receive 0 and receive 1, or any transmit or general-purpose interrupts) can be asserted simultaneously. The interrupt controller must resolve the priority of these interrupts at the chip level.

Triggering any enabled interrupt wakes the processor from below mode before servicing the interrupt

- Wait mode

The software (as part of the interrupt handler) must clear the general-purpose interrupt pending flags (GSR[GIP*n*]) to deassert the request to the interrupt controller.

The software must also clear the NMI by writing CSSR0[NIMC] (as a part of the interrupt handler) to deassert the NMI request.

When a processor writes to the general-purpose interrupt (GCR[GIR*n*]), MU synchronizes the write event to the other processor to set the general-purpose interrupt request pending flag (GSR[GIP*n*]). When GSR[GIP*n*] is set and the general-purpose interrupt is enabled on the receiving side (GIER[GIE*n*] is 1), the transmitting-side general-purpose interrupt is issued to the receiving processor, which clears this interrupt by writing 1 to GSR[GIP*n*]. The interrupt is deasserted as soon as the write to GSR[GIP*n*] occurs. MU synchronizes the write event of GSR[GIP*n*] to the other processor. The synchronized signal writes 0 to the GIR*n* interrupt.

Before writing 1 to GCR[GIR*n*], verify that the field is 0, which means that a general interrupt is not pending. Generally, MU ignores writing 1 to this field while the field is already 1, but in some cases it may issue a second interrupt.

26.4 External signals

This module has no external signals.

26.5 Initialization

MU does not require initialization.

26.6 Application information

MU facilitates messages between processors. For example, MU passes:

- Short messages. Transmit registers can pass short messages from 1 to 4 words in length for processor A and from 1 to 4 words for processor B. For example, for a four-word message, only one register must have its corresponding interrupt enabled on the receiving side. The first three words of the message are written to the registers with masked interrupts. The fourth word is written to the last register, triggering an interrupt on the receiving side.
- Frame information. Transmit registers can pass frame information for long messages written to the shared system memory. Such frame information normally includes a start address and a number of words. It can include a message type code.
- Event notices and requests. MU can signal events and requests that do not include data words between processors using general-purpose interrupts. For example, one such event is acknowledging that a long message is read from the shared system memory.
- Fixed-length data. Formatted data with a fixed length can be written to predetermined locations in the shared memory. A processor can use general-purpose interrupts to signal to the other processor that the data is ready.
- Announcements. A processor can use the 3 flags to announce its current program state or other billboard messages to the other processor.

26.6.1 Messaging protocols using interrupts

The example below describes a four-word messaging sequence sent between the processor A and processor B.

The transmitting processor writes to the transmit registers sequentially. When *n* = 0, 1, and 2, the interrupts are disabled, so no interrupt goes to the processor (although interrupt conditions occur). For *n* = 3, the interrupt is enabled, and MU generates the last receive interrupt request.

1. Write sequence:
    a. The transmitting processor writes the message information sequentially to its Transmit registers 0, 1, 2.
    b. When the write to Transmit register 3 occurs, RSR[RF3] is set after synchronization. It immediately triggers the receive full 3 interrupt on the receiving processor.
2. Read sequence:
    a. The receiving processor receives the receive full 3 interrupt and starts reading the message transferred from the receive registers.
    b. After the receiving processor reads Receive register 3, MU clears RSR[RF3].

Table 217 and Figure 80 describe the messaging model, using transmit and receive registers and the interrupt messaging protocol.

Table 217. Interrupt messaging protocol (generalized)

Step	Action	Description
1	Processor A writes data.	RR*n* on processor B's side reflects a data write to TR*n* by processor A.
2	Clear the transmitter empty flag and set the receiver full flag.	The data write to TR*n*: • Clears TSR[TE*n*] on the processor A side. • Sets RSR[RF*n*] on the processor B side.
3	Generate the receive interrupt request.	Setting RSR[RF*n*] generates a receive interrupt request to processor B.
4	Processor B reads the data.	After receiving the receive interrupt request, processor B performs a data read of RR*n*.
5	Clear the receiver full flag and set the transmitter empty flag.	Reading the data from the RR*n* register: • Clears RSR[RF*n*] on the processor B side. • Sets TSR[TE*n*] on the processor A side.
6	Generate the transmit interrupt request.	Setting TSR[TE*n*] generates a transmit interrupt request to processor A.

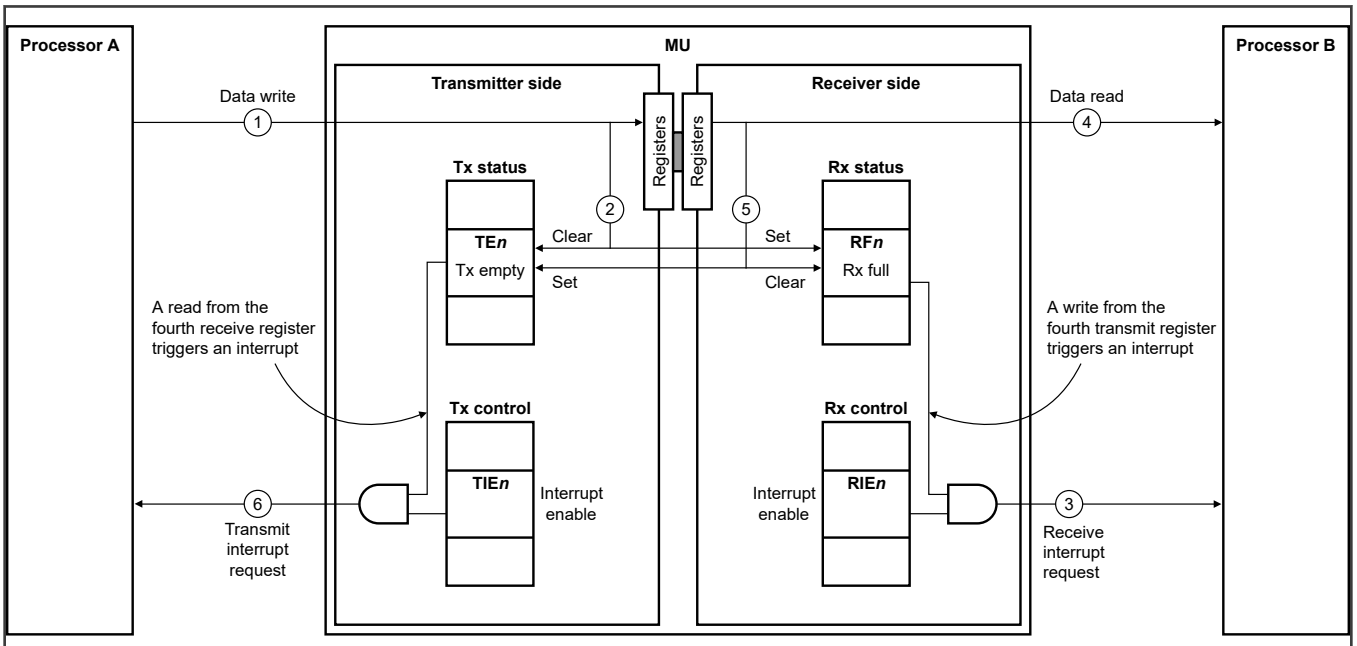

Figure 80. Messaging model using transmit and receive registers

You can use the messaging hardware to implement messaging protocols for an array of message types. MU provides full support for interrupt and polling management schemes.

26.6.2 Messaging protocols using event interrupts

MU can signal events and requests that do not include data words between processors using general-purpose interrupts.

Formatted data with a fixed length can be written to predetermined locations in the shared memory. A processor can use a general-purpose interrupt to signal to the other processor that the data is ready.

A processor can use the 3 flags to announce its current program state (or similar messages) to the other processor.

Table 218 and Figure 81 describe the event steps when the processor triggers a general-purpose interrupt.

Table 218. General-purpose interrupt messaging protocol (generalized)

Step	Action	Description
1	Processor A sets its associated general-purpose interrupt request flag.	Processor A sets GCR[GIR*n*].
2	The general-purpose interrupt request pending status flag is set.	GSR[GIP*n*] is set.
3	MU generates the general-purpose interrupt request to processor B.	Setting GSR[GIP*n*] generates the general-purpose interrupt request to processor B. GIER[GIE*n*] must be set for processor B.
4	Processor B reads the status register.	Processor B reads GSR[GIP*n*].
5	Processor B services the interrupt.	—
6	Processor B sets GSR[GIP*n*] to clear the interrupt.	Processor B writes 1 to the corresponding GSR[GIP*n*] flag to clear the interrupt.
7	GCR[GIR*n*] is cleared.	Setting GSR[GIP*n*] clears GCR[GIR*n*] on the processor A side.

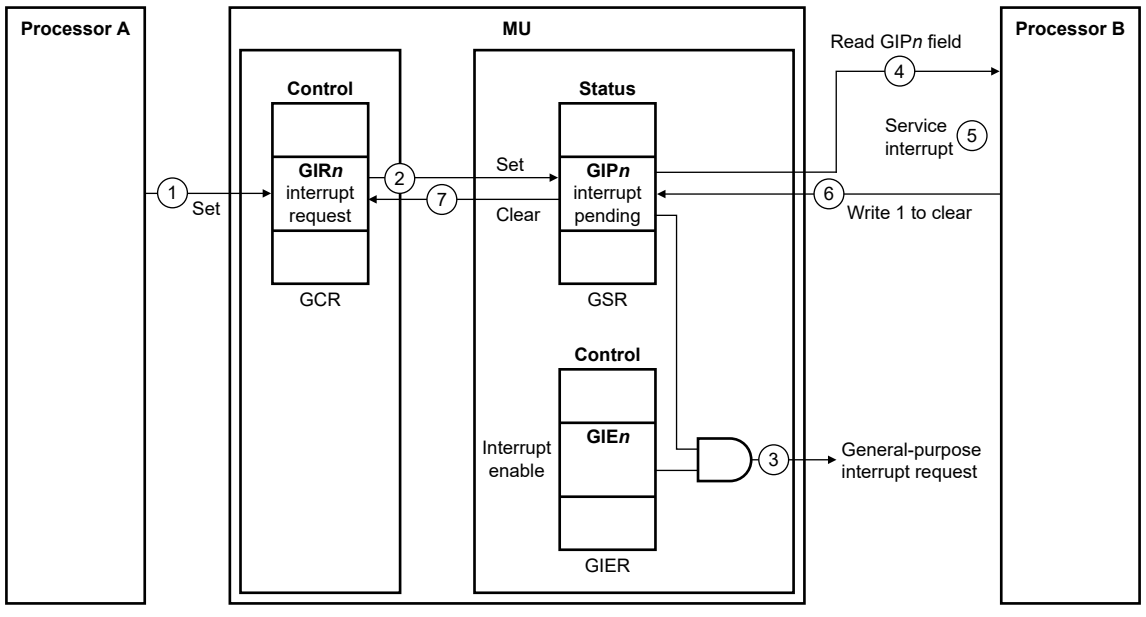

Figure 81. Messaging model using a general-purpose interrupt

26.6.3 Exclusive access to shared memory

MU can signal one processor about its current access to shared memory. This signaling prevents the other processor from overwriting data during the exclusive memory access period.

The following tables describe the signaling protocol that processor A uses to inform processor B about its current access (write) to shared memory:

- Table 219 shows processor A performing an exclusive access to shared memory.
- Table 220 shows processor B scanning for transaction information.
- Table 221 shows processor B accepting exclusive access from processor A.
- Table 222 shows processor B rejecting exclusive access from processor A.

According to the examples shown in the following tables, GCR[GIR*n*], RR*n*, and TR*n* are reserved to support exclusive access to the shared memory protocol.

Table 219. Processor A performs an exclusive access to shared memory

Step	Action	Description
1	Processor A sends the GIR*n* request to processor B using the processor A control register.	Before processor A performs an exclusive access to the shared memory, it sends a GIR*n* request to processor B.
2	Processor A sends an exclusive-access request using a transmit data register (TR*n*).	Processor A sends an exclusive-access request (command, location, and length of target access) to processor B using a selected transmit data register (TR0).
3	Processor A waits for a dedicated interrupt from processor B.	Processor A waits for a dedicated interrupt (as an acknowledgment) triggered by processor B before proceeding.
4	Processor A accesses the shared memory.	After receiving a dedicated interrupt from processor B, processor A proceeds.

Table 220. Processor B scans for transaction information

Step	Action	Description
1	Processor B receives an interrupt from a receive data register (RR*n*).	—
2	Processor B reads the receive data register (RR*n*).	—
3	Processor B scans the receive data register contents.	Processor B scans for transaction information (whether processor A has requested exclusive access).

Table 221. Processor B accepts exclusive access from processor A

Step	Action	Description
1	Processor B triggers a dedicated interrupt.	Processor B acknowledges the request from processor A by triggering a dedicated interrupt (ack) to processor A.
2	Processor B sends a code message to processor A.	With the acknowledge interrupt, processor B sends a code message to processor A through the selected transmit register (TR*n*). The message informs processor A that it can exclusively access the shared memory.

Table 222. Processor B rejects exclusive access from processor A

Step	Action	Description
1	Processor B ignores the request from processor A for exclusive access.	If processor B does not provide permission to processor A, processor B ignores the exclusive-access request.

26.6.4 Packet data transfers

The following table describes an example packet transfer sequence between processor B and processor A subsystems.

Table 223. Packet data transfer sequence

Step	Action	Description
1	Processor B requests DMA.	Processor B sends a DMA request to initiate the packet data transfer.
2	DMA data transfer	DMA acknowledges.
3		DMA starts transferring data from the specified processor B memory location to the specified shared memory.
4		DMA interrupts processor B to signal that the packet transfer has finished.
5	Processor B informs processor A that data is in shared memory.	Using a B-side transmit register, processor B sends a packet information message to processor A about the arrival of new packet data stored in shared memory. The message contains the command, location, and length of packet data.
6	Processor A receives an interrupt.	Processor A receives an interrupt (assuming its corresponding processor A MU-side receive interrupt is enabled). The pending processing task becomes active and processes packet data from memory.
7	Processor A reads data, then writes data.	Processor A reads or processes packet data from shared memory.
8		Processor A writes the result from packet processing to a separate buffer.
9	Processor A informs processor B that the transfer is finished.	After the processing of the packet data finishes, processor A informs processor B (using MU processor A-side transmit register, MUA_TR*n*).
10	Processor A sends an interrupt to processor B (a request for more data).	Processor B receives the next interrupt from processor A, in which processor A requests more packet data.

26.6.5 Freeing a processor from deadlock

During normal operation, one processor may determine that the other processor is not working or is deadlocked. Using Status (SR), the processor can use the methods in the following table to identify and correct the problem.

Table 224. Freeing a processor from deadlock

Processor mode	Technique	Description
—	Processor issues an interrupt.	The other processor can interrupt the processor by issuing one of the 12 (general purpose, receive, or transmit) interrupts.
Normal	Processor issues a non-maskable interrupt.	If a processor is in Normal mode, the other processor can issue a non-maskable interrupt (NMI). You can configure the NMI routine to execute a diagnostic routine that is predefined for such an event.

26.7 Register definition

MU provides transmit and receive data registers (*x*TR0–*n*, *x*RR0–*n*) for communication between processor A and processor B. It also provides control registers (*x*CR) for operations such as interrupts and resets, and status registers (*x*SR) for checking the status of the other MU-side. Figure 82 shows the schematic for MU registers.

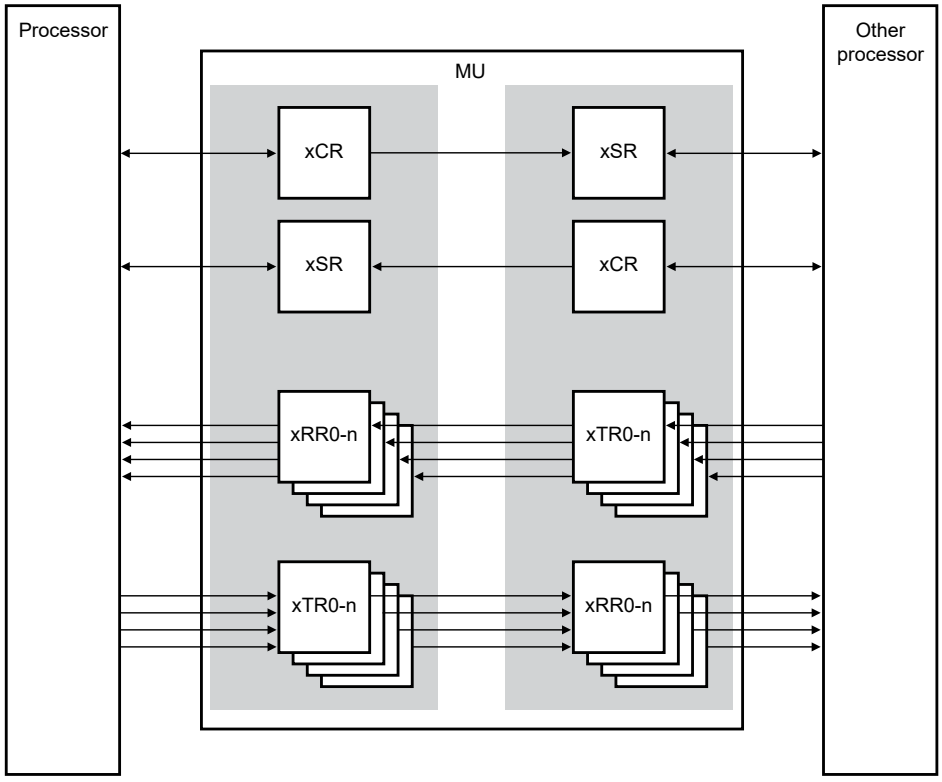

Figure 82. MU registers

26.7.1 MUA register descriptions

This section contains the detailed register descriptions for MUA registers.

NOTE

A module transfer error to processor A or processor B is generated when:

- A read or write access is made to an invalid location.
- A write operation is performed on a read-only register on the processor A side or processor B side of MU.

The only exception to this behavior is the MUA SR register. No transfer error occurs when accessing this location.

26.7.1.1 MUA memory map

MU0.MUA base address: 4020_0000h

MU1.MUA base address: 4020_2000h

MU2.MUA base address: 4020_4000h

MU3.MUA base address: 4031_9000h

MU4.MUA base address: 4018_9000h

Offset	Register	Width (In bits)	Access	Reset value

26.7.1.2 Version ID (VER)

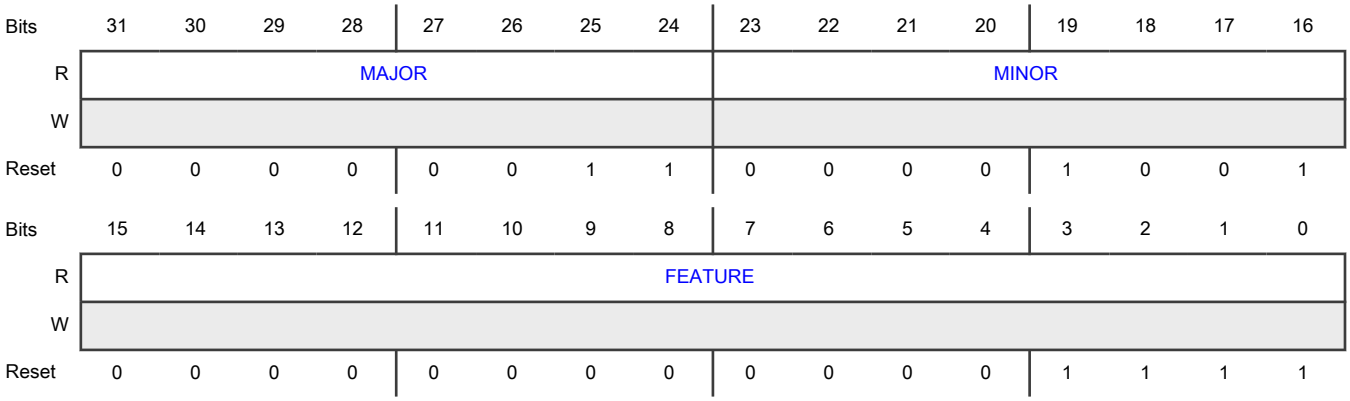
Offset

Register	Offset
VER	0h

Function

Determines the version ID and feature set number of MUA.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number
23-16 MINOR	Minor Version Number
15-0 FEATURE	Feature Set Number Indicates the feature set number. Each bit of this field specifies a different feature: • If FEATURE[0] = 1: Standard features are implemented. • If FEATURE[1] = 1: RAIP and RAIE fields are implemented. • If FEATURE[2] = 1: Core Control and Status registers are implemented in MUA and MUB. • If FEATURE[3] = 1: Expand the number of TR*n* and RR*n* registers. • FEATURE[4] - FEATURE[15]: Reserved for future use.

26.7.1.3 Parameter (PAR)

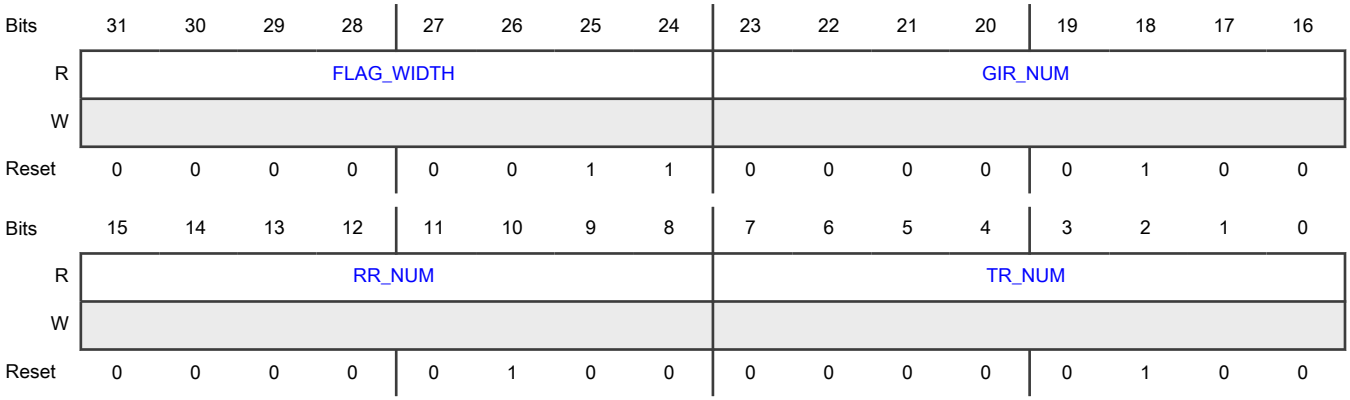
Offset

Register	Offset
PAR	4h

Function

Defines the number of flags, transmit registers, receive registers, and general-purpose interrupt requests available for MU.

Diagram



Fields

Field	Function
31-24 FLAG_WIDTH	Flag Width Specifies the number of flag bits (3) in the Flag Control (FCR) and Flag Status (FSR) registers.
23-16 GIR_NUM	General-Purpose Interrupt Request Number Specifies the number of general-purpose interrupt requests available (4).
15-8 RR_NUM	Receive Register Number Specifies the number of receive registers (4).
7-0 TR_NUM	Transmit Register Number Specifies the number of transmit registers (4).

26.7.1.4 Control (CR)

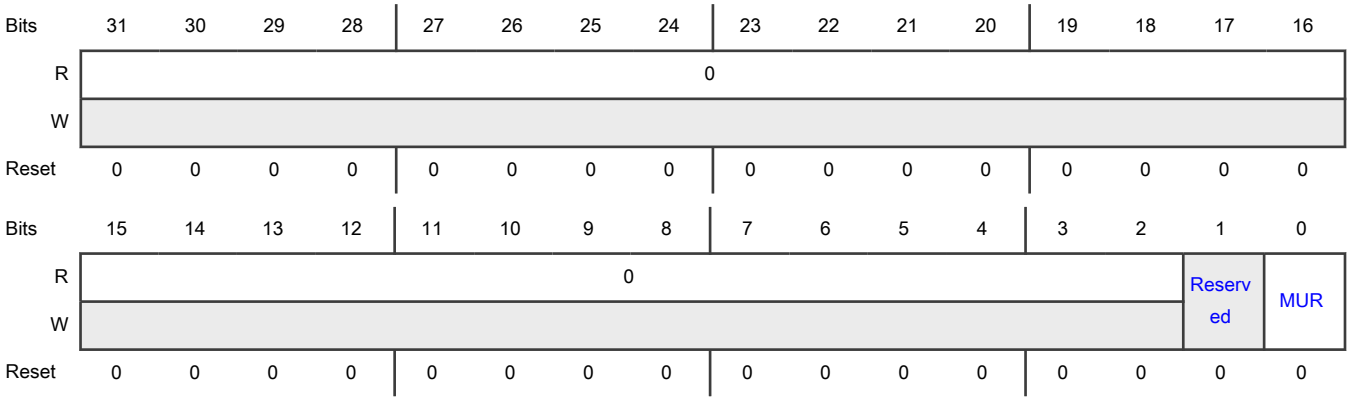
Offset

Register	Offset
CR	8h

Function

Controls MU reset and reset interrupt enable.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 —	Reserved
0 MUR	MU Reset Resets MU. Writing 1 to this field resets the MUA and MUB sides. All internal states are cleared. It forces all control and status registers to return to their default values (except HR, HRM in MUA/B_CCR0 registers; MURS in MUA/B_SR registers and the MUA/B_CSSR0/CSR0 registers). Before writing 1 to this field, interrupt processor B because writing 1 to this field may affect the ongoing processor B program. After writing 1 to this field, monitor the value of MUA_SR[MURS] to know when the reset sequence on the processor B-side has ended. You can only write 1 to MUR when processor B is not in Stop mode or Power-Down mode. This field always reads 0, and it becomes 0 during the MU reset sequence. 0b - Idle 1b - Reset

26.7.1.5 Status (SR)

Offset

Register	Offset
SR	Ch

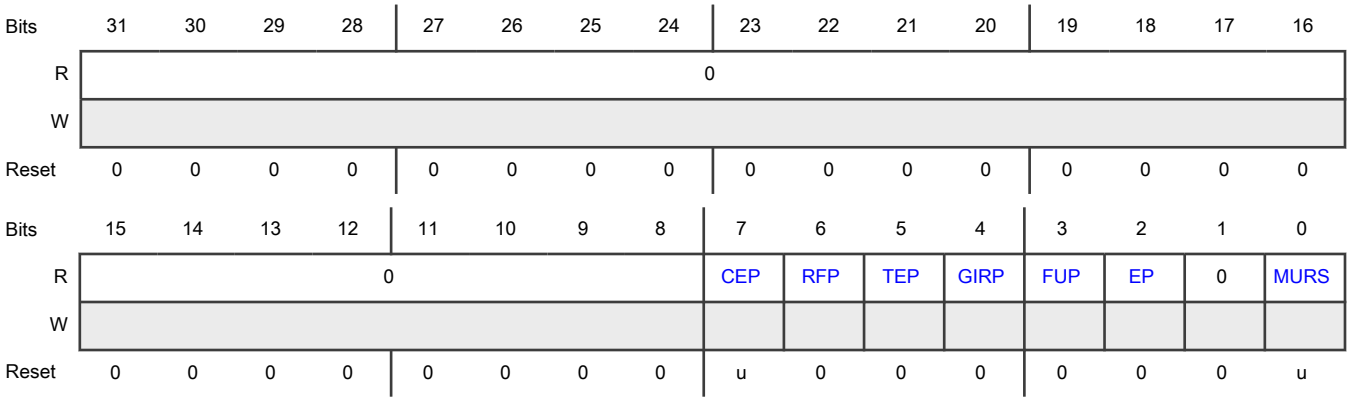
Function

Shows the status of MU resets and the status of pending events and requests.

NOTE

Writing to this register does not generate a transfer error.

Diagram



Fields

Field	Function
31-8 —	Reserved
7 CEP	Processor B Event Pending Indicates whether a processor event is pending. This field becomes 1 when MU detects any core operation mode entry event. After this field becomes 1, MU checks the CSSR0 register to determine which core operation mode entry event in Processor B occurs. This field becomes 0 when all core operation mode entry events are serviced by writing 1 to CSSR0[WAIT] and CSSR0[HRIP]. The reset value of this field is chip-specific. 0b - No event pending 1b - Event pending
6 RFP	MUA Receive Full Pending Indicates whether a receive full message is pending. This field becomes 1 when MUB writes to a TR*n* register to send data to MUA. After this field becomes 1, MU checks RSR[RF*n*] to determine whether the data in the Receive register is ready for MUA to read it. This field becomes 0 when all MUA RR*n* registers are read, or when MU is reset. 0b - Not pending; MUB is not writing to a Transmit register 1b - Pending; MUB is writing to a Transmit register
5	MUA Transmit Empty Pending

Table continues on the next page...

Table continued from the previous page...

Field	Function
TEP	Indicates whether a transmit empty message is pending. This field becomes 1 when any TCR[TIE*n*] field is 1 and TSR[TE*n*] flag is set. After this field becomes 1, MU checks TSR[TE*n*] to determine whether the data in the Transmit (TR*n*) register is ready for MUA to write to it. This field becomes 0 when write operations to all MUA Transmit (TR*n*) registers where TCR[TIE*n*] = 1 (transfer interrupt enabled) are completed, or when MU is reset. 0b - No MUA transmit empty event pending 1b - Pending; any TCR[TIEn] field is 1 and TSR[TEn] flag is set
4 GIRP	MUA General-Purpose Interrupt Pending Indicates that MUB has sent a general-purpose interrupt request. This field becomes 1 when the MUB side sends a general-purpose interrupt request to the MUA side. GSR[GIP*n*] identifies which general-purpose interrupt request is received. This field becomes 0 when all MUA_GSR[GIP*n*] fields are cleared, or when MU is reset. 0b - No request sent 1b - Request sent
3 FUP	MUA Flag Update Pending Indicates whether a flag update request is pending. MU generates this request when there is a change to the F*n*[2:0] bits of MUA_FCR. This field becomes 1 when the MUA side sends a flag update request to the MUB side. This field becomes 0 when MU acknowledges this flag update request internally (the flag is updated) from the MUB side, or during MU reset. No flag update changes are allowed when this field is 1. When FUP = 1, a write to the F*n*[2:0] bits of MUA_FCR does not generate a flag update event. The F*n*[2:0] bits do not change. If SR[EP] = 1 (event pending), writing to MUA_FCR does not immediately cause this field to become 1. 0b - No pending update flags (initiated by MUA) 1b - Pending update flags (initiated by MUA)
2 EP	MUA Side Event Pending Indicates a pending side event when the MUA side sends an event update request to the MUB side. An event is any hardware message that the Status register on the MUB side reflects. For example, an event occurs when Transmit register 0 is the target of a write operation. During normal operations, the update mechanism for this field operates automatically. MU clears this field automatically when the event update acknowledgment is received, or when MU resets. To ensure that events are posted to MUB before entering Stop mode, verify that this field is 0. If it is 1, wait and continue to poll this field before entering Stop mode until it becomes 0. Reading MUA_SR[EP] must be the last access to MUA. Perform this read operation before entering Stop or Wait mode. Otherwise, subsequent actions may cause this field to become 1. If MUB is in Stop mode and the MUA event is triggered, this field remains 1 until MUB wakes up.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not pending 1b - Pending
1 —	Reserved
0 MURS	MUA and MUB Reset State Indicates the reset state of MUA and MUB. This field becomes 1 during any system reset or MU reset from the MUA or MUB side. This field becomes 0 when the reset sequence on both MUA and MUB sides ends. After issuing any of the aforementioned reset events, verify that this field is 0 before starting any access. 0b - Out of reset 1b - In reset

26.7.1.6 Core Control 0 (CCR0)

Offset

Register	Offset
CCR0	10h

Function

Allows MUA to control the processor on the MUB side.

Also allows control of the processor A hardware reset mask.

Diagram

2-0 Fn	MUB to MUA-Side Flag Contains flags configured by the values written to MUB_FCR[F*n*], where *n* = 0 to 2. F*n* is the MUA-side flag configured by the values written to MUB_FCR[F*n*]. When MUB_FCR[F*n*] is written to, the write event updates MUA_FSR[F*n*], after the event update latency. 0b - MUB_FCR[Fn] = 0 1b - MUB_FCR[Fn] = 1

26.7.1.12 General-Purpose Interrupt Enable (GIER)

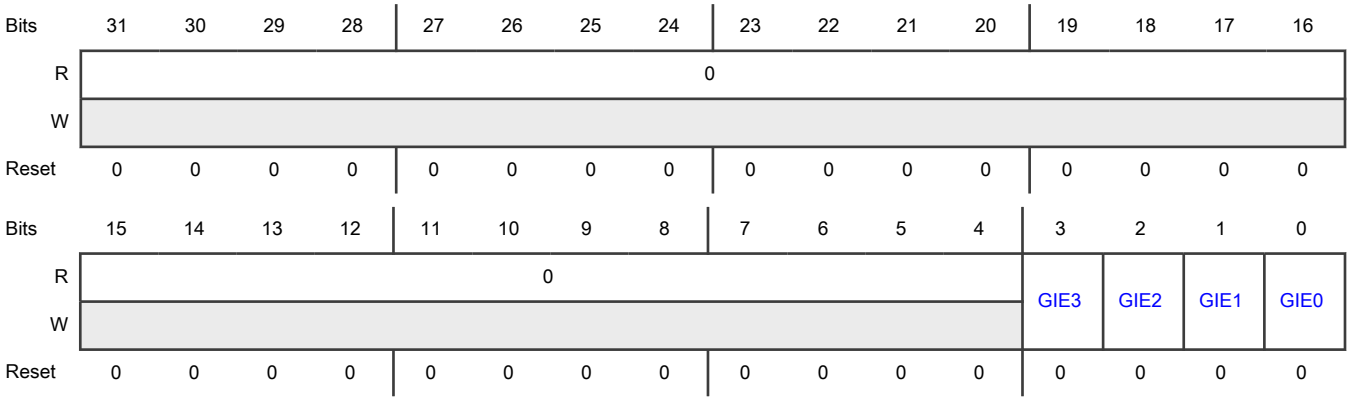
Offset

Register	Offset
GIER	110h

Function

Contains the MUA general-purpose interrupt enable fields.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 GIEn	MUA General-purpose Interrupt Enable Enables general-purpose interrupt. There are 4 general-purpose interrupts (*n* = 0 to 3). When GIE*n* = 1, a general-purpose interrupt *n* request is issued to processor A when MUA GSR[GIP*n*] = 1. If GIE*n* = 0, the general-purpose interrupt request pending does not trigger the general-purpose interrupt. GIE*n* becomes 0 when MU resets. 0b - Disable 1b - Enable

26.7.1.13 General-Purpose Control (GCR)

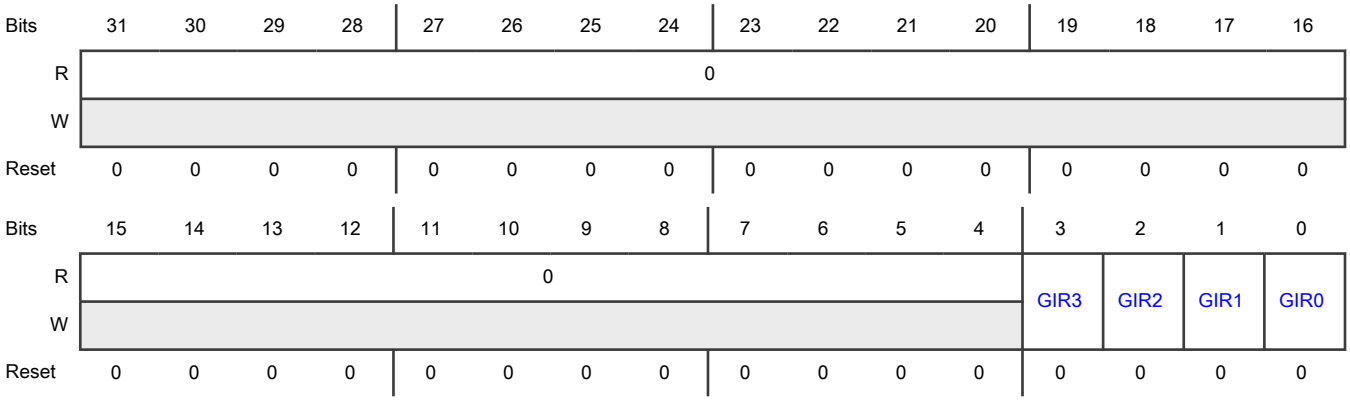
Offset

Register	Offset
GCR	114h

Function

Contains the MUA general-purpose interrupt request fields.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 GIRn	MUA General-Purpose Interrupt Request Specifies whether general-purpose interrupts are requested to MUB. There are 4 general-purpose interrupts (*n* = 0 to 3). Writing 1 to GIR*n* sets MUB_GSR[GIP*n*]. If MUB_GIER[GIE*n*] = 1, a general-purpose interrupt request is triggered on processor B. This field becomes 0 when MUB_GSR[GIP*n*] is cleared. This clearing informs MUA that the interrupt is accepted (cleared by software). To ensure proper operations, verify that GIR*n* is 0 (no pending interrupt) before writing 1 to it. This field becomes 0 when MU resets. 0b - Not requested 1b - Requested

26.7.1.14 General-purpose Status (GSR)

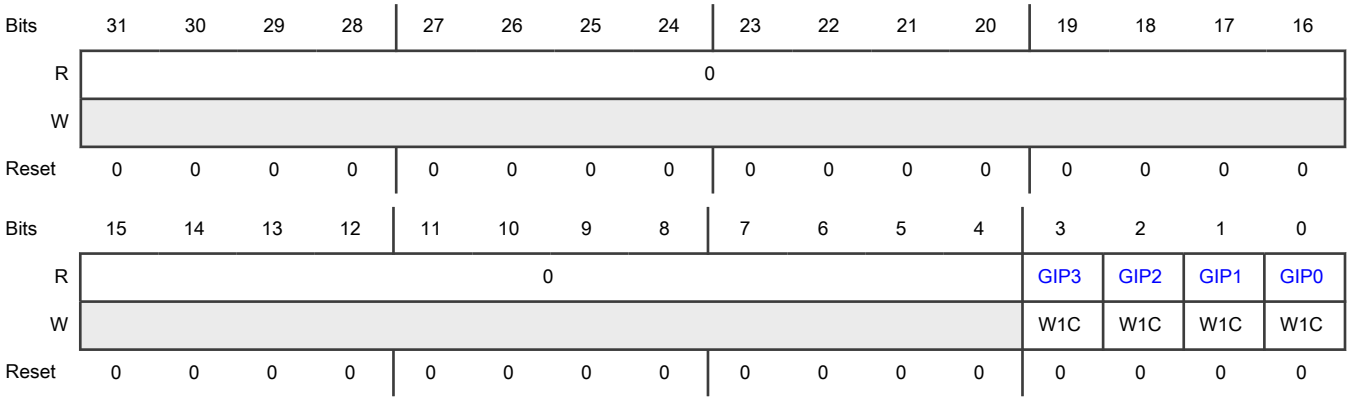
Offset

Register	Offset
GSR	118h

Function

Contains the status of the MUA general-purpose interrupt pending requests.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 GIPn	MUA General-Purpose Interrupt Request Pending Indicates whether a general-purpose interrupt request is pending. There are 4 general-purpose interrupts (*n* = 0 to 3). GIP*n* informs MUA that MUB_GCR[GIR*n*] changed from 0 to 1. If MUA_GIER[GIE*n*] = 1, a general-purpose interrupt request is issued to processor A. GIP*n* is cleared when MU resets. After GIP*n* is cleared, if MUA_GIER[GIE*n*] = 1, the general-purpose interrupt request is cleared on the MUA side. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not pending 1b - Pending When writing 0b - No effect 1b - Clear the flag

26.7.1.15 Transmit Control (TCR)

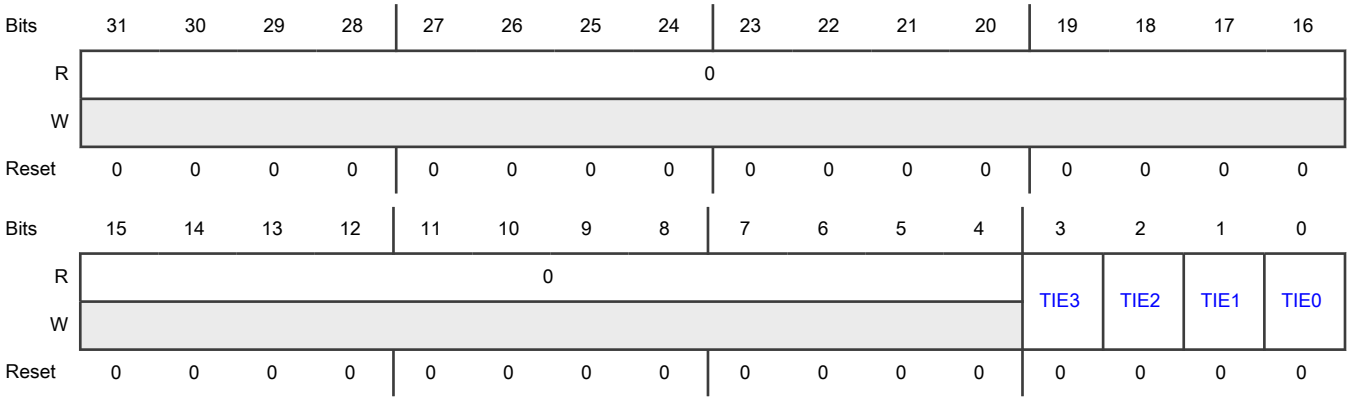
Offset

Register	Offset
TCR	120h

Function

Contains the MUA transmit interrupt enable fields.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 TIEn	MUA Transmit Interrupt Enable Enables MUA transmit interrupt *n*, where *n* = 0 to 3. If this field is 1, an MUA transmit interrupt *n* request is issued when MUA_TSR[TE*n*] is set. If this field is 0, MU ignores the value of MUA_TSR[TE*n*], and no MUA transmit interrupt *n* request is issued. 0b - Disable 1b - Enable

26.7.1.16 Transmit Status (TSR)

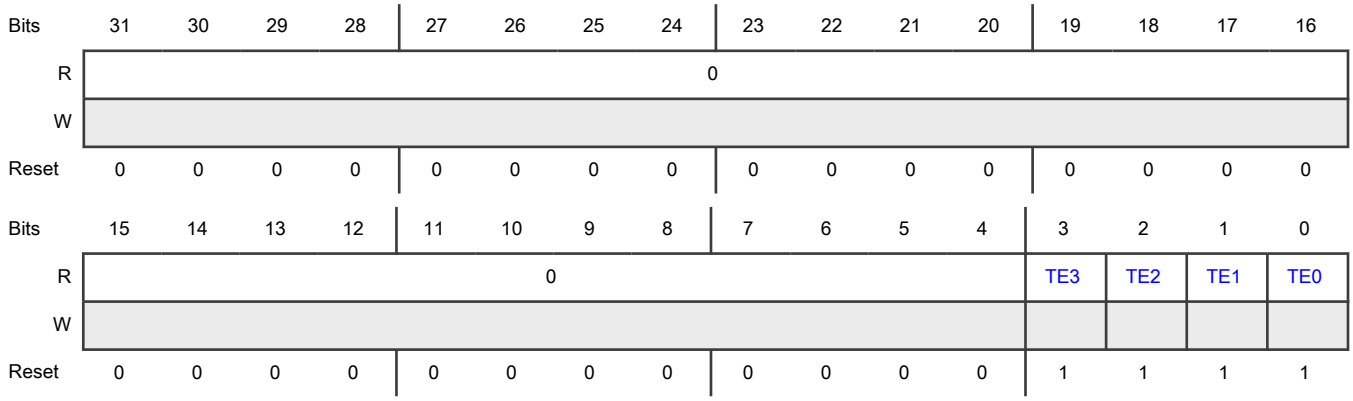
Offset

Register	Offset
TSR	124h

Function

Indicates whether the MUA transmit registers are empty.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 TEn	MUA Transmit Empty Indicates whether MUA Transmit (TR*n*) register is empty, where *n* = 0 to 3. This field becomes 1 after the MUB_RR*n* register is read on the MUB side. When TE*n* = 1, it indicates to the MUA side that the MUA_TR*n* register is ready to be written on the MUA side. If MUA_TCR[TIE*n*] = 1, a transmit *n* interrupt is issued on the MUA side. This field becomes 0 after the MUA_TR*n* register is written to on the MUA side. After this field becomes 0, if MUA_TCR[TIE*n*] = 1, the transmit *n* interrupt request is cleared on the MUA side. This field becomes 1 when MU resets. 0b - Not empty 1b - Empty

26.7.1.17 Receive Control (RCR)

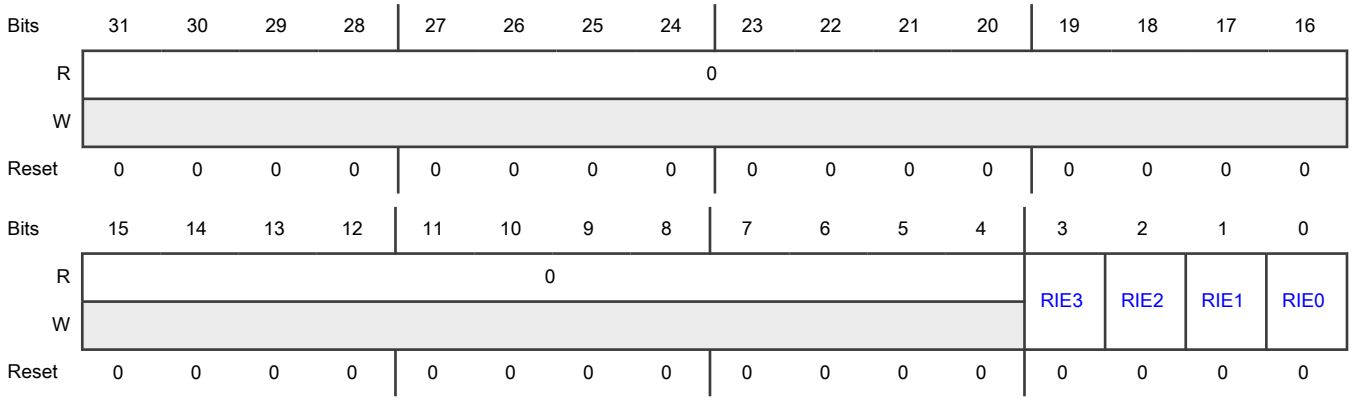
Offset

Register	Offset
RCR	128h

Function

Contains the MUA receive interrupt enables.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 RIEn	MUA Receive Interrupt Enable Enables MUA receive interrupt *n*, where *n* = 0 to 3. If this field is 1, an MUA receive interrupt *n* request is issued when MUA_RSR[RF*n*] is set. If this field is 0, MU ignores the value of MUA_RSR[RF*n*], and no MUA receive interrupt request is issued. 0b - Disable 1b - Enable

26.7.1.18 Receive Status (RSR)

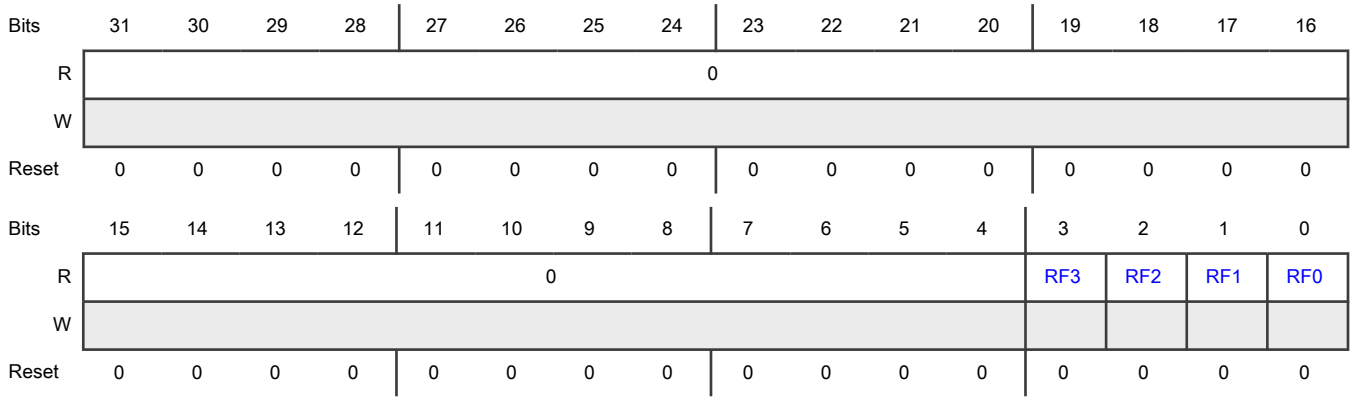
Offset

Register	Offset
RSR	12Ch

Function

Indicates whether the MUA receive registers are full.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 RFn	MUA Receive Register Full Indicates whether MUA Receive register (RR*n*) is full, where *n* = 0 to 3. RF*n* becomes 1 when the MUB_TR*n* register is written to on the MUB side. When RF*n* is 1, it indicates to the MUA side that new data in the MUA_RR*n* register is ready for MUA to read it. If MUA_RCR[RIE*n*] = 1, a receive *n* interrupt is issued on the MUA side. RF*n* becomes 0 when the MUA_RR*n* register is read, or when MU is reset. After RF*n* becomes 0, if MUA_RCR[RIE*n*] = 1, the receive *n* interrupt request is cleared on the MUA side. 0b - Not full 1b - Full

26.7.1.19 Transmit (TR0 - TR3)

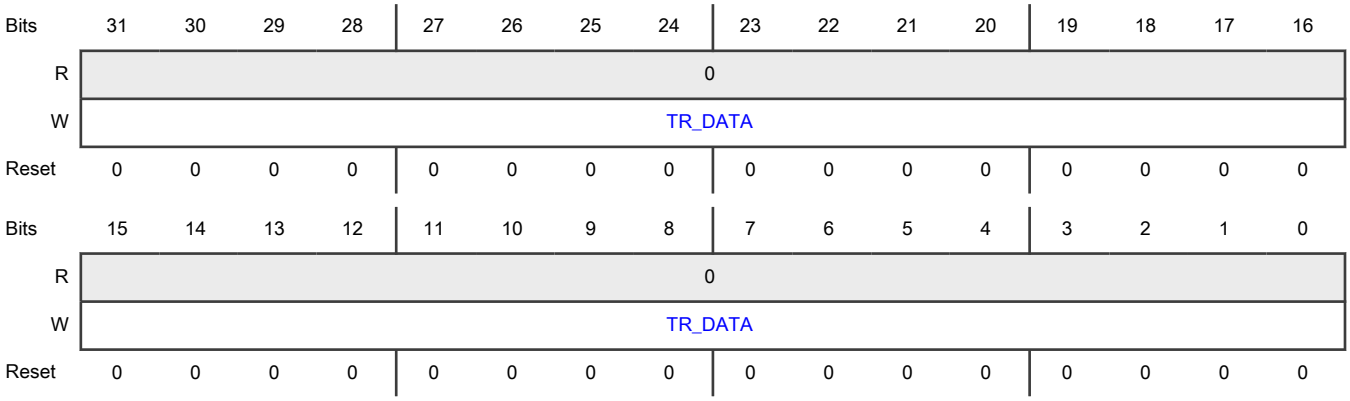
Offset

Register	Offset
TR0	200h
TR1	204h
TR2	208h
TR3	20Ch

Function

Contains MUA transmit data.

Diagram



Fields

Field	Function
31-0 TR_DATA	MUA Transmit Data Contains MUA transmit data. MUB_RR*n* reflects the data written to this register. The TR*n* and RR*n* registers are not double-buffered. Writing to MUA_TR*n* overrides the data readable in the MUA_RR*n* register. A write to the Transmit register clears MUA_TSR[TE*n*] on the transmitter side, and sets MUB_RSR[RF*n*] on the receiver side. You can write to this register only when MUA_TSR[TE*n*] = 1. Reading this register returns all zeroes.

26.7.1.20 Receive (RR0 - RR3)

Offset

Register	Offset
RR0	280h
RR1	284h
RR2	288h
RR3	28Ch

Function

Contains MUA receive data.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	RR_DATA

R	RR_DATA															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 RR_DATA	MUA Receive Data Reflects the data written to MUB TR*n*. Reading this register clears MUA_RSR[RF*n*] on the receiver side, and sets MUB_TSR[TE*n*] on the transmitter side. You can read this register only when MUA_RSR[RF*n*] = 1. Reading it before MUA_RSR[RF*n*] becomes 1 may result in reading incorrect data. Poll MUA_RSR[RF*n*] to confirm it is set before reading RR*n*. Writing to this register generates an error response to MUA.

26.7.2 MUB register descriptions

This section contains the detailed register descriptions for MUB registers.

NOTE

A module transfer error to processor A or processor B is generated when:

- A read or write access is made to an invalid location.
- A write operation is performed on a read-only register on the processor A side or processor B side of MU.

The only exception to this behavior is the MUB SR register. No transfer error occurs when accessing this location.

26.7.2.1 MUB memory map

MU0.MUB base address: 4020_1000h

MU1.MUB base address: 4020_3000h

MU2.MUB base address: 4020_5000h

MU3.MUB base address: 4031_A000h

MU4.MUB base address: 4018_8000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Version ID (VER)	32	R	0309_000Fh
4h	Parameter (PAR)	32	R	0304_0404h
8h	Control (CR)	32	RW	0000_0000h
Ch	Status (SR)	32	R	See section
10h	Core Control 0 (CCR0)	32	RW	0000_0014h
14h	Core Interrupt Enable 0 (CIER0)	32	RW	0000_0000h
18h	Core Sticky Status 0 (CSSR0)	32	RW	See section

200h - 20Ch	Transmit (TR0 - TR3)	32	RW	0000_0000h
280h - 28Ch	Receive (RR0 - RR3)	32	R	0000_0000h

26.7.2.2 Version ID (VER)

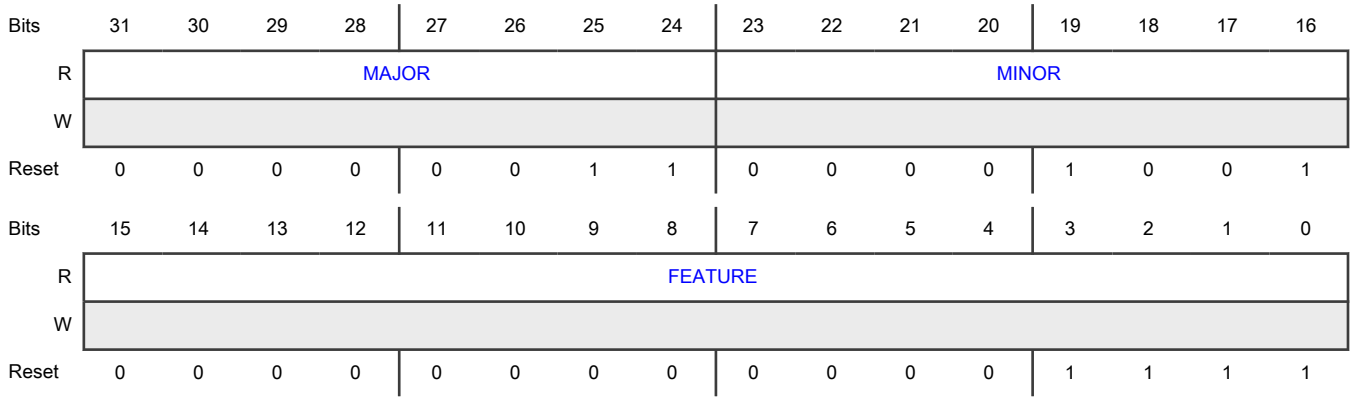
Offset

Register	Offset
VER	0h

Function

Determines the version ID and feature set number of MUB.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number
23-16 MINOR	Minor Version Number
15-0 FEATURE	Feature Set Number Indicates the feature set number. Each bit of this field specifies a different feature: • If FEATURE[0] = 1: Standard features are implemented. • If FEATURE[1] = 1: RAIP and RAIE fields are implemented. • If FEATURE[2] = 1: Core Control and Status registers are implemented in MUA and MUB. • If FEATURE[3] = 1: Expand the number of TR*n* and RR*n* registers. • FEATURE[4] - FEATURE[15]: Reserved for future use.

26.7.2.3 Parameter (PAR)

Offset

Register	Offset
PAR	4h

Function

Defines the number of flags, transmit registers, receive registers, and general-purpose interrupt requests available for MU.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	FLAG_WIDTH								GIR_NUM							
W																
Reset	0	0	0	0	0	0	1	1	0	0	0	0	0	1	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RR_NUM								TR_NUM							
W																
Reset	0	0	0	0	0	1	0	0	0	0	0	0	0	1	0	0

Fields

Field	Function
31-24 FLAG_WIDTH	Flag Width Specifies the number of flag bits (3) in the Flag Control (FCR) and Flag Status (FSR) registers.
23-16 GIR_NUM	General-Purpose Interrupt Request Number Specifies the number of general-purpose interrupt requests available (4).
15-8 RR_NUM	Receive Register Number Specifies the number of receive registers (4).
7-0 TR_NUM	Transmit Register Number Specifies the number of transmit registers (4).

26.7.2.4 Control (CR)

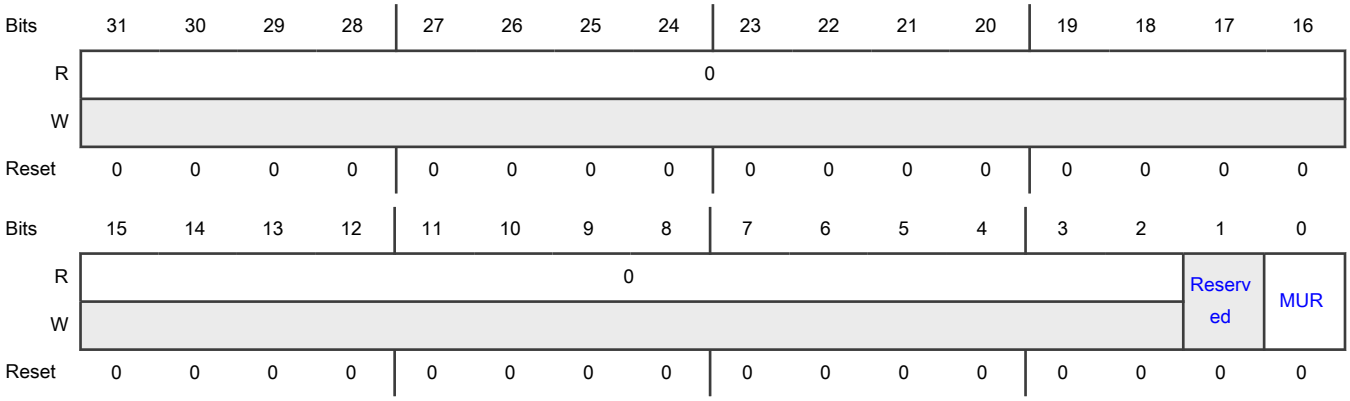
Offset

Register	Offset
CR	8h

Function

Controls MU reset and reset interrupt enable.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 —	Reserved
0 MUR	MU Reset Resets MU. Writing 1 to this field resets the MUB and MUA sides. All internal states are cleared. It forces all control and status registers to return to their default values (except HR, HRM in MUB/A_CCR0 registers; MURS in MUB/A_SR registers and the MUB/A_CSSR0/CSR0 registers). Before writing 1 to this field, interrupt processor A because writing 1 to this field may affect the ongoing processor A program. After writing 1 to this field, monitor the value of MUB_SR[MURS] to know when the reset sequence on the processor A-side has ended. You can only write 1 to MUR when processor A is not in Stop mode or Power-Down mode. This field always reads 0, and it becomes 0 during the MU reset sequence. 0b - Idle 1b - Reset

26.7.2.5 Status (SR)

Offset

Register	Offset
SR	Ch

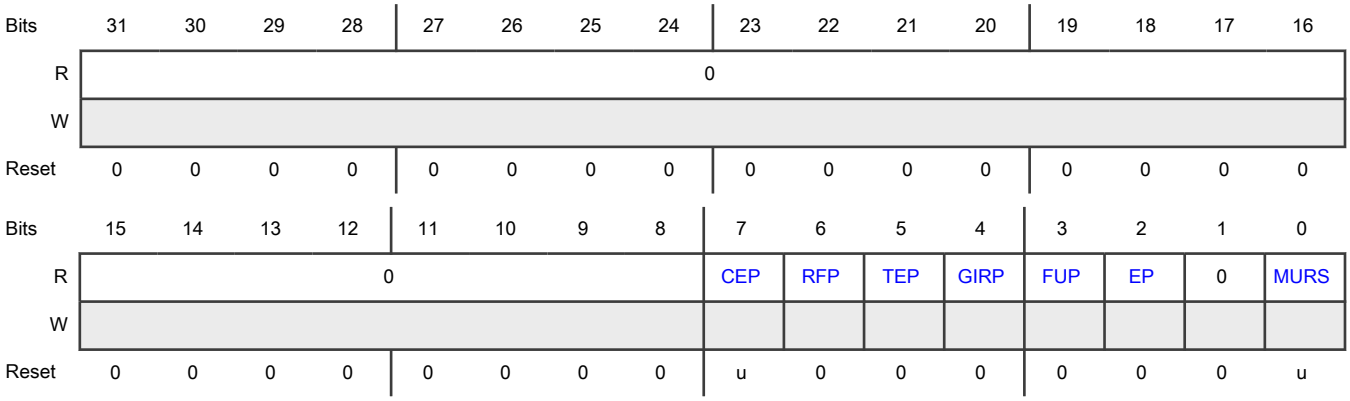
Function

Shows the status of MU resets and the status of pending events and requests.

NOTE

Writing to this register does not generate a transfer error.

Diagram



Fields

Field	Function
31-8 —	Reserved
7 CEP	Processor A Event Pending Indicates whether a processor event is pending. This field becomes 1 when MU detects any core operation mode entry event. After this field becomes 1, MU checks the CSSR0 register to determine which core operation mode entry event in Processor A occurs. This field becomes 0 when all core operation mode entry events are serviced by writing 1 to CSSR0[WAIT] and CSSR0[HRIP]. The reset value of this field is chip-specific. 0b - No event pending 1b - Event pending
6 RFP	MUB Receive Full Pending Indicates whether a receive full message is pending. This field becomes 1 when MUA writes to a TR*n* register to send data to MUB. After this field becomes 1, MU checks RSR[RF*n*] to determine whether the data in the Receive register is ready for MUB to read it. This field becomes 0 when all MUB RR*n* registers are read, or when MU is reset. 0b - Not pending; MUA is not writing to a Transmit register 1b - Pending; MUA is writing to a Transmit register
5 TEP	MUB Transmit Empty Pending Indicates whether a transmit empty message is pending.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field becomes 1 when any TCR[TIE*n*] field is 1 and TSR[TE*n*] flag is set. After this field becomes 1, MU checks TSR[TE*n*] to determine whether the data in the Transmit (TR*n*) register is ready for MUB to write to it. This field becomes 0 when write operations to all MUB Transmit (TR*n*) registers where TCR[TIE*n*] = 1 (transfer interrupt enabled) are completed, or when MU is reset. 0b - No MUB transmit empty event pending 1b - Pending; any TCR[TIEn] field is 1 and TSR[TEn] flag is set
4 GIRP	MUB General-Purpose Interrupt Pending Indicates that MUA has sent a general-purpose interrupt request. This field becomes 1 when the MUA side sends a general-purpose interrupt request to the MUB side. GSR[GIP*n*] identifies which general-purpose interrupt request is received. This field becomes 0 when all MUB_GSR[GIP*n*] fields are cleared, or when MU is reset. 0b - No request sent 1b - Request sent
3 FUP	MUB Flag Update Pending Indicates whether a flag update request is pending. MU generates this request when there is a change to the F*n*[2:0] bits of MUB_FCR. This field becomes 1 when the MUB side sends a flag update request to the MUA side. This field becomes 0 when MU acknowledges this flag update request internally (the flag is updated) from the MUA side, or during MU reset. No flag update changes are allowed when this field is 1. When FUP = 1, a write to the F*n*[2:0] bits of MUB_FCR does not generate a flag update event. The F*n*[2:0] bits do not change. If SR[EP] = 1 (event pending), writing to MUB_FCR does not immediately cause this field to become 1. 0b - No pending update flags (initiated by MUB) 1b - Pending update flags (initiated by MUB)
2 EP	MUB Side Event Pending Indicates a pending side event when the MUB side sends an event update request to the MUA side. An event is any hardware message that the Status register on the MUA side reflects. For example, an event occurs when Transmit register 0 is the target of a write operation. During normal operations, the update mechanism for this field operates automatically. MU clears this field automatically when the event update acknowledgment is received, or when MU resets. To ensure that events are posted to MUA before entering Stop mode, verify that this field is 0. If it is 1, wait and continue to poll this field before entering Stop mode until it becomes 0. Reading MUB_SR[EP] must be the last access to MUB. Perform this read operation before entering Stop or Wait mode. Otherwise, subsequent actions may cause this field to become 1. If MUA is in Stop mode and the MUB event is triggered, this field remains 1 until MUA wakes up.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not pending 1b - Pending
1 —	Reserved
0 MURS	MUA and MUB Reset State Indicates the reset state of MUA and MUB. This field becomes 1 during any system reset or MU reset from the MUA or MUB side. This field becomes 0 when the reset sequence on both MUA and MUB sides ends. After issuing any of the aforementioned reset events, verify that this field is 0 before starting any access. 0b - Out of reset 1b - In reset

26.7.2.6 Core Control 0 (CCR0)

Offset

Register	Offset
CCR0	10h

Function

Allows MUB to control the processor on the MUA side.

Also allows control of the processor B hardware reset mask.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

6	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
5 WAIT	Processor A Wait Mode Entry Interrupt Pending Indicates to Processor B whether Processor A has entered Wait mode. This flag is set after Processor A enters Wait mode. If CIER0[WAITIE] enables the interrupt, the Processor B Wait Mode Entry Interrupt request is issued when Processor A enters Wait mode. Clearing this flag also clears the MU Wait Mode Entry Interrupt request. 0b - Processor A did not enter Wait Mode. 1b - Processor A entered Wait Mode.
4 —	Reserved
3 —	Reserved
2 —	Reserved
1 —	Reserved
0 NMIC	Processor B Nonmaskable Interrupt Clear Clears the nonmaskable interrupt (NMI) request from the MUA side. The MUB-side NMI service routine uses this field. Writing 1 to this field clears MUA_CCR0[NMI], deasserting the NMI request and enabling MUA_CCR0[NMI] to trigger another NMI request. This field always reads as 0, so you cannot poll it. You can only use this field as part of the NMI service routine, in which you must write 1 to this field only once. This field is cleared when MU resets. 0b - Default 1b - Clear MUA_CCR0[NMI]

26.7.2.9 Core Status 0 (CSR0)

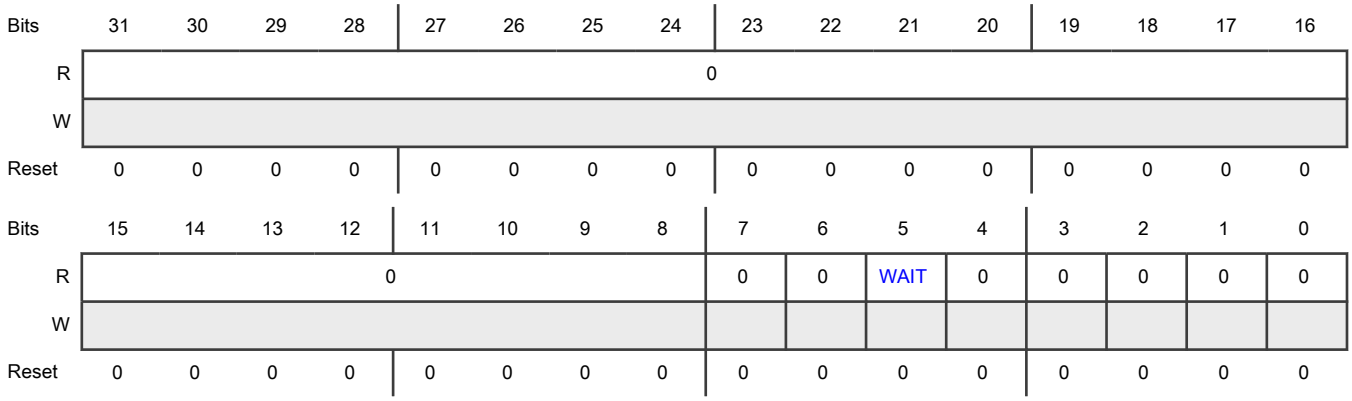
Offset

Register	Offset
CSR0	1Ch

Function

Shows the status of core events.

Diagram



Fields

26.7.2.10 Flag Control (FCR)

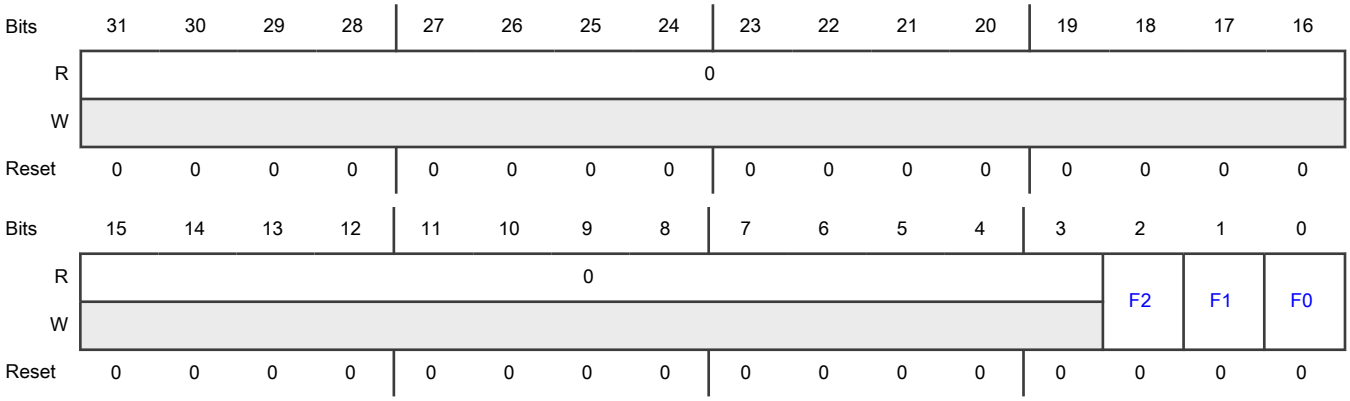
Offset

Register	Offset
FCR	100h

Function

Configures MUA_FSR[F*n*] flags.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 Fn	MUB to MUA Flag Configures MUA_FSR[F*n*] flags, where *n* = 0 to 2. F*n* configures the corresponding MUA_FSR[F*n*] flag. F*n* becomes 0 when MU resets. 0b - Clear MUA_FSR[Fn] 1b - Set MUA_FSR[Fn]

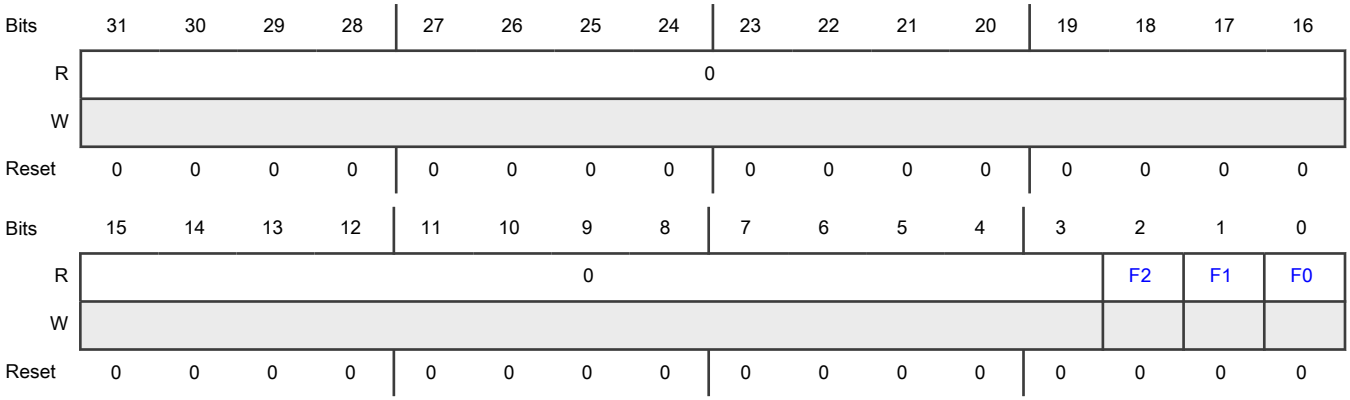
26.7.2.11 Flag Status (FSR)

Offset

Register	Offset
FSR	104h

Function
Contains flags configured by the values written to MUA_FCR[F*n*].

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 Fn	MUA to MUB-Side Flag Contains flags configured by the values written to MUA_FCR[F*n*], where *n* = 0 to 2. F*n* is the MUB-side flag configured by the values written to MUA_FCR[F*n*]. When MUA_FCR[F*n*] is written to, the write event updates MUB_FSR[F*n*], after the event update latency. 0b - MUA_FCR[Fn] = 0 1b - MUA_FCR[Fn] = 1

26.7.2.12 General-Purpose Interrupt Enable (GIER)

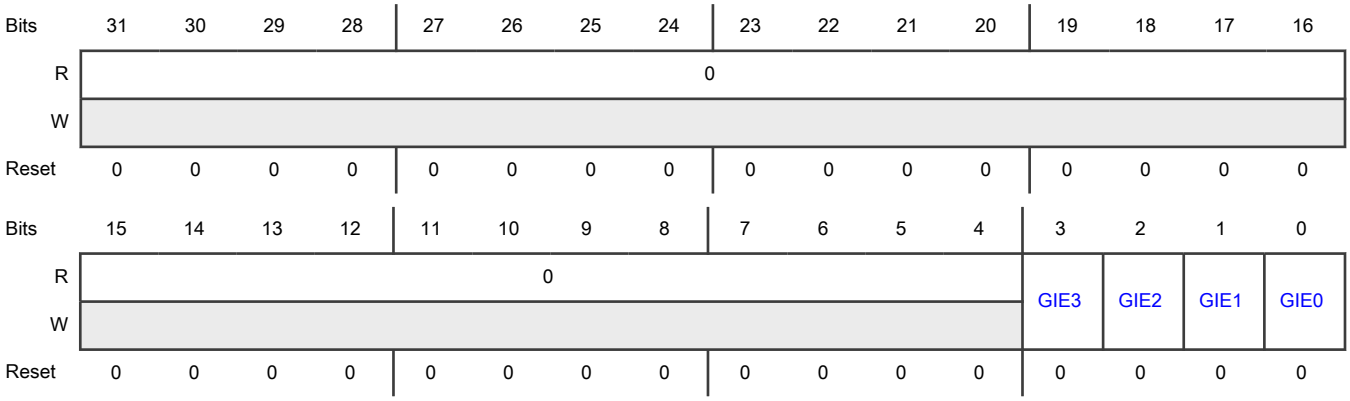
Offset

Register	Offset
GIER	110h

Function

Contains the MUB general-purpose interrupt enable fields.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 GIEn	MUB General-purpose Interrupt Enable Enables general-purpose interrupt. There are 4 general-purpose interrupts (*n* = 0 to 3). When GIE*n* = 1, a general-purpose interrupt *n* request is issued to processor B when MUB GSR[GIP*n*] = 1. If GIE*n* = 0, the general-purpose interrupt request pending does not trigger the general-purpose interrupt. GIE*n* becomes 0 when MU resets. 0b - Disable 1b - Enable

26.7.2.13 General-Purpose Control (GCR)

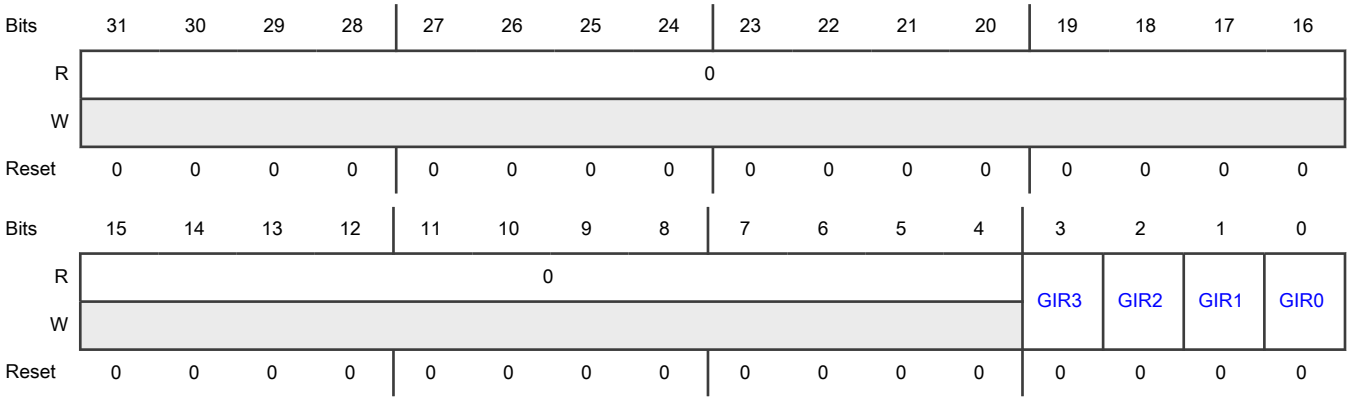
Offset

Register	Offset
GCR	114h

Function

Contains the MUB general-purpose interrupt request fields.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 GIRn	MUB General-Purpose Interrupt Request Specifies whether general-purpose interrupts are requested to MUA. There are 4 general-purpose interrupts (*n* = 0 to 3). Writing 1 to GIR*n* sets MUA_GSR[GIP*n*]. If MUA_GIER[GIE*n*] = 1, a general-purpose interrupt request is triggered on processor A. This field becomes 0 when MUA_GSR[GIP*n*] is cleared. This clearing informs MUB that the interrupt is accepted (cleared by software). To ensure proper operations, verify that GIR*n* is 0 (no pending interrupt) before writing 1 to it. This field becomes 0 when MU resets. 0b - Not requested 1b - Requested

26.7.2.14 General-purpose Status (GSR)

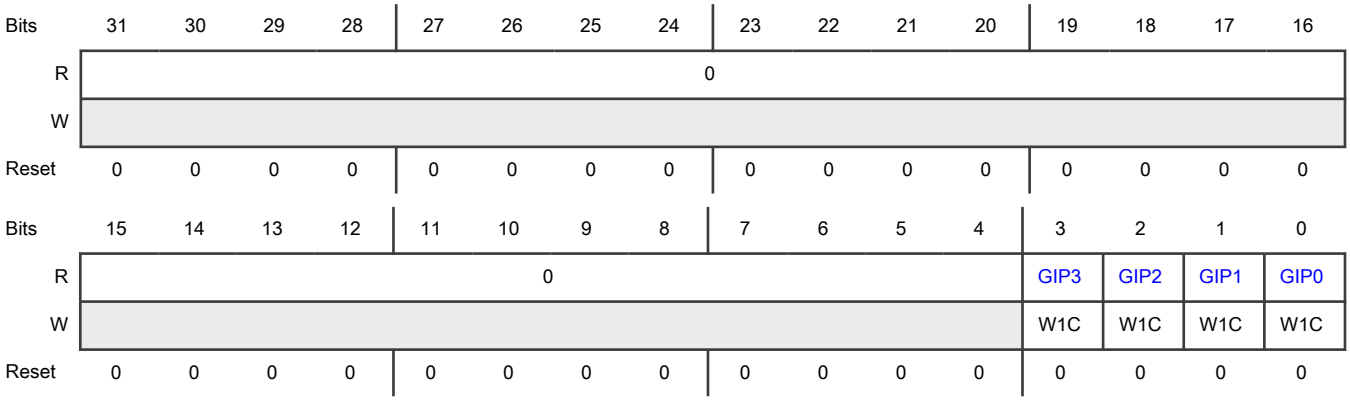
Offset

Register	Offset
GSR	118h

Function

Contains the status of the MUB general-purpose interrupt pending requests.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 GIPn	MUB General-Purpose Interrupt Request Pending Indicates whether a general-purpose interrupt request is pending. There are 4 general-purpose interrupts (*n* = 0 to 3). GIP*n* informs MUB that MUA_GCR[GIR*n*] changed from 0 to 1. If MUB_GIER[GIE*n*] = 1, a general-purpose interrupt request is issued to processor B. GIP*n* is cleared when MU resets. After GIP*n* is cleared, if MUB_GIER[GIE*n*] = 1, the general-purpose interrupt request is cleared on the MUB side. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not pending 1b - Pending When writing 0b - No effect 1b - Clear the flag

26.7.2.15 Transmit Control (TCR)

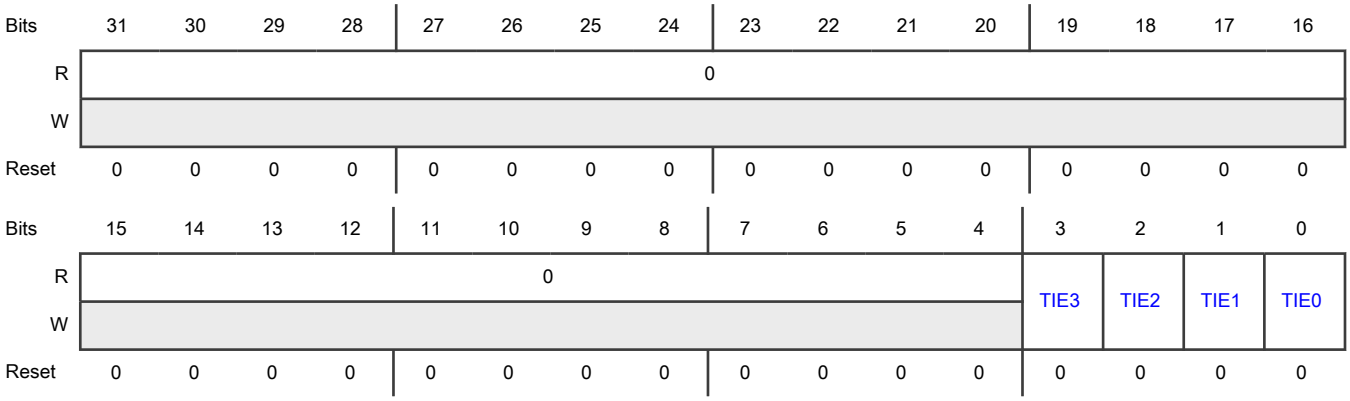
Offset

Register	Offset
TCR	120h

Function

Contains the MUB transmit interrupt enable fields.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 TIEn	MUB Transmit Interrupt Enable Enables MUB transmit interrupt *n*, where *n* = 0 to 3. If this field is 1, an MUB transmit interrupt *n* request is issued when MUB_TSR[TE*n*] is set. If this field is 0, MU ignores the value of MUB_TSR[TE*n*], and no MUB transmit interrupt *n* request is issued. 0b - Disable 1b - Enable

26.7.2.16 Transmit Status (TSR)

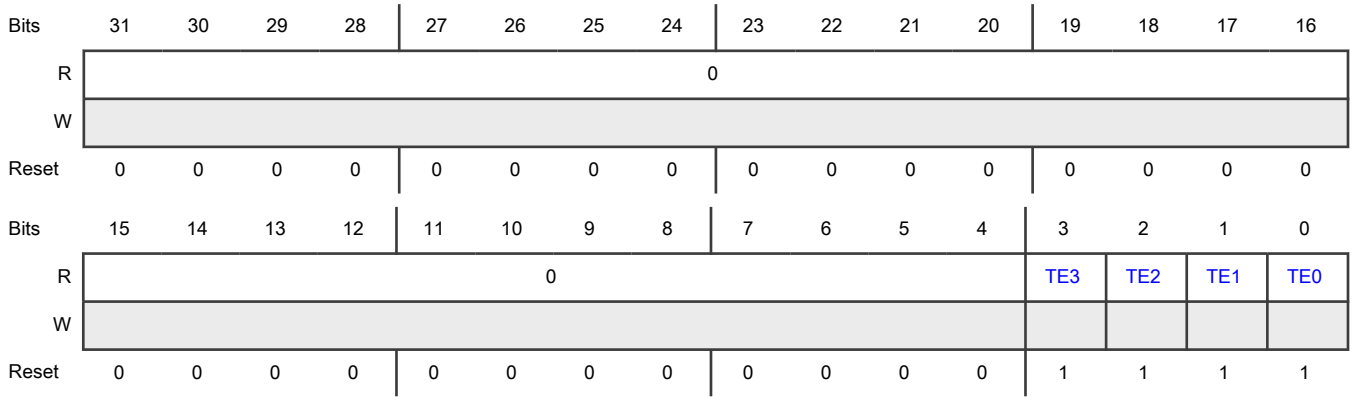
Offset

Register	Offset
TSR	124h

Function

Indicates whether the MUB transmit registers are empty.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 TEn	MUB Transmit Empty Indicates whether MUB Transmit (TR*n*) register is empty, where *n* = 0 to 3. This field becomes 1 after the MUA_RR*n* register is read on the MUA side. When TE*n* = 1, it indicates to the MUB side that the MUB_TR*n* register is ready to be written on the MUB side. If MUB_TCR[TIE*n*] = 1, a transmit *n* interrupt is issued on the MUB side. This field becomes 0 after the MUB_TR*n* register is written to on the MUB side. After this field becomes 0, if MUB_TCR[TIE*n*] = 1, the transmit *n* interrupt request is cleared on the MUB side. This field becomes 1 when MU resets. 0b - Not empty 1b - Empty

26.7.2.17 Receive Control (RCR)

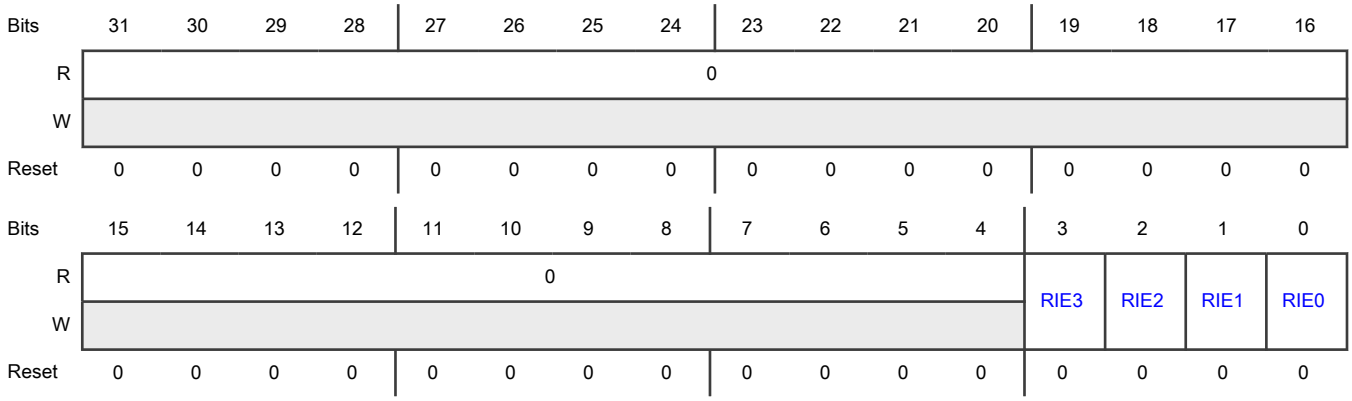
Offset

Register	Offset
RCR	128h

Function

Contains the MUB receive interrupt enables.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 RIEn	MUB Receive Interrupt Enable Enables MUB receive interrupt *n*, where *n* = 0 to 3. If this field is 1, an MUB receive interrupt *n* request is issued when MUB_RSR[RF*n*] is set. If this field is 0, MU ignores the value of MUB_RSR[RF*n*], and no MUB receive interrupt request is issued. 0b - Disable 1b - Enable

26.7.2.18 Receive Status (RSR)

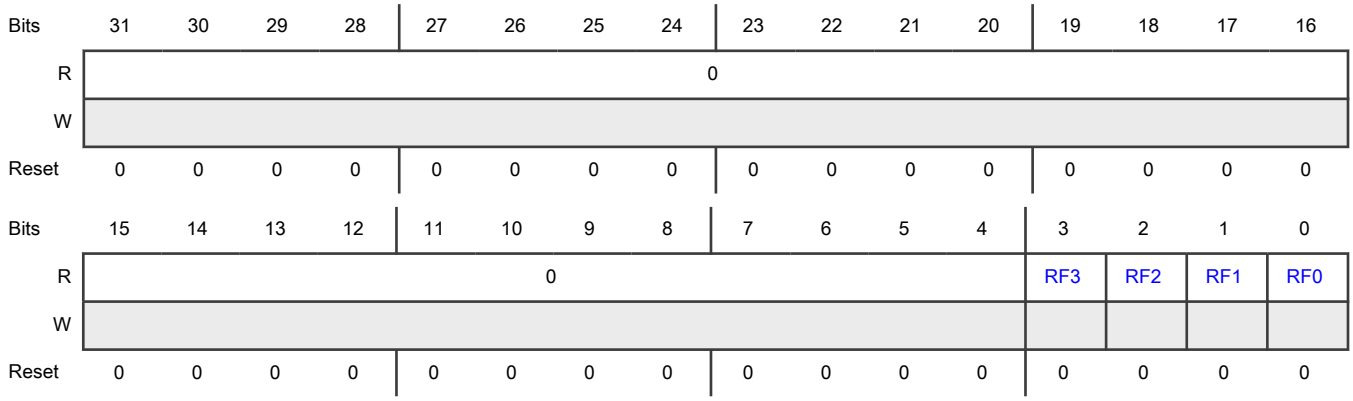
Offset

Register	Offset
RSR	12Ch

Function

Indicates whether the MUB receive registers are full.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 RFn	MUB Receive Register Full Indicates whether MUB Receive register (RR*n*) is full, where *n* = 0 to 3. RF*n* becomes 1 when the MUA_TR*n* register is written to on the MUA side. When RF*n* is 1, it indicates to the MUB side that new data in the MUB_RR*n* register is ready for MUB to read it. If MUB_RCR[RIE*n*] = 1, a receive *n* interrupt is issued on the MUB side. RF*n* becomes 0 when the MUB_RR*n* register is read, or when MU is reset. After RF*n* becomes 0, if MUB_RCR[RIE*n*] = 1, the receive *n* interrupt request is cleared on the MUB side. 0b - Not full 1b - Full

26.7.2.19 Transmit (TR0 - TR3)

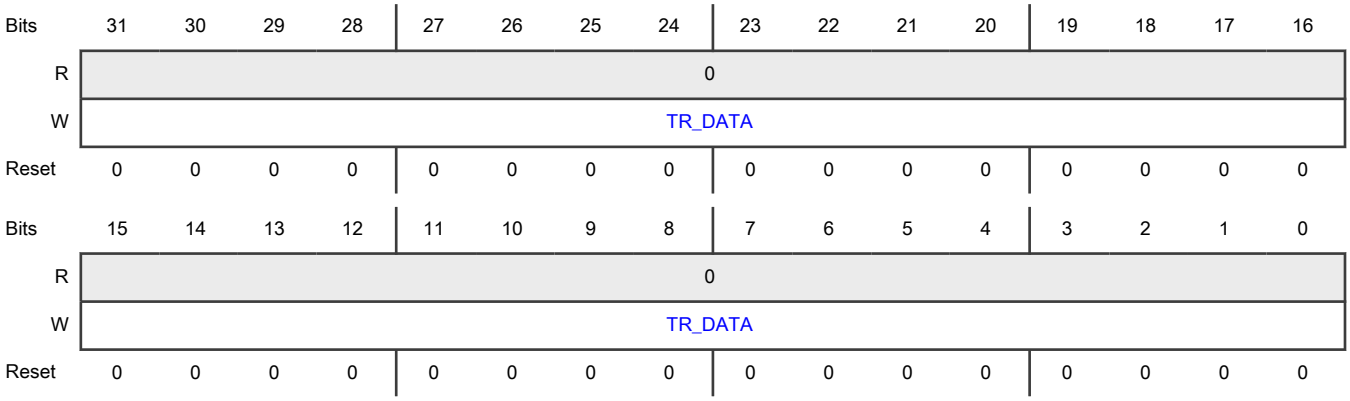
Offset

Register	Offset
TR0	200h
TR1	204h
TR2	208h
TR3	20Ch

Function

Contains MUB transmit data.

Diagram



Fields

Field	Function
31-0 TR_DATA	MUB Transmit Data Contains MUB transmit data. MUA_RR*n* reflects the data written to this register. The TR*n* and RR*n* registers are not double-buffered. Writing to MUB_TR*n* overrides the data readable in the MUA_RR*n* register. A write to the Transmit register clears MUB_TSR[TE*n*] on the transmitter side, and sets MUA_RSR[RF*n*] on the receiver side. You can write to this register only when MUB_TSR[TE*n*] = 1. Reading this register returns all zeroes.

26.7.2.20 Receive (RR0 - RR3)

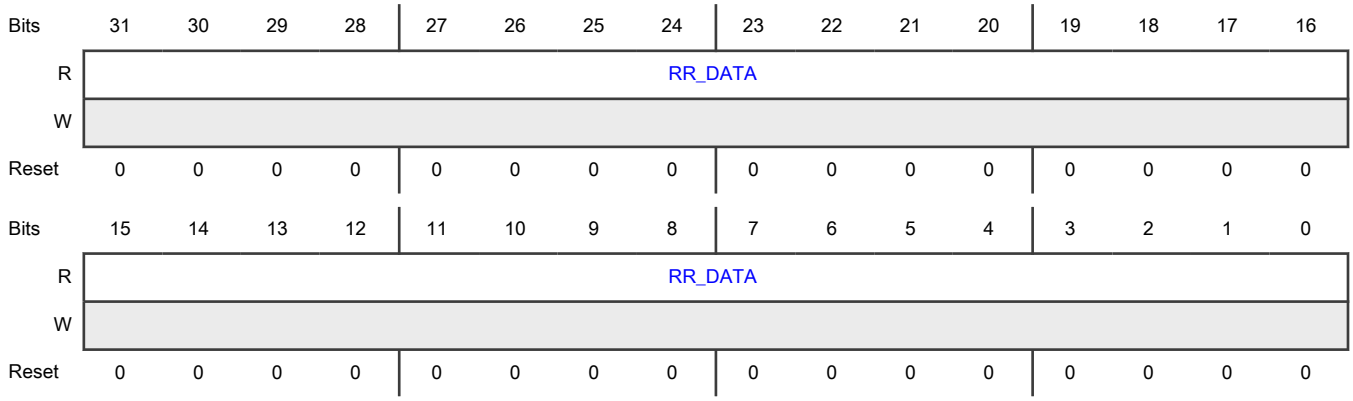
Offset

Register	Offset
RR0	280h
RR1	284h
RR2	288h
RR3	28Ch

Function

Contains MUB receive data.

Diagram



Fields

Field	Function
31-0 RR_DATA	MUB Receive Data Reflects the data written to MUA TR*n*. Reading this register clears MUB_RSR[RF*n*] on the receiver side, and sets MUA_TSR[TE*n*] on the transmitter side. You can read this register only when MUB_RSR[RF*n*] = 1. Reading it before MUB_RSR[RF*n*] becomes 1 may result in reading incorrect data. Poll MUB_RSR[RF*n*] to confirm it is set before reading RR*n*. Writing to this register generates an error response to MUB.

Chapter 27
Power Management Controller (PMC)

27.1 Chip-specific PMC information

Table 225. Reference links to related information

Topic	Related module	Reference
Full description	PMC	PMC
Peripheral memory map		Memory map overview
Power overview		Power overview
Clocking		Clock overview Clock controller
Signal multiplexing	IOPCTL	External signals and pin multiplexing IO PAD controller
Sleep Controller	SLEEPCON	SLEEPCON

NOTE

The device has one analog voltage glitch detector (aGDET) and two digital voltage glitch detectors (GDET) which enhance protection against voltage manipulation. The NXP boot ROM configures aGDET and GDET during device initialization to reset the device when voltage manipulation is detected. The aGDET and GDET were validated on silicon across multiple process, voltage, and temperature corners with maximum noise profile generated by activating a large number of possible boot paths. To avoid false triggering due to unforeseen environment or application behavior, NXP recommends disabling aGDET and GDET in early start-up code. You can use aGDET and/or GDET in the application when security-critical operations are taking place, e.g., cryptographic operation using private or symmetric keys (digital signature, encryption, decryption, etc.), or sensitive decision-making process. However, characterization of the system noise profile and interactions with the sensors are required.

27.1.1 Module instances

This chip has two instances of the PMC module: PMC0 and PMC1.

Table 226. PMC instances

	PMC0	PMC1
Located in	VDD1V8_PMC	VDD1V8_PMC
Access	CPU0, eDMA0, eDMA1	CPU1, eDMA2, eDMA3

27.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

27.1.3 Clock for PMC register access

The PMC instances are attached to the VDD1_SENSE bus. For either CPU to be able to access the PMC registers, SENSE_MAIN_CLK_1 must be enabled (controlled by RUNCFG[SENSES_MAINCLK_SHUTOFF] and/or SLEEPCFG[SENSES_MAINCLK_SHUTOFF] fields of the SLEEPCON0 and SLEEPCON1).

27.2 Overview

PMC controls the power-related functions of the chip, including the following:

- Internal regulators
- Voltage and current references
- Supply voltage monitors
- Power switches
- Asymmetric forward body bias (AFBB) and reverse body bias (RBB)
- Oscillators for the PMC analog and logic blocks
- Temperature sensor
- SRAM power switches
- State retention and reset of the GPIOs
- Logic to respond to both PMC and SoC initiated mode changes.

The PMC control logic includes state machines and controls for regulator modes, supply levels, power switch sequencing, PMC low-power mode entry and exit sequencing, event triggered wake-ups and interrupts, memory supply power switch control, pad reset and state retention, and the PMIC_MODE[1:0] and PMIC_IRQN pins control interface.

The power management functions support the defined power modes of the chip, the power and reset sequences controlled by the chip's reset and mode controls, and miscellaneous power control and monitoring functions. This chapter covers the hardware details of the PMC digital logic, analog submodules, and the functions they support.

27.2.1 Block diagram

The block diagram below shows the analog submodules controlled by the PMC logic, the logic blocks, and the main power supplies used and/or generated by PMC.

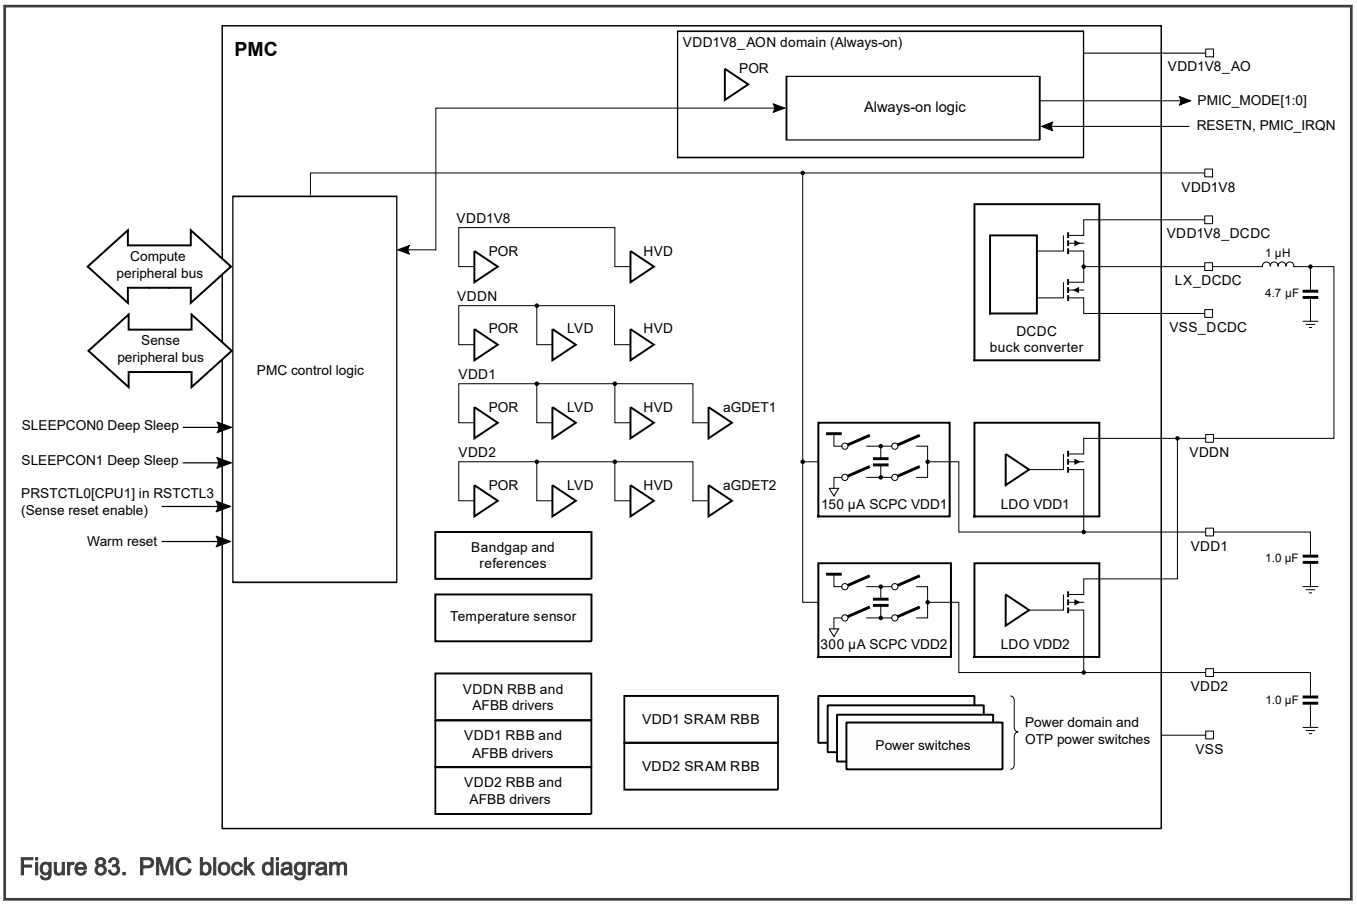


Figure 83. PMC block diagram

27.2.2 Features

- Three separate core supplies (VDDN, VDD1, VDD2) to support the lowest possible voltages needed by the various logic and memory domains, and some analog blocks' interfaces.
- Ultra low-power DC to DC (DCDC) buck regulator with a low-power mode for optimum efficiency over a wide load current range to optionally power VDDN.
- Two (2x) low-dropout (LDO) regulators with bypass mode, supplied by VDDN, to optionally power VDD1 and VDD2.
- Two (2x) switched capacitor power converters (SCPC) to optionally power VDD1 and VDD2, supports state retention of logic and memory, while VDDN is powered down.
- Multiple application supply configurations:
  - Supply the 3 low-voltage core supply domains using the on-chip DCDC for VDDN and the two on-chips LDOs and two on-chip SCPC regulators for VDD1 and VDD2
  - Supply VDDN externally, with VDD1 and VDD2 supplied by the internal LDOs or SCPCs
  - All low-voltage supplies from an external PMIC.
- Analog PMC block containing a band gap reference, current and voltage references, voltage monitors, clock sources, and a temperature sensor.
- Support for reduced supply voltage and lower active power using asymmetric forward body biasing (AFBB) on low-voltage logic.
- Support full-logic state retention at very low-power including reverse body biasing (RBB) for the core logic and SRAMs.
- Low-leakage power switches for each internal low-voltage domain.

- Power mux for internal VDDN_SR rail allows the VDDN supply to power off while the VDDN logic and memory are retained using VDD2 as the supply.
- 1.8 V PMC control logic (VDD1V8):
  - Hardware sequencing for isolation, references, voltage monitors, regulators, body bias, logic power switches and mux, SRAM power switches, and OTP power switch during mode transitions.
  - Generate logic POR for 1.8 V (VDD1V8) and low-voltage domains.
  - Monitor supply voltages for overvoltage (HVD) and low voltage (LVD) and analog glitch detection (aGDET) and generate corresponding interrupts and/or resets.
  - Monitor analog submodules for error conditions and generate corresponding interrupts and/or resets.
  - Provide software and hardware interface to the chip's power management functions (CPUs and SLEEPCON blocks).
  - Provide enable bits for triggering interrupts, wake-up, and resets from various detectors, timers, etc.
  - Provide status and sticky flag bits for software polling and interrupt service routine (ISR) acknowledgement.
  - Automatic pad state retention controls.
- 1.8 V PMC always on control logic (VDD1V8_AO):
  - RESETN, PMIC_IRQN, and PMIC_MODE pad interface
  - RTC wake-up interface logic
  - Always-on VDD1V8_AO POR

27.3 Functional description

The supported domains and operations of hardware logic blocks and connections of PMC are covered in the sections below.

NOTE

PMC includes two sets of registers used to configure operation in Active mode and low-power modes. Many control options are duplicated between these two sets of registers, so throughout this chapter, "*" is used in register names, where the * can be replaced by "RUN" or "SLEEP." For example, PD*CFG0 refers to PDRUNCFG0 and PDSLEEPCFG0 registers.

27.3.1 Analog submodules

27.3.1.1 Regulators

There are five on-chip regulators in PMC. They can be used to supply the low-voltage power rails in the chip, or can be disabled by software when the low-voltage rails of the chip are powered by external supplies. Mixed on-chip and off-chip supply configurations are also supported.

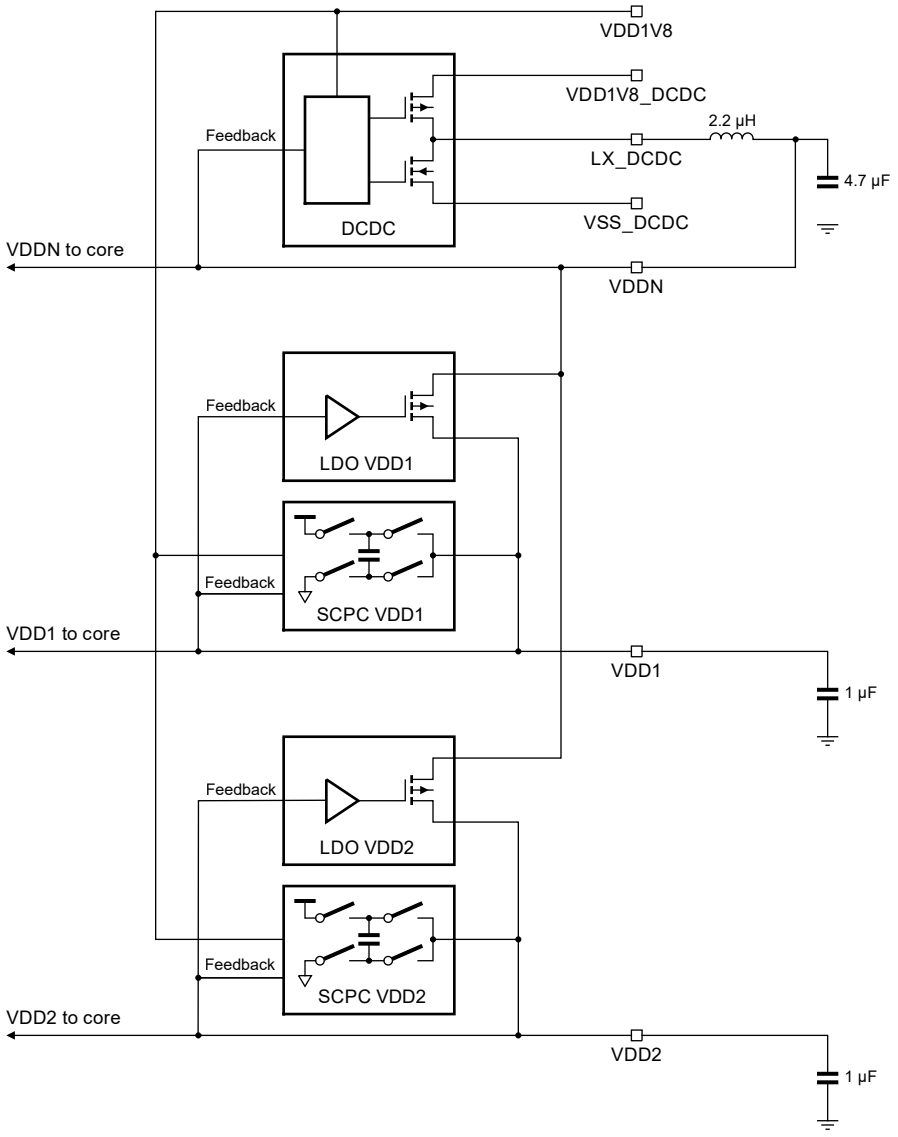

Figure 84. PMC regulators and associated package pins

27.3.1.1.1 DCDC buck converter (DCDC)

The on-chip DCDC Buck Converter is a step down inductive switched regulator that converts the 1.8 V input supply down to a 0.5 to 1.15 V level. This is optionally used to power the VDDN supply for logic and the 2 on-chip LDO regulators.

The DCDC features include:

- Input range from 1.71 to 1.98 V
- Output range programmable from 0.5 V to 1.15 V in steps of 6.25 mV (see DCDCVSEL registers)
- High efficiency even at small loads
- High-power (HP) mode supports active chip power modes.
- Low-power (LP) mode supports low activity modes at higher efficiency than HP mode
- Ultra-low-power (ULP) mode supports retention modes while maintaining high efficiency

- Provides overcurrent warnings that can trigger interrupts.

The DCDC control interface uses these registers:

- Power mode: PD*CFG0[DCDC_MODE]
- Voltage level: PD*CFG0[DCDC_VSEL] and DCDCVSEL registers
- Disable DCDC when using external VDDN by setting POWERCFG[DCDCPD]
- Enable DCDC during FDSR mode by clearing POWERCFG[FDDCPD]
- Overcurrent warning flags and interrupt enables: FLAGS and INTRCTRL

27.3.1.1.2 Low-dropout (LDO) regulators

PMC has two LDO regulators, LDO VDD1 for VDD1 and LDO VDD2 for VDD2 supplies respectively. They can be powered down when VDD1 and VDD2 are externally powered.

These regulators' output drivers are supplied by VDDN and drop the voltage by as little as 50 mV in bypass mode, or regulate down to as low as 0.5 V in either high-power (HP) or low-power (LP) regulation modes.

The output voltages and power modes are separately controllable, allowing the VDD1 and VDD2 logic supplies to be independently optimized to support the required logic performance.

The LDO features include:

- High-power mode with fast load step response
- Low-power regulation mode with low quiescent current consumption
- Low-power bypass mode with low quiescent current consumption and only a 50 mV drop from VDDN (see PD*CFG0[LDOn_MODE])
- Configurable output voltage from 0.5 V to 1.15 V by the step of 12.5 mV
- Soft start up by limiting the output current

The LDO control interface uses these registers:

- Power mode: PD*CFG0[LDOn_MODE]
- Voltage level: PD*CFG0[LDOn_VSEL] and LDOVDDnVSEL registers
- Disable LDO when using external VDD1 and VDD2 by setting POWERCFG[LDOnPD]
- Enable LDO during FDSR mode by clearing POWERCFG[FDLDOnPD]

27.3.1.1.3 Switched capacitor power converters (SCPC)

The on-chip switched capacitor power converters, SCPC VDD1 and SCPC VDD2, optionally supply the state retained logic and SRAM memory arrays during full deep sleep retention (FDSR) mode. These regulators divide the VDD1V8 supply by a ratio of about 3 to supply 0.5 V. When the SCPCs are used to power VDD1 and VDD2 in FDSR mode, LDO VDD1 and LDO VDD2 can be powered down. This is the default configuration in POWERCFG.

- One to three ratio down conversion
- The SCPC's undervoltage flag is set when the voltage drops too low to support logic retention. This event can be configured to trigger an interrupt.
- High efficiency at very low loads

The SCPC control interface uses these registers:

- PDSLEEPCFG0[FDSR]: Set in both Compute and Sense domain to enter FDSR mode when both CPUs enter Deep Sleep, enabling the SCPCs depending on the POWERCFG settings.
- POWERCFG[SCPCPD] = 1 disables both regulators all the time. Set this bit when application powers VDD1 and VDD2 externally.

- POWERCFG[FDSCPnPD]: Set to disable the SCPCs in FDSR mode when using the on chip LDOs during FDSR mode.

27.3.1.2 PMC voltage and current references

The PMC voltage and current references are used inside the PMC subsystem and available for blocks outside PMC like ADC.

The band gap, voltage, and current references automatically go to high-power mode if any PMC module (e.g. regulators, monitors, or temperature sensor) needs them. For external modules that need the high-power references, software should clear the [PMCREF_LP] field in the appropriate PD*CFG1 register to force the references into high-power mode.

The high-power references are turned off when no PMC blocks need high-power references and the aggregated PD*CFG1[PMCREF_LP] bit is set.

The SCPC regulators only use the low-power references, so they never cause the references to go to high power mode. The LDO regulators use only low-power references when in bypass or low-power mode. However, the LDO regulators automatically enable the high-power references when in high-power mode. The DCDC, PORs, and LVDs use high-power references when they are in their respective high-power modes, so force the references into high-power mode when they are in high-power mode. The HVDs, aGDETs, and PMC temperature sensor use high-power references so force the references into high-power mode when they are enabled.

27.3.1.3 Supply voltage monitors

There are four different types of voltage monitors in PMC: PORs, HVDs, LVDs, and aGDETs. Each monitor type is described below, including which voltage supplies are monitored by each type.

27.3.1.3.1 Power-on reset (POR)

There are five power-on reset modules that provide undervoltage detection for these supply rails:

- VDD1V8_AO
- VDD1V8
- VDDN
- VDD1
- VDD2

POR modules always trigger cold resets when tripped:

- The VDD1V8_AO POR triggers a full chip reset, including the always on logic.
- The VDD1V8 POR triggers a full chip reset, except for a few bits in the FLAGS register.
- The VDD1, VDD2, and VDDN PORs trigger cold resets that reset all the PD*CFG registers to the default values, including the memory and logic power switch controls.

The POR modules will hold the chip in reset until the supplies exceed the trip point. They assert reset when the supplies drop below the trip point minus a small amount of hysteresis. The VDD1, VDD2, and VDDN POR resets are forced active when PMC is in deep power down (DPD) mode or full deep power down (FDPD) mode. The VDD1V8 POR is forced active when PMC is in FDPD mode except when configured to use for wake-up by clearing POWERCFG[FDPDBGLP], which causes PMC to exit FDPD when VDD1V8 drops below the trip point minus hysteresis then rises back up above the trip point. Note this keeps the voltage references in high-power mode which consumes about 85 µA.

The VDD1, VDD2, and VDDN PORs have programmable trip points. The VDD1V8_AO and VDD1V8 PORs have fixed trip points.

27.3.1.3.1.1 VDD1, VDD2, VDDN POR features

- Programmable falling trip point from 0.40 V to 0.71 V (32 steps of 10 mV)
- Always enabled when VDD1V8 is powered
- Low-power or high-power mode
- When in high-power mode it automatically puts the references into high-power mode

27.3.1.3.1.2 VDD1V8 POR features

- Fixed falling trip voltage
- Always enabled when VDD1V8 is powered
- Low-power or high-power mode based on reference voltage power mode

27.3.1.3.1.3 VDD1V8_AO POR features

- Fixed falling trip voltage = 1.46 V (typical)
- Always enabled when VDD1V8_AO is powered
- Always in low-power mode

27.3.1.3.2 High Voltage Detectors (HVD)

There are four HVDs, one each for VDD1, VDD2, and VDDN, and one for VDD1V8. Each HVD can optionally trigger a reset and interrupt, or simply set their FLAGS and STATUS bits.

The HVDs are enabled or powered down by their respective aggregated PD*CFG bits. When enabled the references are automatically put in high-power mode.

27.3.1.3.2.1 HVD features

- HVDs can be powered down
- HVDs do not have a low-power mode, so the references are forced high-power mode when an HVD is enabled
- VDD1, VDD2, VDDN assertion (rising VDD) trip voltage = 1.25 V (typical)
- VDD1V8 assertion trip voltage = 2.115 V (typical)

27.3.1.3.3 Low Voltage Detectors (LVD)

There are three LVDs, one each for VDD1, VDD2, and VDDN. Each can optionally trigger a reset, an interrupt, or simply set their FLAGS and STATUS bits.

The LVDs are also used to detect the supply rails when using off chip supplies for the core supplies. When PMC changes modes, the LVDs must detect voltages higher than the currently selected trip points to complete the mode transition.

The LVD trip points are selected by the aggregated PD*CFG0[DCDC_VSEL] for VDDN which selects one of two values from the LVDVDDNCTRL register, the PD*CFG0[LDO1_VSEL] field which selects one of four values from the LVDVDD1CTRL register, and the PD*CFG0[LDO2_VSEL] field which selects one of four values from the LVDVDD2CTRL register.

27.3.1.3.3.1 LVD features

- Trimmable falling trip point from 0.5 V to 1.13 V (64 steps of 10 mV)
- Always enabled when VDD1V8 is powered
- Low-power or high-power mode
- When in high-power mode it automatically puts the references into high-power mode

27.3.1.3.4 Analog Glitch Detectors (aGDET)

There are two aGDETs, one each for VDD1 and VDD2. Each can optionally trigger a reset, an interrupt, or simply set their FLAGS bits when the supply drops quickly or VSS spikes up quickly. These blocks are intended to detect voltage attacks by malicious users.

The aGDETs are enabled when the aggregated PD*CFG1[AGDET1_PD] and/or [AGDET2_PD] fields are cleared. When the aGDETs are enabled, the references are in high-power mode.

27.3.1.3.4.1 aGDET features

- The aGDET is triggered by low going supply glitches or high going VSS glitches of 300 mV or more, but is not triggered by glitches less than 60 mV in magnitude to avoid triggering due to normal supply noise. Glitches with magnitudes between 60 mV and 300 mV may trigger the aGDET. Typically glitches of about 150 mV in magnitude will trigger the aGDET.
- When enabled the aGDET detector automatically puts the references into high power mode

27.3.1.4 Power switches and power mux

There are nine power switches implemented in PMC. All are controlled by the aggregated values of their respective PD*CFG PD (Power Down) or DSR (Deep Sleep Retention) bits: [V2COMP_DSR], [V2NMED_DSR] (controls both VDDN_MEDIA and VDD2_MEDIA switches), [V2COM_DSR], [VNCOM_DSR], [V2DSP_PD], [V2MIPI_PD], and [OTP_PD].

There is also one power mux. It is used during FDSR mode to switch the supply for the VDDN powered logic over to VDD2, allowing the VDDN supply to be powered off.

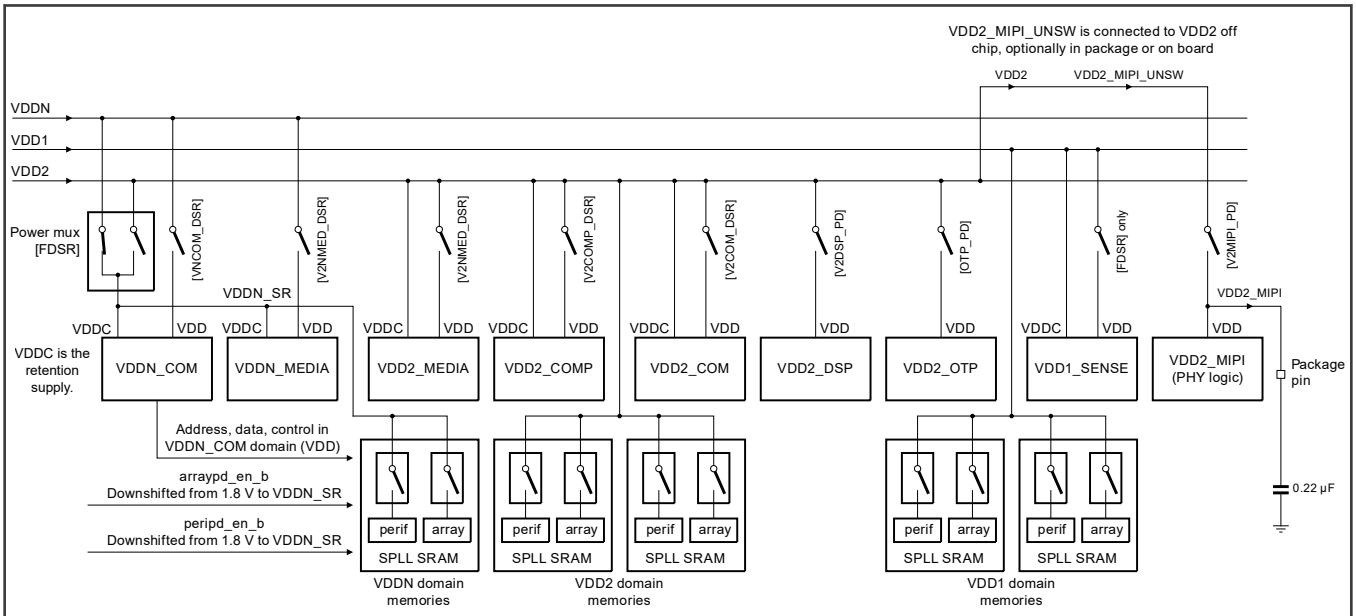

Figure 85. Power switches and power mux diagram

It is the software's responsibility to ensure that the following restrictions are maintained. The [FDPD], [DPD], and [FDSR] bits override the other PD*CFG power switch controls. When all of these 3 bits are clear, then the individual power gates may be enabled or disabled as indicated. Software is required to set the PD/DSR bits as shown in the table below when the bit in the left column is set. An 'X' in the other columns indicates when a bit may be either asserted or negated.

Table 227. Power switch restrictions

Aggregated PD*CFG bit is set and domain power-gated	Required value of other PD*CFG bits and supplies

27.3.1.5 Logic body bias generators

Body biasing consists of applying a voltage to the target transistors' back terminal to control their threshold voltage. Asymmetric forward body bias (AFBB) allows for higher performance while minimizing the increase in leakage current. Reverse body bias (RBB) reduces the leakage current consumption but also performance so is used only for logic that is not clocked.

The logic body bias is applied per main voltage domain (VDD1, VDD2, and VDDN) to allow each to be independently biased based on their supply voltage levels and performance needs.

AFBB is enabled at power up. The applied voltage is fixed.

RBB mode can be enabled via PDSLEEPCFG0 for Deep Sleep modes. Asynchronous activity is allowed while RBB is enabled. The RBB voltage can be selected in BBCTRL for each domain. Generally the application should use 1.3 V to get the smallest amount of leakage, but it is possible that the 1.0 V setting achieves lower total power for applications that frequently toggle between RBB and AFBB because the charge needed to switch modes is smaller with a smaller RBB voltage.

NOTE

For applications where one CPU domain never uses one of the voltage domains, and so the other CPU domain should have complete control, the first domain should configure the body bias for that domain to be RBB (the lowest power mode) so that aggregation will always use the second domain's PD*CFG to control that voltage domain's body bias. For example, if the Compute CPU never uses any VDD1 logic, then the Compute slot should be configured with PDRUNCFG0[AFBB1_PD] = 1, PDRUNCFG0[RBB1_PD] = 0, and the same for PDSLEEPCFG0, so regardless of the activity in the Compute domain, the Sense domain has complete control of the VDD1 body bias.

NOTE

See Enabling body bias for low-power modes for more information on controlling the Logic Body Bias.

27.3.1.6 SRAM reverse body bias generators

Similar to the logic body bias generators, there are two SRAM body bias generators, one for SRAMs in VDD1 and the other for SRAMs in VDD2. These should only be enabled when none of the memories in that voltage domain are being accessed, which is typically when that voltage domain is in a low-power mode. They are fixed voltage and require no configuration other than turning them on via PD*CFG0 registers. To enable SRAM RBB for a voltage domain's SRAMs, clear the associated [RBBSRn_PD].

When the generators are powered down, the SRAMs operate in normal body bias (NBB) mode.

27.3.1.7 PMC temperature sensor

To enable the temperature sensor, the sensor must be enabled by clearing PDRUNCFG1[TEMP_PD] and then setting CTRL[APPLYCFG] to activate PDRUNCFG1 change.

NOTE

The temperature sensor is automatically disabled and powered down when the chip is in DPD or FDPD mode.

27.3.1.7.1 Using the temperature sensor

To configure system for measurement:

- Enable PMC temperature sensor (PDRUNCFG1[TEMP_PD] = 0), set CTRL[APPLYCFG] to trigger the state machine update, wait for STATUS[BUSY] to go low, then wait another 40 µs for the temperature sensor to settle.
- Select ADC differential input channel connected to PMC temperature sensor.
- Configure ADC sampling time to (at least) 15 µs.

Measurement procedure:

1. Set TSENSOR[TSENSM] = 000b, perform AD conversion, and record C1_000
2. Set TSENSOR[TSENSM] = 001b, perform AD conversion, and record C1_001
3. Set TSENSOR[TSENSM] = 011b, perform AD conversion, and record C1_011
4. Set TSENSOR[TSENSM] = 010b, perform AD conversion, and record C1_010
5. Set TSENSOR[TSENSM] = 110b, perform AD conversion, and record C1_110
6. Set TSENSOR[TSENSM] = 111b, perform AD conversion, and record C1_111
7. Set TSENSOR[TSENSM] = 101b, perform AD conversion, and record C1_101
8. Set TSENSOR[TSENSM] = 100b, perform AD conversion, and record CM_100
9. Set TSENSOR[TSENSM] = 101b, perform AD conversion, and record C2_101
10. Set TSENSOR[TSENSM] = 111b, perform AD conversion, and record C2_111
11. Set TSENSOR[TSENSM] = 110b, perform AD conversion, and record C2_110
12. Set TSENSOR[TSENSM] = 010b, perform AD conversion, and record C2_010
13. Set TSENSOR[TSENSM] = 011b, perform AD conversion, and record C2_011
14. Set TSENSOR[TSENSM] = 001b, perform AD conversion, and record C2_001
15. Set TSENSOR[TSENSM] = 000b, perform AD conversion, and record C2_000

Calculate die-temperature using the formula:

$$T[\text{in } °C] = n^{-1} * 370.98 * (CM_TEMP/CM_VREF) - 273.15$$

Where:

- n = 1.0036
- CM_TEMP = (2*C1_000 - C1_010 + 2*C2_000 - C2_010 + 4*CM_100 - C1_110 - C2_110) / 4
- CM_VREF = CM_CTAT + (953.36 + TSENS_CAL) * CM_TEMP * 2^{-11}
  - CM_CTAT = (2*C1_001 - C1_011 + 2*C2_001 - C2_011 + 2*C1_101 - C1_111 + 2*C2_101 - C2_111) / 4
  - TSENS_CAL is an 8-bit signed calibration constant retrieved from the OCOTP fuse word index [2464].

NOTE

- Multiplications and divisions by 2 or 4 may be performed through simple shift-register operations.
- See ADC chapter for information on how to configure the ADC.
- The PMC references are put into high-power mode whenever the PMC temperature sensor is enabled.

27.3.2 PMC control

27.3.2.1 Operating modes

The PMC operating mode depends on a few inputs from the chip, a few register settings in PMC, and changes mode when either Sense or Compute (or both) CPUs enter or wake up from Deep Sleep mode, the Sense or Compute CPU is in Deep Sleep and its SLEEPCON enters or exits a hardware wake event (e.g. a DMA access), a warm or cold reset occurs, or the chip clears PRSTCTL0[CPU1] in RSTCTL3.

A hardware wake in a given domain's SLEEPCON causes PMC to enter Active mode for that domain, using PDRUNCFG instead of PDSLEEPCFG while the hardware wake event is active, then revert to PDSLEEPCFG afterwards. The domain's CPU remains in Deep Sleep during the hardware wake event.

It is possible for both CPUs to change their Deep Sleep state on the same clock cycle and PMC will correctly change modes using the aggregated values of the PD*CFG registers based on both CPUs' new states.

Table 228. PMC operating modes

Mode	Compute CPU Deep Sleep	Sense CPU Deep Sleep	Sense domain reset	Warm reset	Cold reset	Aggregated PDSLEEPCFG			Mode description
						[FDSR]	[DPD]	[FDPD]	
VDD1V8_AO POR	-	-	-	-	VDD1V8_AO POR	-	-	-	All logic is reset.
VDD1V8 POR	-	-	-	-	VDD1V8_POR or FDPD wake-up	-	-	-	Resets all PMC logic, except Always-on logic, including some FLAGS register bits.
Cold reset	-	-	-	-	VDD1, VDD2, or VDDN POR, LVD, HVD, or aGDET reset or VDD1V8 HVD	-	-	-	Resets most PMC logic except for the FLAGS and PWRFLAGS registers
Compute Active / Sense Reset	0	-	1	0	0	-	-	-	Compute PDRUNCFG controls PMC
Compute Active / Sense Active	0	0	0	0	0	-	-	-	Aggregated Compute PDRUNCFG + Sense PDRUNCFG controls PMC
Compute Active / Sense Deep Sleep	0	1	0	0	0	-	-	-	Aggregated Compute PDRUNCFG + Sense PDSLEEPCFG controls PMC

Table continues on the next page...

Table 228. PMC operating modes (continued)

Mode	Compute CPU Deep Sleep	Sense CPU Deep Sleep	Sense domain reset	Warm reset	Cold reset	Aggregated PDSLEEPCFG			Mode description
						[FDSR]	[DPD]	[FDPD]	
Compute Deep Sleep / Sense Active	1	0	0	0	0	-	-	-	Aggregated Compute PDSLEEPCFG + Sense PDRUNCFG controls PMC
Compute Deep Sleep / Sense Deep Sleep	1	1	0	0	0	0	0	0	Aggregated Compute PDSLEEPCFG + Sense PDSLEEPCFG controls PMC
FDSR	1	1	0	0	0	1	0	0	All low-voltage logic power-gated, most state retained. SRAM arrays optionally retained.
DPD	1	1	0	0	0	-	1	0	All chip's low-voltage logic powered off
FDPD	1	1	0	0	0	-	-	1	All chip's low-voltage and VDD1V8 logic powered off

NOTE

When PRSTCTL0[CPU1] in RSTCTL3 = 1 , the aggregated PD*CFG is the same as the Compute PD*CFG. The Sense domain's PD*CFG is ignored.

If there is a mode change in progress, or the PMC state machines are busy due to software setting CTRL[APPLYCFG], the mode change will occur after the current change completes. Software can poll CTRL[APPLYCFG] or the STATUS[BUSY] to see if an operation is in progress.

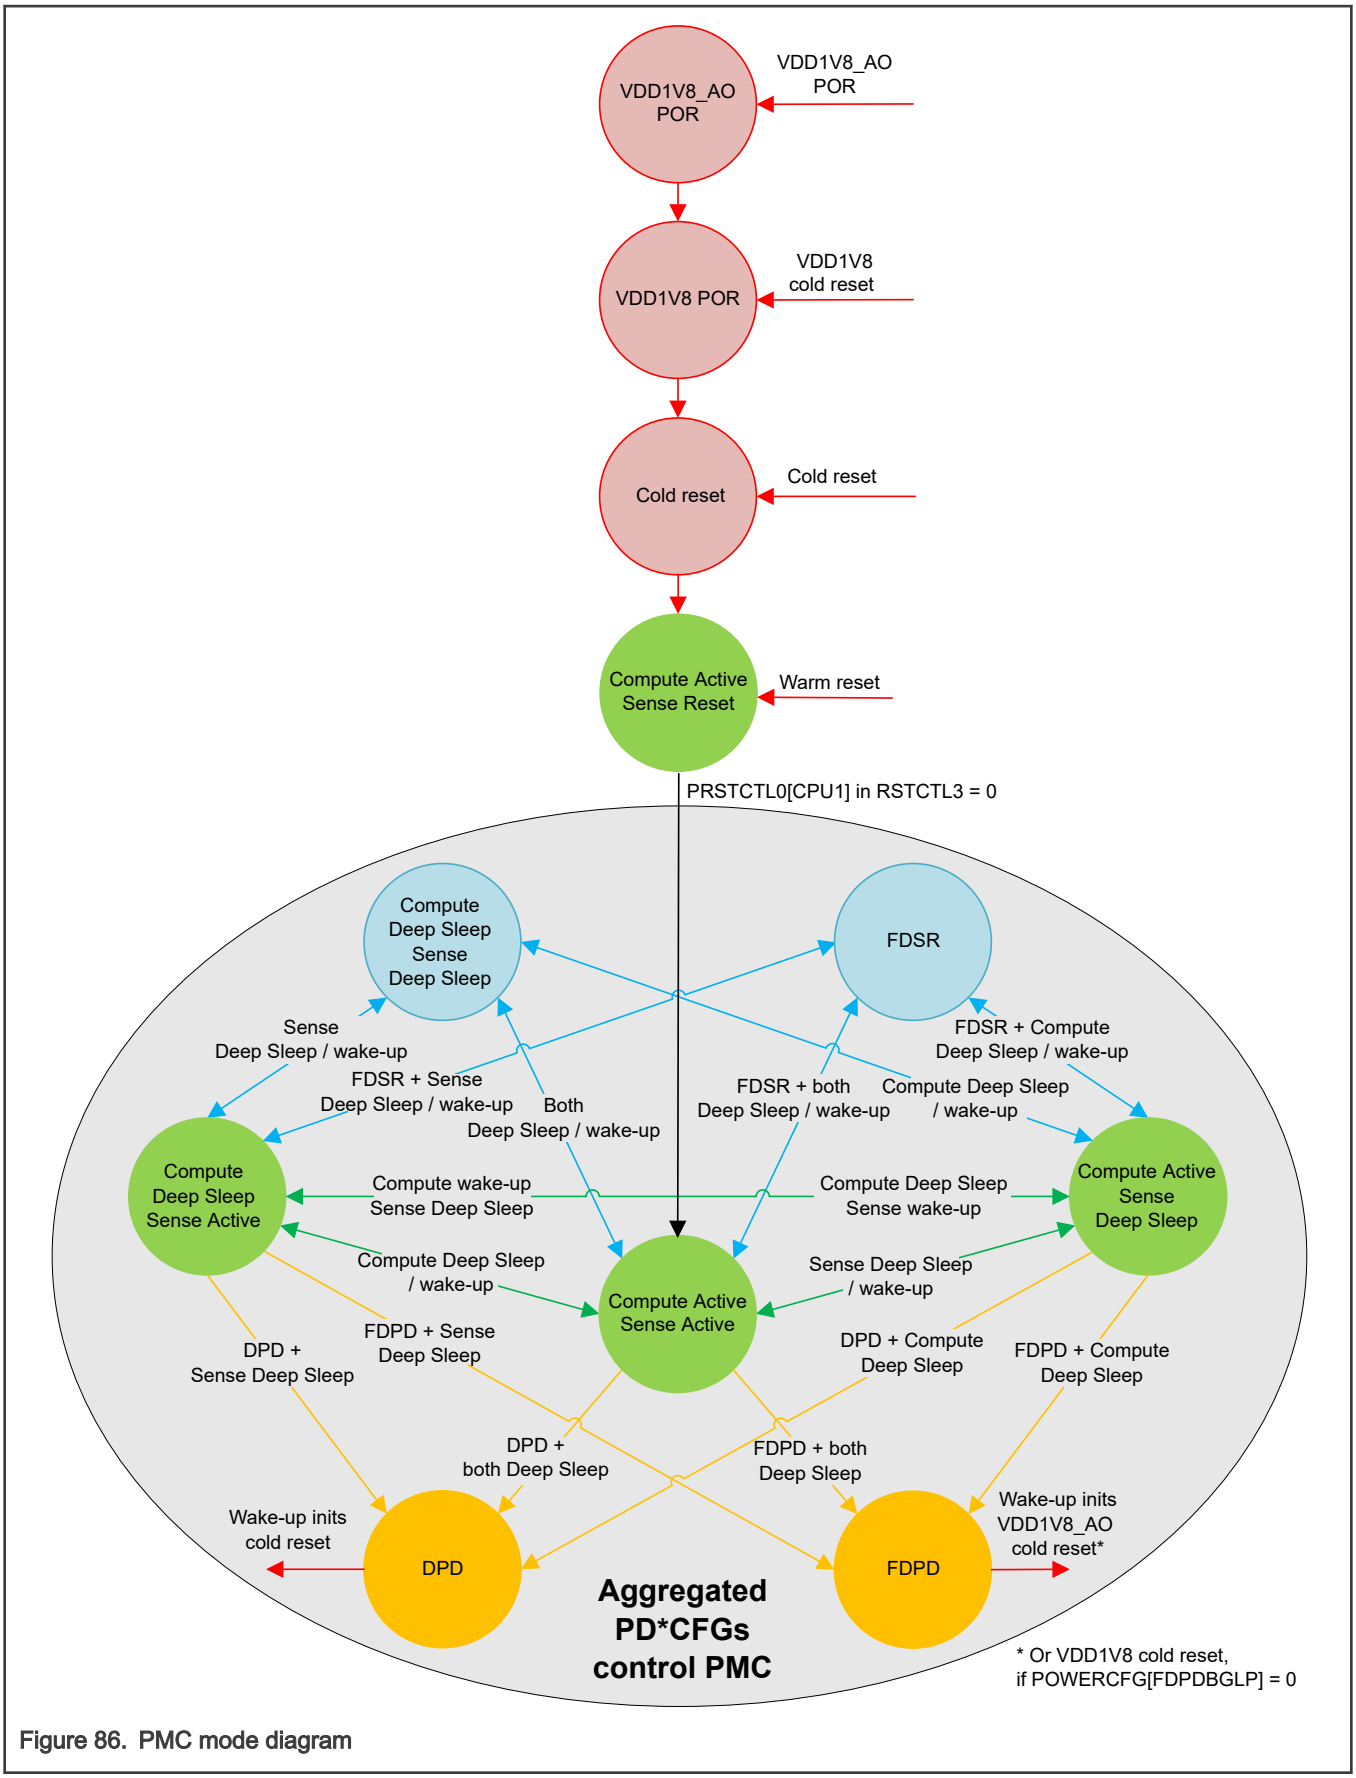

Figure 86. PMC mode diagram

27.3.2.2 PD*CFG and aggregation

PD*CFG refers to PDRUNCFG and PDSLEEPCFG registers that control the PMC block power modes, chip power modes, and core domain voltage levels. There are two sets of PDRUNCFG and PDSLEEPCFG registers, one set for the Compute domain and one for the Sense domain. For each domain, either the PDRUNCFG or the PDSLEEPCFG registers are selected based on that domain's CPU state. When a CPU is in Deep Sleep mode then it's PDSLEEPCFG registers are selected, otherwise it's PDRUNCFG registers are selected.

The selected registers for the Compute domain and the Sense domain are ***aggregated*** and used to control the power states of the PMC submodules, the voltage levels in the core domains, and the power switches for the core sub-domains and SRAMs. The aggregation compares the Compute and Sense domain PD*CFG inputs and selects the higher power state for each control field. For example, the Compute domain CPU is in Deep Sleep and its PDSLEEPCFG0[DCDC_VSEL] = 0, and the Sense domain CPU is active and its PDRUNCFG0[DCDC_VSEL] = 1, then the aggregated DCDC voltage select = 1 because that is higher power, allowing the Sense domain to run at the power level it needs while the Compute domain is in Deep Sleep and simplifying the software coordination needed between the two CPUs.

The aggregation generally uses the lower binary value of the bit fields as the higher power mode, since most fields are "power down" bits, but there are some exceptions in PD*CFG0: [DCDC_VSEL], [LDO1_VSEL], [LDO2_VSEL], [RBB1_PD], [RBB2_PD], [RBBN_PD], [RBBSR1_PD], [RBBSR2_PD] all chose the higher binary value because that is the higher power mode for these fields.

A new aggregated value is calculated any time the PMC state machines are triggered. This occurs when either CPUs' Deep Sleep state changes, the SLEEPCON for a domain in Deep Sleep receives a DMA wake-up request, PRSTCTL0[CPU1] in RSTCTL3 changes state, a reset occurs, or either CPU's CTRL[APPLYCFG] is set to capture and apply the software updates to its PDRUNCFG registers. PDRUNCFG or PDSLEEPCFG is captured only for the domain that has such an event. Unless both domains have an event at the same time, the other domain's old capture value is used for aggregation.

As shown in the figure below, the output of the aggregation scheme is readable via the PDCFGSTATUSn register.

For applications where one CPU domain never uses any resources configurable in PD*CFG and so the other CPU domain should have complete control, the first domain should configure that resource to be in the lowest power mode so that aggregation will always use the second domain's PD*CFG to control that resource.

> For example, if the Compute CPU never uses any VDD1 logic, then the Compute slot should be configured with PDRUNCFG0[AFBB1_PD] = 1, PDRUNCFG0[RBB1_PD] = 0, and the same for PDSLEEPCFG, so regardless of the activity in the Compute domain, the Sense domain has complete control of the VDD1 body bias. If the Compute domain does use VDD1 when the Compute CPU is active, then it should configure PDRUNCFG0[AFBB1_PD] = 0, PDRUNCFG0[RBB1_PD] = 1, and configure PDSLEEPCFG0[AFBB1_PD] = 1, PDSLEEPCFG0[RBB1_PD] = 0 so that when the Compute domain goes to Deep Sleep, the Sense domain can put VDD1 into RBB mode.

NOTE

When PRSTCTL0[CPU1] in RSTCTL3 = 1, the aggregated output is just the Compute domain's selected PDRUNCFG or PDSLEEPCFG and the default Sense domain's PDRUNCFG and PDSLEEPCFG are ignored.

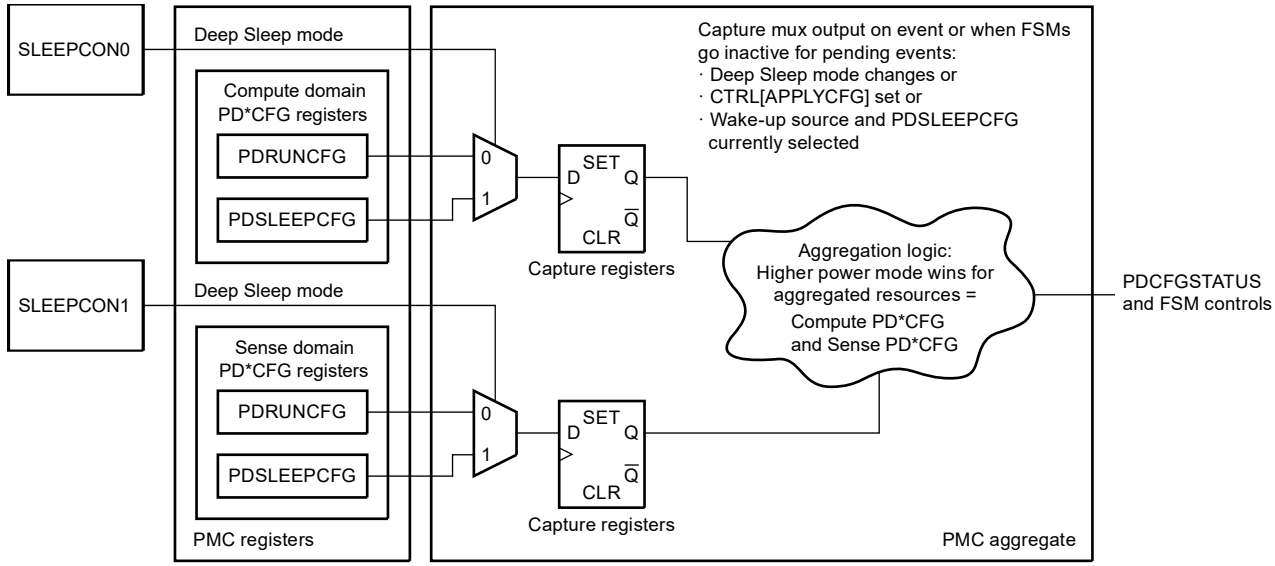

Figure 87. PMC PD*CFG aggregation scheme

27.3.2.3 Control functions

This section describes some of the control functions that may not be obvious from the register descriptions.

27.3.2.3.1 Autowake

This feature allows PMC to wake up some amount of time after the domain enters Deep Sleep. It is enabled for a domain by setting INTRCTRL[AUTOWKIE] and activated when that domain enters Deep Sleep. When PMC has completed the Deep Sleep mode change, the Autowake timer counts down from the value set in WAKEUP[WAKETIME] and when it reaches zero it asserts that domain's PMC interrupt, triggering a wake-up. The timer is clocked by PMC's internal 16 MHz clock. The domain's SLEEPCON and CPU should be configured to wake up and respond to the PMC interrupt. This feature is usable for wake-up from Deep Sleep and FDSR modes.

Autowake has one timer and one time out value, WAKEUP[WAKETIME], for each CPU slot. Both timers can get enabled if both slots go to Deep Sleep mode at the same time, else only 1 will run at a time. New requests blocked until after the Autowake time out. On wake-up via Autowake a pending Deep Sleep entry or wake-up request from the other slot is possible and its PDSLEEPCFG or PDRUNCFG will be aggregated along with the PDRUNCFG of the first slot. If both timers are enabled at the same time, wake-up will occur after BOTH timers time out (i.e. the max timeout value between the two is used).

27.3.2.3.2 Regulator and LVD level control

PD*CFG0[DCDC_VSEL] selects one of two voltage levels for the DCDC regulation voltage and for the VDDN LVD trip level. The actual level values are stored in DCDCVSEL (two values) and LVDVDDNCTRL (two values). Similarly, PD*CFG0[LDO1_VSEL] and PD*CFG0[LDO2_VSEL] select one of the four values stored in LDOVDD1VSEL, LDOVDD2VSEL, LVDVDD1CTRL, and LVDVDD2CTRL. This allows the PDRUNCFG, PDSLEEPCFG, and aggregation logic to select valid LVD and VDD combinations while adjusting the supplies when activity levels change.

27.3.2.3.3 Low-power mode details

27.3.2.3.3.1 Full Deep Sleep Retention (FDSR)

This mode reduces chip's power consumption to the minimum possible level while retaining state. In the default configuration, the DCDC and LDOs are powered down and the VDD1 and VDD2 rails are supplied by SCPC1 and SCPC2. At high temperature, these regulators may not supply sufficient current, so an alternate configuration using the DCDC and the LDOs to power VDD1

and VDD2 can be used. Alternatively, an external PMIC can be used to power VDDN, VDD1, and VDD2 in all modes. In this case, the VDDN supply can be powered down during FDSR mode.

When using the default configuration, the SCPC overcurrent flag triggers when excess load pulls down VDD1 or VDD2. If INTRCTRL[SCP1OCIE] and [SCP2OCIE] are set, then a wake-up and a PMC interrupt occur. The LVDs are masked in this mode because the minimum LVD setting is 0.5 V and the SCPC OC flag serves the same purpose.

At high temperature, the logic leakage can be too high for the SCPC to provide (>400 µA), so this mechanism allows software to go back to FDSR using the LDO + DCDC if desired.

Similarly, the logic leakage can also be too high for DCDC ULP mode to provide at high temperature, in this case, software can use DCDC LP mode.

27.3.2.3.3.2 Full Deep Power Down (FDPD)

Any Always-on wake-up source (the RTC, the PMIC_IRQN pin, or the RESETN pin) will wake up the chip from FDPD mode.

The default configuration keeps the references in high-power mode during FDPD mode so wakeup is triggered when the VDD1V8 supply rises through the VDD1V8 POR trip level.

NOTE

In this case, the VDD1V8 supply must drop below the POR trip level so the POR asserts and then later rise above the trip level so the POR will negate, triggering a wake-up.

To save power when the rising VDD1V8 wake-up feature isn't needed, the references can be put in low-power mode during FDPD by setting POWERCFG[FDPDBGLP]. This causes the references to enter high-power mode only after a wake-up event occurs, but the part will not wake up when VDD1V8 ramps up from below the VDD1V8 POR trip level to above.

In either configuration the wake-up event triggers a VDD1V8 POR cold reset.

27.3.2.4 Always-on domain logic

The Always-on domain logic includes the VDD1V8_AO POR, the PMIC_MODE pin controls, the logic used to trigger wake-up when PMIC_IRQN, RESETN, or RTC wake-up events occur, and the FLAGS fields that are retained through cold resets and VDD1V8 PORs. Access to these functions is accomplished via the register interface, with no special software control needed.

27.3.3 Clocking

PMC is clocked by the internal 16 MHz oscillator. The chip synchronizes all PMC bus accesses to this clock. All counters and state machine timing in PMC are clocked by the 16 MHz oscillator, except for the cyclic wakeup timer to the DCDC which is clocked by a 64 kHz oscillator.

27.3.4 Reset

PMC both generates and responds to a variety of reset sources.

27.3.4.1 PMC generated resets

PMC generates resets from the voltage monitors (POR, LVD, HVD, aGDET) which detect under or overvoltage conditions on the supply rails they monitor as described in Supply voltage monitors.

Table 229. Reset sources and effects

Source	Detector power mode	Enabled	Reset type	Description
POR VDD1V8_AO	Always on	Always	Cold VDD1V8_AO	All chip's logic is reset, including PMC flags.

Table continues on the next page...

Table 229. Reset sources and effects (continued)

Source	Detector power mode	Enabled	Reset type	Description
POR VDD1V8	On when VDD1V8 is powered	Always	Cold VDD1V8	Triggers when VDD1V8 drops below the VDD1V8 POR falling trip level. Resets all core logic and most PMC registers except some FLAGS and PWRFLAGS. **NOTE** When in FDPD, the VDD1V8 POR can be on to use as a wake-up source when VDD1V8 ramps back up, or can be disabled to save power if VDD1V8 may not drop below the POR threshold and other wake-up sources are used. This feature is controlled by POWERCFG[FDPDBGLP].
POR VDD1	PD*CFG1[POR1_LP]	Always	Cold	Triggers when VDD1 drops below the POR level set in PORCTRL register. Resets all core logic and most PMC registers except FLAGS, PWRFLAGS.
POR VDD2	PD*CFG1[POR2_LP]	Always	Cold	Triggers when VDD2 drops below the POR level set in PORCTRL register. Resets all core logic and most PMC registers except FLAGS, PWRFLAGS.
POR VDDN	PD*CFG1[PORN_LP]	Always	Cold	Triggers when VDDN drops below the POR level set in PORCTRL register. Resets all core logic and most PMC registers except FLAGS, PWRFLAGS.
LVD VDD1	PD*CFG1[LVD1_LP]	CTRL[LVD1RE]	Cold	Triggers when VDD1 drops below the LVD level selected by the aggregated PD*CFG0[LDO1_VSEL] and defined in LDOVDD1VSEL register. Resets all core logic and most PMC registers except FLAGS, PWRFLAGS.
LVD VDD2	PD*CFG1[LVD2_LP]	CTRL[LVD2RE]	Cold	Triggers when VDD2 drops below the LVD level selected by the aggregated PD*CFG0[LDO2_VSEL] and defined in LDOVDD2VSEL register. Resets all core logic and most PMC registers except FLAGS, PWRFLAGS.
LVD VDDN	PD*CFG1[LVDN_LP]	CTRL[LVDNRE]	Cold	Triggers when VDDN drops below the LVD level selected by the aggregated PD*CFG0[DCDC_VSEL] and defined in LVDVDDNCTRL register. Resets all core logic

Table continues on the next page...

Table 229. Reset sources and effects (continued)

Source	Detector power mode	Enabled	Reset type	Description
				and most PMC registers except FLAGS, PWRFLAGS.
HVD VDD1V8	PD*CFG1[HVD1V8_PD]	CTRL[HVD1V8RE]	Cold	Triggers when VDD1V8 rises above the HVD level for VDD1V8. Resets all core logic and most PMC registers except FLAGS, PWRFLAGS.
HVD VDD1	PD*CFG1[HVD1_PD]	CTRL[HVDV1RE]	Cold	Triggers when VDD1 rises above the HVD level for VDD1. Resets all core logic and most PMC registers except some FLAGS and PWRFLAGS.
HVD VDD2	PD*CFG1[HVD2_PD]	CTRL[HVDV2RE]	Cold	Triggers when VDD2 rises above the HVD level for VDD2. Resets all core logic and most PMC registers except some FLAGS and PWRFLAGS.
HVD VDDN	PD*CFG1[HVDN_PD]	CTRL[HVDVNRE]	Cold	Triggers when VDDN rises above the HVD level for VDDN. Resets all core logic and most PMC registers except some FLAGS and PWRFLAGS.
aGDET VDD1	PD*CFG1[AGDET1_PD]	CTRL[AGDET1RE]	Cold	Triggers when a negative spike on VDD1 or positive spike on VSS exceeds the glitch detection threshold for VDD1
aGDET VDD2	PD*CFG1[AGDET2_PD]	CTRL[AGDET2RE]	Cold	Triggers when a negative spike on VDD2 or positive spike on VSS exceeds the glitch detection threshold for VDD2

27.3.4.2 PMC reset inputs

PMC receives a warm reset from the chip. Some PD*CFG bit fields, the voltage selection registers, DCDCVSEL, LDOVDDnVSEL, LVDVDDnCTRL, BBCTRL, TSENSOR, WAKEUP, and PDWAKECFG are reset, PMC transitions to Control Active/Sense Reset mode, so that PMC is correctly configured for the chip to boot up.

NOTE

The power switches for logic and memory are only reset by cold resets to maintain state to allow debugging of warm reset events.

The RESETN pin is intercepted by PMC for use as a wake-up source, and to record the pin reset event in FLAGS[RESETNF], but the chip asserts the warm reset input to PMC.

27.3.4.3 RESETN bidirectional pin control

PMC activates the RESETN strong pull down driver when any chip reset occurs. It asserts RESETN until PMC has completed its transition to Compute Active, Sense Reset mode, then releases the pull down and allows the RESETN weak pull up or any external driver in the application to control RESETN.

27.3.5 Interrupts

PMC has 2 interrupts, one for the Compute domain CPU and one for the Sense domain CPU, that are available to the CPUs' NVICs and SLEEPCONs. The sources for these interrupts include the PMIC_IRQN pin, the Autowake feature, Compute CPU Deep Sleep entry, Sense CPU Deep Sleep entry, the voltage monitors, the SCPC and DCDC overcurrent warnings, and the body bias blocks' error warnings. Each source for the two interrupts are enabled by each domain's INTRCTRL register. Only events that have a corresponding INTRCTRL enable can generate interrupts.

In Deep Sleep and FDSR modes, PMC interrupt for each slot will only wake up the CPU that has the source enabled in its slot's INTRCTRL. That domain's input to the aggregation logic will switch to its PDRUNCFG. The other domain's input to the aggregation logic remains unchanged. In DPD and FDPD modes the PMC interrupt event will trigger a cold reset, thus waking up and resetting both domains.

An event on any of the sources also asserts the corresponding FLAGS, whether the source is enabled in INTRCTRL or not. The FLAGS are also implemented as two registers, one for each CPU domain. They are "sticky" in that they are set by the event, but are cleared by software.

There are other flags in FLAGS and PWRFLAGS that are not related to a PMC interrupt source to provide the application with information about previous states for use after a wake-up or reset events.

The STATUS registers show the current state of the CPUs' Deep Sleep mode, PMIC_IRQN pin, RTC wake-up outputs, voltage monitors, and if the PMC sequencing state machines are BUSY.

The following table shows the events and sources that have status and flags that software can interrogate or enable for reset or interrupts. See the associated block descriptions and registers for more information.

Table 230. Event, status, flag, interrupt, and reset sources and controls

Source or event description	Wake-up or reset source for modes	Registers				
		STATUS	FLAGS	PWRFLAGS	CTRL (reset enable)	INTRCTRL (interrupt enable)
Chip entered Deep Power Down mode	-	-	[DEEPPDF]	-	-	-

1. VDD1V8 POR can be used to wake up from FDPD mode only if POWERCFG[FDPDBGLP] = 0.

27.4 External signals

PMC uses the following external signals

Table 231. PMC external signals

Signal	Direction	Description
RESETN	Open drain IO	Reset pin, active low. Used as a wake-up source for all power modes. Used by the chip to generate a chip wide warm reset. RESETN assertions set FLAGS[RESETNF]. PMC will assert the RESETN pin low on any reset event and hold it until PMC has completed transition to the Compute Active / Sense Reset state.
PMIC_IRQN	Input	Interrupt pin, active low. Used as a wake-up source for all power modes when enabled by INTRCTRL[INTNIE]. Triggers an interrupt for the CPU
PMIC_MODE[1:0]	Output	PMIC mode control pins used to activate PMIC power mode changes (e.g. supply voltage changes, external regulator power mode changes, etc.) when the aggregated value of PD*CFG0[PMICMODE] changes due to a software write to PDRUNCFG and CTRL[APPLYCFG] or either CPU entering or exiting Deep Sleep, or a wake-up or reset event.
PRSTCTL0[CPU1] in RSTCTL3	Input	Indicates that the Sense domain CPU is held in reset, causing the aggregation logic to ignore the Sense PD*CFG. When this input negates PMC triggers a mode change to update the PMC state to incorporate the aggregated Compute and Sense domain PD*CFG registers.
RTC wake-up	Input	The interrupt outputs from the RTC for the Compute and Sense domains. Used by PMC to trigger an interrupt when the associated INTRCTRL bit is set to wake up from power modes where the core logic is not available (FDSR, DPD, FDPD), allowing PMC to apply power to the core logic. When asserted, the event is captured in FLAGS. When the INTRCTRL enable bit is set and the RTC alarm or wakeup asserts, the PMC interrupt will remain asserted until the core clears the RTCF flag or the INTRCTRL RTCIE bit.

27.5 Initialization

This module comes up in a valid state and does not require initialization.

27.6 Application information

This section provides some information about how applications should use some of PMC features.

27.6.1 Enabling body bias for low-power modes

To enable RBB during low-power modes for the voltage domains (VDD1, VDD2, VDDN) that have their clocks stopped:

1. Enable the desired mode in PDSLEEPCFG:
   - RBB: clear PDSLEEPCFG0[RBBn_PD]] and set PDSLEEPCFG0[AFBBn_PD]]

   NOTE

   Software is responsible for ensuring the clocks are stopped during Deep Sleep. PMC will activate RBB regardless of the state of the clocks.

2. If only one CPU uses a voltage domain while that CPU is Active, then set the other CPU's PDRUNCFG0[AFBBn_PD] so that AFBB is disabled when the first CPU is in Deep Sleep mode, otherwise aggregation will keep AFBB on even though the first CPU doesn't use that voltage domain.

3. Enter Deep Sleep mode

27.6.2 Using a PMIC

PMC supports using an external PMIC to power VDD1V8, VDDN, VDD2, and VDD1, in a few different configurations. The external PMIC can be as simple as a single external 1.8 V regulator to a complex PMIC with multiple supplies that can be independently adjusted.

Support includes:

- PMIC_MODE pins to control the PMIC configuration automatically during mode changes, no I2C needed.
- [MODEDLY] timer to select how long to wait for a higher power PMIC configuration to take effect after PMIC_MODE changes state.
- PMIC_IRQN pin can be used by the PMIC (or any other external control) to interrupt the device during any power mode, including FDPD mode, triggering a wake-up and an interrupt to either or both CPUs.
- LVD handshaking holds off operation until the PMIC supplied voltages reach a new higher value during a mode change.
- Internal regulator power down controls in POWERCFG to disable the internal regulator for rails that are powered externally.

When using a PMIC to supply the internal logic rails, the PMIC should be configured at startup or cold reset to supply VDDN at 1.1 V nominal, and VDD1 and VDD2 at 1.0 V nominal.

27.6.2.1 Supported configurations

PMC supports these configurations for externally supplied voltages. There is a lot of different ways to use these configurations based on the capability of the PMIC.

27.6.2.1.1 Internal core regulators

This is the default configuration. The PMC reset values are sufficient.

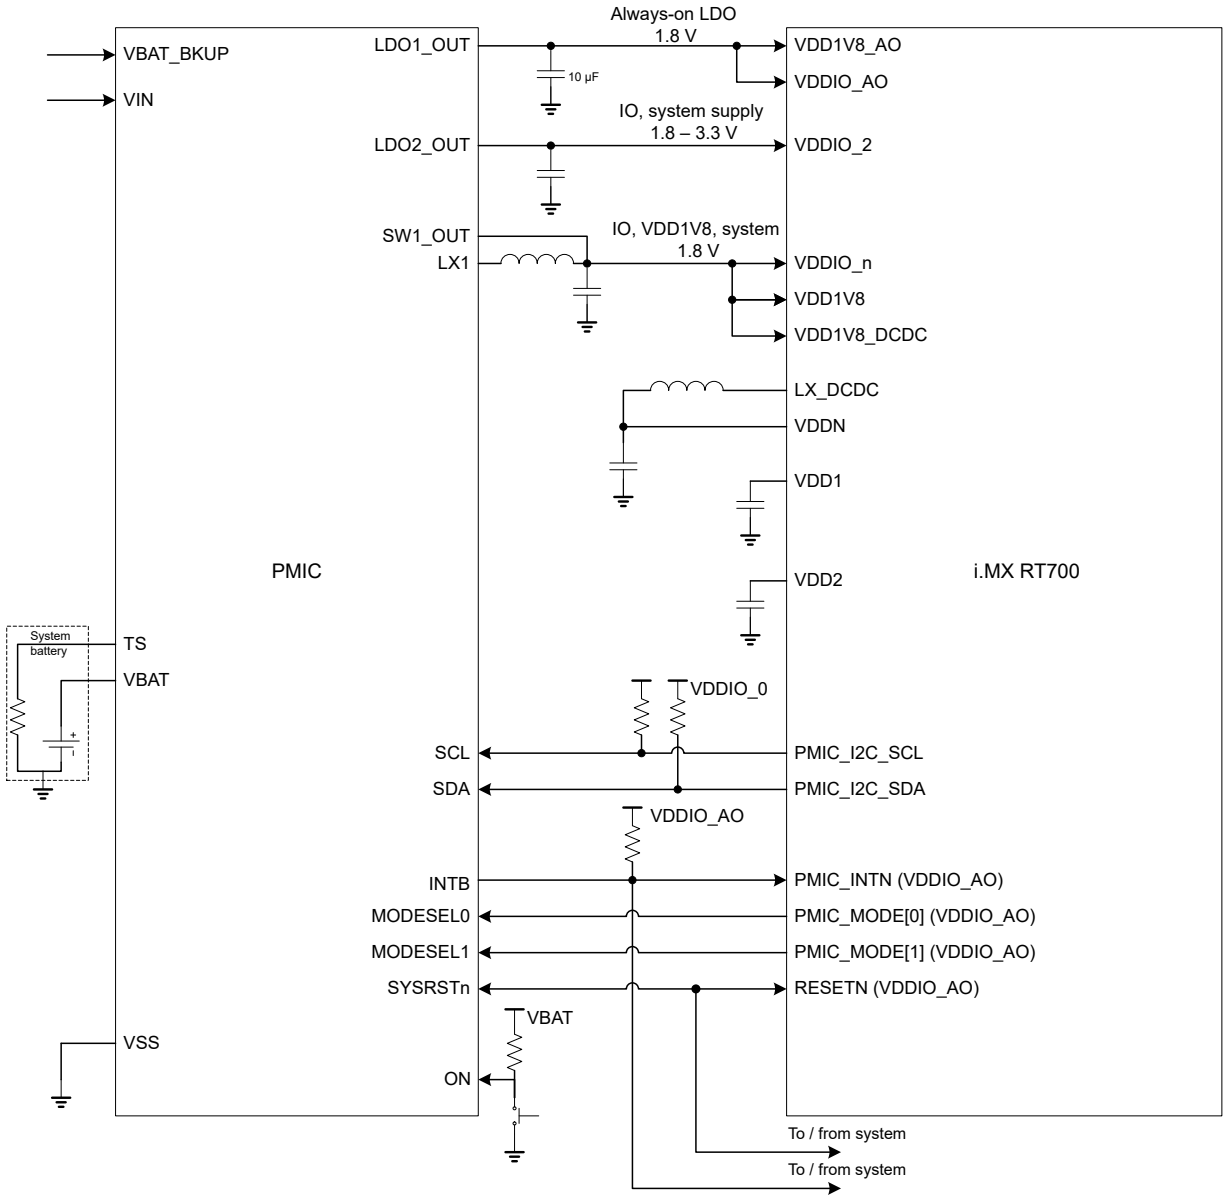

Figure 88. PMIC for 1.8 V and 3 V supplies only

27.6.2.1.2 External VDDN, internal VDD1 and VDD2

This is a slight variation from the default configuration, using the PMIC to supply VDDN while the internal LDOs power VDD1 and VDD2. The PMIC must ensure that VDDN ramps up to a voltage higher than the default VDDN LVD trip level, and provides enough head room to the VDD1 and VDD2 LDOs so they can ramp up correctly. PMIC_MODE can be used to change the voltage level of VDDN or power it down as needed. VDDN can be powered down in FDSR, DPD, and FDPD modes. The application must set [MODEDLY] so that VDDN ramps up to at least 1.0 V before the LDOs turn on when waking from FDSR mode. PMC will wait for VDDN to rise above the aggregated PD*CFG0[DCDC_VSEL] LVD trip before turning on the LDOs.

PMC should be configured to disable the DCDC after every cold reset by setting POWERCFG[DCDCPD].

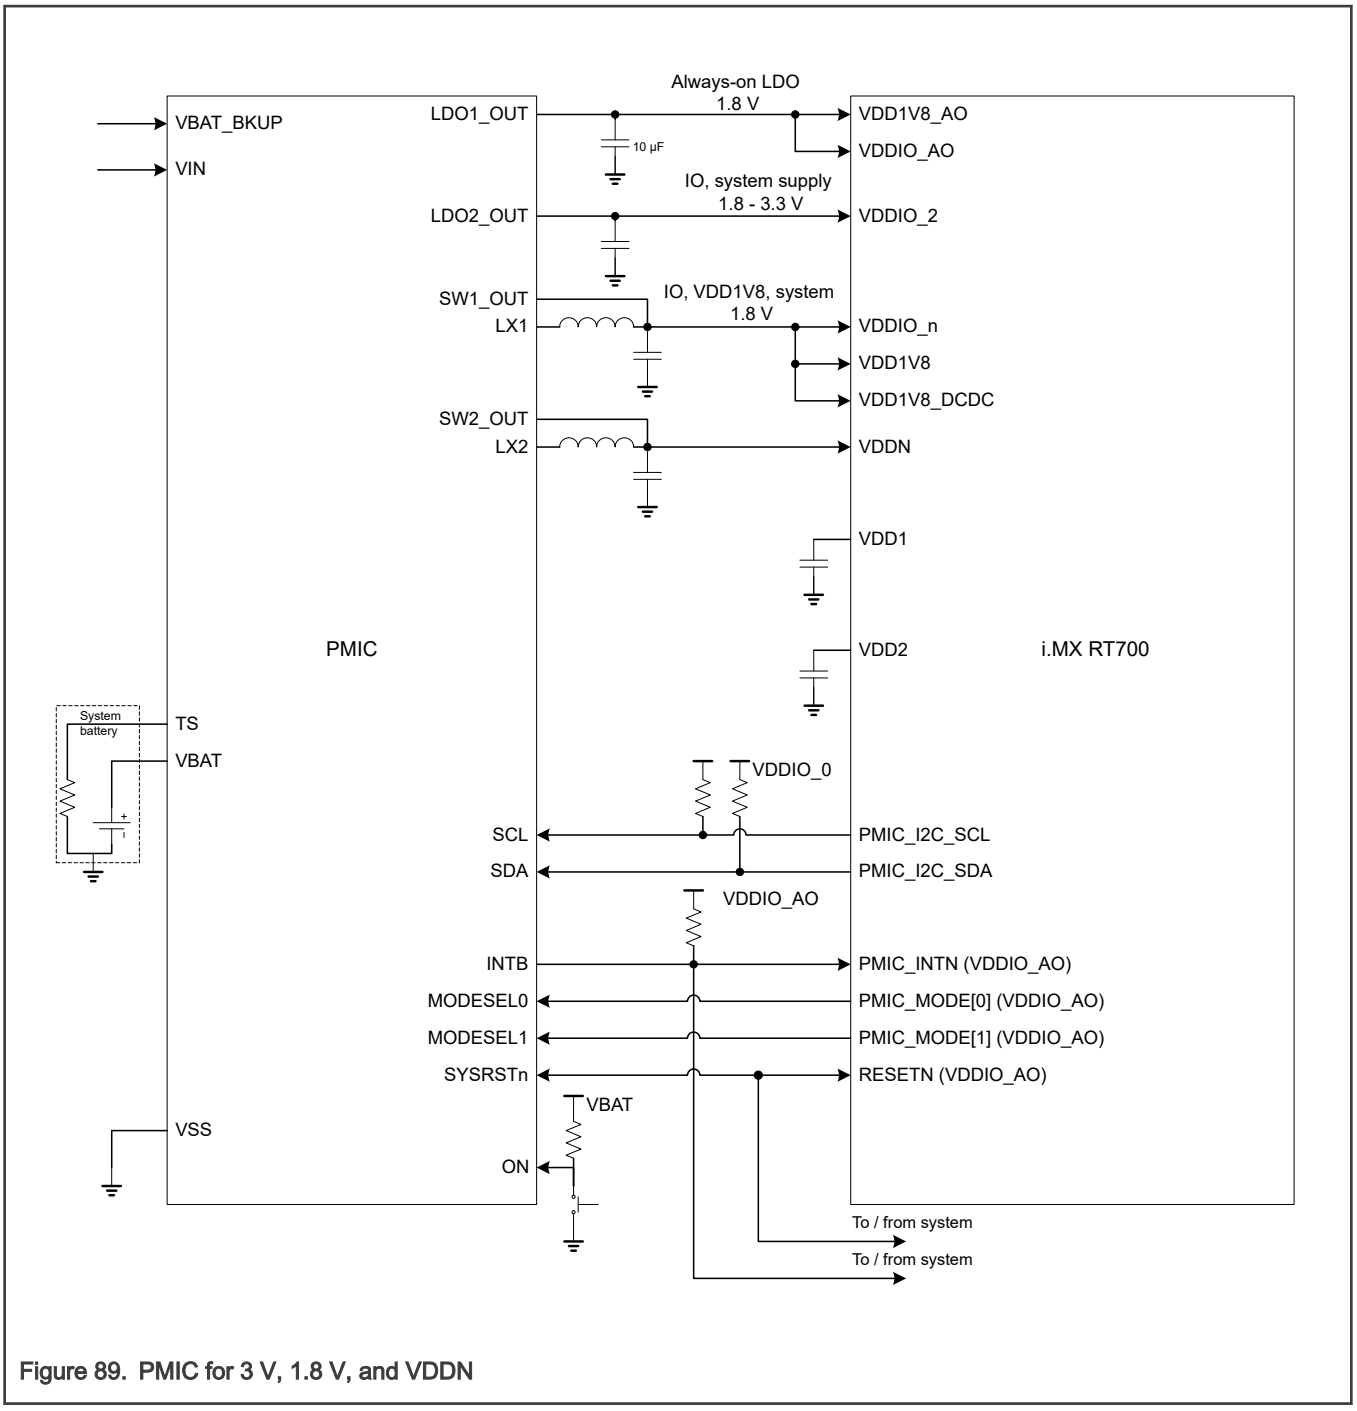

Figure 89. PMIC for 3 V, 1.8 V, and VDDN

27.6.2.1.3 External VDDN, VDD1, VDD2 with VDD1=VDD2

This configuration uses only external supplies, using the PMIC to supply VDDN, VDD1, and VDD2. The PMIC must ensure that VDDN, VDD1, and VDD2 ramp up to voltages between the minimum and maximum levels defined by the boot configuration. PMIC_MODE can be used to change the voltage level of VDDN, VDD1, VDD2, or power them down as needed. VDDN can be powered down in FDSR mode. VDD1, VDD2, and VDDN can all be powered down in DPD and FDPD modes. The application should set [MODEDLY] to allow for the supplies to ramp back up after PMIC_MODE changes. PMC will wait for VDDN, VDD1, and VDD2 to rise above the trip points selected by PD*CFG0[DCDC_VSEL], PD*CFG0[LDO1_VSEL], and PD*CFG0[LDO2_VSEL] before waking up the rest of the chip.

PMC should be configured to disable the DCDC and LDOs after every cold reset by setting POWERCFG[DCDCPD], POWERCFG[LDO1PD], and POWERCFG[LDO2PD].

If the SCPCs are used in FDSR mode, the PMIC should be configured to supply 0.5 V to VDD1 and VDD2 during FDSR mode because the on-board SCPCs may not be able to overdrive the connections on VDD1 and VDD2. Set POWERCFG[SCPCPD] to prevent the SCPCs from turning on in FDSR.

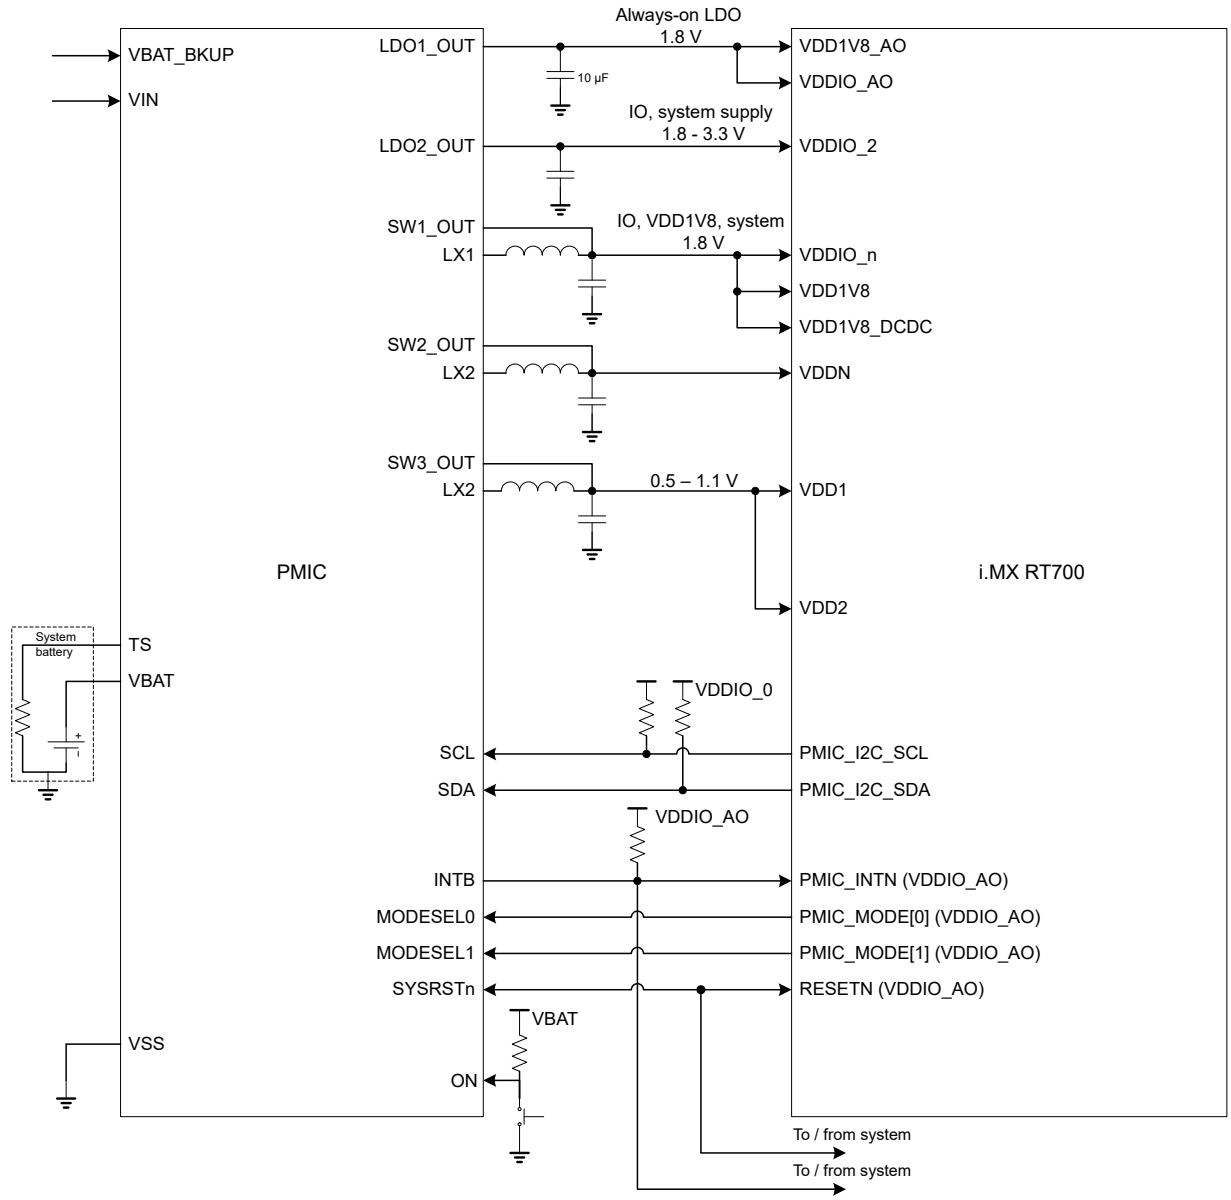

Figure 90. PMIC for 3.3 V, 1.8 V, VDDN, and shred for VDD1 and VDD2

27.6.2.1.4 External VDDN, VDD1, VDD2

This configuration uses only external supplies, using the PMIC to supply VDDN, VDD1, and VDD2, but provides more opportunities to reduce power when parts of the chip are active by decoupling the voltages supplied to VDD1 and VDD2, allowing one or the other to be reduced when activity in that domain is low. The PMIC must ensure that VDDN, VDD1, and VDD2 ramp up to

voltages between the minimum and maximum levels defined by the boot configuration. PMIC_MODE can be used to change the voltage level of VDDN, VDD1, VDD2, or power them down as needed. VDDN can be powered down in FDSR mode. VDD1, VDD2, and VDDN can all be powered down in DPD and FDPD modes. The application should set [MODEDLY] to allow for the supplies to ramp back up after PMIC_MODE changes. PMC will wait for VDDN, VDD1, and VDD2 to rise above the trip points selected by PD*CFG0[DCDC_VSEL], PD*CFG0[LDO1_VSEL], and PD*CFG0[LDO2_VSEL] before waking up the rest of the chip.

PMC should be configured to disable the DCDC and LDOs after every cold reset by setting POWERCFG[DCDCPD], POWERCFG[LDO1PD], and POWERCFG[LDO2PD].

If the SCPCs are used in FDSR mode, the PMIC should be configured to supply 0.5 V to VDD1 and VDD2 during FDSR mode because the on-board SCPCs may not be able to overdrive the connections on VDD1 and VDD2. Set POWERCFG[SCPCPD] to prevent the SCPCs from turning on in FDSR.

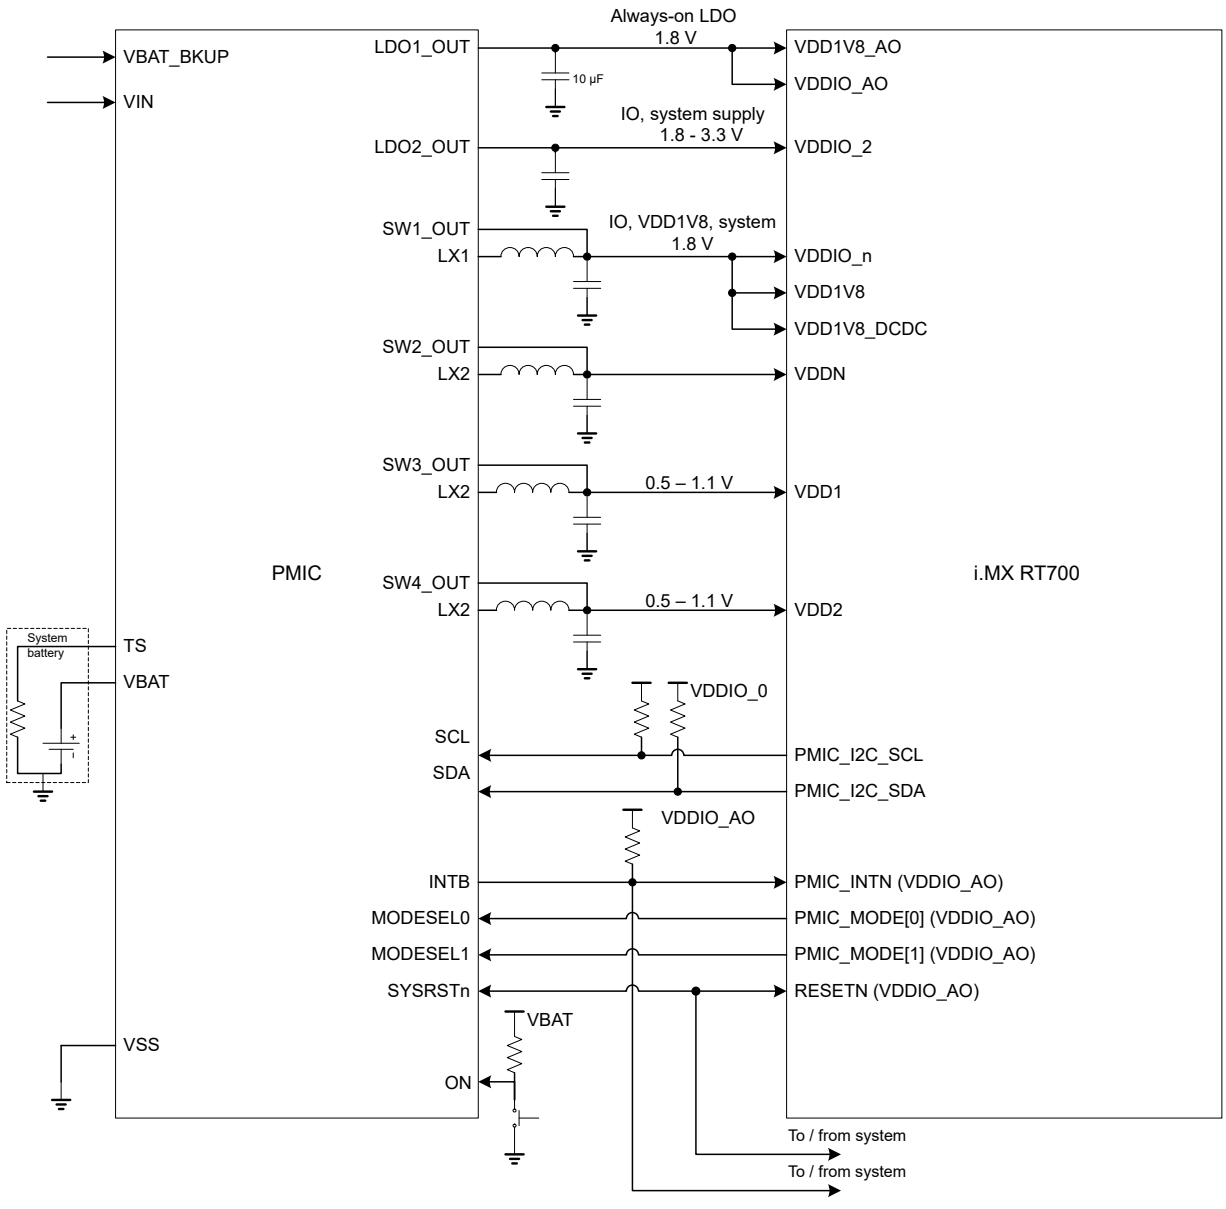

Figure 91. PMIC for 3.3 V, 1.8 V, VDDN, VDD2, and VDD1

27.7 Memory map and register definitions

PMC has 2 sets of registers, one is for the Compute domain, the other is for the Sense domain. Each domain accesses its set of registers via a separately mapped range of addresses, also referred to as the domain slot. Some registers and fields are shared allowing read and write access from either domain (e.g. LDOVDD1VSEL). Others are readable by both domains but writable by only one domain (e.g. LDOVDD2VSEL). Others are separate storage elements, accessible only via that slot (e.g. PDRUNCFG0). See individual register descriptions for more information.

In this chapter, the register descriptions are divided into two sections, one for each slot: ***PMC0*** for Compute domain and ***PMC1*** for Sense domain.

27.7.1 PMC register descriptions

27.7.1.1 PMC register description memory map

This section includes the memory map and detailed description of all registers and their fields of PMC0 in Compute domain.

PMC.PMC0 base address: 4020_F000h

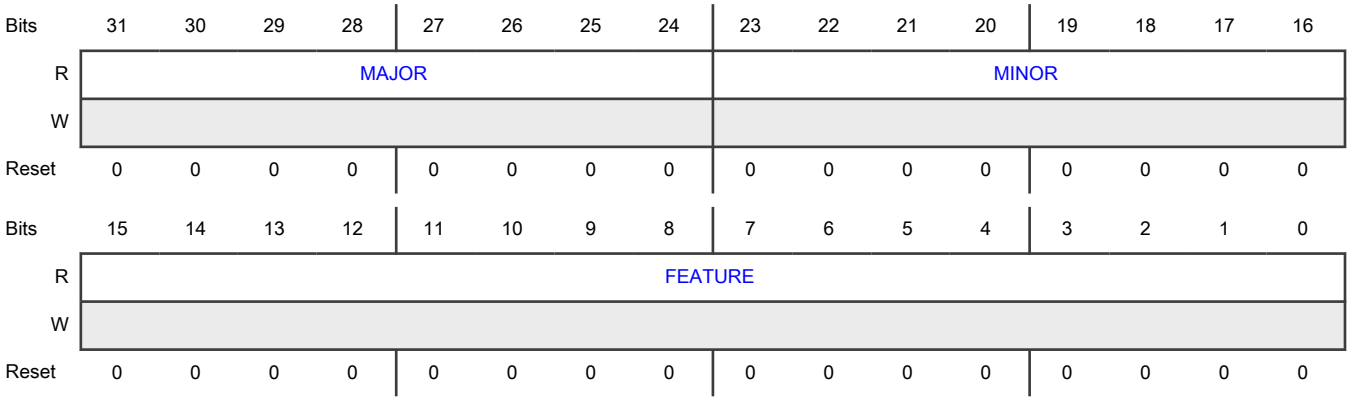
27.7.1.2 PMC Version and Feature ID (VERID)

Offset

Register	Offset
VERID	0h

Function
Indicates the version integrated for this instance on the chip.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number Reads the major version number for the module specification.
23-16 MINOR	Minor Version Number Reads the minor version number for the module specification.
15-0 FEATURE	Feature Identification Number Reads the feature set number.

27.7.1.3 PMC Status (STATUS)

Offset

Register	Offset
STATUS	4h

Function

Indicates current status of PMC sources, not latched, but synchronized to PMC clock. See PMC Flags for latched versions of sources that are enabled to generate resets or interrupts.

Diagram

Fields

Field	Function
31 —	Reserved
30 —	Reserved
29 DSSENS	CPU1 Deep Sleep Indicates that CPU1 is in Deep Sleep mode. 0b - CPU1 is in Active mode 1b - CPU1 is in Deep Sleep mode
28 —	Reserved
27 INTN	PMIC_IRQN Interrupt Input Shows the interrupt input pin status. 0b - Negated. Pin is high 1b - Asserted. Pin is low
26 —	Reserved
25 RTCWKUP	RTC Wake-up Shows RTC wake-up status. 0b - Compute RTC wake-up is not active 1b - Compute RTC wake-up is asserted
24	VDD1V8 High-Voltage Detector

Table continues on the next page...

Table continued from the previous page...

Field	Function
HVD1V8	Shows VDD1V8 high-voltage detector status. 0b - Detector is not tripped 1b - Detector is tripped
23 HVDVDDN	VDDN High-Voltage Detector Shows VDDN high-voltage detector status. 0b - Detector is not tripped 1b - Detector is tripped
22 HVDVDD2	VDD2 High-Voltage Detector Shows VDD2 high-voltage detector status. 0b - Detector is not tripped 1b - Detector is tripped
21 HVDVDD1	VDD1 High-Voltage Detector Shows VDD1 high-voltage detector status. 0b - Detector is not tripped 1b - Detector is tripped
20 LVDVDDN	VDDN Low-Voltage Detector Shows VDDN low-voltage detector status. 0b - Detector is not tripped 1b - Detector is tripped
19 LVDVDD2	VDD2 Low-Voltage Detector Shows VDD2 low-voltage detector status. 0b - Detector is not tripped 1b - Detector is tripped
18 LVDVDD1	VDD1 Low-Voltage Detector Shows VDD1 low-voltage detector status. 0b - Detector is not tripped 1b - Detector is tripped
17-1 —	Reserved
0 BUSY	Finite State Machine Status Shows if PMC is currently processing a mode transition.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - PMC state machines are idle 1b - PMC state machine is busy

27.7.1.4 PMC Flags in Compute Domain (FLAGS)

Offset

Register	Offset
FLAGS	8h

Function

Indicates PMC event flags in Compute domain. This register is cleared by software, and set by hardware when event occurs. The flags in Sense and Compute domains are cleared respectively by writing 1 to corresponding bit fields.

Diagram

Fields

Field	Function
31 DEEPPDF	DPD Wake-up Flag Indicates the wake-up status of PMC in DPD (Deep Power Down) mode. This bit is reset by VDD1V8_AO POR. 0b - DPD wake-up cleared 1b - DPD wake-up asserted
30 DSCOMPF	CPU0 Deep Sleep Flag Indicates that CPU0 entered Deep Sleep mode. This bit is set at Deep Sleep mode entry.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - CPU0 Deep Sleep cleared 1b - CPU0 Deep Sleep asserted
29 DSSENSF	CPU1 Deep Sleep Mode Flag Indicates that CPU1 entered Deep Sleep mode. This bit is set at Deep Sleep mode entry, and can be cleared while CPU1 is still in Deep Sleep mode. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - CPU1 Deep Sleep cleared 1b - CPU1 Deep Sleep asserted
28 RESETNF	Reset Pin Flag Indicates reset pin status. This bit is reset by VDD1V8_AO POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - Reset pin status cleared 1b - Reset pin status asserted
27 INTNF	PMIC_IRQN Interrupt Pin Flag Indicates interrupt pin status. This bit is reset by VDD1V8_AO POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - Interrupt pin status cleared 1b - Interrupt pin status asserted
26 AUTOWKF	Auto Wake-up Flag Indicates auto wake-up interrupt status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - Auto wake-up status cleared 1b - Auto wake-up status asserted
25 RTCF	RTC Flag Indicates RTC alarm or wake was asserted. This bit is reset by VDD1V8_AO POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - RTC status cleared 1b - RTC status asserted
24	VDD1V8 High-Voltage Detector Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
HVD1V8F	Indicates VDD1V8 high-voltage detector status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - High-voltage detector status cleared 1b - High-voltage detector status asserted
23 HVDVDDNF	VDDN High-Voltage Detector Flag Indicates VDDN high-voltage detector status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - High-voltage detector status cleared 1b - High-voltage detector status asserted
22 HVDVDD2F	VDD2 High-Voltage Detector Flag Indicates VDD2 high-voltage detector status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - High-voltage detector status cleared 1b - High-voltage detector status asserted
21 HVDVDD1F	VDD1 High-Voltage Detector Flag Indicates VDD1 high-voltage detector status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - High-voltage detector status cleared 1b - High-voltage detector status asserted
20 LVDVDDNF	VDDN Low-Voltage Detector Flag Indicates VDDN low-voltage detector status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - Low-voltage detector status cleared 1b - Low-voltage detector status asserted
19 LVDVDD2F	VDD2 Low-Voltage Detector Flag Indicates VDD2 low-voltage detector status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - Low-voltage detector status cleared 1b - Low-voltage detector status asserted
18 LVDVDD1F	VDD1 Low-Voltage Detector Flag Indicates VDD1 low-voltage detector status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Low-voltage detector status cleared 1b - Low-voltage detector status asserted
17 AGDET2F	VDD2 Glitch Detector Flag Indicates VDD2 glitch detector status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - Glitch detector status cleared 1b - Glitch detector status asserted
16 AGDET1F	VDD1 Glitch Detector Flag Indicates VDD1 glitch detector status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - Glitch detector status cleared 1b - Glitch detector status asserted
15 PORAO18F	VDD1V8_AO Power-on Reset Flag Indicates VDD1V8_AO power-on reset status. This bit is set by VDD1V8_AO POR. 0b - POR status cleared 1b - POR status asserted
14 POR1V8F	VDD1V8 Power-on Reset Flag Indicates VDD1V8 power-on reset status. This bit is set by VDD1V8 POR. 0b - POR status cleared 1b - POR status asserted
13 PORVDDNF	VDDN Power-on Reset Flag Indicates VDDN power-on reset status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - POR status cleared 1b - POR status asserted
12 PORVDD2F	VDD2 Power-on Reset Flag Indicates VDD2 power-on reset status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - POR status cleared 1b - POR status asserted
11	VDD1 Power-on Reset Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
PORVDD1F	Indicates VDD1 power-on reset status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - POR status cleared 1b - POR status asserted
10 DCLPOCF	DCDC Low-Power Mode Overcurrent Flag Indicates the DCDC had an overcurrent event while in low-power mode. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - No overcurrent event detected 1b - Overcurrent event detected
9 DCHPOCF	DCDC High-Power Mode Overcurrent Flag Indicates the DCDC had an overcurrent event while in high-power mode. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - No overcurrent event detected 1b - Overcurrent event detected
8 SCP2OCF	SCPC VDD2 Overcurrent Flag Indicates that an SCPC2 overcurrent event was detected. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - No overcurrent event detected 1b - Overcurrent event detected
7 SCP1OCF	SCPC VDD1 Overcurrent Flag Indicates that an SCPC1 overcurrent event was detected. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - No overcurrent event detected 1b - Overcurrent event detected
6 BBNEF	VDDN Body Bias Error Flag Indicates body bias error in VDDN domain. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - No body bias error 1b - Body bias error detected
5	VDD2 Body Bias Error Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
BB2EF	Indicates body bias error in VDD2 domain. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - No body bias error 1b - Body bias error detected
4 BB1EF	VDD1 Body Bias Error Flag Indicates body bias error in VDD1 domain. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - No body bias error 1b - Body bias error detected
3 BBSR2EF	VDD2 SRAM Body Bias Error Flag Indicates SRAM body bias error in VDD2 domain. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - No SRAM body bias error 1b - SRAM body bias error detected
2 BBSR1EF	VDD1 SRAM Body Bias Error Flag Indicates SRAM body bias error in VDD1 domain. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - No SRAM body bias error 1b - SRAM body bias error detected
1 ITRCRF	ITRC RAM ZEROIZE Flag Indicates ITRC triggered RAM ZEROIZE. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - Not detected 1b - ITRC RAM ZEROIZE detected
0 DSALLF	Deep Sleep Flag Indicates whether CPU0 and CPU1 are in Deep Sleep mode at the same time. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - CPU0 and CPU1 are not in Deep Sleep mode at the same time 1b - CPU0 and CPU1 have both been in Deep Sleep mode at the same time

27.7.1.5 Control (CTRL)

Offset

Register	Offset
CTRL	Ch

Function

Enables controls for triggering configuration updates and enabling voltage monitor resets.

Diagram

27.7.1.7 DCDC Voltage Selection (DCDCVSEL)

Offset

Register	Offset
DCDCVSEL	20h

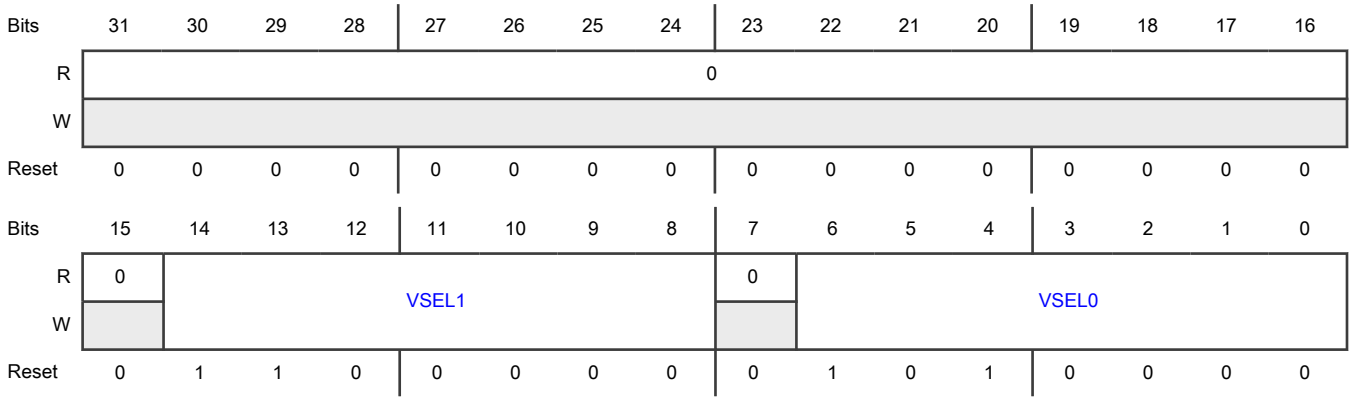
Function

Configures DCDC voltage levels for selection by PDRUNCFG0[DCDC_VSEL] and PDSLEEPCFG0[DCDC_VSEL].

NOTE

To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur.

Diagram



Fields

Field	Function
31-15 —	Reserved
14-8 VSEL1	DCDC Voltage Level 1 Sets the DCDC voltage when the aggregated value of PDRUNCFG0[DCDC_VSEL] and PDSLEEPCFG0[DCDC_VSEL] is 1. This is the level selected by PD*CFG after reset, where • Voltage = 0.5 V + 6.25 mV * value of [VSEL1] • Reset value = 1.1 V • Written value is clipped to 68h • Maximum value = 1.15 V **NOTE** The value of [VSEL1] must be set larger than that of [VSEL0]. The Sense slot version of this field is read-only. This bit is reset by warm reset. 000_0000b - 0.50 V 010_0000b - 0.70 V 100_0000b - 0.90 V 110_0000b - 1.10 V 110_1000b - 1.15 V (maximum) 111_1111b - 1.15 V (clipped)
7 —	Reserved
6-0	DCDC Voltage Level 0

Table continues on the next page...

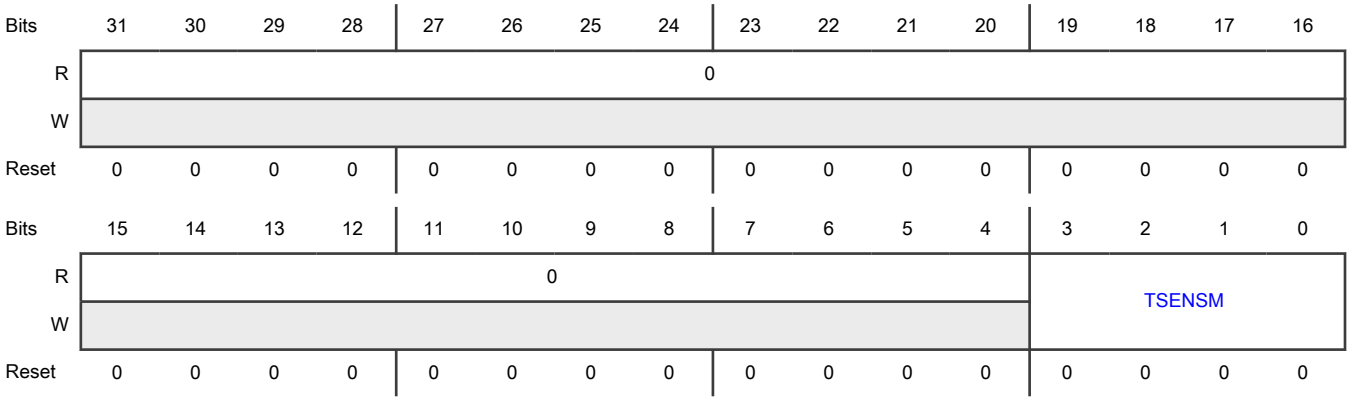
27.7.1.15 Temperature Sensor Control (TSENSOR)

Offset

Register	Offset
TSENSOR	44h

Function
Controls the PMC temperature sensor measurement mode. See PMC temperature sensor for details.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 TSENSM	Temperature Sensor Mode Select Selects the temperature sensor mode according to the procedure described in PMC temperature sensor. All modes must be selected in sequence during the temperature measurement procedure to dynamically cancel various internal error sources. **NOTE** This field is shared between PMC0 and PMC1. Software should only do temperature measurement from one slot at a time. 0000b - Perform AD conversion and record C*_000 0001b - Perform AD conversion and record C*_001 0010b - Perform AD conversion and record C*_010 0011b - Perform AD conversion and record C*_011 0100b - Perform AD conversion and record CM_100 0101b - Perform AD conversion and record C*_101 0110b - Perform AD conversion and record C*_110 0111b - Perform AD conversion and record C*_111

27.7.1.16 Wake-up Configuration for Compute Domain (WAKEUP)

Offset

Register	Offset
WAKEUP	50h

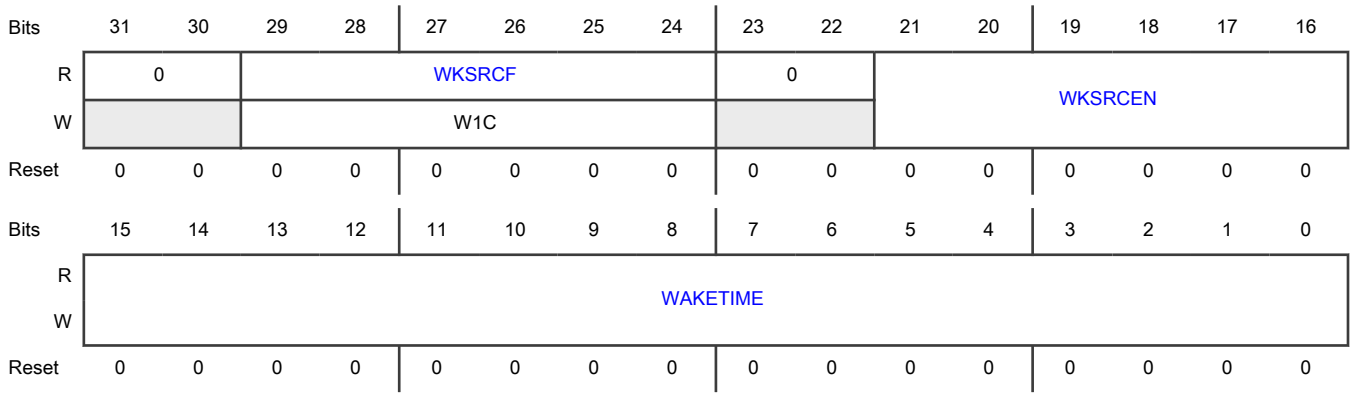
Function

Sets wake-up sources for PMC when VDD2_COMP and VDD2_COM domains are in DSR (Deep Sleep Retention) mode, and sets the configuration of the general purpose wake-up counter.

When VDD2_COMP and VDD2_COM domains are both in DSR mode, but VDD1_SENSE domain is not (i.e. the chip is not in FDSR mode), SLEEPCON0 is powered down, so it cannot wake up from sources in the VDD1_SENSE domain. When wake-up is enabled here, PMC can wake up from some VDD1_SENSE domain sources.

The wake-up timer is enabled by INTRCTRL[AUTOWKIE], and will wake up the associated PMC slot when the associated CPU enters the Deep Sleep mode. When the counter times out, PMC wakes up and generates an interrupt for that slot.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-24 WKSRCF	Wake-up Source Flags Indicates if wake-ups have been triggered by the respective source. Bit 29: ADC0 Bit 28: ACMP Bit 27: MU1 Bit 26: MU0 Bit 25: MICFIL Bit 24: OSTIMER This bit is reset by warm reset. 00_0000b - No wake-up from source 00_0001b - Source has triggered a wake-up
23-22 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
21-16 WKSRCEN	Wake-up Source Enable Enables wake-up from Sense domain MU, OSTIMER, or other sources. Bit 21: ADC0 Bit 20: ACMP Bit 19: MU1 Bit 18: MU0 Bit 17: MICFIL[1] Bit 16: OSTIMER This bit is reset by warm reset. 00_0000b - Wake-up disabled 00_0001b - Wake-up enabled
15-0 WAKETIME	Wake-up Timer Sets timer to wake up from Deep Sleep mode after mode sequencing is completed. See Autowake for more information. Time = value of [WAKETIME] / 16 MHz = value of [WAKETIME] / 16 in µs This field has two copies separately accessed by the Compute and Sense slots. This bit is reset by warm reset. 0000_0000_0000_0000b - 0 0000_0000_0000_0001b - 62.5 ns = 1 / (16e + 6) 0000_0000_0000_0010b - 125 ns = 2 / (16e + 6) ...

1. There are two MICFIL interrupts:
   - Interrupt for read data or error
   - Interrupt for hardware voice activity detector (HWVAD) or HWVAD error

   Only the MICFIL interrupt for read data or error can be used as the wake-up source.

27.7.1.17 Power Configuration (POWERCFG)

Offset

Register	Offset
POWERCFG	64h

Function

Configures internal regulators and internal references during FDSR (Full Deep Sleep Retention) mode and FDPD (Full Deep Power Down) modes, or when external supplies are used. Also configures the wait time for PMIC or external supplies to respond to changes on the PMIC_MODE pins.

Diagram

Fields

Field	Function
31-28 MODEDLY	Mode Delay Sets delay to wait for external PMIC mode changes to complete after any mode value change occurs on the PMIC_MODE[1:0] pins. The PMIC_MODE pins change state whenever the aggregated PD*CFG0[PMICMODE] changes. • Time = Period of 4 clocks * 2 ^ value of [MODEDLY] • Reset value = 16 µs The Sense slot version of this field is read-only. This bit is reset by cold reset. Values shown below are examples based on calculations with the period of 4 clocks (250 ns) at a frequency of 16 MHz. 0000b - 250 ns 0001b - 500 ns 0010b - 1000 ns 0011b - 2000 ns 0100b - 4000 ns 0101b - 8000 ns 0110b - 16 µs 0111b - 32 µs 1000b - 64 µs 1001b - 128 µs 1010b - 256 µs 1011b - 512 µs 1100b - 1024 µs 1101b - 2048 µs 1110b - 4096 µs

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1111b - 8192 µs
27-25 —	Reserved
24 FDPDBGLP	Force Band Gap during FDPD Mode to LP Mode In FDPD mode, force band gap to low-power mode. Rising VDD1V8 will not wake up the chip from FDPD mode when this bit is set. If clear, band gap will remain in high-power mode and consume 85 µA. The Sense slot version of this field is read-only. This bit is reset by cold reset. **NOTE** This bit is cleared on wake-up from FDPD mode and any other cold reset! If the rising VDD1V8 is not used as the wake-up source then this bit should be set before entering FDPD every time. 0b - Enables band gap to high-power mode during FDPD mode and wakes up if VDD1V8 POR is asserted then negated 1b - Enables band gap to low-power mode during FDPD mode and will not wake up on VDD1V8 POR negation. RTC, PMIC_IRQN, or reset is used as wake-up
23-13 —	Reserved
12 DCDCPD	DCDC Power Down Disables DCDC when using a PMIC or other external supply to drive VDDN. The Sense slot version of this field is read-only. This bit is reset by cold reset. **NOTE** When set, the control logic waits for the external supply to rise above LVD trip whenever mode changes occur (APPLY_CFG/DeepSleep, etc.). If VDDN never rises above the LVD trip then the control state machines will get stuck. Software and the external supply controls must make sure that the LVD trip level is less than the final value of the external supply during mode changes. **NOTE** If this bit is set, then software should also write 11b to PMC0.PDRUNCFG0[DCDC_MODE], PMC0.PDSLEEPCFG0[DCDC_MODE], PMC1.PDRUNCFG0[DCDC_MODE], and PMC1.PDSLEEPCFG0[DCDC_MODE]. to minimize power when the other blocks of the PMC are all in low power mode and/or powered down. 0b - Not powered down, except in FDSR mode when [FDDCPD] = 1, or in DPD or FDPD mode 1b - Powered down (until the next cold reset)
11-10	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
9 LDO2PD	LDO VDD2 Power Down Disables LDO VDD2 when using a PMIC or other external supply to drive VDD2. The Sense slot version of this field is read-only. This bit is reset by cold reset. **NOTE** When set, the control logic waits for the external supply to rise above LVD trip whenever mode changes occur (APPLY_CFG/DeepSleep, etc.). If VDD2 never rises above the LVD trip then the control state machines will get stuck. Software and the external supply controls must make sure that the LVD trip level is less than the final value of the external supply during mode changes. 0b - Not powered down, except in FDSR mode when [FDLDO2PD] = 1, or in DPD or FDPD mode 1b - Powered down (until the next cold reset)
8 LDO1PD	LDO VDD1 Power Down Disables LDO VDD1 when using a PMIC or other external supply to drive VDD1. The Sense slot version of this field is read-only. This bit is reset by cold reset. **NOTE** When set, the control logic waits for the external supply to rise above LVD trip whenever mode changes occur (APPLY_CFG/DeepSleep, etc.). If VDD1 never rises above the LVD trip then the control state machines will get stuck. Software and the external supply controls must make sure that the LVD trip level is less than the final value of the external supply during mode changes. 0b - Not powered down, except in FDSR mode when [FDLDO1PD] = 1, or in DPD or FDPD mode 1b - Powered down (until the next cold reset)
7 SCPCPD	SCPC Power Down Disables both SCPCs when a PMIC is driving. **NOTE** This field should only be set if FDSR mode is configured to always use the LDOs, or in applications that always use external supplies for VDD1 and VDD2. The Sense slot version of this field is read-only. This bit is reset by cold reset. 0b - Not powered down in FDSR mode, except in FDSR mode when [FDSCPnPD] = 1. SCPC might be powered down in FDSR depending on [FDSCPnPD] field 1b - Powered down (until the next cold reset)
6 FDDCPD	DCDC Power Down in FDSR Mode Disables DCDC in FDSR mode. This bit is overridden by [DCDCPD] = 1. The Sense slot version of this field is read-only. This bit is reset by cold reset.

Table continues on the next page...

Field	Function
	0b - Not powered down 1b - Powered down
5 FDLDO2PD	LDO VDD2 Power Down in FDSR Mode Disables LDO VDD2 in FDSR mode. This bit is overridden by [LDO2PD] = 1. The Sense slot version of this field is read-only. This bit is reset by cold reset. 0b - Not powered down 1b - Powered down
4 FDLDO1PD	LDO VDD1 Power Down in FDSR Mode Disables LDO VDD1 in FDSR mode. This bit is overridden by [LDO1PD] = 1. The Sense slot version of this field is read-only. This bit is reset by cold reset. 0b - Not powered down 1b - Powered down
3-2 —	Reserved
1 FDSCP2PD	SCPC VDD2 Power Down in FDSR Mode Disables SCPC VDD2 in FDSR mode. This bit is overridden by [SCPCPD] = 1. The Sense slot version of this field is read-only. This bit is reset by cold reset. 0b - Not powered down 1b - Powered down
0 FDSCP1PD	SCPC VDD1 Power Down in FDSR Mode Disables SCPC VDD1 in FDSR mode. This bit is overridden by [SCPCPD] = 1. The Sense slot version of this field is read-only. This bit is reset by cold reset. 0b - Not powered down 1b - Powered down

27.7.1.18 3 V Capable VDDIO Range Select (PADVRANGE)

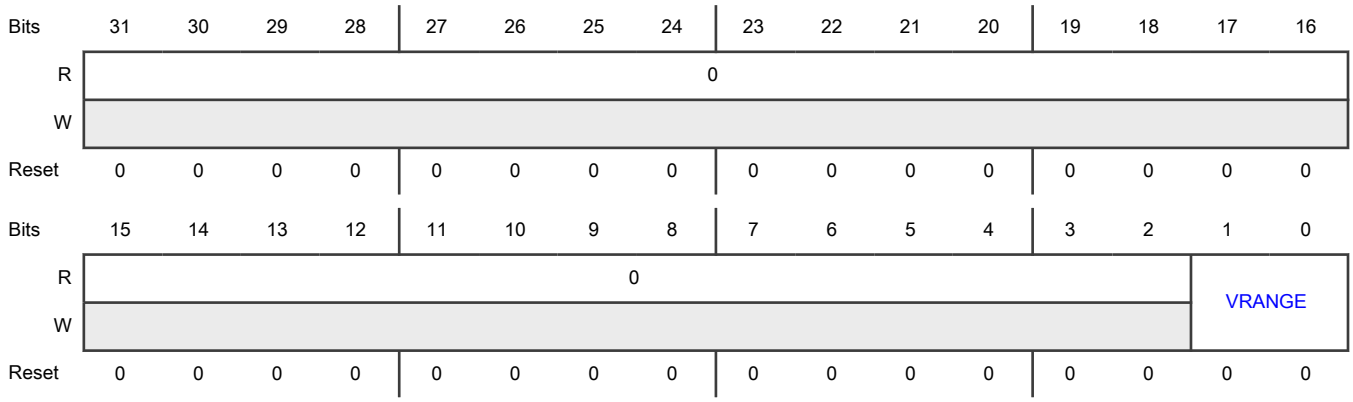
Offset

Register	Offset
PADVRANGE	68h

Function

Selects the allowed voltage range for the 3 V capable IOs which have a detector to Sense the value of supply, but this consumes current. To reduce power the IOs can be configured for 1.8 V or 3.3 V operation, powering down the detector, but requiring the application to restrict the IO supply voltage to the selected range. The detector is enabled after any cold reset.

Diagram



Fields

Field	Function
31-2 —	Reserved
1-0 VRANGE	3 V Capable IO Bank VDDIO Range Select Selects the VDDIO range configuration. The Sense slot version of this field is read-only. This bit is reset by cold reset. 00b - Continuous mode. Allows 1.71 - 3.6 V range but consumes static current. 01b - 1.71 - 1.98 V, supply detector off 10b - 3.00 - 3.6 V, supply detector off 11b - Reserved

27.7.1.19 IO Bank State Configuration (PADCFG)

Offset

Register	Offset
PADCFG	6Ch

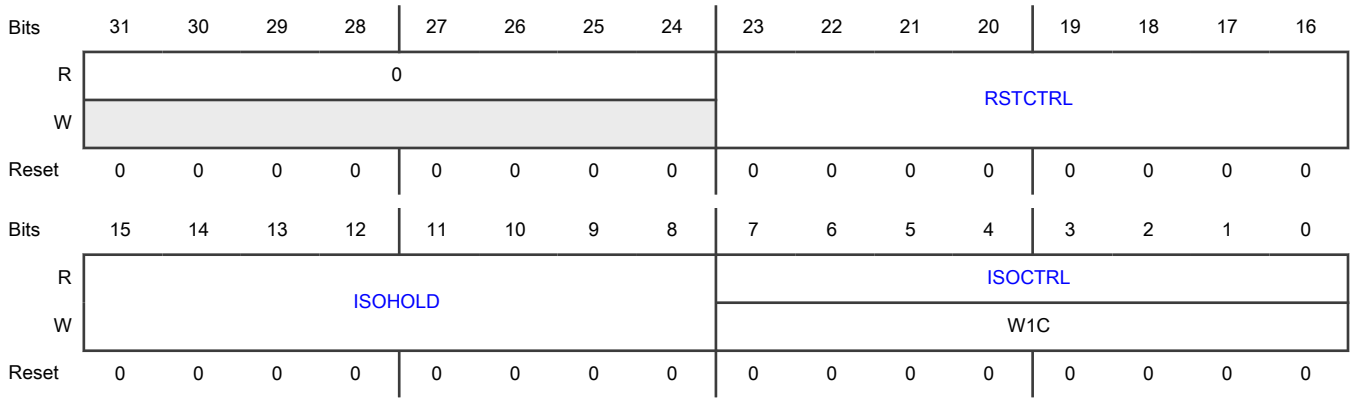
Function

Controls IO bank reset and state retain. Each bit field has the same IO bank distribution map.

Table 232. IO bank mapping

Bit	IO bank(s)	Domain
Bit 7	PMIC_I2C	VDD1_SENSE
Bit 6	Port 8/9/10	VDD1_SENSE
Bit 5	Port 7	VDDN_COM
Bit 4	Port 6	VDDN_COM
Bit 3	Port 5	VDDN_COM
Bit 2	Port 4	VDDN_COM
Bit 1	Port 2	VDD2_COM
Bit 0	Port 0/1/3	VDD2_COM

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 RSTCTRL	Reset Control Sets the IO bank reset which tristates the ports. Intended to be used prior to powering off the VDDIO supplies. This bit is reset by cold reset. 0000_0000b - IO banks are not reset 1xxx_xxxxb - PMIC_I2C reset = tristate x1xx_xxxxb - Port 8/9/10 reset = tristate xx1x_xxxxb - Port 7 reset = tristate xxx1_xxxxb - Port 6 reset = tristate

Table continues on the next page...

Table continued from the previous page...

Field	Function
	xxxx_1xxxb - Port 5 reset = tristate xxxx_x1xxb - Port 4 reset = tristate xxxx_xx1xb - Port 2 reset = tristate xxxx_xxx1b - Port 0/1/3 reset = tristate
15-8 ISOHOLD	IO Bank Isolation Hold Maintains IO bank isolation state after wake-up from FDSR/DPD modes. If clear, the IO bank's state will be retained during FDSR & DPD modes, but will be controllable after wake-up. Clear to 0 so that after PMC powers the controlling logic domain, the isolation is automatically removed and the port is once again controlled by the controlling domain. If the controlling domain is state-retained, then the port state will not change when the isolation is auto-negated. If set, the IO bank will remain in retain mode until ISOCTRL cleared by software. Set to 1 for banks that you want to remain isolated even after power is restored to the controlling logic. If the controlling logic's state is not retained, this enables the software to configure the controlling logic back to its previous state before clearing the isolation/retention to restore control back to the logic. This bit is reset by cold reset. 0000_0000b - IO bank is controllable on wake-up from FDSR/DPD mode 1xxx_xxxxb - PMIC_I2C is retained/isolated on wake-up from FDSR/DPD mode. Software must clear [ISOCTRL] bit 7 to regain control x1xx_xxxxb - Port 8/9/10 is retained/isolated on wake-up from FDSR/DPD mode. Software must clear [ISOCTRL] bit 6 to regain control xx1x_xxxxb - Port 7 is retained/isolated on wake-up from FDSR/DPD mode. Software must clear [ISOCTRL] bit 5 to regain control xxx1_xxxxb - Port 6 is retained/isolated on wake-up from FDSR/DPD mode. Software must clear [ISOCTRL] bit 4 to regain control xxxx_1xxxb - Port 5 is retained/isolated on wake-up from FDSR/DPD mode. Software must clear [ISOCTRL] bit 3 to regain control xxxx_x1xxb - Port 4 is retained/isolated on wake-up from FDSR/DPD mode. Software must clear [ISOCTRL] bit 2 to regain control xxxx_xx1xb - Port 2 is retained/isolated on wake-up from FDSR/DPD mode. Software must clear [ISOCTRL] bit 1 to regain control xxxx_xxx1b - Port 0/1/3 is retained/isolated on wake-up from FDSR/DPD mode. Software must clear [ISOCTRL] bit 0 to regain control
7-0 ISOCTRL	IO bank State Retain Control Controls IO bank state retain, one bit for each VDDIO/VDD domain pair that consists of a controlling VDD logic domain (for example, VDD2_COM or VDD1_SENSE) and a VDDIO supply (VDDIO, VDDIO1, etc.). Hardware sets this bit when driving domain powers down (FDSR/DPD). This bit cannot be cleared if associated domain is not powered. This bit is reset by cold reset.

Table continues on the next page...

	0000_0000b - IO bank is controllable 1xxx_xxxxb - PMIC_I2C is in retain mode x1xx_xxxxb - Port 8/9/10 is in retain mode xx1x_xxxxb - Port 7 is in retain mode xxx1_xxxxb - Port 6 is in retain mode xxxx_1xxxb - Port 5 is in retain mode xxxx_x1xxb - Port 4 is in retain mode xxxx_xx1xb - Port 2 is in retain mode xxxx_xxx1b - Port 0/1/3 is in retain mode

27.7.1.20 PD Run Configuration 0 in Compute Domain (PDRUNCFG0)

Offset

Register	Offset
PDRUNCFG0	A0h

Function

Configures power down for CPU0 in active mode. This drives the aggregation input for the power down and other controls of PMC functions when the Compute domain is in active mode. See PD*CFG and aggregation. Reserved bits must not be changed by user software.

NOTE

Changes to this register do not affect PMC until Compute domain CTRL[APPLYCFG] is set, triggering the state machines or CPU0 enters and then exits Deep Sleep mode.

Field	Function
	NOTE To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 00b - Bypass mode 01b - High-power mode 10b,11b - Low-power mode
17-16 LDO1_VSEL	LDO VDD1 Voltage Select Selects one of four voltages in LDOVDD1VSEL register. Also selects from one of four LVD trip points in LVDVDD1CTRL. 00b means the lowest voltage and 11b means the highest voltage. This field is aggregated high. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 00b - Selects LDOVDD1VSEL[VSEL0] and LVDVDD1CTRL[LVL0] level 01b - Selects LDOVDD1VSEL[VSEL1] and LVDVDD1CTRL[LVL1] level 10b - Selects LDOVDD1VSEL[VSEL2] and LVDVDD1CTRL[LVL2] level 11b - Selects LDOVDD1VSEL[VSEL3] and LVDVDD1CTRL[LVL3] level
15-14 LDO1_MODE	LDO VDD1 Mode Selects regulation mode of LDO VDD1. When high-power mode is selected, the PMC references automatically enter the high-power mode. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 00b - Bypass mode 01b - High-power mode 10b,11b - Low-power mode
13 DCDC_VSEL	Select DCDC Voltage Selects PMC DCDC voltage and LVD level VDDN supply rail from DCDCVSEL registers. DCDCVSEL[VSEL1] is the higher voltage for aggregation. This field is aggregated high. For details on aggregation logic, see PD*CFG and aggregation. This field has 2 copies separately accessed by the Compute and Sense slots.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Selects DCDCVSEL[VSEL0] level 1b - Selects DCDCVSEL[VSEL1] level
12-11 DCDC_MODE	DCDC Power Mode Selects DCDC power mode. When high-power mode is selected, the PMC references automatically enter the high-power mode. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has 2 copies separately accessed by the Compute and Sense slots. This field is reset by warm reset. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. **NOTE** When using an external supply to power VDDN and POWERCFG[DCDCPD] = 1b, software must also set field DCDC_MODE = 11b in PMC0.PDRUNCFG0, PMC0.PDSLEEPCFG0, PMC1.PDRUNCFG0, and PMC1.PDSLEEPCFG to minimze power when all other PMC subblocks go to low power or power down mode. 00b - Enables DCDC in high-power mode 01b - Enables DCDC in low-power mode 10b - Enables DCDC in ultra-low-power mode 11b - Enables DCDC in ultra-low-power mode
10 V2MIPI_PD	Power Down MIPI PHY in VDD2 Domain Controls power down of the MIPI PHY. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. **NOTE** MIPI PHY must be powered down if VDD2_MEDIA is in DSR mode. 0b - Power on 1b - Power down

Table continues on the next page...

Table continued from the previous page...

Field	Function
9 V2DSP_PD	Power Down VDD2_DSP Disables VDD2_DSP (HiFi4). Software must power down the HiFi4 cache and TCM periphery power switches prior to powering down the HiFi4, and the memories must not be powered on until after the HiFi4 is powered on. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. The Sense slot version of this field is read-only. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. **NOTE** VDD2_DSP must be powered down if VDD2_COMP is in DSR mode. 0b - Power on 1b - Power down
8 VNCOM_DSR	Power Switch and DSR for VDDN_COM Enables DSR mode for VDDN_COM domain. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. You must write 0 to this bit and apply it before entering DPD mode. Write 0 to the bit in either Compute or Sense slot since it is aggregated low. You can write 1 to this bit again after DPD wakeup. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Powers on VDDN_COM domain 1b - Enables VDDN_COM domain in DSR mode
7 V2COM_DSR	Power Switch and DSR Enable for VDD2_COM **NOTE** Read only. Value used for aggregation. Enables DSR mode for VDD2_COM domain. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. 0b - Powers on VDD2_COM 1b - Enables DSR mode in VDD2_COM
6 V2NMED_DSR	Power Switch and DSR for VDD2 and VDDN Media Enables DSR mode for VDD2 and VDDN media domains. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation.

Table continues on the next page...

Field	Function
	You must write 0 to this bit and apply it before entering DPD mode. Write 0 to the bit in either Compute or Sense slot since it is aggregated low. You can write 1 to this bit again after DPD wakeup. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Powers on VDD2 and VDDN media domains 1b - Enables VDD2 and VDDN media domains in DSR mode
5 V2COMP_DSR	Power Switch and DSR Enable in VDD2_COMP Domain **NOTE** Read only. Value used for aggregation. Enables DSR mode for VDD2_COMP domain. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. The Sense slot version of this field is read-only. 0b - Powers on VDD2_COMP 1b - Enables DSR mode in VDD2_COMP
4 FDPD	Full Deep Power Down (FDPD) Mode **NOTE** Read only. Value used for aggregation. Activates isolation and corrects sequencing for FDPD mode. The chip will only go to FDPD mode if both domains enter Deep Sleep with this bit set. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. 0b - Disables 1b - Enables FDPD mode
3 DPD	Deep Power Down (DPD) Mode **NOTE** Read only. Value used for aggregation. Activates isolation and corrects sequencing for DPD mode. The chip will only go to DPD mode if both domains enter Deep Sleep with this bit set, and at least one domain has [FDPD] cleared. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. 0b - Disables 1b - Enables DPD mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
2 FDSR	Full Deep Sleep Retention (FDSR) Mode **NOTE** Read only. Value used for aggregation. Puts all power switches into DSR or power down. All core domains go to DSR mode or power down mode depending on domain. Muxes VDDN_SR to VDD2 before ramping down supply voltages and turning off VDDN. This is the only way to put VDD1_SENSE domain into DSR mode and control the associated power switch. The chip will only go to FDSR mode if both domains enter Deep Sleep with this bit set, and [DPD] and [FDPD] are not set. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. 0b - All power switch states controlled by their respective PD*CFG bits 1b - All core domains in DSR or Power Down mode
1-0 PMICMODE	PMIC Power Mode Select Sets value of PMIC_MODE output pins. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 00b - Drives PMIC_MODE pins to 0h 01b - Drives PMIC_MODE pins to 1h 10b - Drives PMIC_MODE pins to 2h 11b - Drives PMIC_MODE pins to 3h

Register	Offset
PDRUNCFG1	A4h

Function

Configures power down for CPU0 in active mode. This drives the aggregation input for the power down and other controls of PMC functions when Compute domain is in active mode. See PD*CFG and aggregation. Reserved bits must not be changed by user software.

NOTE

Changes to this register do not affect PMC until Compute domain CTRL[APPLYCFG] is set, triggering the state machines or CPU0 enters and then exits the Deep Sleep mode.

	1b - Sets POR in low-power mode
2 HVD1V8_PD	HVD Power Down Controls the power switch for the VDD1V8 high-voltage detect. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Power on. In this case, PMC references will be in high-power mode 1b - Power down
1 PMCREF_LP	PMC References in Low-Power Mode Sets PMC references in low-power mode if high power is not needed by any regulators, HVDs, POR, LVD, AFBB, or the PMC temperature sensor. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Sets PMC references in high-power mode 1b - Sets PMC references in low-power mode if not overridden by any *_PD bits
0 TEMP_PD	Power Down PMC Temperature Sensor Controls the power switch for the PMC temperature sensor. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Power on. In this case, PMC references will be in high-power mode 1b - Power down

27.7.1.22 PD Run Configuration 2 in Compute Domain (PDRUNCFG2)

Offset

Register	Offset
PDRUNCFG2	A8h

Function

Configures main memory array and periphery power down for CPU0 in active mode. This drives aggregation input for the power down control of the arrays and peripheries of the main SRAM partitions when CPU0 is in active mode. If a partition's aggregated PD*CFG2[SRAMn] is 0, then the array is powered and the periphery power is controlled by PD*CFG3. If PD*CFG2[SRAMn] is 1, then the partition's array and periphery are both powered off.

This register is reset by cold reset.

NOTE

Changes to this register do not affect the memories until Compute domain CTRL[APPLYCFG] is set, triggering the state machines, or CPU0 enters and then exits Deep Sleep mode.

0 —	Reserved

27.7.1.23 PD Run Configuration 3 in Compute Domain (PDRUNCFG3)

Offset

Register	Offset
PDRUNCFG3	ACh

Function

Powers down the selected main memory partitions' periphery logic to save power, while maintaining the contents if the corresponding PD*CFG2[SRAMn] is configured to keep the array on.

This register is reset by cold reset.

NOTE

SRAM0 to SRAM17 are the VDD2_COM main memories. SRAM18 to SRAM29 are the VDD1_SENSE main memories.

NOTE

- Memory peripheries are powered down whenever **the array is powered down** or **the associated power domain is in *DSR mode* or *powered down***
- Changes to this register do not affect the memories until Compute domain CTRL[APPLYCFG] is set, triggering the state machines, or CPU0 enters and then exits Deep Sleep mode.

27.7.1.25 PD Run Configuration 5 in Compute Domain (PDRUNCFG5)

Offset

Register	Offset
PDRUNCFG5	B4h

Function

Configures peripheral memory periphery power down for CPU0 in active mode. This drives aggregation input for the power down control of the peripheries of the Peripherals" SRAM partitions when CPU0 is in active mode. If a partition's aggregated PD*CFG4 bit is 0, then the array is powered and the periphery power is controlled by PD*CFG5. If the PD*CFG4 bit is 1, then the periphery is powered off and the array power is determined by PD*CFG4. When the power domain of the peripheral in DSR mode, the peripheries for all SRAMs in that domain are automatically powered down.

This register is reset by cold reset.

NOTE

- Memory peripheries are powered down whenever **the array is powered down** or **the associated power domain is in *DSR mode* or *powered down***
- Changes to this register do not affect the memories until Compute domain CTRL[APPLYCFG] is set, triggering the state machines, or CPU0 enters and then exits Deep Sleep mode.

27.7.1.26 PD Sleep Configuration 0 in Compute Domain (PDSLEEPCFG0)

Offset

Register	Offset
PDSLEEPCFG0	B8h

Function

Configures power down for CPU0 in Deep Sleep mode. This drives the aggregation input for the power down and other controls of PMC functions when Compute domain is in Deep Sleep mode. See PD*CFG and aggregation. Reserved bits must not be changed by user software.

NOTE

Changes to this register do not affect PMC until Compute domain enters Deep Sleep mode.

	01b - High-power mode 10b,11b - Low-power mode
17-16 LDO1_VSEL	LDO VDD1 Voltage Select Selects one of four voltages in LDOVDD1VSEL register. Also selects from one of four LVD trip points in LVDVDD1CTRL. 00b means the lowest voltage and 11b means the highest voltage. This field is aggregated high. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 00b - Selects LDOVDD1VSEL[VSEL0] and LVDVDD1CTRL[LVL0] level 01b - Selects LDOVDD1VSEL[VSEL1] and LVDVDD1CTRL[LVL1] level 10b - Selects LDOVDD1VSEL[VSEL2] and LVDVDD1CTRL[LVL2] level 11b - Selects LDOVDD1VSEL[VSEL3] and LVDVDD1CTRL[LVL3] level
15-14 LDO1_MODE	LDO VDD1 Regulator Mode Selects regulation mode of LDO VDD1. When high-power mode is selected, the PMC references automatically enter high-power mode. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 00b - Bypass mode 01b - High-power mode 10b,11b - Low-power mode
13 DCDC_VSEL	DCDC Voltage Select Selects the PMC DCDC voltage and LVD level VDDN supply rail from the DCDCVSEL register. DCDCVSEL[VSEL1] is the higher voltage for aggregation. This field is aggregated high. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Selects DCDCVSEL[VSEL0] level 1b - Selects DCDCVSEL[VSEL1] level
12-11 DCDC_MODE	DCDC Power Mode Selects DCDC power mode. When high-power mode is selected, the PMC references automatically enter the high-power mode. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. This field is reset by warm reset. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. **NOTE** When using an external supply to power VDDN and POWERCFG[DCDCPD] = 1b, software must also set field DCDC_MODE = 11b in PMC0.PDRUNCFG0, PMC0.PDSLEEPCFG0, PMC1.PDRUNCFG0, and PMC1.PDSLEEPCFG to minimze power when all other PMC subblocks go to low power or power down mode. 00b - Enables DCDC in high-power mode 01b - Enables DCDC in low-power mode 10b - Enables DCDC in ultra-low-power mode 11b - Enables DCDC in ultra-low-power mode
10 V2MIPI_PD	Power Down MIPI PHY in VDD2 Domain Controls power down of the MIPI PHY. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. **NOTE** MIPI PHY must be powered down if VDD2_MEDIA is in DSR mode. 0b - Power on 1b - Power down
9 V2DSP_PD	Power Down VDD2_DSP Disables VDD2_DSP (HiFi4). This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. The Sense slot version of this field is read-only.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. **NOTE** VDD2_DSP must be powered down if VDD2_COMP is in DSR mode. **NOTE** Software must power down the HiFi4 cache and TCM periphery power switches prior to powering down the HiFi4, and the memories must not be powered on until the HiFi4 is powered. 0b - Power on 1b - Power down
8 VNCOM_DSR	Power Switch and DSR Enable in VDDN_COM Domain Enables DSR mode for VDDN_COM domain. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Powers on VDDN_COM 1b - Enables DSR mode in VDDN_COM
7 V2COM_DSR	Power Switch and DSR Enable in VDD2_COM Domain Enables DSR mode for VDD2_COM domain. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Powers on VDD2_COM 1b - Enables DSR mode in VDD2_COM
6 V2NMED_DSR	Power Switch and DSR Enable in VDD2_MEDIA and VDDN_MEDIA Domains Enables DSR mode for VDD2_MEDIA and VDDN_MEDIA domains. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. **NOTE** Merged VDD2 and VDDN media switch controls. 0b - Powers on VDD2_MEDIA and VDDN_MEDIA 1b - Enables DSR mode in VDD2_MEDIA and VDDN_MEDIA
5 V2COMP_DSR	Power Switch and DSR Enable in VDD2_COMP Domain Enables DSR mode for VDD2_COMP domain. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. The Sense slot version of this field is read-only. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Powers on VDD2_COMP 1b - Enables DSR mode in VDD2_COMP
4 FDPD	Full Deep Power Down (FDPD) Mode Activates isolation and corrects sequencing for FDPD mode. The chip will only go to FDPD mode if both domains enter Deep Sleep with this bit set. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. 0b - Disables 1b - Enables FDPD mode
3 DPD	Deep Power Down (DPD) Mode Activates isolation and corrects sequencing for DPD mode. The chip will only go to DPD mode if both domains enter Deep Sleep with this bit set, and at least one domain has [FDPD] cleared. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. You must clear this bit whenever PDSLEEPCFG0[FDSR] is set. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Disables 1b - Enables DPD mode
2	Full Deep Sleep Retention (FDSR) Mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
FDSR	Puts all power switches into DSR or power down. All core domains go to DSR mode or power down mode depending on domain. Muxes VDDN_SR to VDD2 before ramping down supply voltages and turning off VDDN. This is the only way to put VDD1_SENSE domain into DSR mode and control the associated power switch. The chip will only go to FDSR mode if both domains enter Deep Sleep with this bit set, and [DPD] and [FDPD] are not selected instead. You must clear this bit whenever PDSLEEPCFG0[DPD] is set. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - All power switch states controlled by their respective PD*CFG bits 1b - All core domains in DSR or Power Down mode
1-0 PMICMODE	PMIC Mode Sets value of PMIC_MODE output pins. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 00b - Drives PMIC_MODE pins to 0h 01b - Drives PMIC_MODE pins to 1h 10b - Drives PMIC_MODE pins to 2h 11b - Drives PMIC_MODE pins to 3h

27.7.1.27 PD Sleep Configuration 1 in Compute Domain (PDSLEEPCFG1)

Offset

Register	Offset
PDSLEEPCFG1	BCh

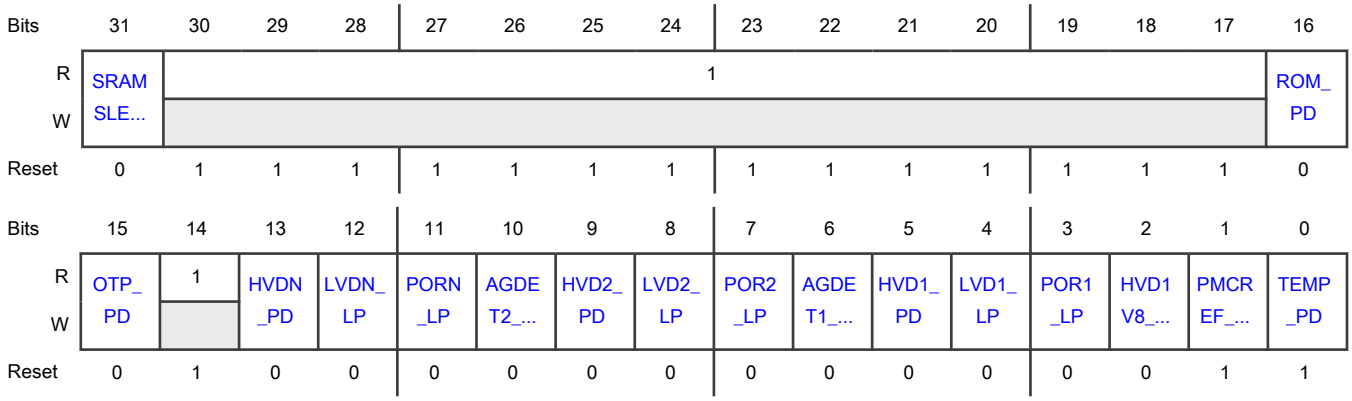
Function

Configures power down for CPU0 in Deep Sleep mode. This drives the aggregation input for the power down and other controls of PMC functions when Compute domain is in Deep Sleep mode. See PD*CFG and aggregation. Reserved bits must not be changed by user software.

NOTE

Changes to this register do not affect PMC until Compute domain enters Deep Sleep mode.

Diagram



Fields

Field	Function
31 SRAMSLEEP	SRAM Sleep Mode Sets SRAM sleep mode. This is needed when VDD Core can be < 0.85 V to ensure contents retained. No power savings. Memories are not accessible in RAM sleep mode. It should only be set in PDSLEEPCFG. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Normal 1b - Sleep
30-17 —	Reserved
16 ROM_PD	ROM Power Down Controls the power switch for the ROM. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. The Sense slot version of this field is read-only. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Power on 1b - Power down
15	OTP Power Down in VDD2 Domain

Table continues on the next page...

Table continued from the previous page...

Field	Function
OTP_PD	Controls the power switch for OTP0 VDD2 Core. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. The Sense slot version of this field is read-only. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Power on 1b - Power down
14 —	Reserved
13 HVDN_PD	HVD Power Down in VDDN Domain Controls the power mode of the VDDN high-voltage detect. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Power on. In this case the aggregated PDCFGSTATUS1[PMCREF_LP] bit will be in high-power mode 1b - Power down
12 LVDN_LP	LVD Low power in VDDN Domain Sets LVD in low-power mode in VDDN domain. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - High-power mode. In this case the aggregated PDCFGSTATUS1[PMCREF_LP] bit will be in high-power mode 1b - Low-power mode
11 PORN_LP	POR Low Power in VDDN Domain Sets POR in low-power mode in VDDN domain. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots.

Table continues on the next page...

	1b - Low-power mode if not overridden by any *_PD bits
0 TEMP_PD	PMC Temperature Sensor Power Down Controls the power switch for the PMC temperature sensor. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Power on. In this case, PMC references will be in high-power mode 1b - Power down

27.7.1.28 PD Sleep Configuration 2 in Compute Domain (PDSLEEPCFG2)

Offset

Register	Offset
PDSLEEPCFG2	C0h

Function

Configures power down for main memory array and periphery for CPU0 in Deep Sleep mode. This drives aggregation input for the power down control of the arrays and peripheries of the min SRAM partitions when CPU0 is in Deep Sleep mode. If a partition's aggregated PD*CFG2[SRAMn] is 0, then the array is powered and the periphery power is controlled by PD*CFG3. If PD*CFG2[SRAMn] is 1, then the partition's array and periphery are both powered off.

This register is reset by cold reset.

NOTE

Changes to this register do not affect the memories until CPU0 enters Deep Sleep mode.

27.7.1.29 PD Sleep Configuration 3 in Compute Domain (PDSLEEPCFG3)

Offset

Register	Offset
PDSLEEPCFG3	C4h

Function

Powers down the selected main memory partitions' periphery logic to save power, while maintaining the contents if the corresponding PD*CFG2[SRAMn] is configured to keep the array on.

This register is reset by cold reset.

NOTE

- Memory peripheries are powered down whenever **the array is powered down** or **the associated power domain is in *DSR mode* or *powered down*** .
- Changes to this register do not affect the memories until CPU0 enters Deep Sleep mode.

27.7.1.30 PD Sleep Configuration 4 in Compute Domain (PDSLEEPCFG4)

Offset

Register	Offset
PDSLEEPCFG4	C8h

Function

Configures power down for peripheral memory array and periphery for CPU0 in Deep Sleep mode. This drives aggregation input for the power down control of the arrays and peripheries of the peripherals" SRAM partitions when CPU0 is in Deep Sleep mode. If a partition's aggregated PD*CFG4[PD] bit is 0, then the array is powered and the periphery power is controlled by PD*CFG5. If the PD*CFG4[PD] bit is 1, then the partition's array and periphery are both powered off.

This register is reset by cold reset.

NOTE

Changes to this register do not affect the memories until CPU0 enters Deep Sleep mode.

27.7.1.31 PD Sleep Configuration 5 in Compute Domain (PDSLEEPCFG5)

Offset

Register	Offset
PDSLEEPCFG5	CCh

Function

Configures power down for peripheral memory periphery for CPU0 in Deep Sleep mode. This drives aggregation input for the power down control of the peripheries of the Peripherals" SRAM partitions when CPU0 is in Deep Sleep. If a partition's aggregated PD*CFG4 bit is 0, then the array is powered and the periphery power is controlled by PD*CFG5. If the PD*CFG4 bit is 1, then the periphery is powered off and the array power is determined by PD*CFG4. When the power domain of the Peripheral in DSR mode the peripheries for all SRAMs in that domain are automatically powered down.

This register is reset by cold reset.

NOTE

- Memory peripheries are powered down whenever **the array is powered down** or **the associated power domain is in *DSR mode* or *powered down*** .
- Changes to this register do not affect the memories until CPU0 enters Deep Sleep mode.

Field	Function
DCDC_MODE	Indicates DCDC power mode. This field is reset by warm reset. 00b - DCDC in high-power mode 01b - DCDC in low-power mode 10b - DCDC in ultra-low-power mode 11b - DCDC in ultra-low-power mode
10 V2MIPI_PD	MIPI PHY Power Down Indicates the power down status of MIPI PHY. This bit is reset by warm reset. **NOTE** MIPI PHY must be powered down if VDD2_MEDIA is in DSR mode. 0b - Power on 1b - Power down
9 V2DSP_PD	HiFi4 Power Down Indicates the power down status of HiFi4. This bit is reset by warm reset. **NOTE** Must be powered down if VDD2_COMP is in DSR mode. **NOTE** Software must power down the HiFi4 cache and TCM periphery power switches prior to powering down the HiFi4, and the memories must not be powered on until the HiFi4 is powered. 0b - Power on 1b - Power down
8 VNCOM_DSR	DSR of VDDN_COM Domain Indicates the DSR status of VDDN_COM domain. This bit is reset by warm reset. 0b - Power on 1b - DSR mode
7 V2COM_DSR	DSR of VDD2_COM Domain Indicates the DSR status of VDD2_COM domain. This bit is reset by warm reset.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Power on 1b - DSR mode
6 V2NMED_DSR	DSR of VDD2_MEDIA and VDDN_MEDIA Domains Indicates the DSR status of VDD2_MEDIA and VDDN_MEDIA domains. **NOTE** Merged VDD2 and VDDN media switch controls. This bit is reset by warm reset. 0b - Power on 1b - DSR mode
5 V2COMP_DSR	DSR of VDD2_COMP Domain Indicates the DSR status of VDD2_COMP domain. This bit is reset by warm reset. 0b - Power on 1b - DSR mode
4 FDPD	FDPD Mode Indicates FDPD status. This bit is reset by warm reset. 0b - Enables 1b - Activates isolation and correct sequencing for FDPD mode
3 DPD	DPD Mode Indicates DPD status. This bit is reset by warm reset. 0b - Enables 1b - Activates isolation and correct sequencing for DPD mode
2 FDSR	FDSR Mode Indicates the FDSR mode of all core domains. This bit is reset by warm reset. 0b - Power switches and DSR status are determined by the single power domain controls 1b - All core domains are in FDSR mode or power down
1-0 PMICMODE	PMIC_MODE Output Value This bit is reset by warm reset.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates the aggregated PMIC_MODE output value driven to PMIC_MODE[1:0] pins, which is lowest value (highest power) mode selected by the active PD*CFG registers in Compute and Sense domains. PMIC_MODE output value is used to control external power supplies. 00b - PMIC_MODE[1:0] pins = 00 01b - PMIC_MODE[1:0] pins = 01 10b - PMIC_MODE[1:0] pins = 10 11b - PMIC_MODE[1:0] pins = 11

27.7.1.33 PD Configuration Status 1 (PDCFGSTATUS1)

Offset

Register	Offset
PDCFGSTATUS1	D4h

Function

Shows the currently aggregated value of Sense and Compute domains in PD*CFG1 registers. Updates immediately after the mode change event (e.g. CTRL[APPLYCFG] = 1, CPUx enters Deep Sleep, etc), while PMC is transitioning to the new configuration (as indicated by reading STATUS[BUSY] and CTRL[APPLYCFG]) and held until the next mode transition or APPLYCFG.

27.7.1.38 PD Wake-up Configuration for Compute Domain (PDWAKECFG)

Offset

Register	Offset
PDWAKECFG	E8h

Function

Copies the selected values from the Compute slot PDSLEEPCFG0 to PDRUNCFG0 when CPU0 wakes up from Deep Sleep mode.

Power down wake-up is used when the PMC module switches from one body bias mode to another body bias mode in active mode, but it allows the change to occur while the affected domains are in Deep Sleep mode and the clocks are stopped to avoid timing issues during the transition. The clock controls need to be configured to stop in Deep Sleep mode in the domain's clock controls.

When PMC enters in Deep Sleep mode, the PDSLEEPCFG0 changes the body bias modes and the PDRUNCFG0 body bias power down controls are replaced with the PDSLEEPCFG0 controls selected in PDWAKECFG. This feature is used with INTRCTRL[AUTOWKIE] which enables the AUTOWAKE feature that wakes up PMC when the transition to Deep Sleep is completed and the updated body bias modes are active. The AUTOWAKE triggers a PMC interrupt which triggers a wake-up. Since PDRUNCFG0 was updated with the body bias state from PDSLEEPCFG0, the body bias for the selected domains is maintained.

Diagram

27.7.1.39 Power Domain Flags for Compute Domain (PWRFLAGS)

Offset

Register	Offset
PWRFLAGS	ECh

Function

Indicates which domains were put into Deep Sleep Retain mode or Power Down mode since the last time the flag was cleared by software. Flags are clearable only when the domain is powered.

NOTE

The Compute and Sense slots each have their own set of flags. Clearing a flag in the Compute slot will not clear the corresponding flag in the Sense slot.

Diagram

Field	Function
	This field has 2 copies separately accessed by the Compute and Sense slots. This bit is reset by VDD1V8 POR reset. 0b - No DSR event occurred 1b - DSR event occurred
3 V2COMF	VDD2_COM Domain Flag Indicates if VDD2_COM domain enters DSR mode. This field has 2 copies separately accessed by the Compute and Sense slots. This bit is reset by VDD1V8 POR reset. 0b - No DSR event occurred 1b - DSR event occurred
2 V2NMEDF	VDD2_MEDIA and VDDN_MEDIA Domain Flag Indicates if VDD2_MEDIA and VDDN_MEDIA domains enter DSR mode. This field has 2 copies separately accessed by the Compute and Sense slots. This bit is reset by VDD1V8 POR reset. 0b - No DSR event occurred 1b - DSR event occurred
1 V2COMPF	VDD2_COMP Domain Flag Indicates if VDD2_COMP domain enters DSR mode. This field has 2 copies separately accessed by the Compute and Sense slots. This bit is reset by VDD1V8 POR reset. 0b - No DSR event occurred 1b - DSR event occurred
0 V1SENSF	VDD1_SENSE Domain Flag Indicates if VDD1_SENSE domain enters DSR mode. This field has 2 copies separately accessed by the Compute and Sense slots. This bit is reset by VDD1V8 POR reset. 0b - No DSR event occurred 1b - DSR event occurred

27.7.2 PMC register descriptions

27.7.2.1 PMC register description memory map

This section includes the memory map and detailed description of all registers and their fields of PMC1 in Sense domain.

PMC.PMC1 base address: 4021_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	PMC Version and Feature ID (VERID)	32	R	0000_0000h
4h	PMC Status (STATUS)	32	R	0000_0000h
8h	PMC Flags in Sense Domain (FLAGS)	32	RW	001C_F800h
Ch	Control (CTRL)	32	RW	001C_0000h
10h	Interrupt Control in Sense Domain (INTRCTRL)	32	RW	0000_0000h
20h	DCDC Voltage Selection (DCDCVSEL)	32	R	0000_6050h
24h	LDO VDD2 Voltage Selection (LDOVDD2VSEL)	32	R	2C24_1C14h
28h	LDO VDD1 Voltage Selection (LDOVDD1VSEL)	32	RW	2C24_1C14h
2Ch	VDDN LVD Control (LVDVDDNCTRL)	32	R	0000_2C28h
30h	VDD2 LVD Control (LVDVDD2CTRL)	32	R	281E_140Ah
34h	VDD1 LVD Control (LVDVDD1CTRL)	32	RW	281E_140Ah
38h	Power-on Reset Control (PORCTRL)	32	R	0008_0808h
40h	Body Bias Control (BBCTRL)	32	R	0001_0101h
44h	Temperature Sensor Control (TSENSOR)	32	RW	0000_0000h
50h	Wake-up Configuration for Sense Domain (WAKEUP)	32	RW	0000_0000h
64h	Power Configuration (POWERCFG)	32	R	6000_0070h
68h	3 V Capable VDDIO Range Select (PADVRANGE)	32	R	0000_0000h
6Ch	IO Bank State Configuration (PADCFG)	32	RW	0000_0000h

ECh	Power Domain Flags for Sense Domain (PWRFLAGS)	32	RW	0000_0074h

27.7.2.2 PMC Version and Feature ID (VERID)

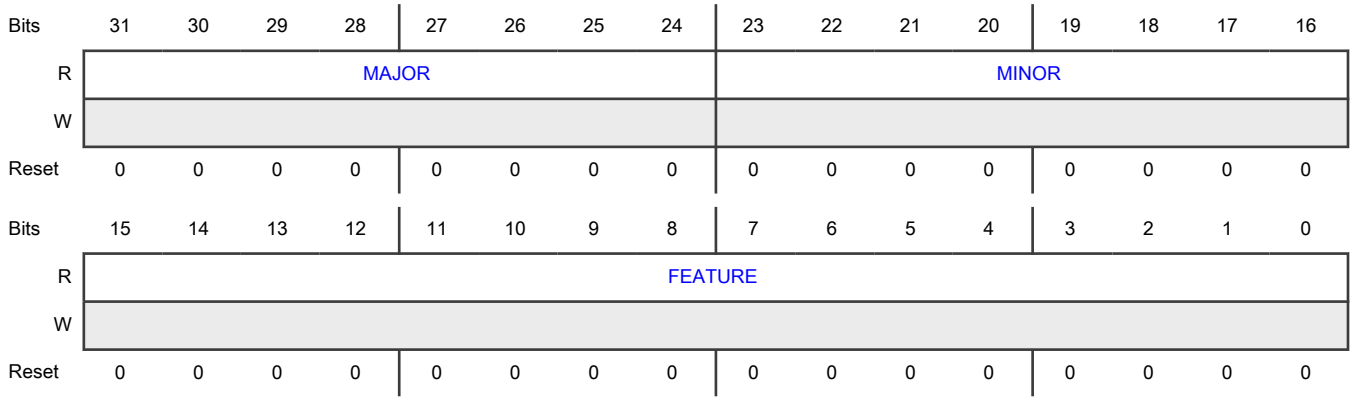
Offset

Register	Offset
VERID	0h

Function

Indicates the version integrated for this instance on the chip.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number Reads the major version number for the module specification.
23-16	Minor Version Number

Table continues on the next page...

Table continued from the previous page...

Field	Function
MINOR	Reads the minor version number for the module specification.
15-0 FEATURE	Feature Identification Number Reads the feature set number.

27.7.2.3 PMC Status (STATUS)

Offset

Register	Offset
STATUS	4h

Function

Indicates current status of PMC sources, not latched, but synchronized to PMC clock. See PMC Flags for latched versions of sources that are enabled to generate resets or interrupts.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 —	Reserved
30 DSCOMP	CPU0 Deep Sleep Indicates that CPU0 is in Deep Sleep mode. 0b - CPU0 is in Active mode 1b - CPU0 is in Deep Sleep mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
29 —	Reserved
28 —	Reserved
27 INTN	PMIC_IRQN Interrupt Input Show the interrupt input pin status. 0b - Negated. Pin is high 1b - Asserted. Pin is low
26 —	Reserved
25 RTCWKUP	RTC Wake-up Shows RTC wake-up status. 0b - Sense RTC wake-up is negated 1b - Sense RTC wake-up is asserted
24 HVD1V8	VDD1V8 High-Voltage Detector Shows VDD1V8 high-voltage detector status. 0b - Detector is not tripped 1b - Detector is tripped
23 HVDVDDN	VDDN High-Voltage Detector Shows VDDN high-voltage detector status. 0b - Detector is not tripped 1b - Detector is tripped
22 HVDVDD2	VDD2 High-Voltage Detector Shows VDD2 high-voltage detector status. 0b - Detector is not tripped 1b - Detector is tripped
21 HVDVDD1	VDD1 High-Voltage Detector Shows VDD1 high-voltage detector status. 0b - Detector is not tripped 1b - Detector is tripped
20	VDDN Low-Voltage Detector

Table continues on the next page...

Table continued from the previous page...

Field	Function
LVDVDDN	Shows VDDN low-voltage detector status. 0b - Detector is not tripped 1b - Detector is tripped
19 LVDVDD2	VDD2 Low-Voltage Detector Shows VDD2 low-voltage detector status. 0b - Detector is not tripped 1b - Detector is tripped
18 LVDVDD1	VDD1 Low-Voltage Detector Shows VDD1 low-voltage detector status. 0b - Detector is not tripped 1b - Detector is tripped
17-1 —	Reserved
0 BUSY	Finite State Machine Status Shows if PMC is currently processing a mode transition. 0b - PMC state machines are idle 1b - PMC state machine is busy

27.7.2.4 PMC Flags in Sense Domain (FLAGS)

Offset

Register	Offset
FLAGS	8h

Function

Indicates PMC event flags in Sense domain. This register is cleared by software, and set by hardware when event occurs. The flags in Sense and Compute domains are cleared respectively by writing 1 to corresponding bit fields.

Diagram

Fields

Field	Function
31 DEEPPDF	DPD Wake-up Flag Indicates the wake-up status of PMC in DPD mode. This bit is reset by VDD1V8_AO POR. 0b - DPD wake-up cleared 1b - DPD wake-up asserted
30 DSCOMPF	CPU0 Deep Sleep Flag Indicates that CPU0 entered Deep Sleep mode. This bit is set at Deep Sleep mode entry, and can be cleared while CPU0 is still in Deep Sleep mode. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - CPU0 Deep Sleep cleared 1b - CPU0 Deep Sleep asserted
29 DSSENSF	CPU1 Deep Sleep Mode Flag Indicates that CPU1 entered Deep Sleep mode. This bit is set at Deep Sleep mode entry. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - CPU1 Deep Sleep cleared 1b - CPU1 Deep Sleep asserted
28 RESETNF	Reset Pin Flag Indicates reset pin status. This bit is reset by VDD1V8_AO POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - Reset pin status cleared 1b - Reset pin status asserted

Table continues on the next page...

Table continued from the previous page...

Field	Function
27 INTNF	PMIC_IRQN Interrupt Pin Flag Indicates interrupt pin status. This bit is reset by VDD1V8_AO POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - Interrupt pin status cleared 1b - Interrupt pin status asserted
26 AUTOWKF	Auto Wake-up Flag Indicates auto wake-up interrupt status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - Auto wake-up status cleared 1b - Auto wake-up status asserted
25 RTCF	RTC Flag Indicates RTC alarm or wake was asserted. This bit is reset by VDD1V8_AO POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - RTC status cleared 1b - RTC status asserted
24 HVD1V8F	VDD1V8 High-Voltage Detector Flag Indicates VDD1V8 high-voltage detector status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - High-voltage detector status cleared 1b - High-voltage detector status asserted
23 HVDVDDNF	VDDN High-Voltage Detector Flag Indicates VDDN high-voltage detector status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - High-voltage detector status cleared 1b - High-voltage detector status asserted
22 HVDVDD2F	VDD2 High-Voltage Detector Flag Indicates VDD2 high-voltage detector status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - High-voltage detector status cleared 1b - High-voltage detector status asserted
21	VDD1 High-Voltage Detector Flag Indicates VDD1 high-voltage detector status. This bit is reset by VDD1V8 POR.

Table continues on the next page...

Table continued from the previous page...

Field	Function
HVDVDD1F	This field has two copies separately accessed by the Compute and Sense slots. 0b - High-voltage detector status cleared 1b - High-voltage detector status asserted
20 LVDVDDNF	VDDN Low-Voltage Detector Flag Indicates VDDN low-voltage detector status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - Low-voltage detector status cleared 1b - Low-voltage detector status asserted
19 LVDVDD2F	VDD2 Low-Voltage Detector Flag Indicates VDD2 low-voltage detector status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - Low-voltage detector status cleared 1b - Low-voltage detector status asserted
18 LVDVDD1F	VDD1 Low-Voltage Detector Flag Indicates VDD1 low-voltage detector status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - Low-voltage detector status cleared 1b - Low-voltage detector status asserted
17 AGDET2F	VDD2 Glitch Detector Flag Indicates VDD2 glitch detector status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - Glitch detector status cleared 1b - Glitch detector status asserted
16 AGDET1F	VDD1 Glitch Detector Flag Indicates VDD1 glitch detector status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - Glitch detector status cleared 1b - Glitch detector status asserted
15 PORAO18F	VDD1V8_AO Power-on Reset Flag Indicates VDD1V8_AO power-on reset status. This bit is set by VDD1V8_AO POR. 0b - POR status cleared 1b - POR status asserted

Table continues on the next page...

Table continued from the previous page...

Field	Function
14 POR1V8F	VDD1V8 Power-on Reset Flag Indicates VDD1V8 power-on reset status. This bit is set by VDD1V8 POR. 0b - POR status cleared 1b - POR status asserted
13 PORVDDNF	VDDN Power-on Reset Flag Indicates VDDN power-on reset status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - POR status cleared 1b - POR status asserted
12 PORVDD2F	VDD2 Power-on Reset Flag Indicates VDD2 power-on reset status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - POR status cleared 1b - POR status asserted
11 PORVDD1F	VDD1 Power-on Reset Flag Indicates VDD1 power-on reset status. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - POR status cleared 1b - POR status asserted
10 DCLPOCF	DCDC Low-Power Mode Overcurrent Flag Indicates the DCDC had an overcurrent event while in low-power mode. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - No overcurrent event detected 1b - Overcurrent event detected
9 DCHPOCF	DCDC High-Power Mode Overcurrent Flag Indicates the DCDC had an overcurrent event while in high-power mode. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - No overcurrent event detected 1b - Overcurrent event detected
8	SCPC VDD2 Overcurrent Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
SCP2OCF	Indicates that an SCPC2 overcurrent event was detected. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - No overcurrent event detected 1b - Overcurrent event detected
7 SCP1OCF	SCPC VDD1 Overcurrent Flag Indicates that an SCPC1 overcurrent event was detected. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - No overcurrent event detected 1b - Overcurrent event detected
6 BBNEF	VDDN Body Bias Error Flag Indicates body bias error in VDDN domain. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - No body bias error 1b - Body bias error detected
5 BB2EF	VDD2 Body Bias Error Flag Indicates body bias error in VDD2 domain. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - No body bias error 1b - Body bias error detected
4 BB1EF	VDD1 Body Bias Error Flag Indicates body bias error in VDD1 domain. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - No body bias error 1b - Body bias error detected
3 BBSR2EF	VDD2 SRAM Body Bias Error Flag Indicates SRAM body bias error in VDD2 domain. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - No SRAM body bias error 1b - SRAM body bias error detected
2 BBSR1EF	VDD1 SRAM Body Bias Error Flag Indicates SRAM body bias error in VDD1 domain. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No SRAM body bias error 1b - SRAM body bias error detected
1 ITRCRF	ITRC RAM ZEROIZE Flag Indicates ITRC triggered RAM ZEROIZE. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - Not detected 1b - ITRC RAM ZEROIZE detected
0 DSALLF	Deep Sleep Flag CPU0 and CPU1 are in Deep Sleep mode at the same time. This bit is reset by VDD1V8 POR. This field has two copies separately accessed by the Compute and Sense slots. 0b - CPU0 and CPU1 are not in Deep Sleep mode at the same time 1b - CPU0 and CPU1 have both been in Deep Sleep mode at the same time

27.7.2.5 Control (CTRL)

Offset

Register	Offset
CTRL	Ch

Function

Enables controls for triggering configuration updates and indicates voltage monitor resets.

Diagram

Fields

Field	Function
31-25 —	Reserved
24 HVD1V8RE	VDD1V8 High-Voltage Detector Reset Enable Indicates reset for VDD1V8 high-voltage detector. The Compute slot version of this field is read-write. This bit is reset by cold reset. 0b - Disabled 1b - Enabled
23 HVDVNRE	VDDN High-Voltage Detector Reset Enable Indicates reset for VDDN high-voltage detector. The Compute slot version of this field is read-write. This bit is reset by cold reset. 0b - Disabled 1b - Enabled
22 HVDV2RE	VDD2 High-Voltage Detector Reset Enable Indicates reset for VDD2 high-voltage detector. The Compute slot version of this field is read-write. This bit is reset by cold reset. 0b - Disabled 1b - Enabled
21 HVDV1RE	VDD1 High-Voltage Detector Reset Enable Indicates reset for VDD1 high-voltage detector. The Compute slot version of this field is read-write. This bit is reset by cold reset. 0b - Disabled 1b - Enabled
20 LVDNRE	VDDN Low-Voltage Detector Reset Enable Indicates reset for VDDN low-voltage detector. The Compute slot version of this field is read-write. This bit is reset by cold reset. 0b - Disabled 1b - Enabled
19 LVD2RE	VDD2 Low-Voltage Detector Reset Enable Indicates reset for VDD2 low-voltage detector. The Compute slot version of this field is read-write. This bit is reset by cold reset. 0b - Disabled 1b - Enabled
18	VDD1 Low-Voltage Detector Reset Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
LVD1RE	Indicates reset for VDD1 low-voltage detector. The Compute slot version of this field is read-write. This bit is reset by cold reset. 0b - Disabled 1b - Enabled
17 AGDET2RE	VDD2 Glitch Detector Reset Enable Indicates reset for VDD2 glitch detector. The Compute slot version of this field is read-write. This bit is reset by cold reset. 0b - Disabled 1b - Enabled
16 AGDET1RE	VDD1 Glitch Detector Reset Enable Indicates reset for VDD1 glitch detector. The Compute slot version of this field is read-write. This bit is reset by cold reset. 0b - Disabled 1b - Enabled
15-1 —	Reserved
0 APPLYCFG	Apply Configure for PMC1 Applies updated PDRUNCFG bits (SRAM power gates, RBB, AFBB, LVD, and HVD control bits) and/or RUNCTRL setting. Automatically clears when operation is done. This bit is reset by cold reset. This field has two copies separately accessed by the Compute and Sense slots. 0b - Operation is done 1b - Start configuration change, or operation has not completed

27.7.2.6 Interrupt Control in Sense Domain (INTRCTRL)

Offset

Register	Offset
INTRCTRL	10h

Function
Enables interrupt control for PMC interrupt sources.

Diagram

0 RBB1LVL	Reverse Body Bias Voltage for VDD1 Domain Indicates RBB Voltage for VDD1 domain. The Compute slot version of this field is read-write. This bit is reset by warm reset. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. **NOTE** Value change only takes affect after setting CTRL[APPLYCFG] or a mode change occurs. 0b - Voltage is set to 1.0 V 1b - Voltage is set to 1.3 V

27.7.2.15 Temperature Sensor Control (TSENSOR)

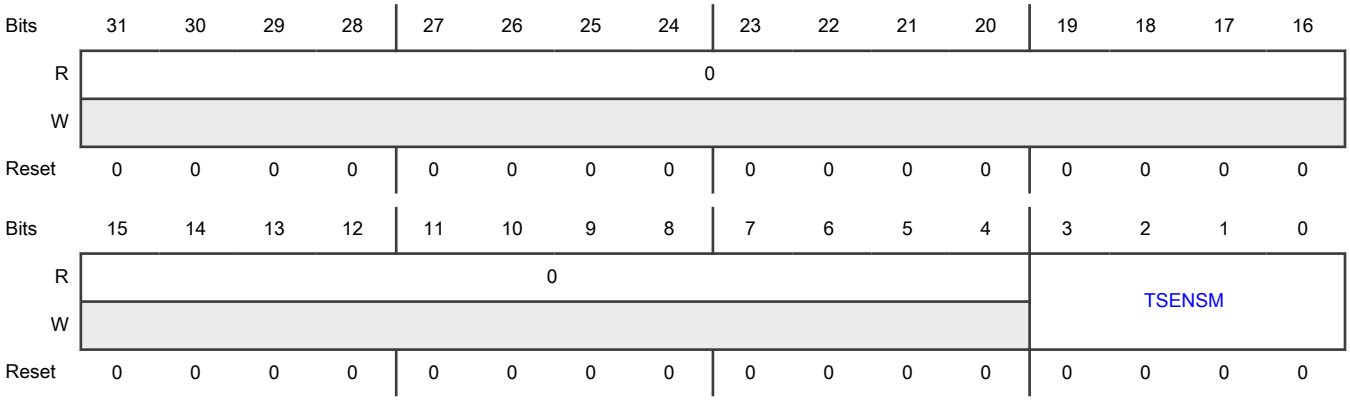
Offset

Register	Offset
TSENSOR	44h

Function

Controls the PMC temperature sensor measurement mode. See PMC temperature sensor for details.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 TSENSM	Temperature Sensor Mode Select Selects the temperature sensor mode according to the procedure described in PMC temperature sensor. All modes must be selected in sequence during the temperature measurement procedure to dynamically cancel various internal error sources. **NOTE** This field is shared between PMC0 and PMC1. Software should only do temperature measurement from one slot at a time. 0000b - Perform AD conversion and record C*_000 0001b - Perform AD conversion and record C*_001 0010b - Perform AD conversion and record C*_010 0011b - Perform AD conversion and record C*_011 0100b - Perform AD conversion and record CM_100 0101b - Perform AD conversion and record C*_101 0110b - Perform AD conversion and record C*_110 0111b - Perform AD conversion and record C*_111

27.7.2.16 Wake-up Configuration for Sense Domain (WAKEUP)

Offset

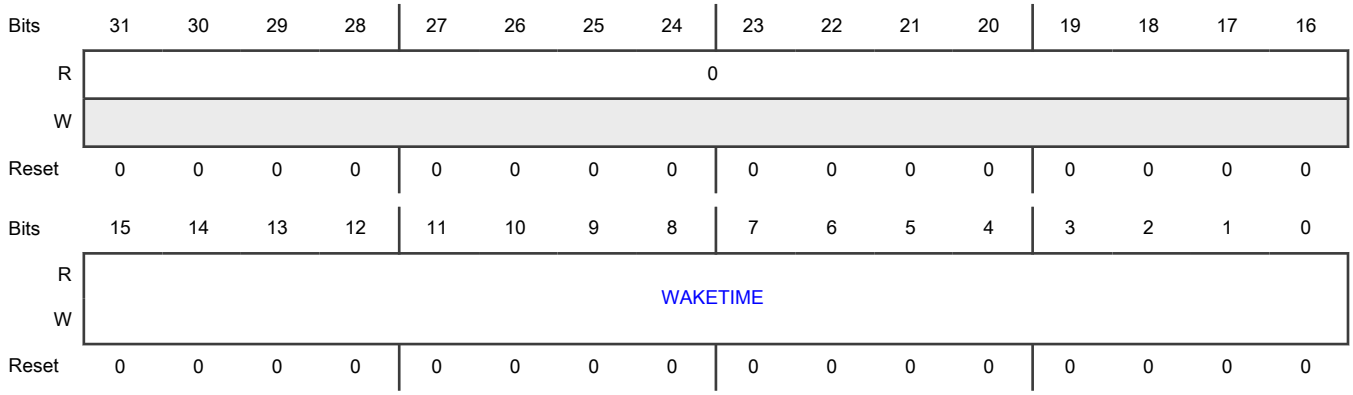
Register	Offset
WAKEUP	50h

Function

Sets the configuration of the general purpose wake-up counter.

The wake-up timer is enabled by INTRCTRL[AUTOWKIE], and will wake up the associated PMC slot when the associated CPU enters Deep Sleep mode. When the counter times out, PMC wakes up and generates an interrupt for that slot.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 WAKETIME	Wake-up Timer Sets timer to wake up from Deep Sleep mode after mode sequencing is completed. Time = value of [WAKETIME] / 16 MHz = value of [WAKETIME] / 16 in µs This bit is reset by warm reset. 0000_0000_0000_0000b - 0 0000_0000_0000_0001b - 62.5 ns = 1 / (16e + 6) 0000_0000_0000_0010b - 125 ns = 2 / (16e + 6) ...

27.7.2.17 Power Configuration (POWERCFG)

Offset

Register	Offset
POWERCFG	64h

Function

Indicates internal regulators and internal references during FDSR mode, FDPD modes, or when external supplies are used. Also configures the wait time for PMIC or external supplies to respond to changes on the PMIC_MODE pins.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-28 MODEDLY	Mode Delay Indicates delay to wait for external PMIC mode changes to complete after any mode value change occurs on the PMIC_MODE[1:0] pins. The PMIC_MODE pins change state whenever the aggregated PD*CFG0[PMICMODE] changes. • Time = Period of 4 clocks * 2 ^ value of [MODEDLY] • Reset value = 16 µs The Compute slot version of this field is read-write. This field in the Sense slot is read-only and shows the values written to the Compute slot. This bit is reset by cold reset. Values shown below are examples based on calculations with the period of 4 clocks (250 ns) at a frequency of 16 MHz. 0000b - 250 ns 0001b - 500 ns 0010b - 1000 ns 0011b - 2000 ns 0100b - 4000 ns 0101b - 8000 ns 0110b - 16 µs 0111b - 32 µs 1000b - 64 µs 1001b - 128 µs 1010b - 256 µs 1011b - 512 µs

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1100b - 1024 µs 1101b - 2048 µs 1110b - 4096 µs 1111b - 8192 µs
27-25 —	Reserved
24 FDPDBGLP	Force Band Gap during FDPD Mode to LP Mode In FDPD mode, force band gap to low-power mode. Rising VDD1V8 will not wake up the chip from FDPD mode when this bit is set. If clear, band gap will remain in high-power mode and consume 85 µA. This bit is reset by cold reset. **NOTE** This bit is cleared on wake-up from FDPD mode and any other cold reset! If the rising VDD1V8 is not used as the wake-up source then this bit should be set before entering FDPD every time. 0b - Enables band gap to high-power mode during FDPD mode and wakes up if VDD1V8 POR is asserted then negated 1b - Enables band gap to low-power mode during FDPD mode and will not wake up on VDD1V8 POR negation. RTC, INTR, or reset is used as wake-up
23-13 —	Reserved
12 DCDCPD	DCDC Power Down Indicates power down configuration for DCDC when using a PMIC or other external supply to drive VDDN. This bit is reset by cold reset. **NOTE** When set, the control logic waits for the external supply to rise above LVD trip whenever mode changes occur (APPLY_CFG/DeepSleep, etc.). If VDDN never rises above the LVD trip then the control state machines will get stuck. Software and the external supply controls must make sure that the LVD trip level is less than the final value of the external supply during mode changes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE If this bit is set, then software should also write 11b to PMC0.PDRUNCFG0[DCDC_MODE], PMC0.PDSLEEPCFG0[DCDC_MODE], PMC1.PDRUNCFG0[DCDC_MODE], and PMC1.PDSLEEPCFG0[DCDC_MODE] to minimize power when the other blocks of the PMC are all in low power mode and/or powered down. 0b - Power on 1b - Power down
11-10 —	Reserved
9 LDO2PD	LDO VDD2 Power Down Indicates power down configuration for DCDC when using a PMIC or other external supply to drive VDD2. This bit is reset by cold reset. **NOTE** When set, the control logic waits for the external supply to rise above LVD trip whenever mode changes occur (APPLY_CFG/DeepSleep, etc.). If VDD2 never rises above the LVD trip then the control state machines will get stuck. Software and the external supply controls must make sure that the LVD trip level is less than the final value of the external supply during mode changes. 0b - Power on 1b - Power down
8 LDO1PD	LDO VDD1 Power Down Indicates power down configuration for DCDC when using a PMIC or other external supply to drive VDD1. This bit is reset by cold reset. **NOTE** When set, the control logic waits for the external supply to rise above LVD trip whenever mode changes occur (APPLY_CFG/DeepSleep, etc.). If VDD1 never rises above the LVD trip then the control state machines will get stuck. Software and the external supply controls must make sure that the LVD trip level is less than the final value of the external supply during mode changes. 0b - Power on 1b - Power down
7 SCPCPD	SCPC Power Down Indicates power down configuration for both SCPCs when a PMIC is driving. This bit is reset by cold reset.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Power on 1b - Power down
6 FDDCPD	DCDC Power Down in FDSR Mode Indicates power down configuration for DCDC in FDSR mode. This bit is overridden by [DCDCPD] when [DCDCPD] is set to 1. This bit is reset by cold reset. 0b - Power on 1b - Power down
5 FDLDO2PD	LDO VDD2 Power Down in FDSR Mode Indicates power down configuration for LDO VDD2 in FDSR mode. This bit is overridden by [LDO2PD] when [LDO2PD] is set to 1. This bit is reset by cold reset. 0b - Power on 1b - Power down
4 FDLDO1PD	LDO VDD1 Power Down in FDSR Mode Indicates power down configuration for LDO VDD1 in FDSR mode. This bit is overridden by [LDO1PD] when [LDO1PD] is set to 1. This bit is reset by cold reset. 0b - Power on 1b - Power down
3-2 —	Reserved
1 FDSCP2PD	SCPC VDD2 Power Down in FDSR Mode Indicates power down configuration for SCPC VDD2 in FDSR mode. This bit is overridden by [SCPCPD] when [SCPCPD] is set to 1. This bit is reset by cold reset. 0b - Power on 1b - Power down
0 FDSCP1PD	SCPC VDD1 Power Down in FDSR Mode Indicates power down configuration for SCPC VDD1 in FDSR mode. This bit is overridden by [SCPCPD] when [SCPCPD] is set to 1. This bit is reset by cold reset. 0b - Power on

27.7.2.18 3 V Capable VDDIO Range Select (PADVRANGE)

Offset

Register	Offset
PADVRANGE	68h

Function

Indicates the allowed voltage range for the 3 V capable IOs which have a detector to Sense the value of supply, but this consumes current. To reduce power the IOs can be configured for 1.8 V or 3.3 V operation, powering down the detector, but requiring the application to restrict the IO supply voltage to the selected range. The detector is enabled after any cold reset.

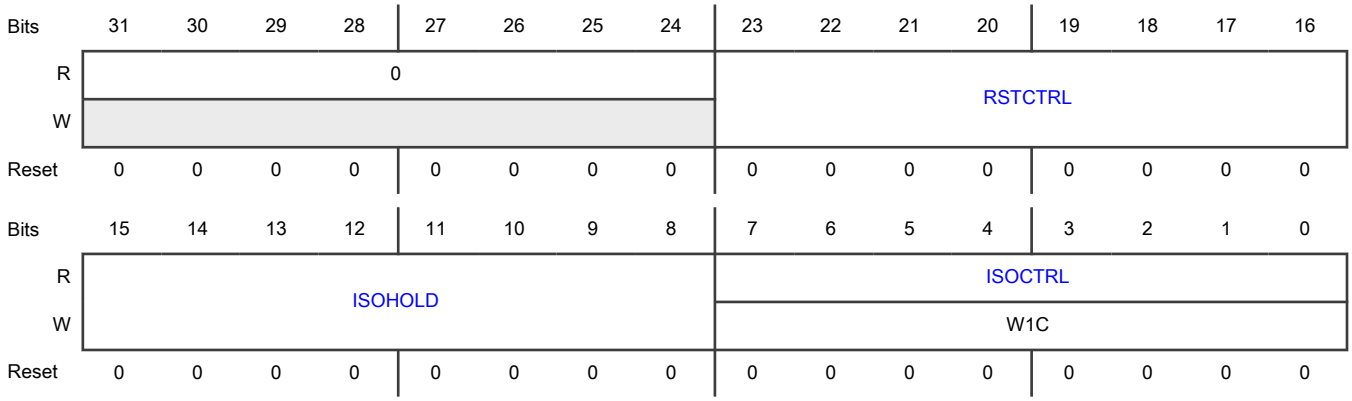
Bit 1	Port 2	VDD2_COM
Bit 0	Port 0/1/3	VDD2_COM

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16	Reset Control

Table continues on the next page...

Table continued from the previous page...

Field	Function
RSTCTRL	Sets the IO bank reset which tristates the ports. Intended to be used prior to powering off the VDDIO supplies. This bit is reset by cold reset. 0000_0000b - IO banks are not reset 1xxx_xxxxb - PMIC_I2C reset = tristate x1xx_xxxxb - Port 8/9/10 reset = tristate xx1x_xxxxb - Port 7 reset = tristate xxx1_xxxxb - Port 6 reset = tristate xxxx_1xxxb - Port 5 reset = tristate xxxx_x1xxb - Port 4 reset = tristate xxxx_xx1xb - Port 2 reset = tristate xxxx_xxx1b - Port 0/1/3 reset = tristate
15-8 ISOHOLD	IO Bank Isolation Hold Maintains IO bank isolation state after wake-up from FDSR/DPD modes. If clear, the IO bank's state will be retained during FDSR & DPD modes, but will be controllable after wake-up. Clear to 0 so that after PMC powers the controlling logic domain, the isolation is automatically removed and the port is once again controlled by the controlling domain. If the controlling domain is state-retained, then the port state will not change when the isolation is auto-negated. If set, the IO bank will remain in retain mode until ISOCTRL cleared by software. Set to 1 for banks that you want to remain isolated even after power is restored to the controlling logic. If the controlling logic's state is not retained, this enables the software to configure the controlling logic back to its previous state before clearing the isolation/retention to restore control back to the logic. This bit is reset by cold reset. 0000_0000b - IO bank is controllable on wake-up from FDSR/DPD mode 1xxx_xxxxb - PMIC_I2C is retained/isolated on wake-up from FDSR/DPD mode. Software must clear [ISOCTRL] bit 7 to regain control x1xx_xxxxb - Port 8/9/10 is retained/isolated on wake-up from FDSR/DPD mode. Software must clear [ISOCTRL] bit 6 to regain control xx1x_xxxxb - Port 7 is retained/isolated on wake-up from FDSR/DPD mode. Software must clear [ISOCTRL] bit 5 to regain control xxx1_xxxxb - Port 6 is retained/isolated on wake-up from FDSR/DPD mode. Software must clear [ISOCTRL] bit 4 to regain control xxxx_1xxxb - Port 5 is retained/isolated on wake-up from FDSR/DPD mode. Software must clear [ISOCTRL] bit 3 to regain control xxxx_x1xxb - Port 4 is retained/isolated on wake-up from FDSR/DPD mode. Software must clear [ISOCTRL] bit 2 to regain control xxxx_xx1xb - Port 2 is retained/isolated on wake-up from FDSR/DPD mode. Software must clear [ISOCTRL] bit 1 to regain control

Table continues on the next page...

Table continued from the previous page...

Field	Function
	xxxx_xxx1b - Port 0/1/3 is retained/isolated on wake-up from FDSR/DPD mode. Software must clear [ISOCTRL] bit 0 to regain control
7-0 ISOCTRL	IO bank State Retain Control Controls IO bank state retain, one bit for each VDDIO/VDD domain pair that consists of a controlling VDD logic domain (for example, VDD2_COM or VDD1_SENSE) and a VDDIO supply (VDDIO, VDDIO1, etc.). Hardware sets this bit when driving domain powers down (FDSR/DPD). This bit cannot be cleared if associated domain is not powered. This bit is reset by cold reset. 0000_0000b - IO bank is controllable 1xxx_xxxxb - PMIC_I2C is in retain mode x1xx_xxxxb - Port 8/9/10 is in retain mode xx1x_xxxxb - Port 7 is in retain mode xxx1_xxxxb - Port 6 is in retain mode xxxx_1xxxb - Port 5 is in retain mode xxxx_x1xxb - Port 4 is in retain mode xxxx_xx1xb - Port 2 is in retain mode xxxx_xxx1b - Port 0/1/3 is in retain mode

27.7.2.20 PD Run Configuration 0 in Sense Domain (PDRUNCFG0)

Offset

Register	Offset
PDRUNCFG0	A0h

Function

Configures power down for CPU1 in active mode. This drives the aggregation input for the power down and other controls of PMC functions when the Compute domain is in active mode. See PD*CFG and aggregation. Reserved bits must not be changed by user software.

NOTE

Changes to this register do not affect PMC until Sense domain CTRL[APPLYCFG] is set, triggering the state machines or CPU1 enters and then exits Deep Sleep mode.

Field	Function
	NOTE To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 00b - Bypass mode 01b - High-power mode 10b,11b - Low-power mode
13 DCDC_VSEL	Select DCDC Voltage Selects PMC DCDC voltage and LVD level VDDN supply rail from DCDCVSEL registers. DCDCVSEL[VSEL1] is the higher voltage for aggregation. This field is aggregated high. For details on aggregation logic, see PD*CFG and aggregation. This field has 2 copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Selects DCDCVSEL[VSEL0] level 1b - Selects DCDCVSEL[VSEL1] level
12-11 DCDC_MODE	DCDC Power Mode Selects DCDC power mode. When high-power mode is selected, the PMC references automatically enter the high-power mode. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has 2 copies separately accessed by the Compute and Sense slots. This field is reset by warm reset. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. **NOTE** When using an external supply to power VDDN and POWERCFG[DCDCPD] = 1b, software must also set field DCDC_MODE = 11b in PMC0.PDRUNCFG0, PMC0.PDSLEEPCFG0, PMC1.PDRUNCFG0, and PMC1.PDSLEEPCFG to minimze power when all other PMC subblocks go to low power or power down mode. 00b - Enables DCDC in high-power mode 01b - Enables DCDC in low-power mode 10b - Enables DCDC in ultra-low-power mode 11b - Enables DCDC in ultra-low-power mode
10	Power Down MIPI PHY in VDD2 Domain

Table continues on the next page...

Table continued from the previous page...

Field	Function
V2MIPI_PD	Controls power down of the MIPI PHY. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. **NOTE** MIPI PHY must be powered down if VDD2_MEDIA is in DSR mode. 0b - Power on 1b - Power down
9 V2DSP_PD	Power Down VDD2_DSP **NOTE** Read only. Value used for aggregation. Disables VDD2_DSP (HiFi4). Software must power down the HiFi4 cache and TCM periphery power switches prior to powering down the HiFi4, and the memories must not be powered on until after the HiFi4 is powered on. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. **NOTE** VDD2_DSP must be powered down if VDD2_COMP is in DSR mode. 0b - Power on 1b - Power down
8 VNCOM_DSR	Power Switch and DSR for VDDN_COM Enables DSR mode for VDDN_COM domain. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. You must write 0 to this bit and apply it before entering DPD mode. Write 0 to the bit in either Compute or Sense slot since it is aggregated low. You can write 1 to this bit again after DPD wakeup. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Powers on VDDN_COM domain 1b - Enables VDDN_COM domain in DSR mode
7 V2COM_DSR	Power Switch and DSR Enable for VDD2_COM

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Enables DSR mode for VDD2_COM domain. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. The Compute slot version of this field is read-only. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Powers on VDD2_COM 1b - Enables DSR mode in VDD2_COM
6 V2NMED_DSR	Power Switch and DSR for VDD2 and VDDN Media Enables DSR mode for VDD2 and VDDN media domains. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. You must write 0 to this bit and apply it before entering DPD mode. Write 0 to the bit in either Compute or Sense slot since it is aggregated low. You can write 1 to this bit again after DPD wakeup. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Powers on VDD2 and VDDN media domains 1b - Enables VDD2 and VDDN media domains in DSR mode
5 V2COMP_DSR	Power Switch and DSR Enable in VDD2_COMP Domain **NOTE** Read only. Value used for aggregation. Enables DSR mode for VDD2_COMP domain. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. The Sense slot version of this field is read-only. 0b - Powers on VDD2_COMP 1b - Enables DSR mode in VDD2_COMP
4 FDPD	Full Deep Power Down (FDPD) Mode **NOTE** Read only. Value used for aggregation. Activates isolation and corrects sequencing for FDPD mode. The chip will only go to FDPD mode if both domains enter Deep Sleep with this bit set. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. 0b - Disables

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enables FDPD mode
3 DPD	Deep Power Down (DPD) Mode **NOTE** Read only. Value used for aggregation. Activates isolation and corrects sequencing for DPD mode. The chip will only go to DPD mode if both domains enter Deep Sleep with this bit set, and at least one domain has [FDPD] cleared. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. 0b - Disables 1b - Enables DPD mode
2 FDSR	Full Deep Sleep Retention (FDSR) Mode **NOTE** Read only. Value used for aggregation. Puts all power switches into DSR or power down. All core domains go to DSR mode or power down mode depending on domain. Muxes VDDN_SR to VDD2 before ramping down supply voltages and turning off VDDN. This is the only way to put VDD1_SENSE domain into DSR mode and control the associated power switch. The chip will only go to FDSR mode if both domains enter Deep Sleep with this bit set, and [DPD] and [FDPD] are not set. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. 0b - All power switch states controlled by their respective PD*CFG bits 1b - All core domains in DSR or Power Down mode
1-0 PMICMODE	PMIC Power Mode Select Sets value of PMIC_MODE output pins. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 00b - Drives PMIC_MODE pins to 0h 01b - Drives PMIC_MODE pins to 1h 10b - Drives PMIC_MODE pins to 2h 11b - Drives PMIC_MODE pins to 3h

27.7.2.21 PD Run Configuration 1 in Sense Domain (PDRUNCFG1)

Offset

Register	Offset
PDRUNCFG1	A4h

Function

Configures power down for CPU1 in active mode. This drives the aggregation input for the power down and other controls of PMC functions when Compute domain is in active mode. See PD*CFG and aggregation. Reserved bits must not be changed by user software.

NOTE

Changes to this register do not affect PMC until Sense domain CTRL[APPLYCFG] is set, triggering the state machines or CPU1 enters and then exits the Deep Sleep mode.

In this case, PMC references will be in high-power mode 1b - Power down

27.7.2.22 PD Run Configuration 2 in Sense Domain (PDRUNCFG2)

Offset

Register	Offset
PDRUNCFG2	A8h

Function

Configures main memory array and periphery power down for CPU1 in active mode. This drives aggregation input for the power down control of the arrays and peripheries of the main SRAM partitions when CPU1 is in active mode. If a partition's aggregated PD*CFG2[SRAMn] is 0, then the array is powered and the periphery power is controlled by PD*CFG3. If PD*CFG2[SRAMn] is 1, then the partition's array and periphery are both powered off.

This register is reset by cold reset.

NOTE

Changes to this register do not affect the memories until Sense domain CTRL[APPLYCFG] is set, triggering the state machines, or CPU1 enters and then exits Deep Sleep mode.

29-0 SRAMn	Power Down RAM Partition n Array Powers down the array and periphery of the associated memory, regardless of PD*CFG3 state. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Array power on, periphery power controlled by PD*CFG3 1b - Power down

27.7.2.23 PD Run Configuration 3 in Sense Domain (PDRUNCFG3)

Offset

Register	Offset
PDRUNCFG3	ACh

Function

Powers down the selected main memory partitions' periphery logic to save power, while maintaining the contents if the corresponding PD*CFG2[SRAMn] is configured to keep the array on.

This register is reset by cold reset.

NOTE

SRAM0 to SRAM17 are the VDD2_COM main memories. SRAM18 to SRAM29 are the VDD1_SENSE main memories. The memory map in some other part of the RM should have this info, and should also include (for internal use) how many instances are in each partition, and size of these memory instances.

NOTE

- Memory peripheries are powered down whenever **the array is powered down** or **the associated power domain is in *DSR mode* or *powered down***
- Changes to this register do not affect the memories until Sense domain CTRL[APPLYCFG] is set, triggering the state machines, or CPU1 enters and then exits Deep Sleep mode.

27.7.2.25 PD Run Configuration 5 in Sense Domain (PDRUNCFG5)

Offset

Register	Offset
PDRUNCFG5	B4h

Function

Configures peripheral memory periphery power down for CPU1 in active mode. This drives aggregation input for the power down control of the peripheries of the Peripherals" SRAM partitions when CPU1 is in active mode. If a partition's aggregated PD*CFG4 bit is 0, then the array is powered and the periphery power is controlled by PD*CFG5. If the PD*CFG4 bit is 1, then the periphery is powered off and the array power is determined by PD*CFG4. When the power domain of the peripheral in DSR mode, the peripheries for all SRAMs in that domain are automatically powered down.

This register is reset by cold reset.

NOTE

- Memory peripheries are powered down whenever **the array is powered down** or **the associated power domain is in *DSR mode* or *powered down***
- Changes to this register do not affect the memories until Sense domain CTRL[APPLYCFG] is set, triggering the state machines, or CPU1 enters and then exits Deep Sleep mode.

27.7.2.26 PD Sleep Configuration 0 in Sense Domain (PDSLEEPCFG0)

Offset

Register	Offset
PDSLEEPCFG0	B8h

Function

Configures power down for CPU1 in Deep Sleep mode. This drives the aggregation input for the power down and other controls of PMC functions when Sense domain is in Deep Sleep mode. See PD*CFG and aggregation. Reserved bits must not be changed by user software.

NOTE

Changes to this register do not affect PMC until Sense domain enters Deep Sleep mode.

	0b - Power on 1b - Power down
22 RBB1_PD	Power Down RBB in VDD1 Domain Controls RBB mode for VDD1 domain. RBB mode should only be enabled when VDD1 domain is not clocked. This field is aggregated high. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - If PDSLEEPCFG0[AFBB1_PD] = 1, power on. Else power down 1b - Power down
21-20 LDO2_VSEL	LDO VDD2 Voltage Select Selects one of four voltages in LDOVDD2VSEL register. Also selects from one of four LVD trip points in LVDVDD2CTRL. 00b means the lowest voltage and 11b means the highest voltage. This field is aggregated high. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 00b - Selects LDOVDD2VSEL[VSEL0] and LVDVDD2CTRL[LVL0] level 01b - Selects LDOVDD2VSEL[VSEL1] and LVDVDD2CTRL[LVL1] level 10b - Selects LDOVDD2VSEL[VSEL2] and LVDVDD2CTRL[LVL2] level 11b - Selects LDOVDD2VSEL[VSEL3] and LVDVDD2CTRL[LVL3] level
19-18 LDO2_MODE	LDO VDD2 Regulator Mode Selects regulation mode of LDO VDD2. When high-power mode is selected, the PMC references automatically enter high-power mode. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 00b - Bypass mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
	01b - High-power mode 10b,11b - Low-power mode
17-16 LDO1_VSEL	LDO VDD1 Voltage Select Selects one of four voltages in LDOVDD1VSEL register. Also selects from one of four LVD trip points in LVDVDD1CTRL. 00b means the lowest voltage and 11b means the highest voltage. This field is aggregated high. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 00b - Selects LDOVDD1VSEL[VSEL0] and LVDVDD1CTRL[LVL0] level 01b - Selects LDOVDD1VSEL[VSEL1] and LVDVDD1CTRL[LVL1] level 10b - Selects LDOVDD1VSEL[VSEL2] and LVDVDD1CTRL[LVL2] level 11b - Selects LDOVDD1VSEL[VSEL3] and LVDVDD1CTRL[LVL3] level
15-14 LDO1_MODE	LDO VDD1 Regulator Mode Selects regulation mode of LDO VDD1. When high-power mode is selected, the PMC references automatically enter high-power mode. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 00b - Bypass mode 01b - High-power mode 10b,11b - Low-power mode
13 DCDC_VSEL	DCDC Voltage Select Selects the PMC DCDC voltage and LVD level VDDN supply rail from the DCDCVSEL register. DCDCVSEL[VSEL1] is the higher voltage for aggregation. This field is aggregated high. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Selects DCDCVSEL[VSEL0] level 1b - Selects DCDCVSEL[VSEL1] level
12-11 DCDC_MODE	DCDC Power Mode Selects DCDC power mode. When high-power mode is selected, the PMC references automatically enter the high-power mode. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has 2 copies separately accessed by the Compute and Sense slots. This field is reset by warm reset. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. **NOTE** When using an external supply to power VDDN and POWERCFG[DCDCPD] = 1b, software must also set field DCDC_MODE = 11b in PMC0.PDRUNCFG0, PMC0.PDSLEEPCFG0, PMC1.PDRUNCFG0, and PMC1.PDSLEEPCFG to minimze power when all other PMC subblocks go to low power or power down mode. 00b - Enables DCDC in high-power mode 01b - Enables DCDC in low-power mode 10b - Enables DCDC in ultra-low-power mode 11b - Enables DCDC in ultra-low-power mode
10 V2MIPI_PD	Power Down MIPI PHY in VDD2 Domain Controls power down of the MIPI PHY. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. **NOTE** MIPI PHY must be powered down if VDD2_MEDIA is in DSR mode. 0b - Power on 1b - Power down
9 V2DSP_PD	Power Down VDD2_DSP Configuration used for V2DSP_PD for aggregation. Disables VDD2_DSP (HiFi4). This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. The Compute slot version of this field is read-write.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. **NOTE** VDD2_DSP must be powered down if VDD2_COMP is in DSR mode. **NOTE** Software must power down the HiFi4 cache and TCM periphery power switches prior to powering down the HiFi4, and the memories must not be powered on until the HiFi4 is powered. 0b - Power on 1b - Power down
8 VNCOM_DSR	Power Switch and DSR Enable in VDDN_COM Domain Enables DSR mode for VDDN_COM domain. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Powers on VDDN_COM 1b - Enables DSR mode in VDDN_COM
7 V2COM_DSR	Power Switch and DSR Enable in VDD2_COM Domain Enables DSR mode for VDD2_COM domain. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Powers on VDD2_COM 1b - Enables DSR mode in VDD2_COM
6 V2NMED_DSR	Power Switch and DSR Enable in VDD2_MEDIA and VDDN_MEDIA Domains Enables DSR mode for VDD2_MEDIA and VDDN_MEDIA domains. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. **NOTE** Merged VDD2 and VDDN media switch controls. 0b - Powers on VDD2_MEDIA and VDDN_MEDIA 1b - Enables DSR mode in VDD2_MEDIA and VDDN_MEDIA
5 V2COMP_DSR	Power Switch and DSR Enable in VDD2_COMP Domain Configuration for V2COMP_DSR used for aggregation. Enables DSR mode for VDD2_COMP domain. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. The Compute slot version of this field is read-write. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Powers on VDD2_COMP 1b - Enables DSR mode in VDD2_COMP
4 FDPD	Full Deep Power Down (FDPD) Mode Activates isolation and corrects sequencing for FDPD mode. The chip will only go to FDPD mode if both domains enter Deep Sleep with this bit set. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. 0b - Disables 1b - Enables FDPD mode
3 DPD	Deep Power Down (DPD) Mode Activates isolation and corrects sequencing for DPD mode. The chip will only go to DPD mode if both domains enter Deep Sleep with this bit set, and at least one domain has [FDPD] cleared. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. You must clear this bit whenever PDSLEEPCFG0[FDSR] is set. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Disables 1b - Enables DPD mode
2	Full Deep Sleep Retention (FDSR) Mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
FDSR	Puts all power switches into DSR or power down. All core domains go to DSR mode or power down mode depending on domain. Muxes VDDN_SR to VDD2 before ramping down supply voltages and turning off VDDN. This is the only way to put VDD1_SENSE domain into DSR mode and control the associated power switch. The chip will only go to FDSR mode if both domains enter Deep Sleep with this bit set, and [DPD] and [FDPD] are not selected instead. You must clear this bit whenever PDSLEEPCFG0[DPD] is set. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - All power switch states controlled by their respective PD*CFG bits 1b - All core domains in DSR or Power Down mode
1-0 PMICMODE	PMIC Mode Sets value of PMIC_MODE output pins. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 00b - Drives PMIC_MODE pins to 0h 01b - Drives PMIC_MODE pins to 1h 10b - Drives PMIC_MODE pins to 2h 11b - Drives PMIC_MODE pins to 3h

27.7.2.27 PD Sleep Configuration 1 in Sense Domain (PDSLEEPCFG1)

Offset

Register	Offset
PDSLEEPCFG1	BCh

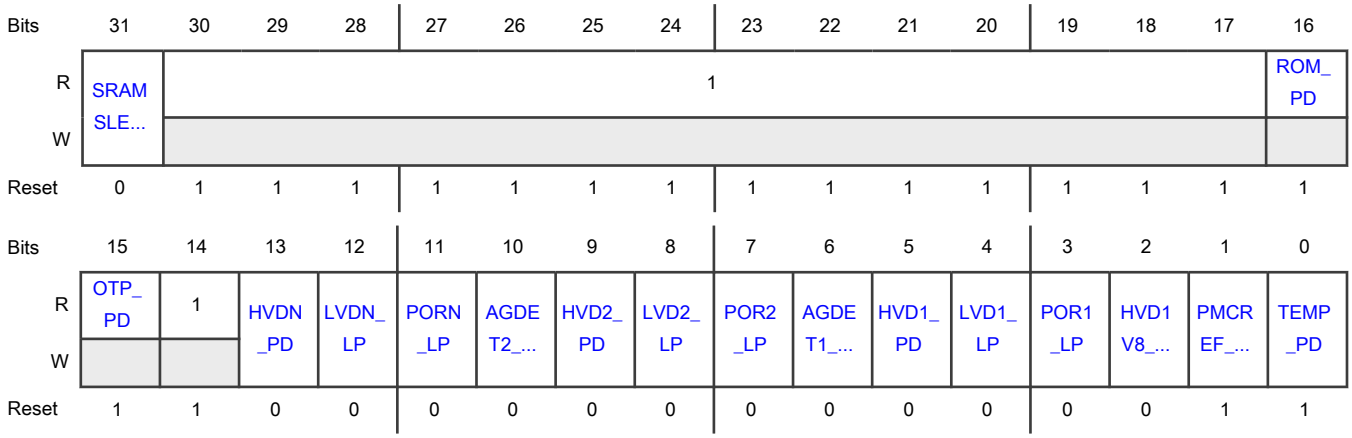
Function

Configures power down for CPU1 in Deep Sleep mode. This drives the aggregation input for the power down and other controls of PMC functions when Sense domain is in Deep Sleep mode. See PD*CFG and aggregation. Reserved bits must not be changed by user software.

NOTE

Changes to this register do not affect PMC until Sense domain enters Deep Sleep mode.

Diagram



Fields

Field	Function
31 SRAMSLEEP	SRAM Sleep Mode Sets SRAM sleep mode. This is needed when VDD Core can be < 0.85 V to ensure contents retained. No power savings. Memories are not accessible in RAM sleep mode. It should only be set in PDSLEEPCFG. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Normal 1b - Sleep
30-17 —	Reserved
16 ROM_PD	ROM Power Down Configuration used for ROM_PD for aggregation. Controls the power switch configuration for the ROM. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. The Compute slot version of this field is read-write. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Power on 1b - Power down
15	OTP Power Down in VDD2 Domain

Table continues on the next page...

Table continued from the previous page...

Field	Function
OTP_PD	Configuration used for OTP_PD for aggregation. Controls the power switch configuration for OTP0 VDD2 Core. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. The Compute slot version of this field is read-write. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Power on 1b - Power down
14 —	Reserved
13 HVDN_PD	HVD Power Down in VDDN Domain Controls the power mode of the VDDN high-voltage detect. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Power on. In this case the aggregated PDCFGSTATUS1[PMCREF_LP] bit will be in high-power mode 1b - Power down
12 LVDN_LP	LVD Low power in VDDN Domain Sets LVD in low-power mode in VDDN domain. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - High-power mode. In this case the aggregated PDCFGSTATUS1[PMCREF_LP] bit will be in high-power mode 1b - Low-power mode
11 PORN_LP	POR Low Power in VDDN Domain Sets POR in low-power mode in VDDN domain. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots.

Field	Function
	NOTE To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - High-power mode. In this case the aggregated PDCFGSTATUS1[PMCREF_LP] bit will be in high-power mode 1b - Low-power mode
10 AGDET2_PD	aGDET Power Down in VDD2 Domain Powers down the VDD2 analog glitch detect. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Power on 1b - Power down
9 HVD2_PD	HVD Power Down in VDD2 Domain Controls the power mode of the VDD2 high-voltage detect. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Power on. In this case the aggregated PDCFGSTATUS1[PMCREF_LP] bit will be in high-power mode 1b - Power down
8 LVD2_LP	LVD Low power in VDD2 Domain Sets LVD in low-power mode in VDD2 domain. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - High-power mode. In this case the aggregated PDCFGSTATUS1[PMCREF_LP] bit will be in high-power mode 1b - Low-power mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
7 POR2_LP	POR Low power in VDD2 Domain Sets POR in low-power mode in VDD2 domain. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - High-power mode. In this case the aggregated PDCFGSTATUS1[PMCREF_LP] bit will be in high-power mode 1b - Low-power mode
6 AGDET1_PD	aGDET Power Down in VDD1 Domain Powers down the VDD1 analog glitch detect. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Power on 1b - Power down
5 HVD1_PD	HVD Power Down in VDD1 Domain Controls the power mode of the VDD1 high-voltage detect. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Power on. In this case the aggregated PDCFGSTATUS1[PMCREF_LP] bit will be in high-power mode 1b - Power down
4 LVD1_LP	LVD Low power in VDD1 Domain Sets LVD in low-power mode in VDD1 domain. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - High-power mode. In this case the aggregated PDCFGSTATUS1[PMCREF_LP] bit will be in high-power mode 1b - Low-power mode
3 POR1_LP	POR Low Power in VDD1 Domain Sets POR in low-power mode in VDD1 domain. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - High-power mode. In this case the aggregated PDCFGSTATUS1[PMCREF_LP] bit will be in high-power mode 1b - Low-power mode
2 HVD1V8_PD	HVD VDD1V8 Power Down This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Power on. In this case the aggregated PDCFGSTATUS1[PMCREF_LP] bit will be in high-power mode 1b - Power down
1 PMCREF_LP	PMC References Low Power Sets PMC reference in low-power mode if high power is not needed by any regulators, HVDs, POR, LVD, AFBB, or the PMC temperature sensor. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - High-power mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Low-power mode if not overridden by any *_PD bits
0 TEMP_PD	PMC Temperature Sensor Power Down Controls the power switch for the PMC temperature sensor. This field is aggregated low. For details on aggregation logic, see PD*CFG and aggregation. This field has two copies separately accessed by the Compute and Sense slots. **NOTE** To update PMC's configuration with the updated register value software needs to set CTRL[APPLYCFG], or a mode change must occur. 0b - Power on. In this case, PMC references will be in high-power mode 1b - Power down

27.7.2.28 PD Sleep Configuration 2 in Sense Domain (PDSLEEPCFG2)

Offset

Register	Offset
PDSLEEPCFG2	C0h

Function

Configures power down for main memory array and periphery for CPU1 in Deep Sleep mode. This drives aggregation input for the power down control of the arrays and peripheries of the min SRAM partitions when CPU1 is in Deep Sleep mode. If a partition's aggregated PD*CFG2[SRAMn] is 0, then the array is powered and the periphery power is controlled by PD*CFG3. If PD*CFG2[SRAMn] is 1, then the partition's array and periphery are both powered off.

This register is reset by cold reset.

NOTE

Changes to this register do not affect the memories until CPU1 enters Deep Sleep mode.

27.7.2.29 PD Sleep Configuration 3 in Sense Domain (PDSLEEPCFG3)

Offset

Register	Offset
PDSLEEPCFG3	C4h

Function

Powers down the selected main memory partitions' periphery logic to save power, while maintaining the contents if the corresponding PD*CFG2[SRAMn] is configured to keep the array on.

This register is reset by cold reset.

NOTE

- Memory peripheries are powered down whenever **the array is powered down** or **the associated power domain is in *DSR mode* or *powered down*** .
- Changes to this register do not affect the memories until CPU1 enters Deep Sleep mode.

27.7.2.31 PD Sleep Configuration 5 in Sense Domain (PDSLEEPCFG5)

Offset

Register	Offset
PDSLEEPCFG5	CCh

Function

Configures power down for peripheral memory periphery for CPU1 in Deep Sleep mode. This drives aggregation input for the power down control of the peripheries of the Peripherals" SRAM partitions when CPU1 is in Deep Sleep. If a partition's aggregated PD*CFG4 bit is 0, then the array is powered and the periphery power is controlled by PD*CFG5. If the PD*CFG4 bit is 1, then the periphery is powered off and the array power is determined by PD*CFG4. When the power domain of the Peripheral in DSR mode the peripheries for all SRAMs in that domain are automatically powered down.

This register is reset by cold reset.

NOTE

- Memory peripheries are powered down whenever **the array is powered down** or **the associated power domain is in *DSR mode* or *powered down*** .
- Changes to this register do not affect the memories until CPU1 enters Deep Sleep mode.

Fields

Field	Function
31 —	Reserved
30 —	Reserved
29 RBBSR2_PD	SRAM RBB Power Down in VDD2 Domain Indicates SRAM RBB power down status in VDD2 domain. SRAM RBB should be activated only when no SRAMs in the domain are accessed. This bit is reset by warm reset. 0b - Power on 1b - Power down
28 RBBSR1_PD	Power Down SRAM RBB in VDD1 Domain Indicates SRAM RBB power down status in VDD1 domain. SRAM RBB should be activated only when no SRAMs in the domain are accessed. This bit is reset by warm reset. 0b - Power on 1b - Power down
27	AFBB Power Down in VDDN domain Indicates AFBB power down status in VDDN domain.

Table continues on the next page...

Table continued from the previous page...

Field	Function
AFBBN_PD	This bit is reset by warm reset. 0b - Power on 1b - Power down
26 RBBN_PD	RBB Power Down in VDDN domain Indicates RBB power down status in VDDN domain. This bit is reset by warm reset. 0b - Enables RBB if the aggregated value of [AFBBN_PD] = 1, otherwise RBB is disabled 1b - Power down
25 AFBB2_PD	AFBB Power Down in VDD2 domain Indicates AFBB power down status in VDD2 domain. This bit is reset by warm reset. 0b - Power 1b - Power down
24 RBB2_PD	RBB Power Down in VDD2 domain Indicates RBB power down status in VDD2 domain. This bit is reset by warm reset. 0b - Enables RBB if the aggregated value of [AFBB2_PD] = 1, otherwise RBB is disabled 1b - Power down
23 AFBB1_PD	AFBB Power Down in VDD1 domain Indicates AFBB power down status in VDD1 domain. This bit is reset by warm reset. 0b - Power on 1b - Power down
22 RBB1_PD	Power Down RBB in VDD1 domain Indicates RBB power down status in VDD1 domain. This bit is reset by warm reset. 0b - Enables RBB if the aggregated value of [AFBB1_PD] = 1, otherwise RBB is disabled 1b - Power down
21-20 LDO2_VSEL	LDO VDD2 Voltage Selection Indicates the selected level for LDO VDD2 and LVD from the LDOVDD2VSEL and LVDVDD2CTRL registers. This bit is reset by warm reset.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b - LDOVDD2VSEL[VSEL0] and LVDVDD2CTRL[LVL0] level selected (lowest voltage) 01b - LDOVDD2VSEL[VSEL1] and LVDVDD2CTRL[LVL1] level selected 10b - LDOVDD2VSEL[VSEL2] and LVDVDD2CTRL[LVL2] level selected 11b - LDOVDD2VSEL[VSEL3] and LVDVDD2CTRL[LVL3] level selected (highest voltage)
19-18 LDO2_MODE	LDO VDD2 Regulator Mode Indicates the effective regulation mode for LDO VDD2. This bit is reset by warm reset. 00b - LDO VDD1 is in bypass mode 01b - LDO VDD2 is in high-power mode 10b,11b - LDO VDD2 is in low-power mode
17-16 LDO1_VSEL	LDO VDD1 Voltage Selection Indicates the selected level for LDO VDD1 and LVD from the LDOVDD1VSEL and LVDVDD1CTRL registers. This bit is reset by warm reset. 00b - LDOVDD1VSEL[VSEL0] and LVDVDD1CTRL[LVL0] level selected (lowest voltage) 01b - LDOVDD1VSEL[VSEL1] and LVDVDD1CTRL[LVL1] level selected 10b - LDOVDD1VSEL[VSEL2] and LVDVDD1CTRL[LVL2] level selected 11b - LDOVDD1VSEL[VSEL3] and LVDVDD1CTRL[LVL3] level selected (highest voltage)
15-14 LDO1_MODE	LDO VDD1 Regulator Mode Indicates the effective regulation mode for LDO VDD1. This bit is reset by warm reset. 00b - LDO VDD1 is in bypass mode 01b - LDO VDD1 is in high-power mode 10b,11b - LDO VDD1 is in low-power mode
13 DCDC_VSEL	DCDC Voltage Selection Indicates the selection of DCDC voltage and VDDN LVD levels from the DCDCVSEL and LVDVDDNCTRL registers. This bit is reset by warm reset. This bit shows the effective aggregated value based on the CPU0 and CPU1 status and the PDRUNCFG and PDSLEEPCFG registers. 0b - [VSEL0] level selected 1b - [VSEL1] level selected
12-11	DCDC Power Mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
DCDC_MODE	Indicates DCDC power mode. This field is reset by warm reset. 00b - DCDC in high-power mode 01b - DCDC in low-power mode 10b - DCDC in ultra-low-power mode 11b - DCDC in ultra-low-power mode
10 V2MIPI_PD	MIPI PHY Power Down Indicates the power down status of MIPI PHY. This bit is reset by warm reset. **NOTE** MIPI PHY must be powered down if VDD2_MEDIA is in DSR mode. 0b - Power on 1b - Power down
9 V2DSP_PD	HiFi4 Power Down Indicates the power down status of HiFi4. This bit is reset by warm reset. **NOTE** Must be powered down if VDD2_COMP is in DSR mode. **NOTE** Software must power down the HiFi4 cache and TCM periphery power switches prior to powering down the HiFi4, and the memories must not be powered on until the HiFi4 is powered. 0b - Power on 1b - Power down
8 VNCOM_DSR	DSR of VDDN_COM Domain Indicates the DSR status of VDDN_COM domain. This bit is reset by warm reset. 0b - Power on 1b - DSR mode
7 V2COM_DSR	DSR of VDD2_COM Domain Indicates the DSR status of VDD2_COM domain. This bit is reset by warm reset.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Power on 1b - DSR mode
6 V2NMED_DSR	DSR of VDD2_MEDIA and VDDN_MEDIA Domains Indicates the DSR status of VDD2_MEDIA and VDDN_MEDIA domains. **NOTE** Merged VDD2 and VDDN media switch controls. This bit is reset by warm reset. 0b - Power on 1b - DSR mode
5 V2COMP_DSR	DSR of VDD2_COMP Domain Indicates the DSR status of VDD2_COMP domain. This bit is reset by warm reset. 0b - Power on 1b - DSR mode
4 FDPD	FDPD Mode Indicates FDPD status. This bit is reset by warm reset. 0b - Enables 1b - Activates isolation and correct sequencing for FDPD mode
3 DPD	DPD Mode Indicates DPD status. This bit is reset by warm reset. 0b - Enables 1b - Activates isolation and correct sequencing for DPD mode
2 FDSR	FDSR Mode Indicates the FDSR mode of all core domains. This bit is reset by warm reset. 0b - Power switches and DSR status are determined by the single power domain controls 1b - All core domains are in FDSR mode or power down
1-0 PMICMODE	PMIC_MODE Output Value This bit is reset by warm reset.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates the aggregated PMIC_MODE output value driven to PMIC_MODE[1:0] pins, which is lowest value (highest power) mode selected by the active PD*CFG registers in Compute and Sense domains. PMIC_MODE output value is used to control external power supplies. 00b - PMIC_MODE[1:0] pins = 00 01b - PMIC_MODE[1:0] pins = 01 10b - PMIC_MODE[1:0] pins = 10 11b - PMIC_MODE[1:0] pins = 11

27.7.2.33 PD Configuration Status 1 (PDCFGSTATUS1)

Offset

Register	Offset
PDCFGSTATUS1	D4h

Function

Shows the currently aggregated value of Sense and Compute domains in PD*CFG1 registers. Updates immediately after the mode change event (e.g. CTRL[APPLYCFG] = 1, CPUx enters Deep Sleep, etc), while PMC is transitioning to the new configuration (as indicated by reading STATUS[BUSY] and CTRL[APPLYCFG]) and held until the next mode transition or APPLYCFG.

31	SRAM Sleep Mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
SRAMSLEEP	Indicates the status of SRAM Sleep mode. This is needed when VDD Core can be < 0.85 V to ensure contents retained. No power savings. Memories are not accessible in RAM sleep mode. It should only be set in PDSLEEPCFG. This bit is reset by warm reset. 0b - Normal 1b - Sleep
30-17 —	Reserved
16 ROM_PD	ROM Power Down Indicates the power down status of ROM. This bit is reset by warm reset. 0b - Power on 1b - Power down
15 OTP_PD	OTP Power Down Indicates the power down status of OTP VDD2. This bit is reset by warm reset. 0b - Power on 1b - Power down
14 —	Reserved
13 HVDN_PD	HVD Power Down in VDDN Domain Indicates the power down status of the high-voltage detect in VDDN domain. This bit is reset by warm reset. 0b - Power on 1b - Power down
12 LVDN_LP	LVD Low Power in VDDN Domain Indicates the status of LVD low-power mode in VDDN domain. This bit is reset by warm reset. 0b - High power 1b - Low power
11 PORN_LP	POR Low Power in VDDN Domain Indicates the status of POR low-power mode in VDDN domain.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This bit is reset by warm reset. 0b - High power 1b - Low power
10 AGDET2_PD	aGDET Power Down in VDD2 Domain Indicates the power down status of the analog glitch detect in VDD2 domain. This bit is reset by warm reset. 0b - Power on 1b - Power down
9 HVD2_PD	HVD Power Down in VDD2 Domain Indicates the power down status of the high-voltage detect in VDD2 domain. This bit is reset by warm reset. 0b - Power on 1b - Power down
8 LVD2_LP	LVD Low Power in VDD2 Domain Indicates the status of LVD low-power mode in VDD2 domain. This bit is reset by warm reset. 0b - High power 1b - Low power
7 POR2_LP	POR Low Power in VDD2 Domain Indicates the status of POR low-power mode in VDD2 domain. This bit is reset by warm reset. 0b - High power 1b - Low power
6 AGDET1_PD	aGDET Power Down in VDD1 Domain Indicates the power down status of the analog glitch detect in VDD1 domain. This bit is reset by warm reset. 0b - Power on 1b - Power down
5 HVD1_PD	HVD Power Down in VDD1 Domain Indicates the power down status of the high-voltage detect in VDD1 domain. This bit is reset by warm reset.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Power on 1b - Power down
4 LVD1_LP	LVD Low Power in VDD1 Domain Indicates the status of LVD low-power mode in VDD1 domain. This bit is reset by warm reset. 0b - High power 1b - Low power
3 POR1_LP	POR Low Power in VDD1 Domain Indicates the status of POR low-power mode in VDD1 domain. This bit is reset by warm reset. 0b - High power 1b - Low power
2 HVD1V8_PD	HVD Power Down Indicates the power down status of HVD. This bit is reset by warm reset. 0b - Power on 1b - Power down
1 PMCREF_LP	PMC References Low Power Indicates the status of PMC reference low-power mode. This bit is reset by warm reset. 0b - High-power mode 1b - Low-power mode
0 TEMP_PD	PMC Temperature Sensor Power Down Indicates the power down status of PMC temperature sensor. This bit is reset by warm reset. 0b - Power on 1b - Power down

27.7.2.34 PD Configuration Status 2 (PDCFGSTATUS2)

Offset

Register	Offset

PDWAKECFG	E8h

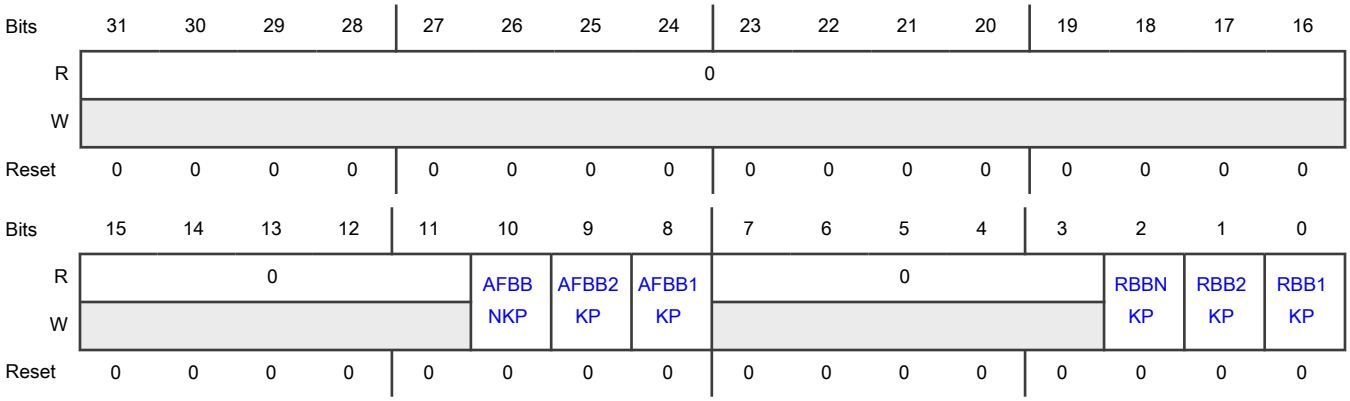
Function

Copies the selected values from the Sense slot PDSLEEPCFG0 to PDRUNCFG0 when CPU1 wakes up from Deep Sleep mode.

Power down wake-up is used when the PMC module switches from one body bias mode to another body bias mode in active mode, but it allows the change to occur while the affected domains are in Deep Sleep mode and the clocks are stopped to avoid timing issues during the transition. The clock controls need to be configured to stop in Deep Sleep mode in the domain's clock controls.

When PMC enters in Deep Sleep mode, the PDSLEEPCFG0 changes the body bias modes and the PDRUNCFG0 body bias power down controls are replaced with the PDSLEEPCFG0 controls selected in PDWAKECFG. This feature is used with INTRCTRL[AUTOWKIE] which enables the AUTOWAKE feature that wakes up PMC when the transition to Deep Sleep is completed and the updated body bias modes are active. The AUTOWAKE triggers a PMC interrupt which triggers a wake-up. Since PDRUNCFG0 was updated with the body bias state from PDSLEEPCFG0, the body bias for the selected domains is maintained.

Diagram



Fields

Field	Function
31-11 —	Reserved
10 AFBBNKP	AFBB Wake-up in VDDN Domain Copies PDSLEEPCFG0[AFBBN_PD] to PDRUNCFG0[AFBBN_PD] on wake-up to maintain AFBB state. This field has 2 copies separately accessed by the Compute and Sense slots. This bit is reset by warm reset. 0b - Do not copy during Deep Sleep 1b - Copy during Deep Sleep
9 AFBB2KP	AFBB Wake-up in VDD2Domain Copies PDSLEEPCFG0[AFBB2_PD] to PDRUNCFG0[AFBB2_PD] on wake-up to maintain AFBB state. This field has 2 copies separately accessed by the Compute and Sense slots. This bit is reset by warm reset. 0b - Do not copy during Deep Sleep 1b - Copy during Deep Sleep
8 AFBB1KP	AFBB Wake-up in VDD1 Domain Copies PDSLEEPCFG0[AFBB1_PD] to PDRUNCFG0[AFBB1_PD] on wake-up to maintain AFBB state. This field has 2 copies separately accessed by the Compute and Sense slots. This bit is reset by warm reset.

Field	Function
	0b - Do not copy during Deep Sleep 1b - Copy during Deep Sleep
7-3 —	Reserved
2 RBBNKP	RBB Wake-up in VDDN Domain Copies PDSLEEPCFG0[RBBN_PD] to PDRUNCFG0[RBBN_PD] on wake-up to maintain RBB state. This field has 2 copies separately accessed by the Compute and Sense slots. This bit is reset by warm reset. 0b - Do not copy during Deep Sleep 1b - Copy during Deep Sleep
1 RBB2KP	RBB Wake-up in VDD2 Domain Copies PDSLEEPCFG0[RBB2_PD] to PDRUNCFG0[RBB2_PD] on wake-up to maintain RBB state. This field has 2 copies separately accessed by the Compute and Sense slots. This bit is reset by warm reset. 0b - Do not copy during Deep Sleep 1b - Copy during Deep Sleep
0 RBB1KP	RBB Wake-up in VDD1 Domain Copies PDSLEEPCFG0[RBB1_PD] to PDRUNCFG0[RBB1_PD] on wake-up to maintain RBB state. This field has 2 copies separately accessed by the Compute and Sense slots. This bit is reset by warm reset. 0b - Do not copy during Deep Sleep 1b - Copy during Deep Sleep

27.7.2.39 Power Domain Flags for Sense Domain (PWRFLAGS)

Offset

Register	Offset
PWRFLAGS	ECh

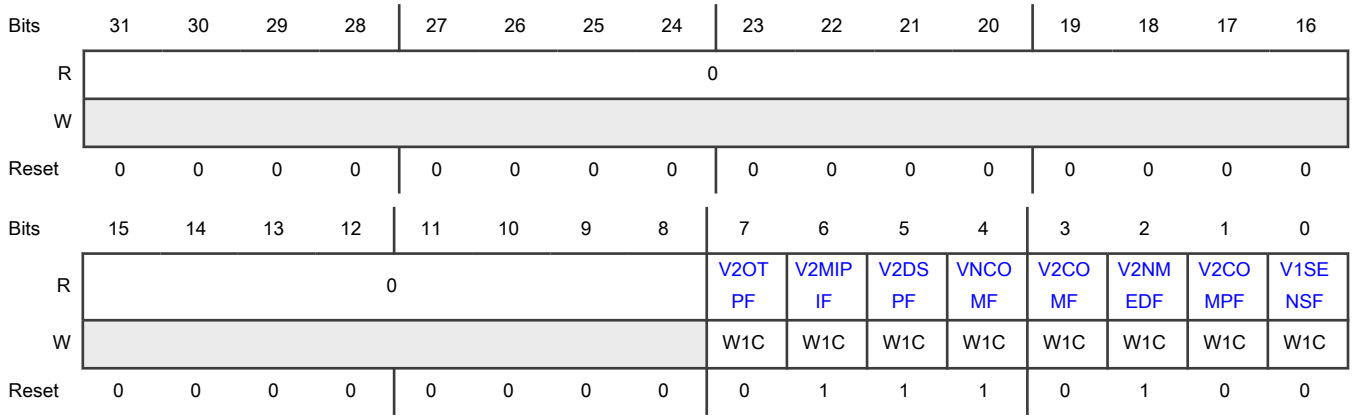
Function

Flags indicate which domains were put into Deep Sleep Retain or Power Down mode since the last time the flag was cleared by software. Flags are clearable only when the domain is powered.

NOTE

The Compute and Sense slots each have their own set of flags. Clearing a flag in the Compute slot will not clear the corresponding flag in the Sense slot.

Diagram



Fields

Field	Function
31-8 —	Reserved
7 V2OTPF	VDD2_OTP Domain Flag Indicates if VDD2_OTP domain enters power down mode. This field has 2 copies separately accessed by the Compute and Sense slots. This bit is reset by VDD1V8 POR reset. 0b - No power-down event occurred 1b - Power-down event occurred
6 V2MIPIF	VDD2_MIPI Domain Flag Indicates if VDD2_MIPI domain enters power down mode. This field has 2 copies separately accessed by the Compute and Sense slots. This bit is reset by VDD1V8 POR reset. 0b - No power-down event occurred 1b - Power-down event occurred
5 V2DSPF	VDD2_DSP Domain Flag Indicates if VDD2_DSP domain enters power down mode. This field has 2 copies separately accessed by the Compute and Sense slots. This bit is reset by VDD1V8 POR reset. 0b - No power-down event occurred 1b - Power-down event occurred
4 VNCOMF	VDDN_COM Domain Flag Indicates if VDDN_COM domain enters DSR mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field has 2 copies separately accessed by the Compute and Sense slots. This bit is reset by VDD1V8 POR reset. 0b - No DSR event occurred 1b - DSR event occurred
3 V2COMF	VDD2_COM Domain Flag Indicates if VDD2_COM domain enters DSR mode. This field has 2 copies separately accessed by the Compute and Sense slots. This bit is reset by VDD1V8 POR reset. 0b - No DSR event occurred 1b - DSR event occurred
2 V2NMEDF	VDD2_MEDIA and VDDN_MEDIA Domain Flag Indicates if VDD2_MEDIA and VDDN_MEDIA domains enter DSR mode. This field has 2 copies separately accessed by the Compute and Sense slots. This bit is reset by VDD1V8 POR reset. 0b - No DSR event occurred 1b - DSR event occurred
1 V2COMPF	VDD2_COMP Domain Flag Indicates if VDD2_COMP domain enters DSR mode. This field has 2 copies separately accessed by the Compute and Sense slots. This bit is reset by VDD1V8 POR reset. 0b - No DSR event occurred 1b - DSR event occurred
0 V1SENSF	VDD1_SENSE Domain Flag Indicates if VDD1_SENSE domain enters DSR mode. This field has 2 copies separately accessed by the Compute and Sense slots. This bit is reset by VDD1V8 POR reset. 0b - No DSR event occurred 1b - DSR event occurred

Chapter 28
Clock Controller (CLKCTL)

28.1 Chip-specific CLKCTL information

Table 234. Reference links to related information

Topic	Related module	Reference
Full description	CLKCTL	CLKCTL
Peripheral memory map		Memory map overview
Power management	PMC	Power overview PMC
Clocking		Clock overview
Signal multiplexing	IOPCTL	Signal multiplexing IO PAD controller

NOTE

The CLKCTL module includes some security functionality that is not described here. Refer to the i.MX RT700 Security Reference Manual for more details.

28.1.1 Module instances

This device has five instances of the CLKCTL modules, CLKCTL0, CLKCTL1, CLKCTL2, CLKCTL3 and CLKCTL4.

Table 235. CLKCTL instances

	CLKCTL0	CLKCTL1	CLKCTL2	CLKCTL3	CLKCTL4
Located in	VDD2_COM	VDD1_SENSE	VDDN_COM	VDD1_SENSE	VDD2_MEDIA
Access	CPU0 HiFi4, EZH-V, eDMA0, eDMA1	CPU1, HiFi1, EZH-V, eDMA2, eDMA3	CPU0, CPU1, HiFi4, HiFi1, EZH-V, eDMA0, eDMA1, eDMA2, eDMA3	CPU0, CPU1, HiFi4, HiFi1, EZH-V, eDMA0, eDMA1, eDMA2, eDMA3	CPU0, CPU1, HiFi4, EZH-V, eDMA0, eDMA1, eDMA2, eDMA3

28.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

28.2 Overview

The CLKCTL modules configure the clocks on the chip, including clock generation and clock gating for system and peripheral clocks. CLKCTL uses a distributed structure to manage domain clocks and are co-located with other system control modules like RSTCTL and SYSCON. The CLKCTL instances are illustrated in the System Diagram below.

28.2.1 System diagram

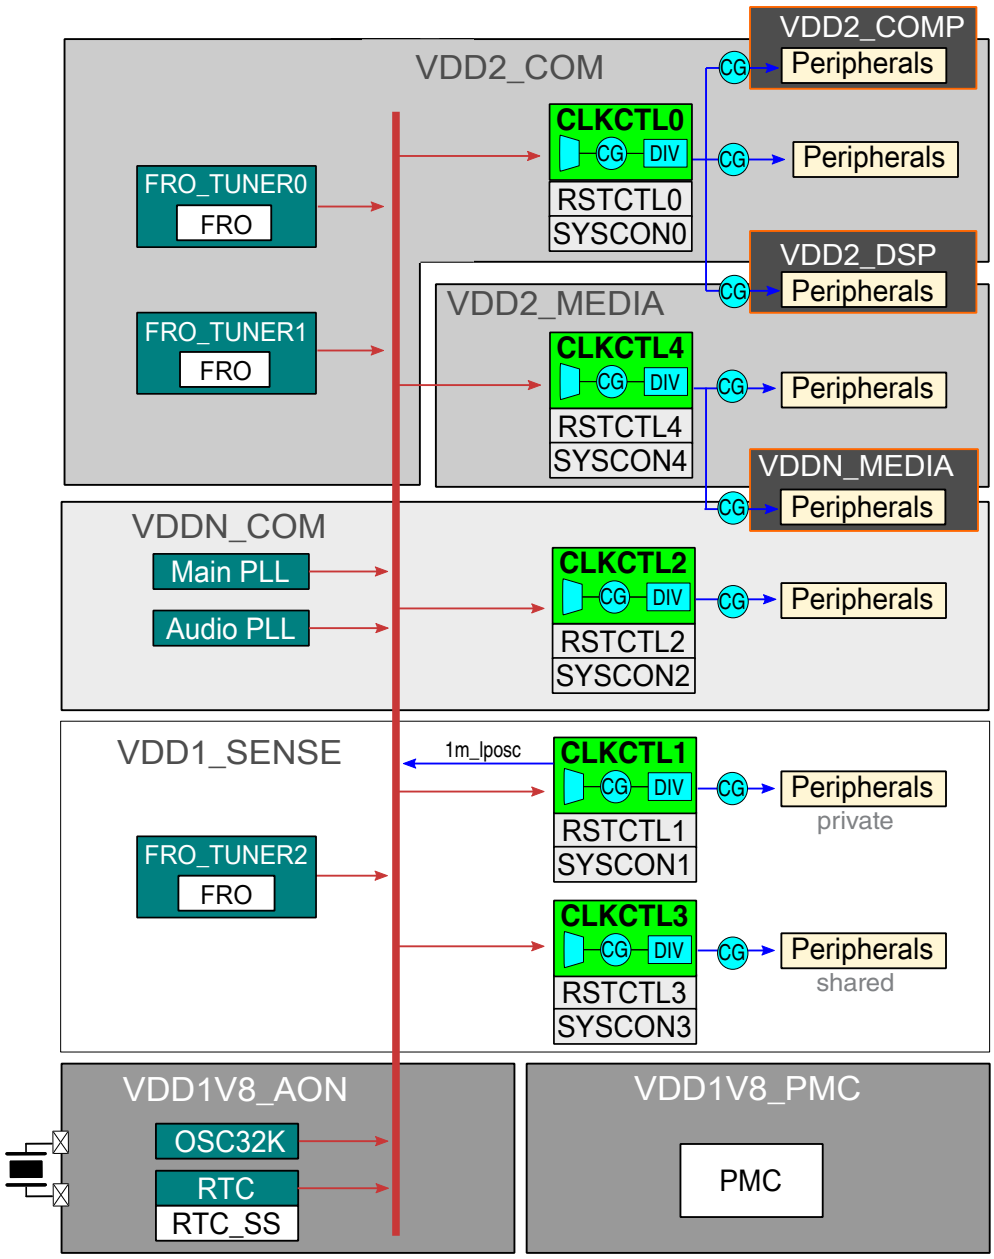


Figure 92. CLKCTL system diagram

28.2.2 Features

CLKCTL has the following features:

- Selects functional clocks from various clock sources:
  - One fixed frequency FRO (FRO1)
  - Two configurable FROs (FRO0 and FRO2)
  - 1 MHz Low-Power Internal Oscillator (LPOSC)
  - XTAL oscillator with frequency range of 4-32 MHz (osc_clk)

  - 32 kHz XTAL oscillator (osc_32k)
  - Separated PLLs (MAIN_PLL and AUDIO_PLL)
- Supports clock gating.
- Supports various clock dividers
  - Fractional PLL dividers
  - Post divider (/2, /3, /6, /8) outputs for FROs
  - Clock slice dividers

28.3 System clocks

This section covers the module clock connections on the chip, and associated clock gating options. For more information about the Clock Root configuration or clock gating enables, refer to the Clock generation section and associated clock gating registers.

NOTE

- SENSE_MAIN_CLK and SENSE_MAIN_CLK_1 are from the same clock mux (CLKCTL3 MAINCLKSEL)
- SENSE_MAIN_CLK is used for the private devices of CPU1 (which is configured by SLEEPCON_SENSE's RUNCFG[SENSEP_MAINCLK_SHUTOFF] and SLEEPCFG[SENSEP_MAINCLK_SHUTOFF])
- SENSE_MAIN_CLK_1 is used for the shared devices between CPU0 and CPU1 (which is configured by SLEEPCON_SENSE's RUNCFG[SENSES_MAINCLK_SHUTOFF] and SLEEPCFG[SENSES_MAINCLK_SHUTOFF])

28.4 Functional description

The following sections describe the clock generation from source to target (peripheral) clocks, covering the related configuration details and programming of the CLKCTL logic and clock mapping of the CLKCTL module instances.

28.4.1 Clock generation

Clock generation is based on a distributed set of clock sources used to generate clock roots across the chip domains. Clock roots are the source clocks for the distributed network of branch clocks and clock gates that supply all the peripheral clocks on the chip. The sections below cover the associated clock generation logic and configuration information.

28.4.1.1 Clock sources

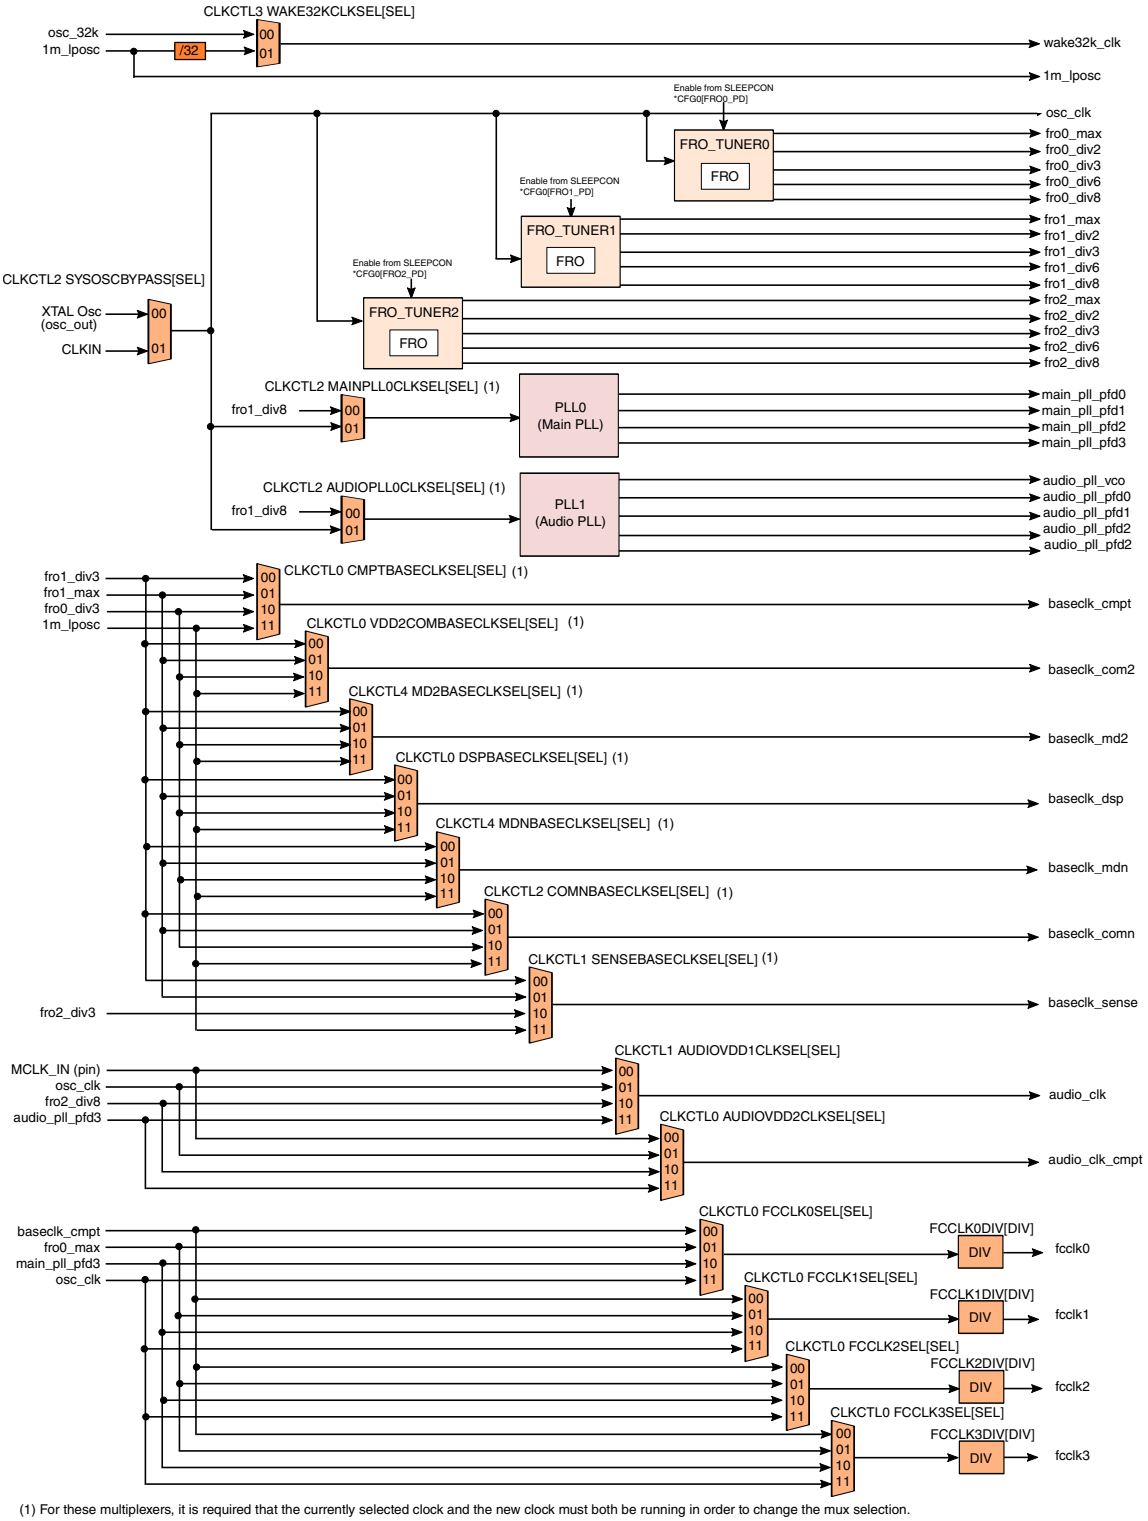
Clock sources include:

- Dynamic FRO
  - Two configurable FROs (150 MHz to 325 MHz) named as FRO0 and FRO2 respectively
  - One fixed frequency FRO (192 MHz) named as FRO1 used for bootup
  - Each FRO has post dividers with divide by 2, 3, 6, and 8 (div2, div3, div6, div8) clock outputs.
  - Digital feedback control block for frequency tuning

NOTE

You can disable fro_clk output and each of the divided outputs individually.

- XTAL Oscillator
- External clock (CLKIN)
- Main PLL
  - Used when high frequencies (> 300MHz) are required, as well as strict clocking specifications, such as jitter and duty cycle are needed.
- Audio PLL
  - Used for audio purposes with strict jitter requirements. The clock inputs and acceptable input frequencies are the same as with the Main PLL.



(1) For these multiplexers, it is required that the currently selected clock and the new clock must both be running in order to change the mux selection.

Figure 93. Clock source diagram

Table 237. Clock sources and generated clock sources

Clock source	Clock source select register	Description
Oscillators		
osc_clk	CLKCTL2.SYSOSCBYPASS	An internal clock that comes from either the CLKIN pin function or the main crystal oscillator. When used, the CLKIN pin function must be connected to a pin by selecting it in the IOPCTL block. osc_clk may be used as a clock source for the main or audio PLLs, FRO tunning clock, common_vddn_clk, and selected peripheral functions including ADC0, OSTIMER, systick and I3C FCLK.
osc_32k	See OSC32KNP chapter for more information	32 kHz output of the RTC oscillator. The 32 kHz clock must be enabled in the OSC32KHZCTL0 register. AON domain clock source's control is not in CLKCTL.
1m_lposc	-	Internal 1 MHz LPOSC that can be used as a low speed or low power system clock to drive selected peripheral functions.
wake32k_clk	CLKCTL3.WAKE32KCLKSEL	Ultra-lower power background clock used by several peripherals. It is selectable from 32k_clk or lp_32k.
ckil_32k	-	This clock only has one source that is wake32k_clk, and it can be gated by CKIL_32K_GATE. It provides the 32K clock required by SDIO0 and SDIO1.
LOW_FREQ_CLKOUT and LOW_FREQ_CLKOUT_N	-	A low-frequency clock-out and its compliment. The low frequency clock is created by routing the 1 kHz output from the 32 kHz clock module through a clock divider. This will provide a clock in the range of 4 Hz to 1 kHz. These two clock pins are multiplexed with two of the 16 FLEXIO pins. The divided 1 kHz clock should go down to 0.5 Hz, which requires 16-bit dividers
Main PLL		
main_pll_pfd0	CLKCTL2.MAINPLL0CLKSEL	PFD0 of the main PLL. It is one clock source of compute_main_clk, dsp_clk, media_main_clk, media_vddn_clk and common_ram_clk, as well as selected peripheral functions including VGPU, dphy_bit_clk, tpiu_clk, sct, i3c01_fclk and lpspi16_fclk
main_pll_pfd1		PFD1 of the main PLL. It is one clock source of dsp_clk and selected peripheral functions including XSPI0, SDIO1, ADC0 and dphy_txrx_clk
main_pll_pfd2		PFD2 of the main PLL. It is one clock source of media_main_clk and media_vddn_clk, as well as selected peripheral functions including XSPI1, SDIO0, VGPU and dcpixel
main_pll_pfd3		PFD3 of the main PLL. It is one clock source of common_vddn_clk, and selected peripheral functions including XSPI2 and FLEXIO

Table continues on the next page...

Table 237. Clock sources and generated clock sources (continued)

Clock source	Clock source select register	Description
Audio PLL		
audio_pll_vco	CLKCTL2.AUDIOPLL0CLKSEL	VCO of the audio PLL. It is one source of SDADC
audio_pll_pfd0		PFD0 of the audio PLL. It is one source of selected peripheral functions including SDIO0, SDIO1 and XSPI2
audio_pll_pfd1		PFD1 of the audio PLL. It is one clock source of compute_main_clk and sense_dsp_clk, as well as selected peripheral functions including XSPI1, XSPI2 and dcpixel
audio_pll_pfd2		PFD2 of the audio PLL. It is one clock source of sense_ram_clk, and selected peripheral functions including dphy_bit_clk and dphy_txrx_clk
audio_pll_pfd3		PFD3 of the audio PLL. It is one clock source of sense_main_clk and selected peripheral functions including MICFIL
FRO_TUNER0		
fro0_max	CLKCTL2.SYSOSCBYPASS See FRO_TUNER chapter for more information. **NOTE:** FRO has a reference clock to auto trim the FRO output frequency, osc_clk is used for this clock. and osc_clk has two clock sources which can be selected by SYSOSCBYPASS.	Output of FRO_TUNER0 clock
fro0_div2		Output of FRO_TUNER0 clock divided by 2
fro0_div3		Output of FRO_TUNER0 clock divided by 3
fro0_div6		Output of FRO_TUNER0 clock divided by 6
fro0_div8		Output of FRO_TUNER0 clock divided by 8
FRO_TUNER1

audio_clk_cmpt	CLKCTL0.AUDIOVDD2CLKSEL	Internal clock of CLKCTL that may be used as the function clock of SAI, and CTIMER peripherals.
fcclk0	CLKCTL0.FCCLK0SEL	Internal clock of CLKCTL that is used as the function clock of any Flexcomm Interface in compute VDD2 domain
fcclk1	CLKCTL0.FCCLK1SEL	
fcclk2	CLKCTL0.FCCLK2SEL	
fcclk3	CLKCTL0.FCCLK3SEL	

28.4.1.2 Clock roots

Each clock slice shown in Figure 92 creates a clock root.

The following tables describe clock root signals shown in the clocking diagrams. See I.MX RT700 Crossover Microcontrollers Data Sheet for clock root frequency data.

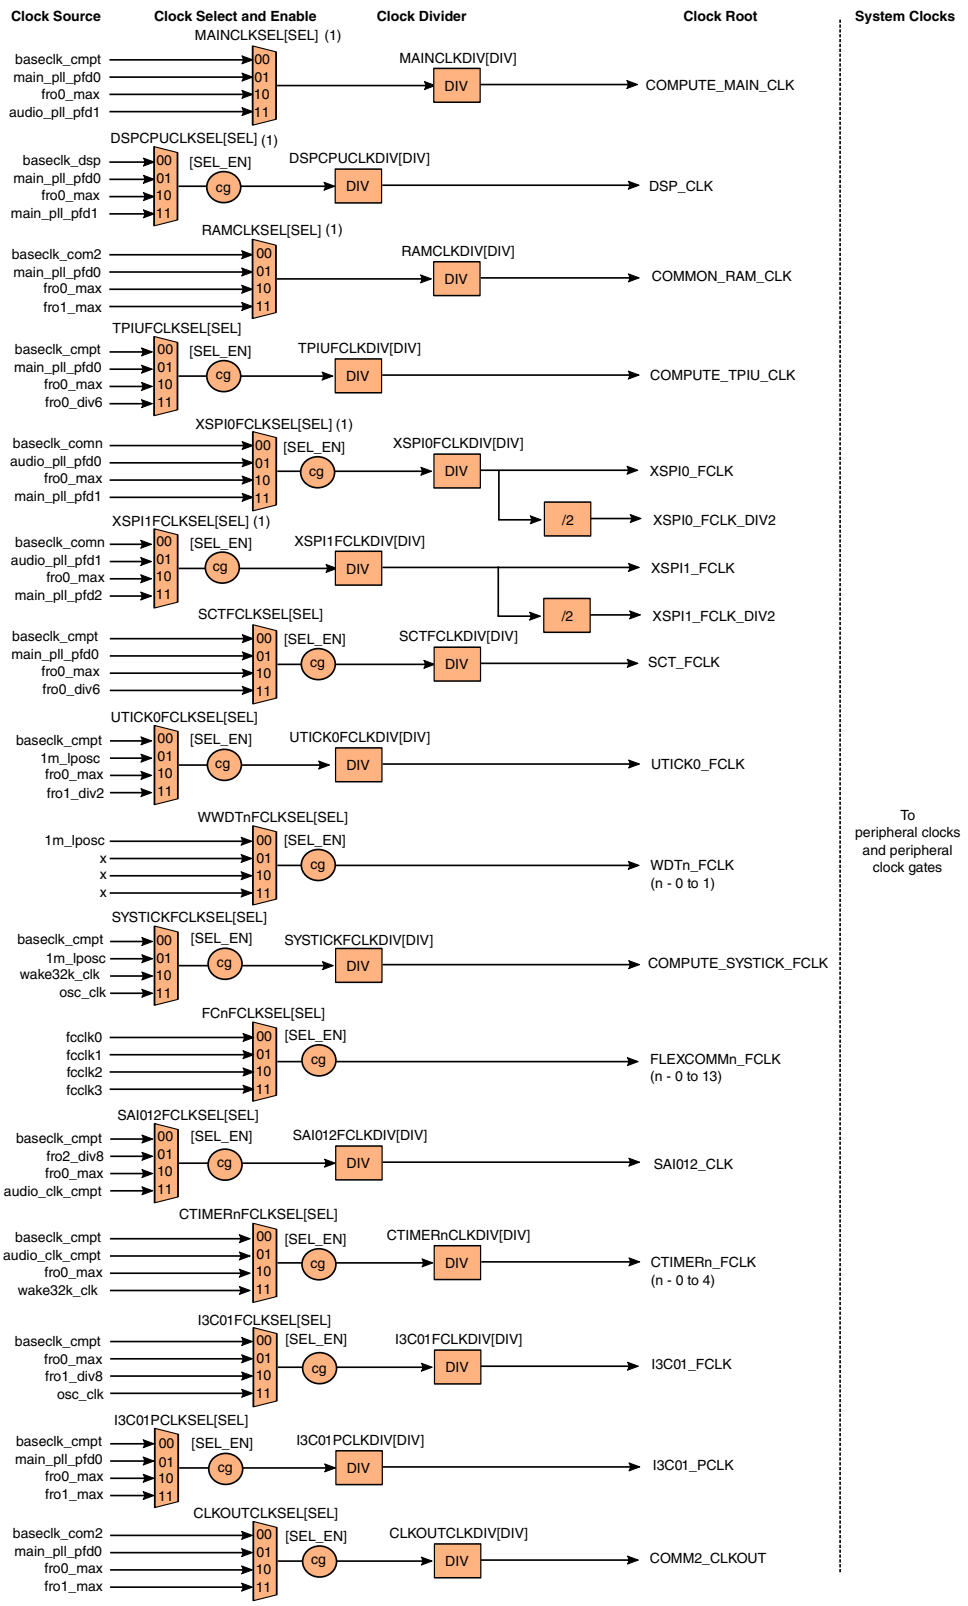
NOTE

The clock source select registers contains MUX output enables (*SEL_EN bitfields) that can disable clock root outputs at the clock source MUX. Disabling the clock root may be useful to reduce power, if the branch clocks sourcing downstream peripherals are unused. If some clocks are used downstream, local clock gating can be used to still save power by gating individual clocks using the associated CLKCTL PSCCTL* register.

28.4.1.2.1 CLKCTL0 clock tree and clock roots

28.4.1.2.1.1 CLKCTL0 clock tree

The following diagram illustrates the clock tree for the CLKCTL0 instance. Detailed configuration information of these clock roots can be found in the CLKCTL0 clock roots section.



(1) For these multiplexers, it is required that the currently selected clock and the new clock must both be running in order to change the mux selection.

Table 242. CLKCTL4 clock roots

Clock source select register	Clock root	Description
MEDIAMAINCLKSEL	MEDIA_MAIN_CLK	Derives the clock of VDD2_MEDIA domain
MEDIAVDDNCLKSEL	MEDIA_VDDN_CLK	Derives the clock of VDDN_MEDIA domain
XSPI2FCLKSEL	XSPI2_FCLK	Derives the clock of XSPI2
SDIO0FCLKSEL (for uSDHC clock select)	SDIO0_FCLK	Derives the clock of SDIO0
SDIO1FCLKSEL	SDIO1_FCLK	Derives the clock of SDIO1
VGPUCLKSEL	GPU_FCLK	Derives the clock of the VGPU
LCDIFPIXELCLKSEL	DCPIXEL_FCLK	Derives the clock of the LCDIF
DPHYCLKSEL	DPHY_BIT_CLK	Derives the MIPI_DSI_HOST PHY bit clock
DPHYESCCLKSEL	DPHY_RXTX_CLK	Derives the MIPI_DSI_HOST PHY RX/TX clock
FLEXIOCLKSEL	FLEXIO_CLK	Derives the clock for the FLEXIO
LPSPI14CLKSEL	LPSPI14_FCLK	Derives the LPSPI14 clock
LPSPI16CLKSEL	LPSPI16_FCLK	Derives the LPSPI16 clock
eUSBFCLKSEL	eUSB_WAKE_CLK	Derives the USB1 input clock
USBFCLKSEL	USB_WAKE_CLK	Derives the USB0 clock

28.4.1.2.6 Clock roots - no clock source select

Table 243. Clock roots - no clock source select

Clock source select register	Clock root	0.7V nom Max Freq (MHz)	1.0V nom Max Freq (MHz)	Description/Source Select (SEL)
-	usbphy0 clk_xtal	-	-	USBPHY0 reference clock (osc_24m)

28.4.1.3 Clock gates

Before a clock root goes to on-chip peripherals, the clock root branches into a distributed network of system clocks, which then interface clock gating logic. Without gating the clock root, this distributed network of clocks can be gated individually at the peripheral interface. CLKCTL provides the enables for these clock gates, in the Peripheral Software Clock Control (PSCCTLn) registers of each CLKCTL instance. These clock gates are also mapped to the peripheral clocks in the System Clocks table. Please see the PSCCTLn registers and System Clocks section for more information.

28.4.2 Phase Locked Loops (PLLs)

The PLLs, including main PLL and audio PLL, support a range of input frequencies and a range of VCO frequencies. In addition to a typical integer frequency multiplier, the PLLs also provide for a fractional frequency multiplier. The PLL VCO frequency is given by:

- PLL output frequency = Fref * (MULT + NUM/DENOM)
- Fref = PLL input reference frequency
- MULT = 8-bit PLL multiplier (See Main PLL0 Control 0 and Audio PLL0 Control 0)
- NUM = 30-bit numerator for fractional multiplier (See Main PLL0 Numerator and Audio PLL0 Numerator)
- DENOM = 30-bit denominator for fractional multiplier (See Main PLL0 Denominator and Audio PLL0 Denominator)

28.4.2.1 PLL limitations

Below lists PLL limitations:

- Input frequencies: 16, 19.2, 24, 26, 30 or 32 MHz
- PLL multiplier values: 16 to 22 in integer.
- PLL PFD: limited to 600 MHz (maximum) at 0.9 V or above voltage.

28.4.2.2 Main PLL

The main PLL can be configured to use a number of clock inputs and produce output clocks up to the maximum chip frequency. You can use the main PLL to run most of on-chip functions. The main PLL creates a stable output clock at a higher frequency than the input clock.

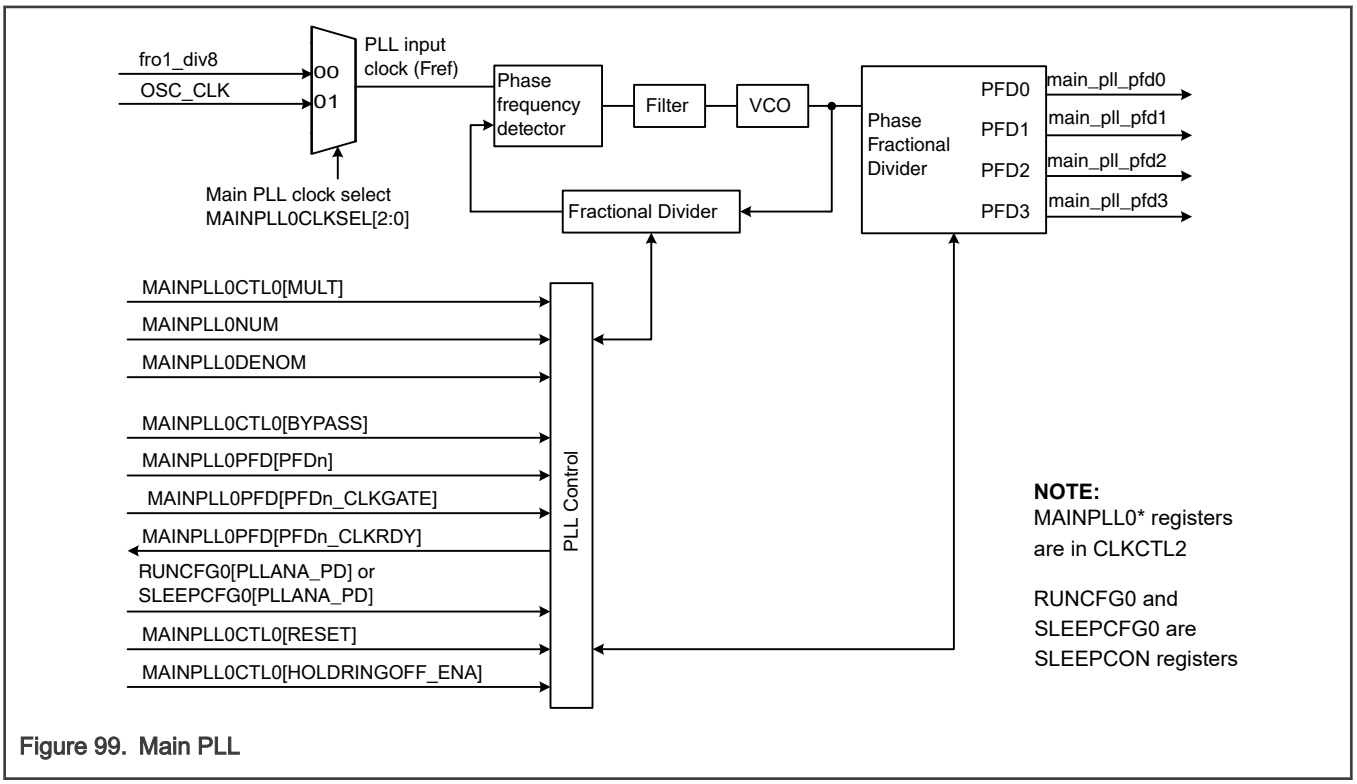

Figure 99. Main PLL

28.4.2.2.1 Setting up the main PLL

When the main PLL is running, you can change the NUM value by a step of 1 at a time and a delay at each change for the main PLL to settle to the new setting. DENUM value cannot be changed while a PLL is running.

The VCO frequency of the main PLL will be outputted on a particular Phase Fractional Divider (PFD) output when the PFD is set to 18. This does not alter the main PLL output (the value 18 causes the PFD to be divided by 1).

You can use PFD settings to alter the VCO frequency of the main PLL before it is outputted. Each PFD output may have a different setting. The PFD output frequency is given by:

- PFD Output = 18/N x FVCO where N = 12 to 35

Table 244. PFD fractions

MAINPLL0PFD[PFDn]	Fraction	Decimal
12	18/12	1.5
13	18/13	1.3846
14	18/14	1.2857
15	18/15	1.2
16	18/16	1.125
17	18/17	1.0588
18	18/18	1
19	18/19	0.9474
20	18/20	0.9
21	18/21	0.8571
22	18/22	0.8182
23	18/23	0.7826
24	18/24	0.75
25	18/25	0.72
26	18/26	0.6923
27	18/27	0.6667
28	18/28	0.6429
29	18/29	0.6207
30	18/30	0.6
31	18/31	0.5806
32	18/32	0.5625
33	18/33	0.5455
34	18/34	0.5294
35	18/35	0.5143

28.4.2.3 Audio PLL

The audio PLL allows using a frequency unrelated to the main PLL for audio processing. It can use a fractional multiplier that is used to generate accurate audio frequencies.

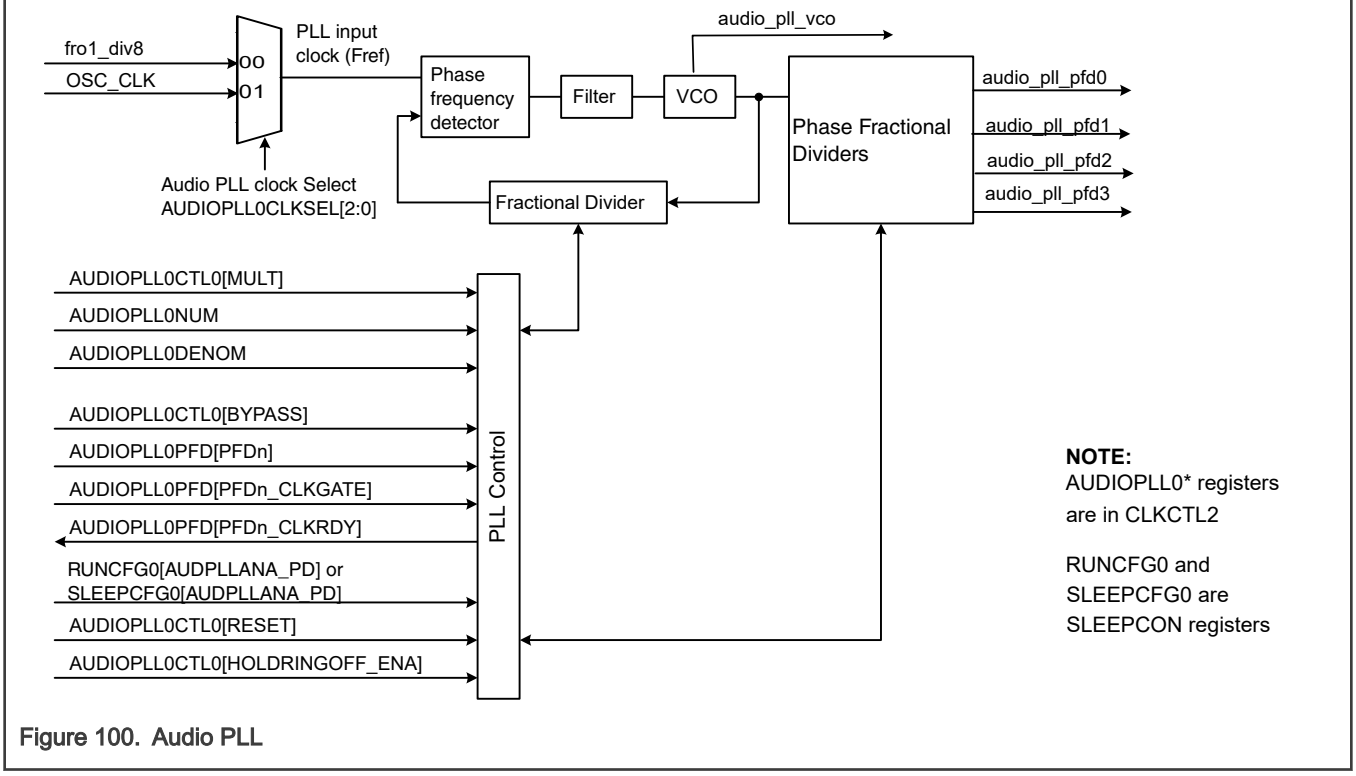

Figure 100. Audio PLL

28.4.2.3.1 Generating audio frequencies for the audio PLL

You can use a fractional multiplier to generate accurate audio frequencies using below settings as an example:

- Input frequency = 24 MHz
- Desired frequency = 44.1 kHz
- Over Sampled frequency = 256 x 44.1 kHz = 11.289 MHz
- Multiplier = 22.578 [AUDIOPLL0CTL0[MULT] = 22, AUDIOPLL0NUM = 578, AUDIOPLL0DENOM = 1000]
- VCO Output = 24 MHz x 22.578 = 541.872 MHz
- The audio PLL output can be divided by 48 to get the 11.289 MHz oversample frequency.

In this case, the related AUDIOPLL0PFD[PFDn] is set to 18, which does not alter the audio PLL output. Other audio frequencies can be similarly generated by manipulating multiplier (AUDIOPLL0CTL0[MULT]), numerator (AUDIOPLL0NUM) and denominator (AUDIOPLL0DENOM). Alternatively, the PFD might be used to create the desired frequency from a different VCO frequency.

28.4.3 Interrupts

This module has no interrupts.

28.5 External signals

Table 245 describes CLKCTL pins.

Table 245. CLKCTL pin description

Name	I/O	Description
CLKIN	I	CLKIN pin. It can optionally be used to supply the internal clock osc_clk. When used, it must be connected to a device pin by selecting it in the IOPCTL block. See IOPCTL chapter for more information.
CLKOUT	O	Many on-chip clocks can potentially be selected to be output on the CLKOUT function. This can be used for debugging purposes or to drive some external logic (see data sheet for limitations on pin output frequency). If used, the CLKOUT pin function must be connected to a pin by selecting it in the IOPCTL block. See IOPCTL chapter for more information.
LOW_FREQ_CLKOUT	O	Output pin for low-frequency clock-out
LOW_FREQ_CLKOUT_N	O	Output pin - complement of LOW_FREQ_CLKOUT
MCLK	I	MCLK input. The MCLK IN pin function is used as base source of the internal clock audio_clk when it is connected to a pin by selecting it in the IOPCTL block. See IOPCTL chapter for more information.
RTCXIN	I	Input pin for the RTC 32 kHz crystal oscillator
RTCXOUT	O	Output pin for the RTC 32 kHz crystal oscillator
XTALIN	I	Input pin for the main crystal oscillator. XTALIN can be input to external square wave when oscillator is bypassed.
XTALOUT	O	Output pin for the main crystal oscillator

28.6 Initialization

This module does not require initialization.

28.7 CLKCTL register descriptions

This section describes the memory map and all registers of CLKCTL. The CLKCTL module is organized into 5 separate clock controllers: CLKCTL0, CLKCTL1, CLKCTL2, CLKCTL3, and CLKCTL4.

28.7.1 CLKCTL0 register descriptions

This section includes the memory map and register descriptions for Clock Controller 0.

28.7.1.1 CLKCTL0 memory map

CLKCTL0 base address: 4000_1000h

28.7.1.2 VDD2_COMP Peripheral Clock Control 0 (PSCCTL0)

Offset

Register	Offset
PSCCTL0	10h

Function

Allows software to control specific peripheral's clock. Writing an one to any assigned bit in this register enables the clock and allows the specified peripheral to operate. Writing a zero disables the clock. If VDD2_COMP power rail is OFF, reset after power on.

NOTE

After enabling the module clock, the software should perform dummy read on the related register field for the clock enablement to be properly propagated.

28.7.1.12 VDD2_COMP Peripheral Clock Control 4 Set (PSCCTL4_SET)

Offset

Register	Offset
PSCCTL4_SET	50h

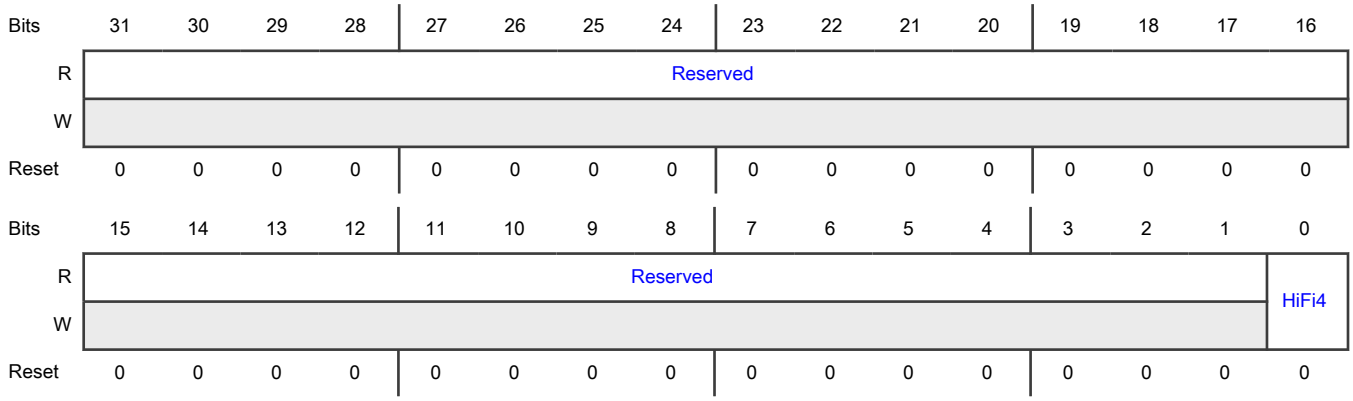
Function

Writing an one to a bit position in PSCCTL4_SET sets the corresponding position in PSCCTL4.

NOTE

After enabling the module clock, the software should perform dummy read on the related register field for the clock enablement to be properly propagated.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 HiFi4	HiFi4 Clock Enables HiFi4 clock. 0b - No effect 1b - Enable

28.7.1.13 VDD2_COMP Peripheral Clock Control 5 Set (PSCCTL5_SET)

Offset

Register	Offset
PSCCTL5_SET	54h

Function

Writing an one to a bit position in PSCCTL5_SET sets the corresponding position in PSCCTL5.

NOTE

After enabling the module clock, the software should perform dummy read on the related register field for the clock enablement to be properly propagated.

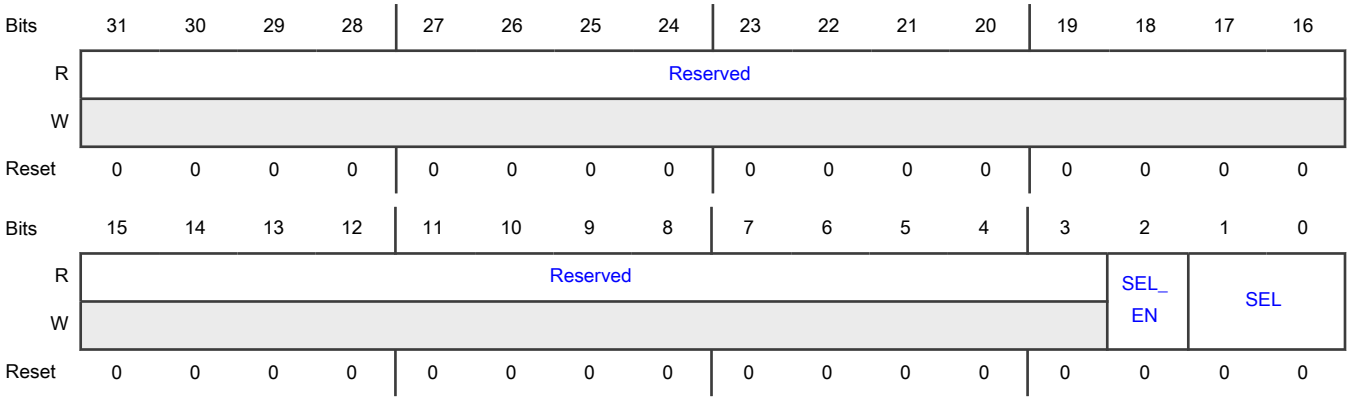
28.7.1.64 LP_FLEXCOMM11 Clock Source Select (FC11FCLKSEL)

Offset

Register	Offset
FC11FCLKSEL	968h

Function
Selects the clock source for LP_FLEXCOMM11.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 SEL_EN	Clock Mux Output Enable Enables mux output for LP_FLEXCOMM11 clock to reduce power. 0b - Gates mux output for LP_FLEXCOMM11 clock. 1b - Enables mux output for LP_FLEXCOMM11 clock.
1-0 SEL	LP_FLEXCOMM Functional Clock Source Select Selects the clock source for LP_FLEXCOMM functional clock. 00b - fcclk0 01b - fcclk1 10b - fcclk2 11b - fcclk3

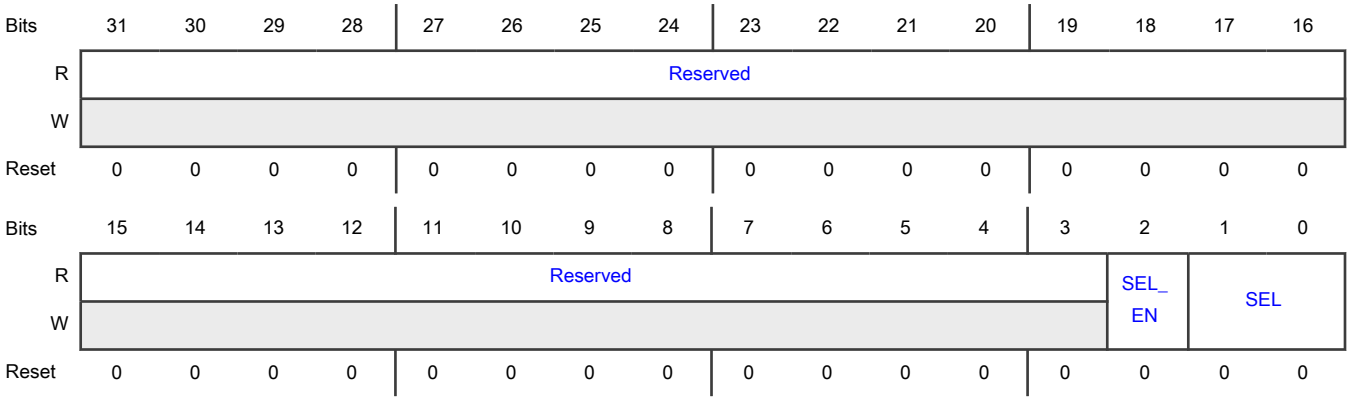
28.7.1.65 LP_FLEXCOMM12 Clock Source Select (FC12FCLKSEL)

Offset

Register	Offset
FC12FCLKSEL	988h

Function
Selects the clock source for LP_FLEXCOMM12.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 SEL_EN	Clock Mux Output Enable Enables mux output for LP_FLEXCOMM12 clock to reduce power. 0b - Gates mux output for LP_FLEXCOMM12 clock. 1b - Enables mux output for LP_FLEXCOMM12 clock.
1-0 SEL	LP_FLEXCOMM Functional Clock Source Select Selects the clock source for LP_FLEXCOMM functional clock. 00b - fcclk0 01b - fcclk1 10b - fcclk2 11b - fcclk3

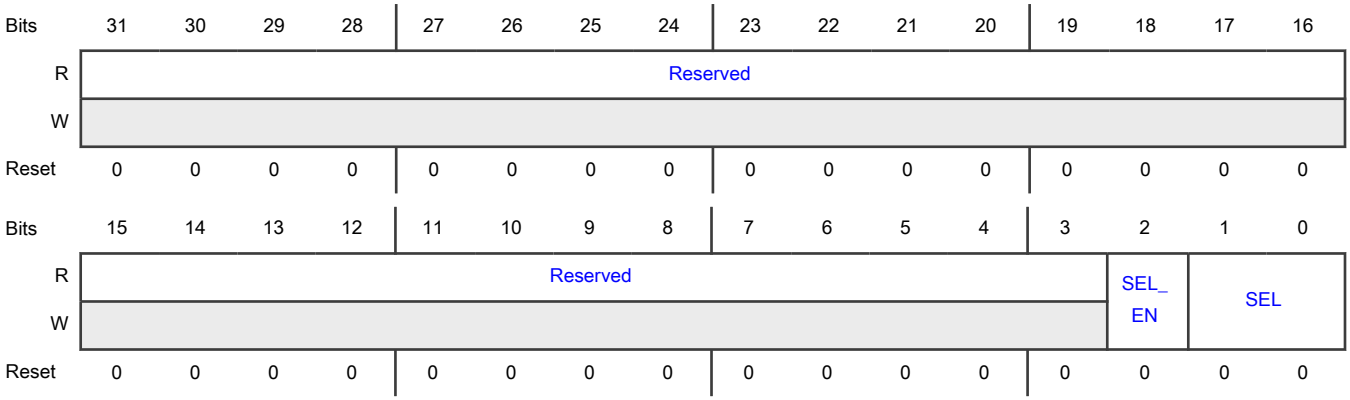
28.7.1.66 LP_FLEXCOMM13 Clock Source Select (FC13FCLKSEL)

Offset

Register	Offset
FC13FCLKSEL	9A8h

Function
Selects the clock source for LP_FLEXCOMM13.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 SEL_EN	Clock Mux Output Enable Enables mux output for LP_FLEXCOMM13 clock to reduce power. 0b - Gates mux output for LP_FLEXCOMM13 clock. 1b - Enables mux output for LP_FLEXCOMM13 clock.
1-0 SEL	LP_FLEXCOMM Functional Clock Source Select Selects the clock source for LP_FLEXCOMM functional clock. 00b - fcclk0 01b - fcclk1 10b - fcclk2 11b - fcclk3

28.7.1.67 SAI0, SAI1 and SAI2 Clock Source Select (SAI012FCLKSEL)

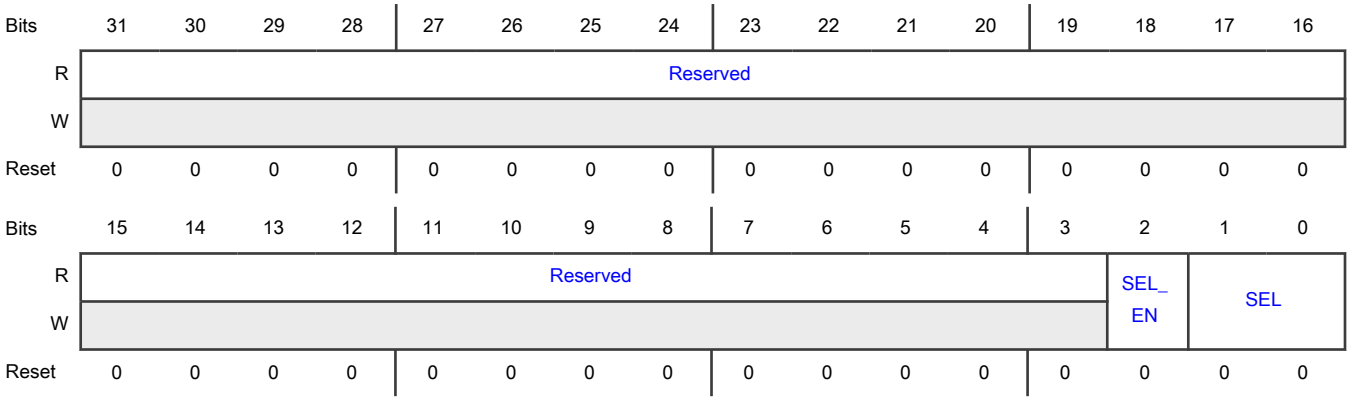
Offset

Register	Offset
SAI012FCLKSEL	9C8h

Function

Selects the clock source for SAI0, SAI1 and SAI2.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 SEL_EN	Clock Mux Output Enable Enables mux output for SAI0, SAI1 and SAI2 clocks to reduce power. 0b - Gates mux output for SAI0, SAI1 and SAI2 clocks. 1b - Enables mux output for SAI0, SAI1 and SAI2 clocks.
1-0 SEL	SAI0, SAI1 and SAI2 Clock Source Select Selects the clock source for SAI0, SAI1 and SAI2. 00b - baseclk_cmpt 01b - fro2_div8 10b - fro0_max 11b - audio_clk_cmpt

28.7.1.68 SAI0, SAI1 and SAI2 Functional Clock Divider (SAI012CLKDIV)

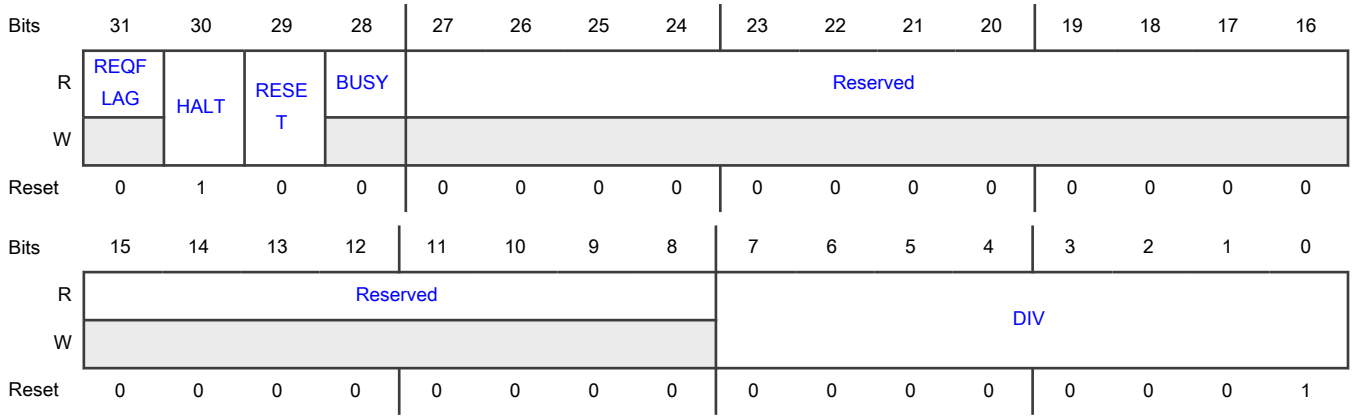
Offset

Register	Offset
SAI012CLKDIV	9CCh

Function

Controls the divider for the SAI0, SAI1 and SAI2s' functional clock sai012_clk.

Diagram



Fields

Field	Function
31 REQFLAG	Request Flag Shows the divider status. The clock to be divided must be running for this status to change. 0b - The change to the divider value has been finished. 1b - A change is being made to the divider value.
30 HALT	Halt Divider Counter Stops the divider counter. 0b - No effect 1b - Halts (stops) the divider counter.
29 RESET	Reset Divider Counter Resets the divider counter to use a new divider value immediately, instead of completing the previous count. **NOTE** This is an asynchronous reset (should only be used when you do not care about clean shut down).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No effect 1b - Reset the divider counter.
28 BUSY	Busy Flag Indicates the divider status. 0b - The CLKOUT is outputted with the new divider value. 1b - A change is being made to the divider value.
27-8 —	Reserved
7-0 DIV	Clock Divider Value Select Selects a clock divider value: • 0: Divide by 1 • 1: Divide by 2 • 2: Divide by 3 • . . . • 255: Divide by 256

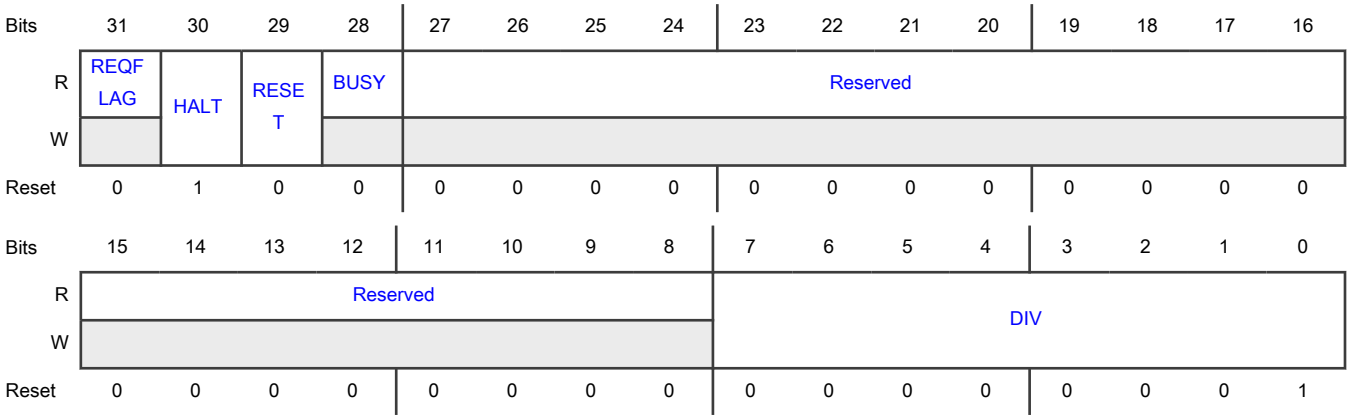
28.7.1.69 CTIMER0 Functional Clock Divider (CTIMER0CLKDIV)

Offset

Register	Offset
CTIMER0CLKDIV	A00h

Function
Controls the divider for the CTIMER0 functional clock ctimer0_fclk.

Diagram



Fields

28.7.2.2 VDD1_SENSE Peripheral Clock Control 0 (PSCCTL0)

Offset

Register	Offset
PSCCTL0	10h

Function

Allows software to control specific peripheral's clock. Writing one to any assigned bit in this register enables the clock and the specified peripheral to operate. Writing zero disables the clock. If VDD1_SENSE power rail is OFF, reset after power on.

NOTE

After enabling the module clock, the software should perform dummy read on the related register field for the clock enablement to be properly propagated.

Diagram

28.7.2.4 VDD1_SENSE Peripheral Clock Control 0 Set (PSCCTL0_SET)

Offset

Register	Offset
PSCCTL0_SET	40h

Function

Enables the corresponding position in PSCCTL0 by writing 1 to a bit position in PSCCTL0_SET.

NOTE

After enabling the module clock, the software should perform dummy read on the related register field for the clock enablement to be properly propagated.

Diagram

28.7.2.8 VDD1_SENSE Base Clock Select Source (SENSEBASECLKSEL)

Offset

Register	Offset
SENSEBASECLKSEL	438h

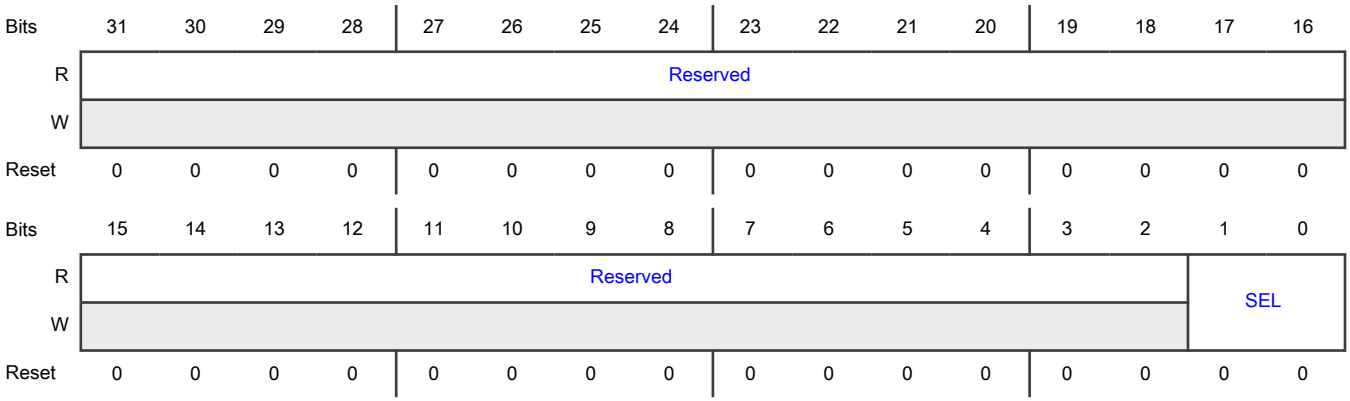
Function

Selects the clock source for VDD1_SENSE base clock.

NOTE

The clock selection is internally synchronized. The clocks that are switched from and switched to must run for changing selection.

Diagram



Fields

Field	Function
31-2 —	Reserved
1-0 SEL	Clock Source Select for Main VDD1_SENSE Base Clock Selects clock source for main VDD1_SENSE base clock. 00b - fro1_div3 01b - fro1_max 10b - fro2_div3 11b - 1m_lposc

28.7.2.9 CPU Clock of DSP in VDD1_SENSE Clock Divider (SENSEDSPCPUCLKDIV)

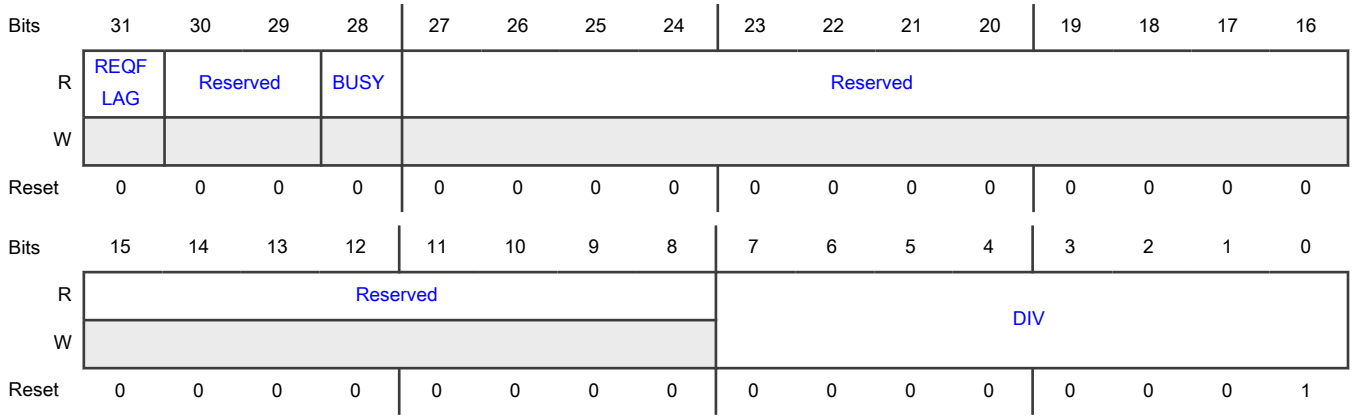
Offset

Register	Offset
SENSEDSPCPUCLKDIV	440h

Function

Controls the divider for the CPU clock of DSP in VDD1_SENSE sense_dsp_clk.

Diagram



Fields

Field	Function
31 REQFLAG	Request Flag Indicates the divider status. The clock to be divided must be running for this status to change. 0b - The change to the divider value has been finished. 1b - A change is being made to the divider value.
30-29 —	Reserved
28 BUSY	Busy Flag Indicates the divider status. 0b - The CLKOUT is outputted with the new divider value. 1b - A change is being made to the divider value.

28.7.3.2 VDDN_COM Peripheral clock 0 (PSCCTL0)

Offset

Register	Offset
PSCCTL0	10h

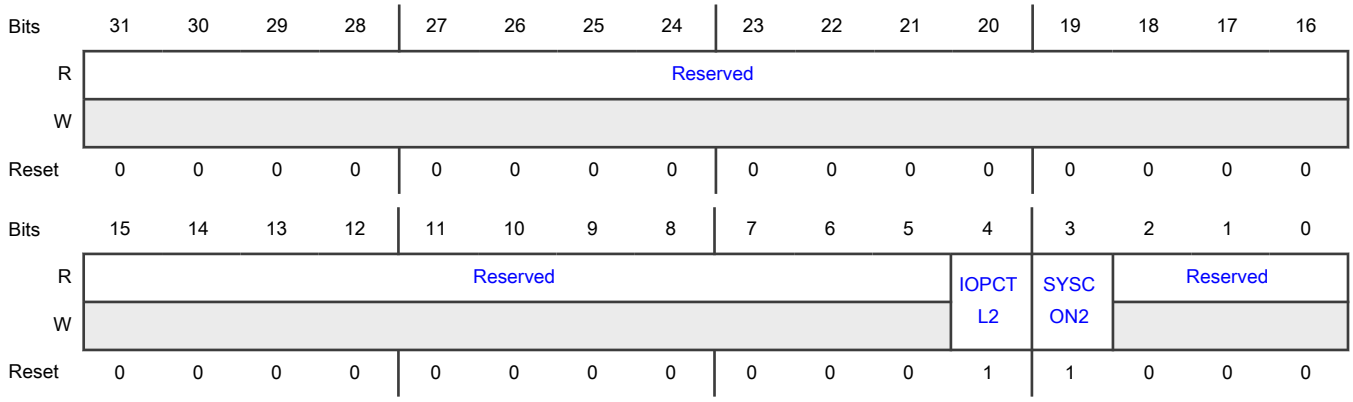
Function

Allows software to control specific peripheral's clock. Writing an one to any assigned bit in this register enables the clock and allows the specified peripheral to operate. Writing zero disables the clock. If VDDN_COM power rail is OFF, reset after power ON.

NOTE

After enabling the module clock, the software should perform dummy read on the related register field for the clock enablement to be properly propagated.

Diagram



Fields

Field	Function
31-5 —	Reserved
4 IOPCTL2	IOPCTL2 clock Enables IOPCTL2 clock. 0b - Disable 1b - Enable
3 SYSCON2	SYSCON2 clock Enables SYSCON2 clock. 0b - Disable 1b - Enable
2-0 —	Reserved

28.7.3.3 VDDN_COM Peripheral Clock 0 Set (PSCCTL0_SET)

Offset

Register	Offset
PSCCTL0_SET	40h

Function

Writing an one to a bit position in PSCCTL0_SET sets the corresponding position in PSCCTL0.

NOTE

After enabling the module clock, the software should perform dummy read on the related register field for the clock enablement to be properly propagated.

Diagram

28.7.3.7 XTAL Oscillator Control 0 (SYSOSCCTL0)

Offset

Register	Offset
SYSOSCCTL0	100h

Function

Controls whether the XTAL oscillator is bypassed, and sets the oscillator mode.

One aspect of the oscillator high gain mode is that a larger voltage swing is used at the crystal pin. This gives a higher noise immunity within the oscillator and less edge to edge jitter of the internal clock. When high gain mode is not required, power used by the XTAL oscillator can be reduced by using low power mode.

NOTE

High gain mode requires a 1 megohm resistor to be inserted in series with the external crystal. For this reason, high gain mode and low power mode cannot both be used in the same application. The board design must reflect the mode that will be used.

28.7.3.12 Main PLL0 Clock Source Select (MAINPLL0CLKSEL)

Offset

Register	Offset
MAINPLL0CLKSEL	200h

Function

The MAINPLL0 output frequency is controlled by the programmed values of MULT, NUM and DENOM, and can be expressed as a function of the MAINPLL0 reference input frequency:

$F_{MAINPLL0_OUTPUT} = f_{PLLREFIN} * (MULT + (NUM/DENOM))$

The input reference frequency can be selected using MAINPLL0CLKSEL[SEL].

NOTE

The PLL reference input frequency is limited to the following discrete frequencies: 32, 30, 26, 24, 19.2, 16 MHz.

After choosing an input frequency, choose MULT so that the MAINPLL0 output frequency is 528 MHz. For example, after choosing a MAINPLL0 reference input frequency of 24 MHz, program MULT as 0x16 (decimal 22), because 24 MHz * 22 = 528 MHz. To fine tune the frequency, use NUM and DENOM.

NOTE

This clock selection is internally synchronized. The clocks that are switched from and switched to must run for clock selection to change.

0 BYPASS	MAINPLL0 BYPASS Enables bypass for MAINPLL0. 0b - PFD outputs are PFD-programmed clocks. 1b - Bypass mode: PFD outputs are sourced directly from the reference input clock.

28.7.3.14 Main PLL0 Lock Time Div2 (MAINPLL0LOCKTIMEDIV2)

Offset

Register	Offset
MAINPLL0LOCKTIMEDIV2	20Ch

Function

During reset, the BOOTROM will copy the MAINPLL0 worst case characterized lock time value found in OTP Fuses into the respective fields (if the OTP valid signature is present).

To get the information on when half of the lock time has expired and when the full lock has passed, software needs this worst case lock time value to control the Hold Ring Off Control bit (MAINPLL0CTL0[HOLD_RING_OFF]). Any PLL lock sequence requires the HOLD_RING_OFF bit:

- to be enabled (‘1’) during the 1st half of the lock time
- to be disabled (‘0’) during the 2nd half of the lock time

28.7.3.17 Main PLL0 PFD (MAINPLL0PFD)

Offset

Register	Offset
MAINPLL0PFD	218h

Function

Defines the control bits for PFD0 to PFD3 clocks derived from MAINPLL0. The PFD output frequencies are governed by:

$F_{PFDx} = F_{MAINPLL0_OUT} * (18 / PFDx)$

When changing PFD values, follow this recommended sequence:

- Ensure that the PFDx clock gets gated by writing 1 to the PFDx_CLKGATE bit.
- Program the new PFD value (which are limited to decimal values 12 to 35).
- Write 0 to the PFDx_CLKGATE register to ungate the PFDx clock.
- Poll the PFDx_CLKRDY status flag until it (the status flag) is set to 1.
- Clear the PFDx_CLKRDY status flag by writing 1 to that specific PFDx_CLKRDY bit.

NOTE

In non-bypass mode, the pfd output should be disabled by the PFDn_CLKGATE bit, until PLL lock.

28.7.3.19 Audio PLL0 Clock Source Select (AUDIOPLL0CLKSEL)

Offset

Register	Offset
AUDIOPLL0CLKSEL	400h

Function
Selects a clock source for audio PLL0 clock.

The Audio PLL0 output frequency is controlled by the programmed values of MULT, NUM and DENOM and can be expressed as a function of the AUDIOPLL0 reference input frequency. Use this AUDIOPLL0CLKSEL register to select the AUDIOPLL0 reference input frequency.

$F_{MAINPLL0} = F_{PLLREFIN} * (MULT + NUM/DENOM)$

After an input frequency has been chosen, MULT must be chosen so that the AUDIOPLL0 output frequency is 528 MHz. Therefore, if choosing an AUDIOPLL0 reference input frequency of 24 MHz, then program MULT as (0x16) or decimal 22, because 24 MHz * 22 = 528 MHz. Fine-tuning of the frequency can be done using NUM and DENOM.

NOTE

The clock selection is internally synchronized. The clocks that are switched from and switched to must run for changing selection.

28.7.3.21 Audio PLL0 Lock Time Divide-by-2 (AUDIOPLL0LOCKTIMEDIV2)

Offset

Register	Offset
AUDIOPLL0LOCKTIMEDIV2	40Ch

Function

When reset, the BOOTROM copies the AUDIOPLL0 worst case characterized lock time value (found in the OTP fuses) into the respective fields (if the OTP valid signature is present) for software to control the HOLD_RING_OFF bit in the AUDIOPLL0CTL0 register, and get the information on when half the lock time has expired and when the full lock has passed. Any PLL lock sequence requires HOLD_RING_OFF to be enabled (') during the first half of the lock time, and HOLD_RING_OFF to be disabled (0' during the second half of the lock time.

Diagram

29-0 DENOM	Denominator Sets the denominator of the Audio PLL0 fractional loop divider. • The value of denominator must always be configured to be greater than the value of the numerator. • The AUDIOPLL0DENOM register can only be changed when the Audio PLL0 is disabled.

28.7.3.24 Audio PLL0 PFD (AUDIOPLL0PFD)

Offset

Register	Offset
AUDIOPLL0PFD	418h

Function

Defines the control bits for the PFD0 to PFD3 clocks derived from the Audio PLL0.

The PFD output frequencies are governed by the following expression:

$F_{PFDx} = F_{AUDIOPLL0_OUT} * (18 / PFDx)$

To change PFD values, follow these steps:

1. Ensure that the PFDx clock gets gated by writing 1 to the PFDx_CLKGATE bit.
2. Program the new PFD value limited to 12 to 35 (in decimal).
3. Write 0 to the PFDx_CLKGATE register to ungate the PFDx clock.
4. Poll the PFDx_CLKRDY status flag until it (the status flag) is set to 1.
5. Clear the PFDx_CLKRDY status flag by writing 1 to that specific PFDx_CLKRDY bit.

NOTE

In non-bypass mode, the pfd output should be disabled by the PFDn_CLKGATE bit, until PLL lock.

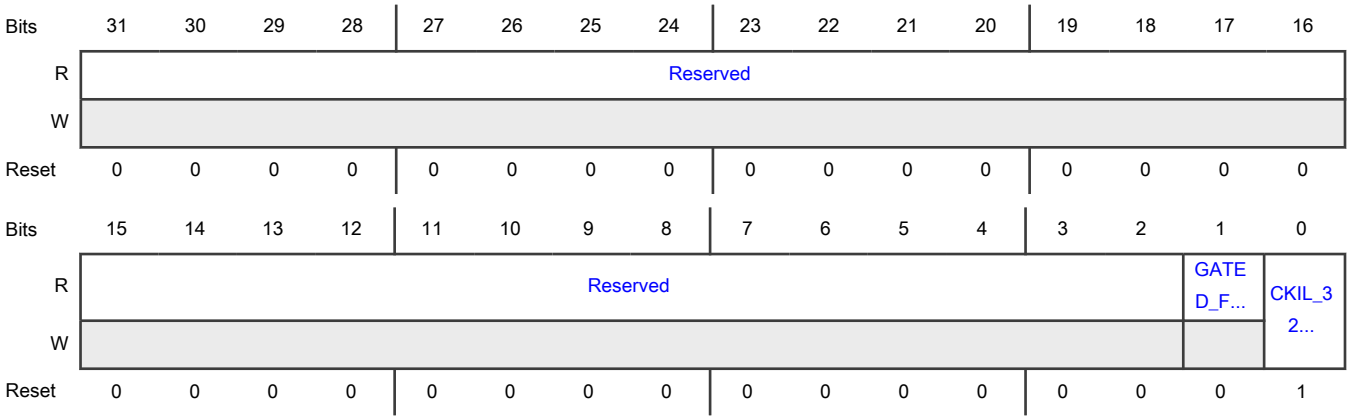
28.7.3.27 CKIL 32kHz Clock Gate (CKIL_32K_GATE)

Offset

Register	Offset
CKIL_32K_GATE	600h

Function
Gates the CKIL 32kHz clock.

Diagram



Fields

Field	Function
31-2 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 GATED_FLAG	Gated Flag Indicates the gating status of CKIL 32kHz clock. 0b - The CKIL 32 kHz clock is not gated. 1b - The CKIL 32 kHz clock is gated.
0 CKIL_32K_EN	CKIL 32 kHz Clock Enable Enables CKIL 32 kHz clock. 0b - Gates CKIL 32 kHz clock. You need to read GATED_FLAG field with the value of 1b to confirm the clock is already gated before going ahead. 1b - Enables CKIL 32 kHz clock.

28.7.4 CLKCTL3 register descriptions

This section includes the memory map and register descriptions for Clock Controller 3.

The peripherals in CLKCTL3 are shared for both CPU0 and CPU1. There is a common scenario where CPU0 wants to turn off one clock, but CPU1 is still using this clock. To handle such kind of scenario, two sets of registers are configured in CLKCTL3 named as PSCCTLn_COMP (these registers can only be written by CPU0, but they can be read by both CPU0 and CPU1.) and PSCCTLn_SENS (these registers can only be written by CPU1, but they can be read by both CPU1 and CPU0.). In this way, if CPU0 does not need such peripheral work, you can disable it by writing PSCCTLn_COMP. It also can read PSCCTLn_SENS back to check whether this clock is really disabled.

28.7.4.1 CLKCTL3 memory map

CLKCTL3 base address: 4006_1000h

28.7.4.2 VDD1_SENSE Peripheral Clock Control 0 (PSCCTL0_COMP)

Offset

Register	Offset
PSCCTL0_COMP	10h

Function

Allows software to enable specific peripherals. Writing a zero to any assigned bit in this register gates the clock. Writing an one enables the clock and allows the specified peripheral to operate. If VDD1_SENSE power domain is power OFF, reset after power ON.

NOTE

This register can only be written by CPU0. CPU1 can not write this register. However, CPU1 can read it to query the really status of device's clock. CPU0 can write zero to PSCCTL0_COMP to disable the clock. But whether this clock is really disabled, software need to read back the related bit from PSCCTL0_SENS, since if one core enables the clock, it cannot be disabled by another core.

NOTE

After enabling the module clock, the software should perform dummy read on the related register field for the clock enablement to be properly propagated.

28.7.4.3 VDD1_SENSE Peripheral Clock Control 0 Set (PSCCTL0_COMP_SET)

Offset

Register	Offset
PSCCTL0_COMP_SET	40h

Function

Writing an one to a bit position in PSCCTL0_SET sets the corresponding position in PSCCTL0.

NOTE

This register can only be written by CPU0, CPU1 can not write this register.

NOTE

After enabling the module clock, the software should perform dummy read on the related register field for the clock enablement to be properly propagated.

28.7.4.5 One Source Clock Slice Enable for VDD2_COMP CPU (ONE_SRC_CLKSLICE_ENABLE_COMP)

Offset

Register	Offset
ONE_SRC_CLKSLICE_ENABLE_COMP	90h

Function

Controls the gating of one source clock slice. Multi source clock slices gating is controlled by enabling the SEL_EN bit field of a series of clock select source registers, for example, XSPI*n*CLKSEL.

NOTE

Not all the clock select source registers have this SEL_EN bit for some clocks cannot be gated, such as base clock.

NOTE

This register is compute core access only.

28.7.4.27 VDD1_SENSE Peripheral Clock Control 0 (PSCCTL0_SENS)

Offset

Register	Offset
PSCCTL0_SENS	810h

Function

Allows software to enable specific peripherals. Writing a zero to any assigned bit in this register gates the clock. Writing an one enables the clock and allows the specified peripheral to operate. If VDD1_SENSE power domain is power OFF, reset after power ON.

NOTE

This register can only be written by CPU1. CPU0 can not write this register. However, CPU0 can read it to query the really status of device's clock. CPU1 can write zero to PSCCTL0_SENS to disable the clock. But whether this clock is really disabled, software need to read back the related bit from PSCCTL0_COMP, since if one core enables the clock, it cannot be disabled by another core.

NOTE

After enabling the module clock, the software should perform dummy read on the related register field for the clock enablement to be properly propagated.

28.7.4.30 One Source Clock Slice Enable for VDD1_SENSE CPU (ONE_SRC_CLKSLICE_ENABLE_SENSE)

Offset

Register	Offset
ONE_SRC_CLKSLICE_ENABLE_SENSE	890h

Function

Controls the gating of one source clock slice. Multi source clock slices gating is controlled by enabling the SEL_EN bit field of a series of clock select source registers, for example, XSPI*n*CLKSEL.

NOTE

Not all the clock select source registers have this SEL_EN bit for some clocks cannot be gated, such as base clock.

NOTE

This register is VDD1_SENSE core access only

0 RTC_FCLK_EN	RTC Functional Clock Gating Enable Enables RTC functional clock. This clock's source is lposc_1m. Make sure lposc_1m is active before enabling the RTC functional clock. 0b - Gates RTC functional clock. 1b - Enables RTC functional clock.

28.7.5 CLKCTL4 register descriptions

This section includes the memory map and register descriptions for Clock Controller 4.

The peripherals in CLKCTL4 are shared for both CPU0 and CPU1. There is a common scenario where CPU0 wants to turn off one clock, but CPU1 is still using this clock. To handle such kind of scenario, two sets of registers are configured in CLKCTL4: PSCCTLn_COMP (these registers can only be written by CPU0, but they can be read by both CPU0 and CPU1.) and PSCCTLn_SENS (these registers can only be written by CPU1, but they can be read by both CPU1 and CPU0.). In this way, if CPU0 does not need such peripheral work, the peripheral can be disabled by writing PSCCTLn_COMP. CPU0 can read PSCCTLn_SENS back to check whether this clock is really disabled.

28.7.5.2 VDD2_COMP Media Peripheral Clock Control 0 (PSCCTL0_MEDIA)

Offset

Register	Offset
PSCCTL0_MEDIA	10h

Function

Allows software to control specific peripheral's clock. Writing an one to any assigned bit in this register enables the clock and allows the specified peripheral to operate. Writing zero disables the clock. If VDD2_MEDIA power rail is OFF, reset after power ON.

NOTE

This register can only be written by CPU0. CPU1 can not write this register but CPU1 can read it to query the real status of the device's clock. CPU0 can write zero to PSCCTL0_MEDIA to disable the clock. But whether this clock is really disabled software need to read back the related bit from PSCCTL0_SENS, since if one core enables the clock, it cannot be disabled by another core.

NOTE

After enabling the module clock, the software should perform dummy read on the related register field for the clock enablement to be properly propagated.

28.7.5.3 VDD2_COMP Media Peripheral Clock Control 1 (PSCCTL1_MEDIA)

Offset

Register	Offset
PSCCTL1_MEDIA	14h

Function

Allows software to control specific peripheral's clock. Writing 1 to any assigned bit in this register enables the clock and allows the specified peripheral to operate. Writing 0 disables the clock. If VDD2_MEDIA power rail is OFF, reset after power ON.

NOTE

This register can only be written by CPU0. CPU1 can not write this register but CPU1 can read it to query the really status of device's clock. CPU0 can write zero to PSCCTL1_MEDIA to disable the clock. But whether this clock is really disabled software need to read back the related bit from PSCCTL1_SENS, since if one core enables the clock, it cannot be disabled by another core.

NOTE

After enabling the module clock, the software should perform dummy read on the related register field for the clock enablement to be properly propagated.

28.7.5.8 One Source Clock Slice Enable for VDD2_COMP Core (ONE_SRC_CLKSLICE_ENABLE)

Offset

Register	Offset
ONE_SRC_CLKSLICE_ENABLE	90h

Function

Controls the gating of one source clock slice. Multi source clock slices gating is controlled by enabling the SEL_EN bit field of a series of clock select source registers, for example, XSPI*n*CLKSEL.

NOTE

Not all the clock select source registers have this SEL_EN bit for some clocks cannot be gated, such as base clock.

NOTE

This register is VDD2_COMP core access only.

28.7.5.39 VDD1_SENSE Media Peripheral Clock Control 0 (PSCCTL0_SENS)

Offset

Register	Offset
PSCCTL0_SENS	810h

Function

Allows software to control specific peripheral's clock. Writing an one to any assigned bit in this register enable the clock and allows the specified peripheral to operate. Writing 0 disables the clock. If VDD2_MEDIA power rail is OFF, this register will be reset after power on.

NOTE

This register can only be written by CPU1. CPU0 can not write this register but CPU0 can read it to query the real status of device's clock. CPU1 can write zero to PSCCTL0_SENS to disable the clock. But whether this clock is really disabled software need to read back the related bit from PSCCTL0_MEDIA, since if one core enables the clock, it cannot be disabled by another core.

NOTE

After enabling the module clock, the software should perform dummy read on the related register field for the clock enablement to be properly propagated.

28.7.5.44 VDD1_SENSE Media Peripheral Clock Control 1 Clear (PSCCTL1_SENS_CLR)

Offset

Register	Offset
PSCCTL1_SENS_CLR	874h

Function

Writing an one to a bit position in PSCCTL1_SENS_CLR clears the corresponding position in PSCCTL1_SENSE.

NOTE

This register can only be written by CPU1, CPU0 should not write this register. CPU1 can write 1 to PSCCTL0_SENS_CLR to disable the clock. But whether this clock is really disabled software need to read back the related bit from PSCCTL1_MEDIA, since if one core enables the clock, it cannot be disabled by another core.

28.7.5.45 One Source Clock Slice Enable for VDD1_SENSE Core (ONE_SRC_CLKSLICE_ENABLE_SENSE)

Offset

Register	Offset
ONE_SRC_CLKSLICE_ENABLE_SENSE	890h

Function

Controls the gating of one source clock slice. Multi source clock slices gating is controlled by enabling the SEL_EN bit field of a series of clock select source registers, for example, XSPI*n*CLKSEL.

NOTE

Not all the clock select source registers have this SEL_EN bit for some clocks cannot be gated, such as base clock.

NOTE

This register is VDD1_SENSE core access only.

Full description	SYSCON	SYSCON
Peripheral memory map		Memory map overview

NOTE

The SYSCON module includes some security functionality that is not described here. Refer to the i.MX RT700 Security Reference Manual for more details.

29.1.1 Module instances

This device has five instances of the SYSCON modules.

Table 247. SYSCON instances

	SYSCON0	SYSCON1	SYSCON2	SYSCON3	SYSCON4
Located in	VDD2_COM	VDD1_SENSE	VDDN_COM	VDD1_SENSE	VDD2_MEDIA

29.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

29.1.3 GLIKEY protection

See GLIKEY protection for SYSCON registers that are protected by GLIKEY.

29.2 Overview

SYSCON configures buses, memory access, clocks, security, GPIO, core communication, interrupts, and associated peripheral control to these functions on the chip.

29.2.1 Block diagram

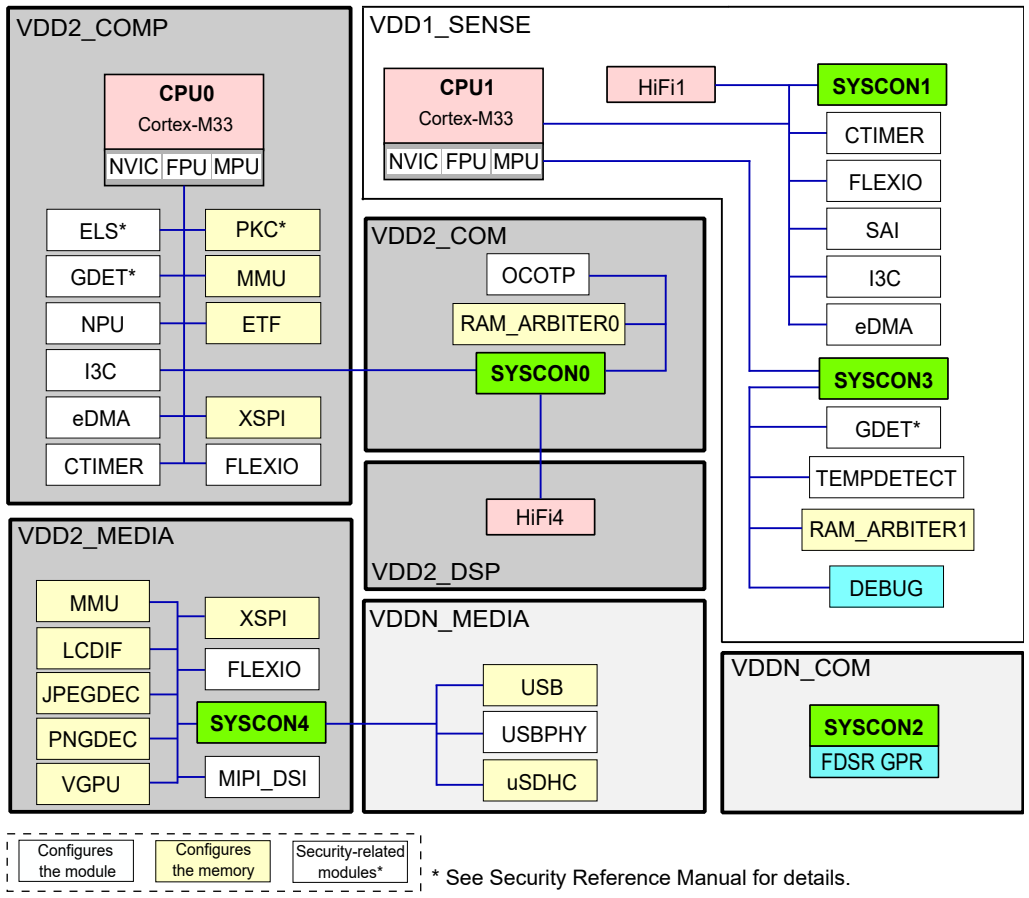

Figure 101. SYSCON block diagram

29.2.2 Features

SYSCON supports the following features and configurations:

- System configuration
  - CPU control and status (SYSCON0, 3)
  - EZH-V control (SYSCON4)
  - Non-Maskable Interrupt (NMI) source select (SYSCON0, 1)
  - Calibration of system tick timer (SYSCON0, 1)
- Memory configuration
  - Memory write mode configuration and speed trim (SYSCON0, 4)
  - Low-power control (SYSCON0, 1, 3, 4)
- Peripherals configuration
  - eDMA request configuration (SYSCON0, 1,)
  - Counter Timer (CTIMER) global start (SYSCON0, 1)
- Temperature detector (TEMPDETECT) controller (SYSCON3)
  - TEMPDETECT control

— TEMPDETECT interrupt set and clear

- General Purpose Input Output (GPIO) control
  - GPIO configuration (SYSCON0, 1)
- EZH-V and Arm core communication (SYSCON4)
  - Arm core to EZH-V interrupt control
  - EZH-V to Arm core interrupt control
- Gray-to-binary converter (SYSCON0, 3)
  - Allows decoding gray value coming from OS Event Timer (OSTIMER)

29.3 Functional description

29.3.1 TEMPDETECT controller

TEMPDETECT delivers a digital output that indicates if the junction temperature is above or below a given temperature threshold. See Temperature threshold. TEMPDETECT would normally be employed for the purpose of threshold.

Whenever the chip temperature crosses that temperature threshold, the sensor immediately signals that event to enable the system to react.

There are two programmable TEMPDETECTs in VDD1_SENSE domain, and each sensor generates a dedicated interrupt, as shown in the block diagram below.

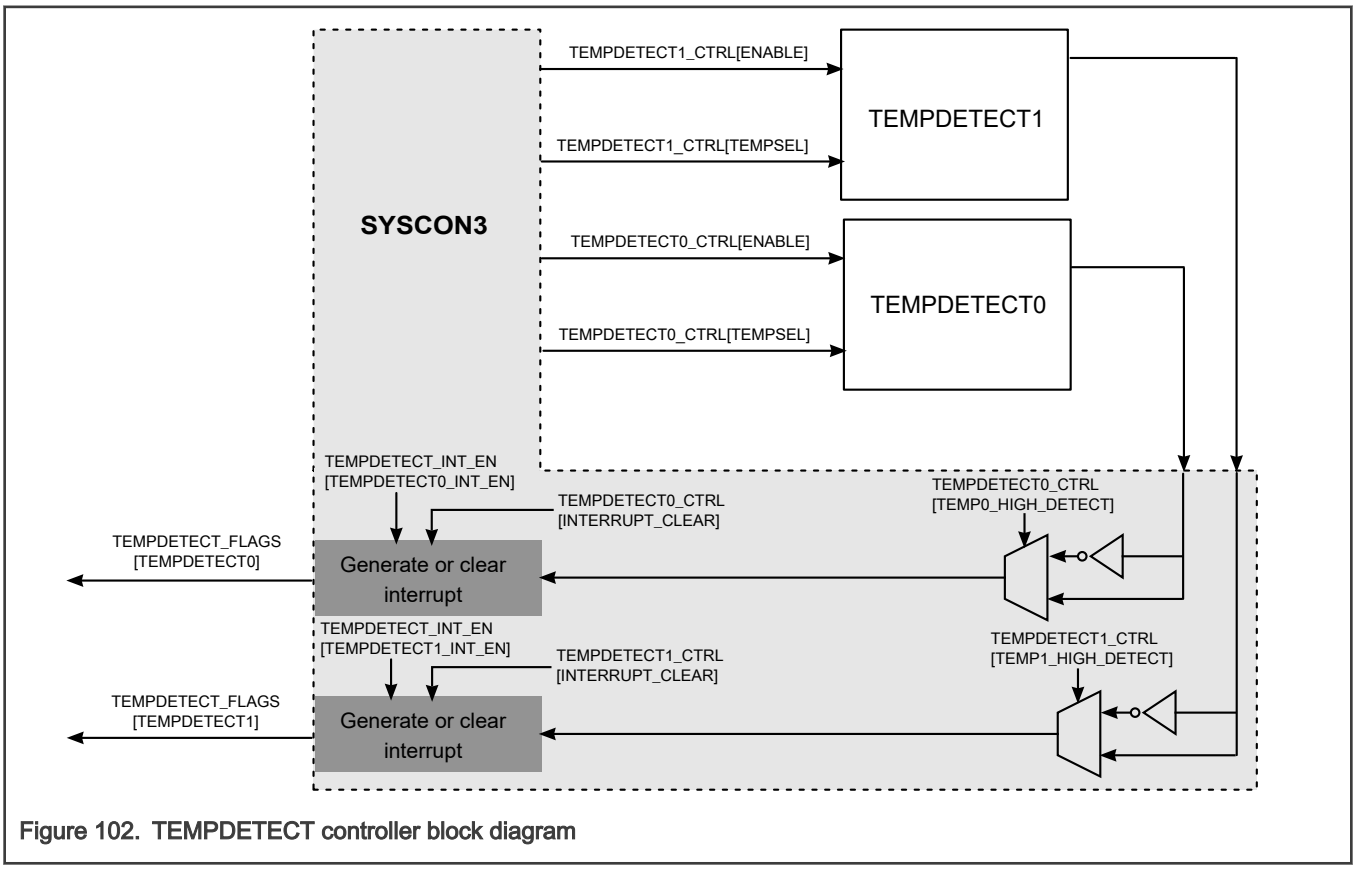

Figure 102. TEMPDETECT controller block diagram

29.3.1.1 Temperature threshold

The temperature threshold value is programmable from -45°C to +130°C.

NOTE

Ambient temperature range for the chip is -30°C to +85°C.

The approximate value of the temperature threshold $T_{TSH_{TYP}}$ (less than 0.25°C error) is calculated using the following polynomial regression:

$T_{TSH_{TYP}}(sel) = 0.000002673049*sel^3 + 0.0003734262*sel^2 + 0.4487042*sel - 46.98694$

Values of $T_{TSH_{TYP}}$ in function of TEMPSEL[7:0] (sel) are shown in Table 248.

Table 248. Temperature threshold values in function of TEMPSEL[7:0]

TEMPSEL [7:0]	$T_{TSH_{TYP}}$ (°C)	TEMPSEL [7:0]	$T_{TSH_{TYP}}$ (°C)	TEMPSEL [7:0]	$T_{TSH_{TYP}}$ (°C)	TEMPSEL [7:0]	$T_{TSH_{TYP}}$ (°C)

63	-16.65	127	21.56	191	70.86	255	136.20

29.3.1.2 TEMPDETECT configuration

All temperature detector inputs should be properly set before TEMPDETECT is enabled. During normal operation (TEMPDETECT enabled), system application can change the temperature threshold value but should not change any other configuration.

TEMPDETECT is enabled by setting TEMPDETECT0_CTRL[ENABLE] = 1 or TEMPDETECT1_CTRL[ENABLE] = 1. When TEMPDETECT is enabled, its output state only becomes valid after 200 µs. If TEMPDETECT is enabled, when the temperature threshold selection is changed, the output state only becomes valid after 200 µs.

29.3.2 GLIKEY protection

GLIKEY controls the access to some security sensitive registers on the chip, which includes the write-access and reset of these registers.

Below SYSCON registers are protected by GLIKEY by providing a 16-bit write enable input and a 16-bit reset input. Before accessing a SYSCON register, you must obtain the index bit high of the GLIKEY write enable inputs. Also, the SYSCON registers will be reset if the GLIKEY reset input is high.

Table 249. GLIKEY protected registers

1. NC = No connection. GLIKEY won't reset this register.

29.3.3 Clocking

Each SYSCON instance receives a single functional clock.

Table 250. SYSCON clocks

Clock	Description
Peripheral clock	Used for register access and related control logic. For information on generation and gating of this clock, see the CLKCTL chapter.

29.3.4 Interrupts

Table 251. SYSCON interrupts

Flag	Description
TEMPDETECT0 Interrupt	Flag generated from TEMPDETECT0, when the temperature is above or below the threshold
TEMPDETECT1 Interrupt	Flag generated from TEMPDETECT1, when the temperature is above or below the threshold

29.4 External signals

This module has no external signals.

29.5 Initialization

All SYSCON instances are enabled by default, no initialization is required.

The following table lists the registers in CLKCTL to enable the clock to each SYSCON instance.

Table 252. SYSCON clock enable register

SYSCON instance	CLKCTL instance	Clock enable register
SYSCON0	CLKCTL0	PSCCTL0[SYSCON0]
SYSCON1	CLKCTL1	PSCCTL0[SYSCON1]
SYSCON2	CLKCTL2	PSCCTL0[SYSCON2]
SYSCON3	CLKCTL3	PSCCTL0_COMP[SYSCON3] or PSCCTL0_SENS[SYSCON3]
SYSCON4	CLKCTL4	PSCCTL0_MEDIA[SYSCON4]

29.6.1.2 NMI Source Select (NMISRC)

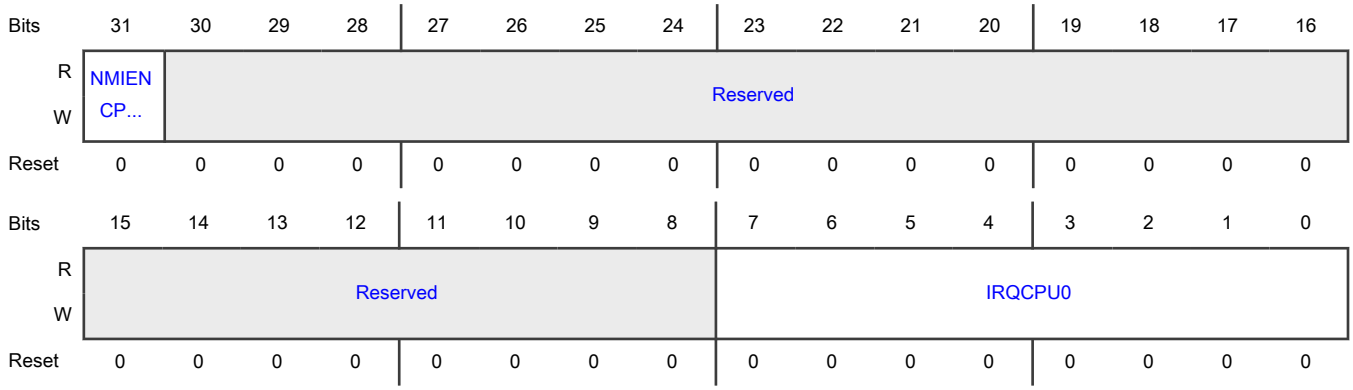
Offset

Register	Offset
NMISRC	14h

Function

Selects peripheral interrupts as source for the Non-Maskable Interrupt (NMI) of CPU0. The NMI source must first be disabled by writing 0 to the NMIENCPU0 bit to change the interrupt source for the NMI. The source can then be changed by updating the IRQCPU0 bits and re-enable the NMI source by setting NMIENCPU0.

Diagram



Fields

Field	Function
31 NMIENCPU0	Enables the Non-Maskable Interrupt (NMI) source selected by IRQCPU0 0b - Disables 1b - Enables
30-8 —	Reserved
7-0 IRQCPU0	The IRQ number of the interrupt that acts as the NMI for CPU0, if enabled by NMIENCPU0

29.6.1.3 CTIMER Global Start Enable (CTIMERGLOBALSTARTEN)

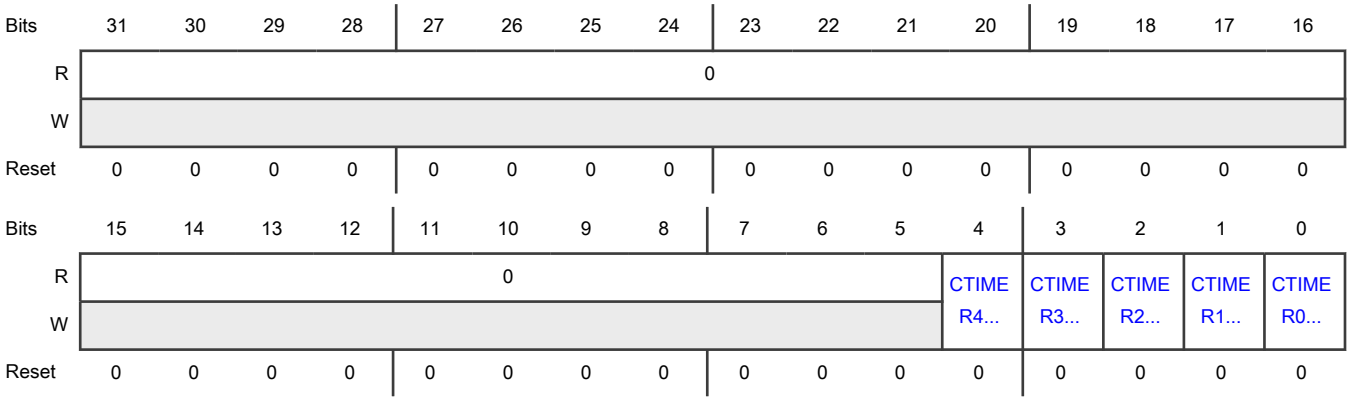
Offset

Register	Offset
CTIMERGLOBALSTARTEN	1Ch

Function

Configures CTIMER function clocks. PSCCTL2 register in CLKCTL0 also controls the clock for these CTIMERs. See CLKCTL chapter for details.

Diagram



Fields

Field	Function
31-5 —	Reserved
4 CTIMER4_CLK_EN	CTIMER4 Function Clock Enable 0b - Disables 1b - Enables

1 CTIMER1_CLK_EN	CTIMER1 Function Clock Enable 0b - Disables 1b - Enables
0 CTIMER0_CLK_EN	CTIMER0 Function Clock Enable 0b - Disables 1b - Enables

29.6.1.4 Bus Matrix Priority (AHBMATPRIO)

Offset

Register	Offset
AHBMATPRIO	78h

Function

The multilayer AHB matrix arbitrates between several initiators, only if they attempt to access the same matrix target port at the same time. Care should be taken if the value in this register is changed, improper settings can seriously degrade performance. Priority values are 0 = highest, 3 = lowest. When the priority is the same, the initiator with the lower M number is given priority. See System bus diagram in Introduction chapter.

NOTE

Be careful when modifying this register as improper settings can seriously degrade the performance.

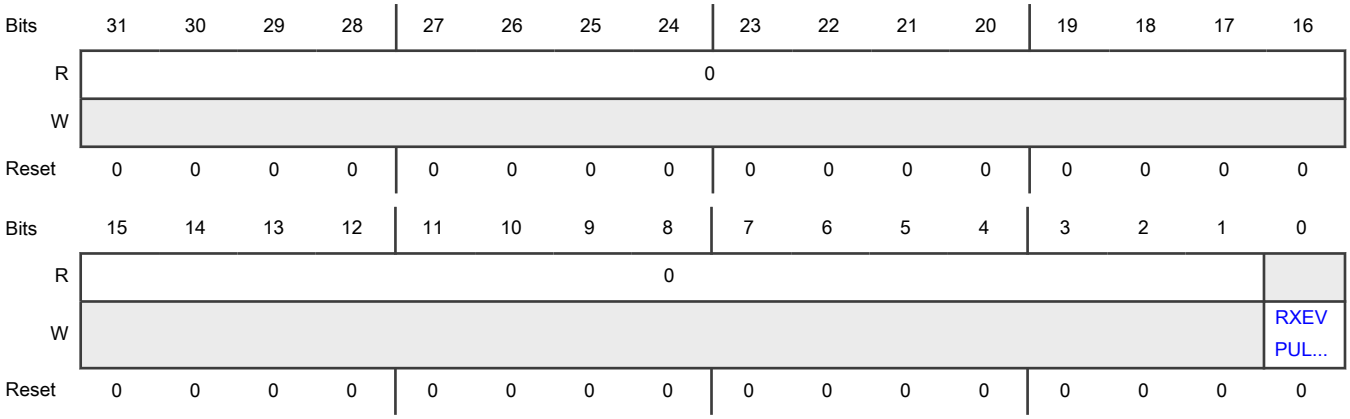
29.6.1.5 Receive Event Pulse Generator (RXEVPULSEGEN)

Offset

Register	Offset
RXEVPULSEGEN	80h

Function
Allows generating a pulse on CPU0 receive event input that will wake it up if it is stopped in a wait for event (WFE) instruction.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 RXEVPULSEGEN	Receive Event Pulse Generator Writing a 1 to this register will create a logic 1 pulse for one APB bus clock when set by HiFi4 or EZH-V. It is automatically cleared. 0b - No effect 1b - Pulse receive event high for one cycle

29.6.1.6 Latched Cortex-M33 Transmit Event (LATCHED_CM33_TXEV)

Offset

Register	Offset
LATCHED_CM33_TXEV	84h

Function
CPU0 TXEV (Cortex-M33 send event) is latched into the register and then cleared by EZH-V writing 1 to the flag.

CPU0 TXEV is a cycle pulse and one of the EZH-V interrupts, so the signal is latched in SYSCON0 and waiting to be cleared by EZH-V.

Diagram

0 LATCHED_TXEV	Cortex-M33 Transmit Event Write a 1 to clear this register. 0b - No effect 1b - Clear the event flag

29.6.1.7 System Secure Tick Calibration (SYSTEM_STICK_CALIB)

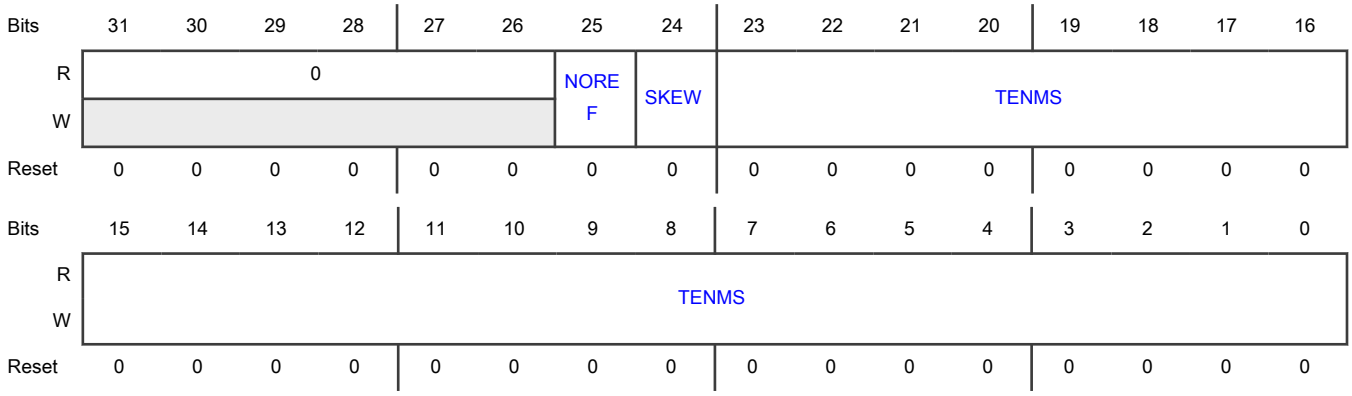
Offset

Register	Offset
SYSTEM_STICK_CALIB	90h

Function

Allows software to set up a default value for the SYST_CALIB register (see Arm documentation) in the System Tick Timer of secure part of CPU0.

Diagram



Fields

Field	Function
31-26 —	Reserved
25 NOREF	No Reference Clock Controls whether the device provides a reference clock to the processor. 0b - Provides 1b - Not provide
24 SKEW	Skew Controls whether [TENMS] value is exact. 0b - Exact 1b - Inexact, or not given
23-0 TENMS	Ten Milliseconds Reload value for 10 ms (100 Hz) timing, subject to system clock skew errors. If the value reads as zero, the calibration value is not known.

29.6.1.8 System Non-Secure Tick Calibration (SYSTEM_NSTICK_CALIB)

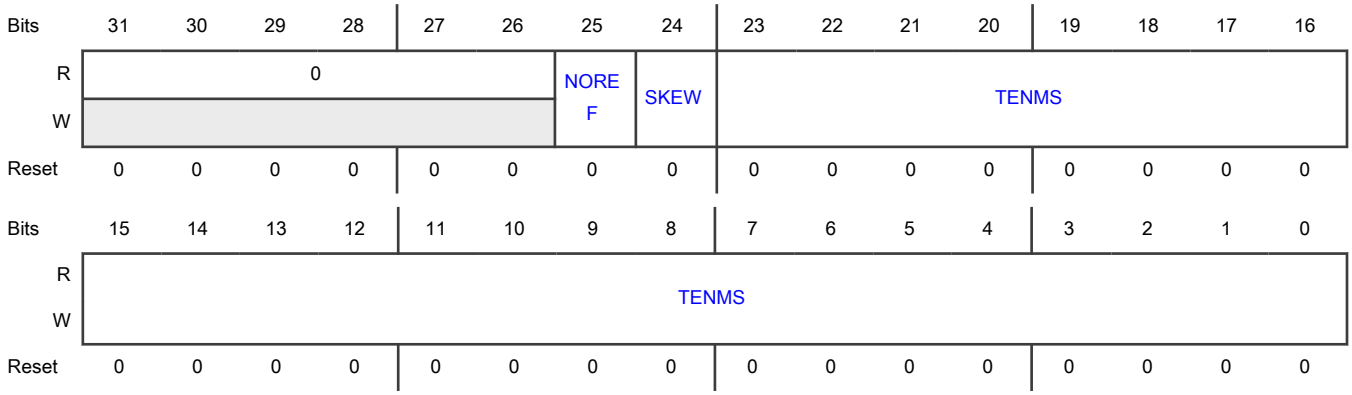
Offset

Register	Offset
SYSTEM_NSTICK_CALIB	94h

Function

Allows software to set up a default value for the SYST_CALIB register in the System Tick Timer of non-secure part of CPU0.

Diagram



Fields

Field	Function
31-26 —	Reserved
25 NOREF	No Reference Clock Controls whether the device provides a reference clock to the processor: 0b - Provides 1b - Not provide
24 SKEW	Skew Controls whether [TENMS] value is exact. 0b - Exact 1b - Inexact, or not given
23-0 TENMS	Ten Milliseconds Reload value for 10 ms (100 Hz) timing, subject to system clock skew errors. If the value reads as zero, the calibration value is not known.

29.6.1.9 CPU0 Status (CPU0_STATUS)

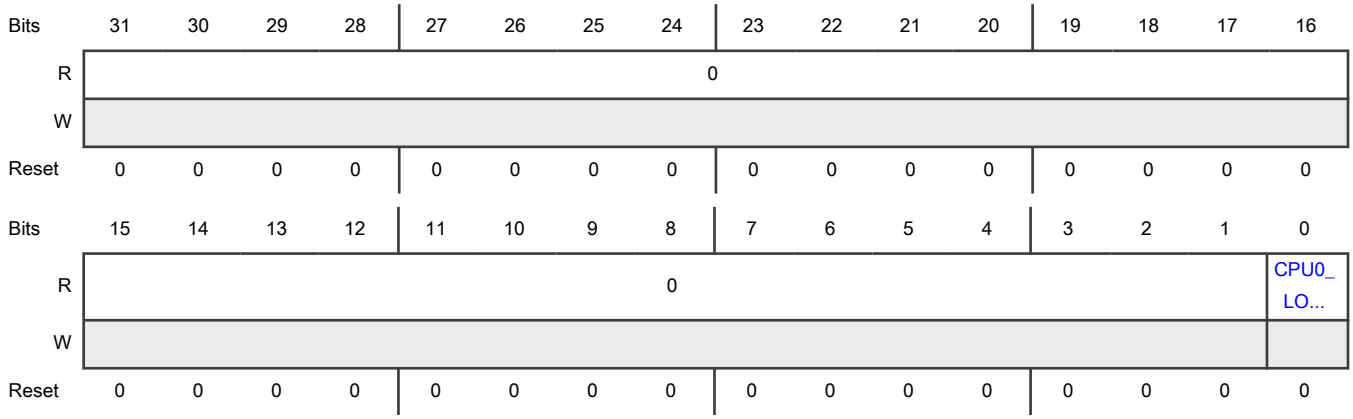
Offset

Register	Offset
CPU0_STATUS	98h

Function

Stores CPU0 status.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 CPU0_LOCKUP	CPU0 Lockup State Indicates whether CPU0 is in lockup state. 0b - Not in lockup 1b - In lockup

29.6.1.10 GPIO Synchronization Stages (GPIO_PSYNC)

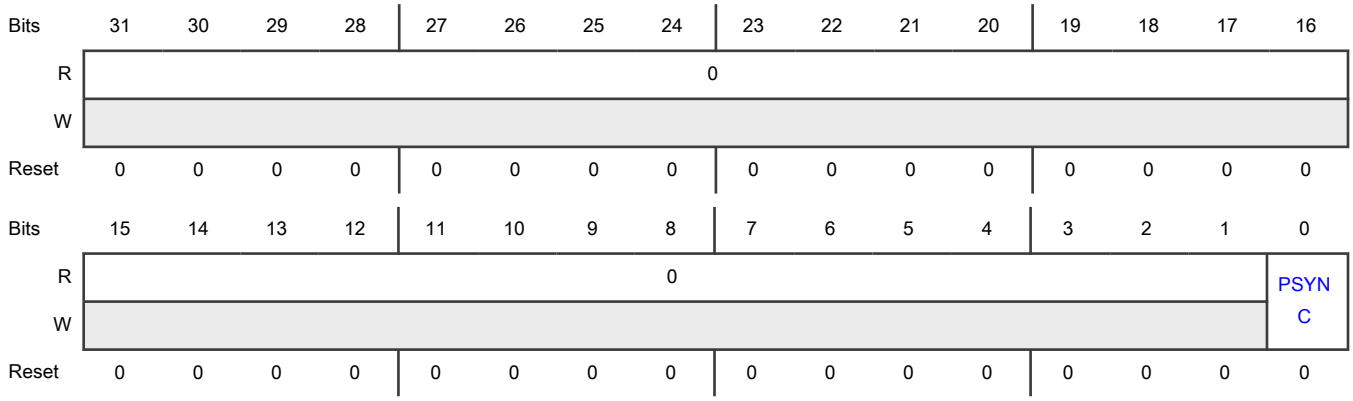
Offset

Register	Offset
GPIO_PSYNC	D0h

Function

Selects the amount of synchronization stages in the GPIO inputs.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 PSYNC	Synchronization Stage Setting The PINT block has two flip-flop synchronizers on the interrupt and pattern match detect circuits based on data inputs from the pads. The first flip-flop stage of synchronization is clocked on the falling edge of the peripheral clock. The second flip-flop stage is clocked on the rising edge of the peripheral clock. The synchronizers can be configured to be 1-stage synchronizers to reduce the signal latency at low peripheral clock frequencies. 0b - 2-stage sync 1b - 1-stage sync

29.6.1.11 Automatic Clock Gate Override (AUTOCLKGATEOVERRIDE0)

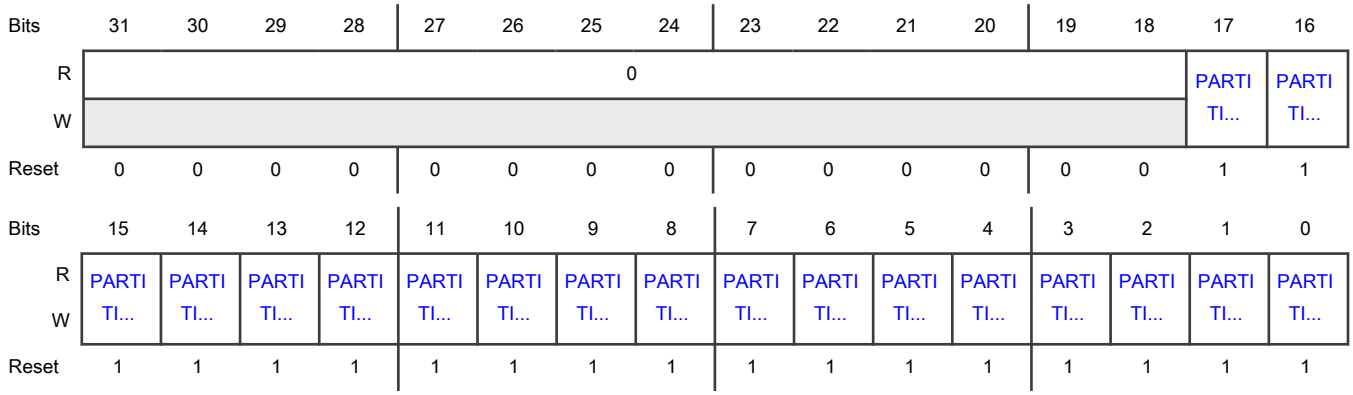
Offset

Register	Offset
AUTOCLKGATEOVERRIDE0	114h

Function

This register allows selectively disabling automatic clock gating for SRAM partitions. By default, automatic clock gating turns off clocks to each internal SRAM after 5 bus clocks with no activity. This saves power when the SRAMs are not used for a period of time. When turned off due to automatic clock gating, there is a 1-clock delay for the next access to an SRAM.

Diagram



Fields

Field	Function
31-18 —	Reserved
17-0 PARTITIONn	Partition n Controls clock gating for Partition 0 (bit 0) to Partition 17 (bit 17). 0b - Enables clock gating 1b - Continuous clocking

29.6.1.12 SRAM Clock Gating Control (SRAM_CLKGATE_CTRL)

Offset

Register	Offset
SRAM_CLKGATE_CTRL	118h

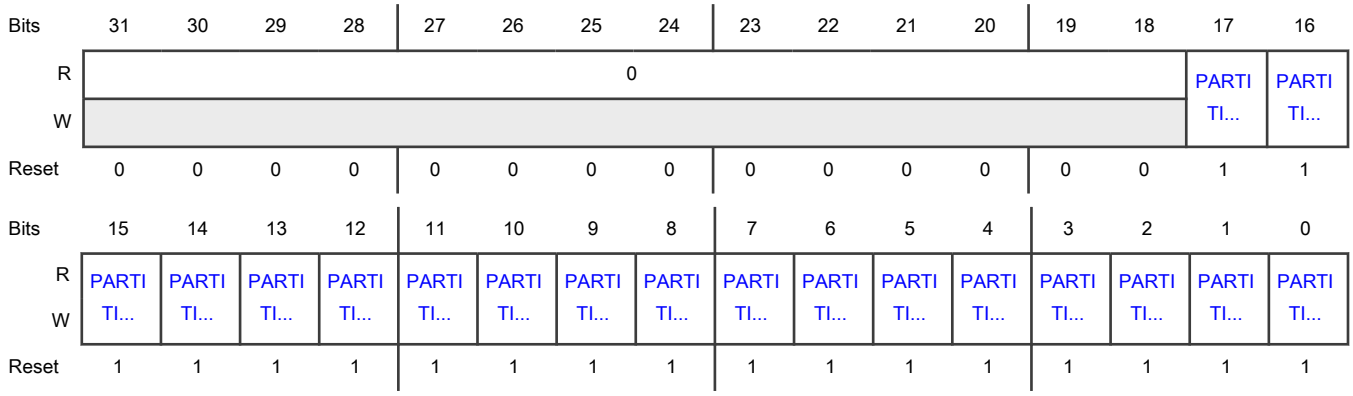
Function

If cleared, the corresponding SRAM partition input clock driven by COMPUTE_MAIN_CLK_1 will be gated off. This provides means to save power if the corresponding partition is not planned to be used for a significant amount of time. To get the power saving, the Compute CPU (CPU0) needs to do a dummy read to the partition to switch the partition clock to COMPUTE_MAIN_CLK_1, and then clear this bit. While the bit for an associated partition is cleared, no bus initiators will be able to access that partition unless the bit is set again.

NOTE

Any core will halt when accessing the gated partition, until CPU0 turns on the partition clock.

Diagram



Fields

Field	Function
31-18 —	Reserved
17-0 PARTITIONn	Partition n Gates off the bus clock input in VDD2_COMP domain for Partition 0 (bit 0) to Partition 17 (bit 17). 0b - Bus clock input gated 1b - No effects

29.6.1.13 MMU0 Memory Control (MMU0_MEM_CTRL)

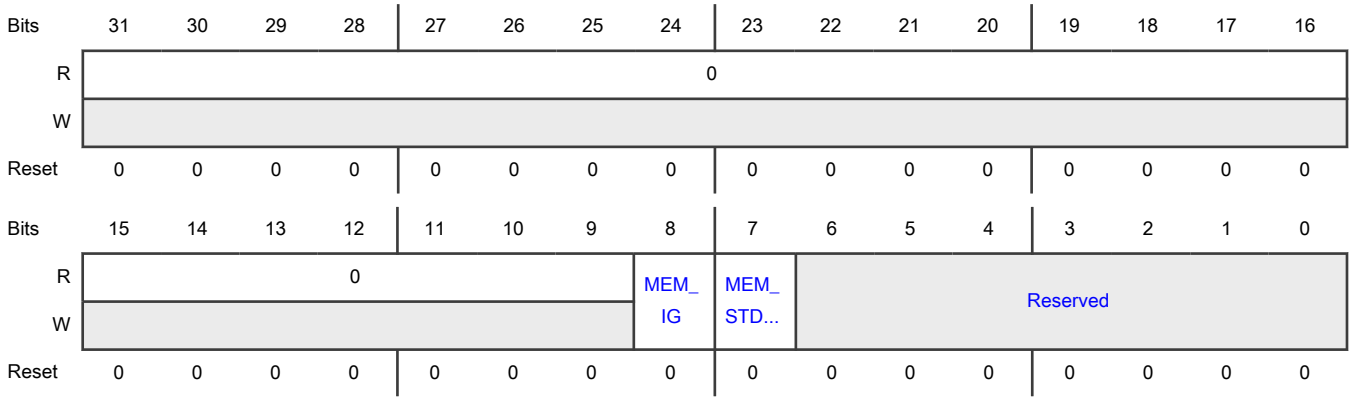
Offset

Register	Offset
MMU0_MEM_CTRL	130h

Function

Controls Memory Map Unit (MMU0) memory.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 MEM_IG	Memory Input Gating When active, gates the selected memory inputs to reduce active power associated with input toggles. This bit can be set to reduce RAM power consumption if reads or writes are not needed for short periods of time. 0b - Inactive 1b - Active
7 MEM_STDBY	Memory Standby Mode When active, puts the memory into standby mode. This bit can be set to reduce RAM power consumption if the RAM is never used or will not be used for long periods of time. There is a brief increase in RAM power created by the shutdown sequence caused by a transition from regular mode to standby mode. Therefore, standby mode should only be used when the RAM array will not be accessed for long periods of time. 0b - Inactive 1b - Active
6-0 —	Reserved

29.6.1.14 eDMA0 Memory Control (EDMA0_MEM_CTRL)

Offset

Register	Offset
EDMA0_MEM_CTRL	140h

Function

Controls Enhanced Direct Memory Access (eDMA) 0 memory.

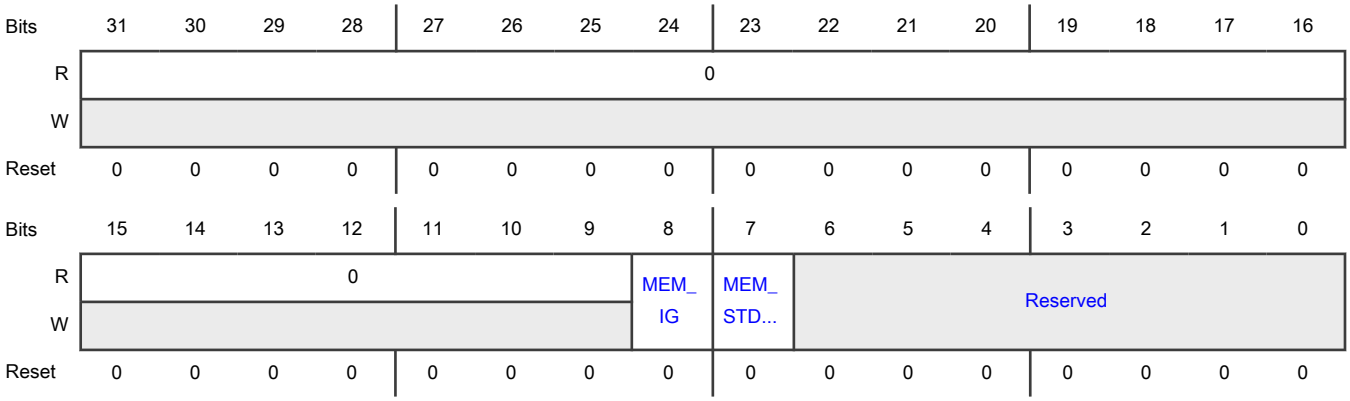
Controls CACHE64_CTRL0 tag memory.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 MEM_IG	Memory Input Gating When active, gates the selected memory inputs to reduce active power associated with input toggles. This bit can be set to reduce RAM power consumption if reads or writes are not needed for short periods of time. 0b - Inactive 1b - Active
7 MEM_STDBY	Memory Standby Mode When active, puts the memory into standby mode. This bit can be set to reduce RAM power consumption if the RAM is never used or will not be used for long periods of time. There is a brief increase in RAM power created by the shutdown sequence caused by a transition from regular mode to standby mode. Therefore, standby mode should only be used when the RAM array will not be accessed for long periods of time.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Inactive 1b - Active
6-0 —	Reserved

29.6.1.28 CACHE64_CTRL1 Tag Memory Control (XSPI1_TAG_MEM_CTRL)

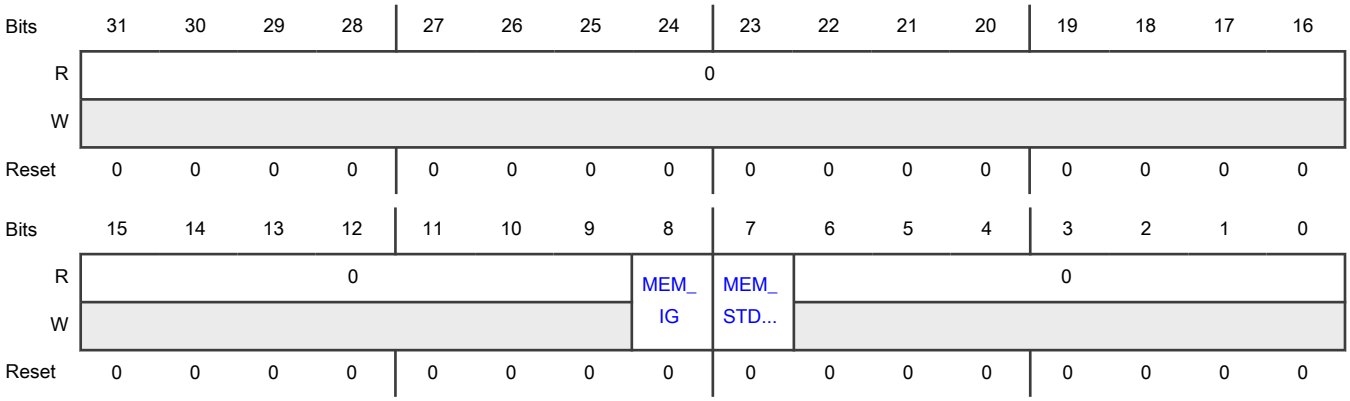
Offset

Register	Offset
XSPI1_TAG_MEM_CTRL	260h

Function

Configures input and power gating for CACHE64_CTRL1 tag memory.

Diagram



Fields

Field	Function
31-9 —	Reserved

29.6.1.29 VDD2_COMP Auto Gating Enable (COMP_AUTOGATE_EN)

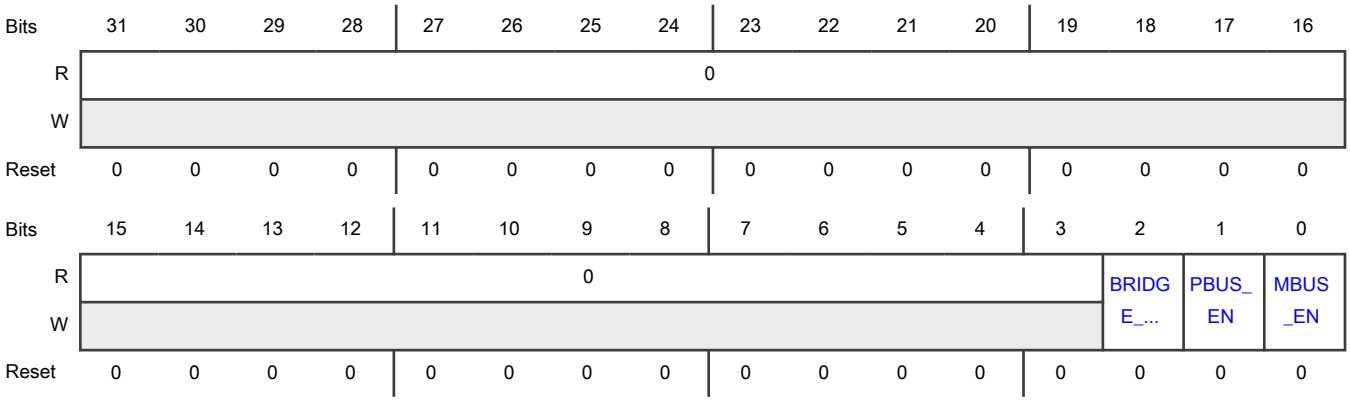
Offset

Register	Offset
COMP_AUTOGATE_EN	280h

Function

Controls clock gating for M-bus, P-bus, AHB2APB bridge, AIPS and AXBS in VDD2_COMP domain. This register allows selectively enabling automatic clock gating for the modules. By default, automatic clock gating turns off clocks to the modules after 2 bus clocks with no bus transaction activity. This saves power when the corresponding modules are not used for a period of time.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 BRIDGE_EN	Automatic Clock Gating Enable for AHB2APB bridge, AIPS and AXBS Controls clock gating for AHB2APB bridge, AIPS and AXBS in VDD2_COMP domain. You can set it to disable the module's clock in order to save power when the module is not working. 0b - Disables clock gating (continuous clock) 1b - Enables clock gating
1 PBUS_EN	Automatic Clock Gating Enable for P-bus Controls clock gating for P-bus in VDD2_COMP domain. You can set it to disable the module's clock in order to save power when the module is not working. 0b - Disables clock gating (continuous clock) 1b - Enables clock gating
0 MBUS_EN	Automatic Clock Gating Enable for M-bus Controls clock gating for M-bus in VDD2_COMP domain. You can set it to disable the module's clock in order to save power when the module is not working. **NOTE** Once CPU0 enters Deep Sleep when accessing RAM arbiter 0, if any other initiator needs to access RAM arbiter 0, you must disable this bit before CPU0 enters Deep Sleep. 0b - Disables clock gating (continuous clock) 1b - Enables clock gating

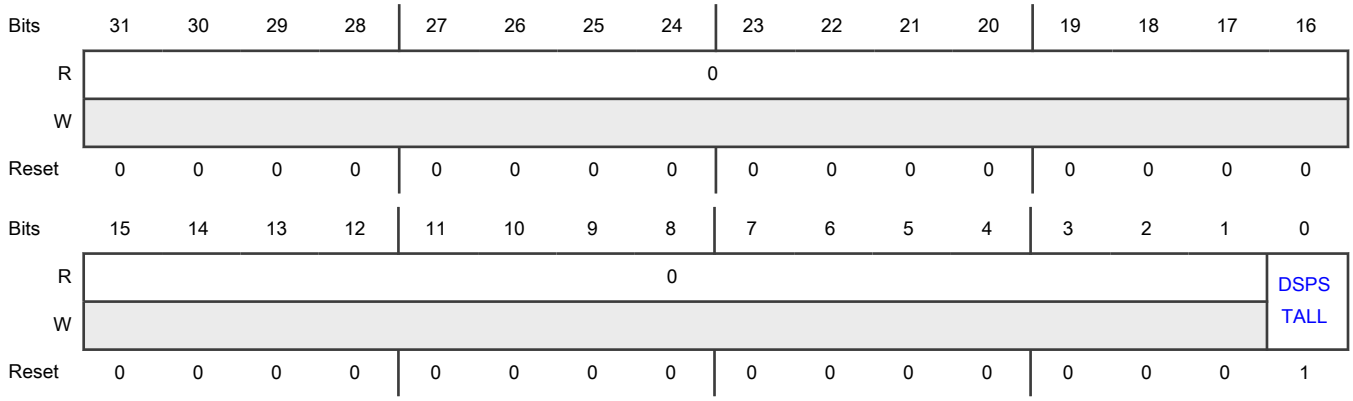
29.6.1.30 HiFi4 Stall (DSPSTALL)

Offset

Register	Offset
DSPSTALL	300h

Function
Controls the operation of HiFi4.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 DSPSTALL	Run and Stall Control 0b - Run (normal mode) 1b - Stall mode

29.6.1.31 HiFi4 OCDHaltOnReset (OCDHALTONRESET)

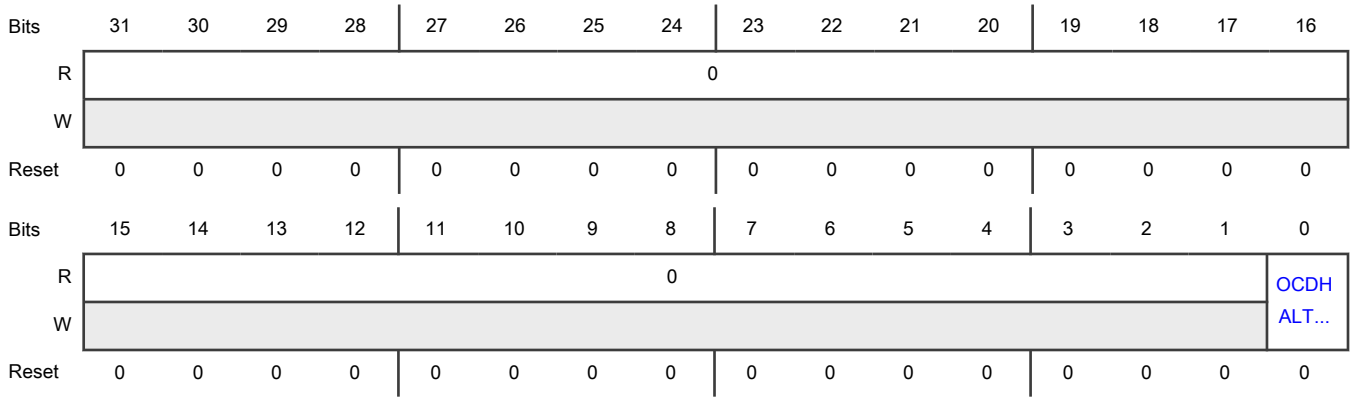
Offset

Register	Offset
OCDHALTONRESET	304h

Function

HiFi4 enters On-Chip Debug (OCD) Halt mode if this signal is sampled asserted on reset.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 OCDHALTONRESET	OCDHaltOnReset 0b - Allow normal operation when HiFi4 exits reset (starts fetching and executing instructions from memory) 1b - Force HiFi4 to enter OCD Halt mode when HiFi4 exits reset

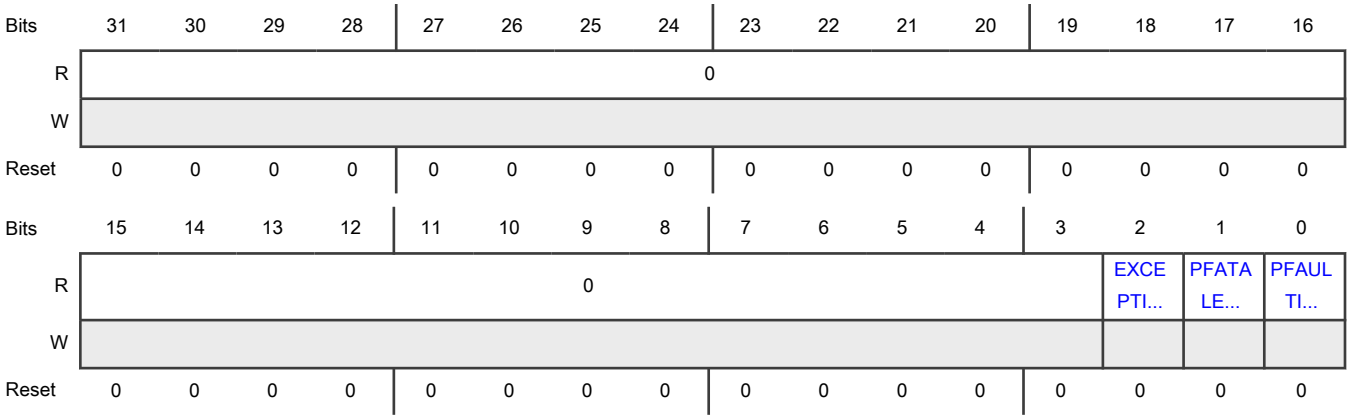
29.6.1.32 HiFi4 General Purpose Register 0 (HIFI4_GPR0)

Offset

Register	Offset
HIFI4_GPR0	308h

Function
General purpose register assigned to capture HiFi4 status signals.

Diagram



Fields

Field	Function
31-3 —	Reserved
2	DoubleExceptionError

Table continues on the next page...

Table continued from the previous page...

Field	Function
EXCEPTIONERR	Single-cycle assertion every time double exception faults occur. Unlike [PFATALERR], this signal is not sticky. The system can use the information presented on [PFATALERR] and HIFI4_GPR1[PFAULTINFO] and decide whether to reset the HIFI4 core or the whole system. 0b - No error occurs 1b - Error occurs
1 PFATALERR	PFatalError Asserted when a fatal error condition occurs due to AXI parity or ECC errors. The PFatalError signal is sticky and is cleared by HiFi4 reset. 0b - No error occurs 1b - Error occurs
0 PFAULTINFOVLD	PFaultInfoValid Asserted when the PFaultInfo signal changes its value. The system can use its rising edge as an enabler to capture PFaultInfo. 0b - Not asserted 1b - Asserted

29.6.1.33 HiFi4 General Purpose Register 1 (HIFI4_GPR1)

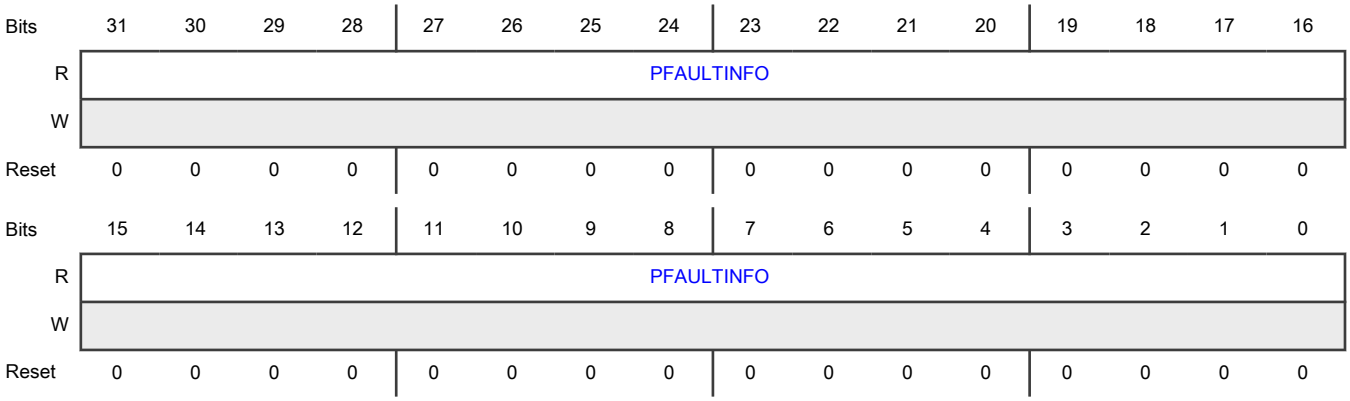
Offset

Register	Offset
HIFI4_GPR1	314h

Function

General purpose register assigned to capture HiFi4 status signals.

Diagram



Fields

Field	Function
31-0 PFAULTINFO	PFaultInfo This signal mirrors HiFi4's internal Fault Information Register and provides the source and severity of the fault. For detailed information, see "PFaultInfo and Fault Information Register (FIR)" section in HiFi4 chapter.

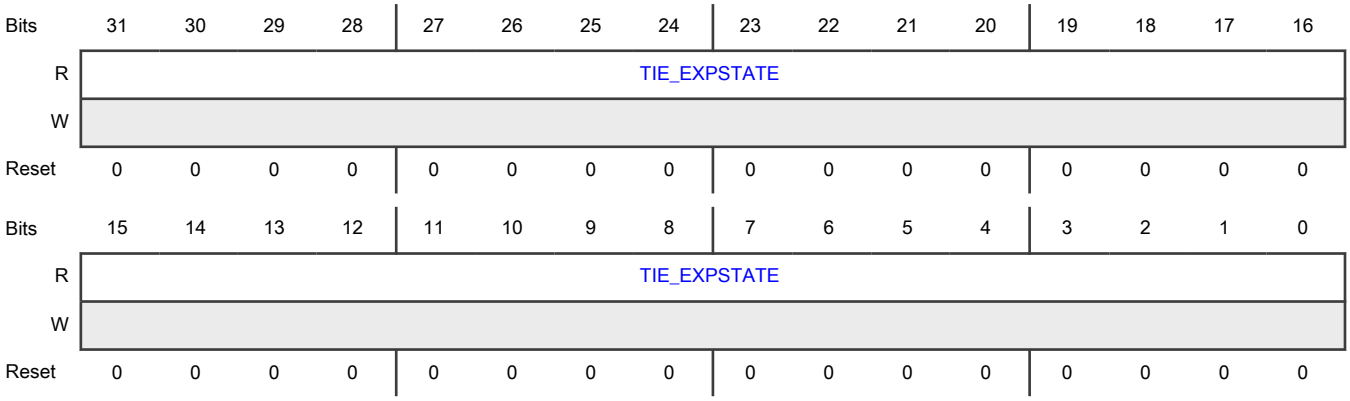
29.6.1.34 HiFi4 General Purpose Register 2 (HIFI4_GPR2)

Offset

Register	Offset
HIFI4_GPR2	318h

Function
General purpose register assigned to capture HiFi4 status signals.

Diagram



Fields

Field	Function
31-0 TIE_EXPSTATE	GPIO32 Option TIE Output State Indicates the state of “tie_expstate” used to capture OSTIMER and to trigger EZH-V.

29.6.1.35 HiFi4 DSP Vector Remap (DSP_VECT_REMAP)

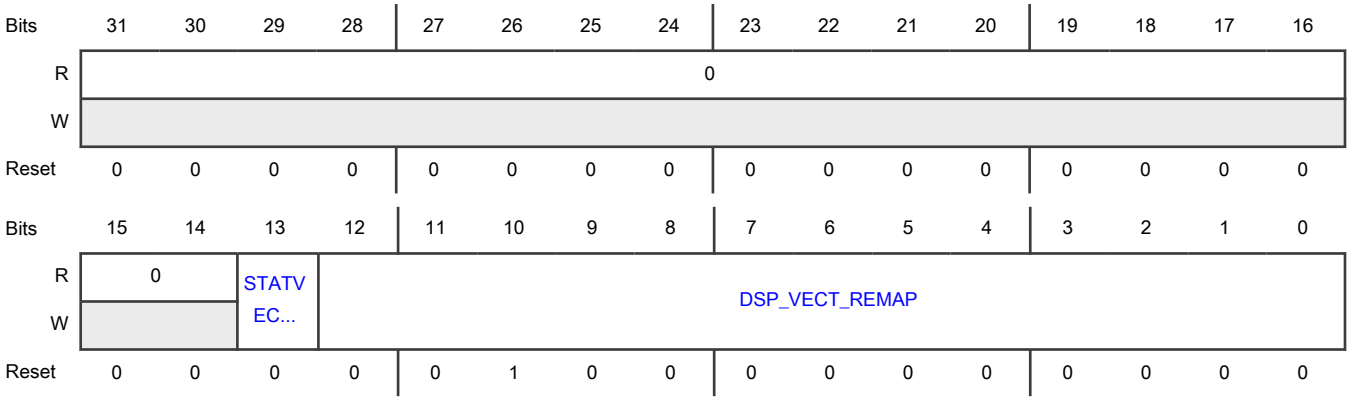
Offset

Register	Offset
DSP_VECT_REMAP	31Ch

Function

Configures HiFi4 remap function.

Diagram



Fields

Field	Function
31-14 —	Reserved
13 STATVECSELECT	HiFi4 Remap Function Enable Enables remap function on HiFi4. When enabled, remaps 2010_0000h to another address in shared RAM. HiFi4 vector base address is always at 2402_0000h although remap function is enabled. This address is HiFi4 local TCM. 0b - Remap function disabled 1b - Remap function enabled
12-0 DSP_VECT_REMAP	DSP Vector Remap Remaps ARADDR[22:10] when [STATVECSELECT] is set and ARADDR hits 1 KB from 2010_0000h. **NOTE** Remapping the vectors will leave a "hole" of 1 KB at the default vector location which HiFi4 DSP will never be able to access (CPU0 and all other initiators will have access though).

29.6.1.36 eDMA0 Request Enable 0 (EDMA0_EN0)

Offset

Register	Offset
EDMA0_EN0	420h

Function
Enables Request 0 for eDMA0.

Diagram

628h	I3C Asynchronous Wake-up Control (I3C_ASYNC_WAKEUP_CTRL)	32	RW	0000_0000h

29.6.2.2 NMI Source Select (NMISRC)

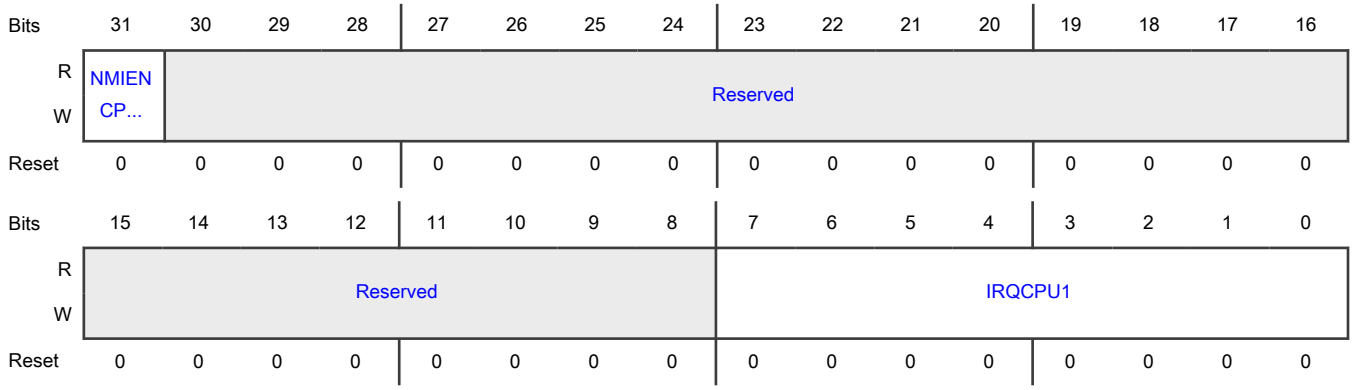
Offset

Register	Offset
NMISRC	14h

Function

Selects peripheral interrupts as source for the Non-Maskable Interrupt (NMI) of CPU1. The NMI source must first be disabled by writing 0 to the NMIENCPU1 bit to change the interrupt source for the NMI. The source can then be changed by updating the IRQCPU1 bits and re-enable the NMI source by setting NMIENCPU1.

Diagram



Fields

Field	Function
31 NMIENCPU1	Enables the Non-Maskable Interrupt (NMI) source selected by IRQCPU1 0b - Disables 1b - Enables
30-8 —	Reserved
7-0 IRQCPU1	The IRQ number of the interrupt that acts as the Non-Maskable Interrupt (NMI) for CPU1, if enabled by NMIENCPU1

29.6.2.3 CTIMER Global Start Enable (CTIMERGLOBALSTARTEN)

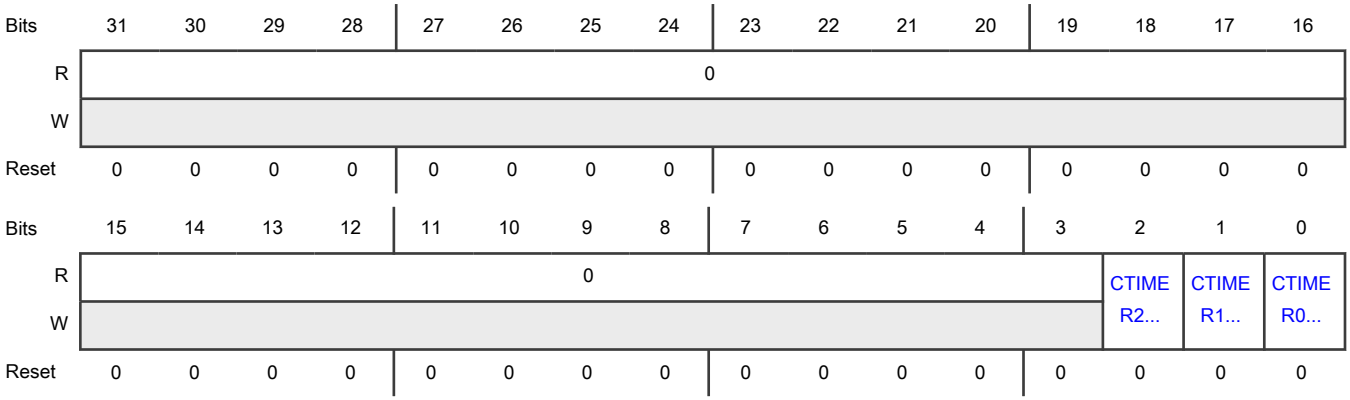
Offset

Register	Offset
CTIMERGLOBALSTARTEN	1Ch

Function

Configures CTIMER function clocks. PSCCTL1 register in CLKCTL1 also controls the clock for these CTIMERs. See CLKCTL chapter for details.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 CTIMER2_CLK_EN	CTIMER7 Function Clock Enable 0b - Disables 1b - Enables
1 CTIMER1_CLK_EN	CTIMER6 Function Clock Enable 0b - Disables 1b - Enables
0 CTIMER0_CLK_EN	CTIMER5 Function Clock Enable 0b - Disables 1b - Enables

29.6.2.4 Bus Matrix Priority (AHBMATPRIO)

Offset

Register	Offset
AHBMATPRIO	78h

Function

The multilayer AHB matrix arbitrates between several initiators, only if they attempt to access the same matrix target port at the same time. Care should be taken if the value in this register is changed, improper settings can seriously degrade performance. Priority values are 0 = highest, 3 = lowest. When the priority is the same, the initiator with the lower M number is given priority. See System bus diagram in Introduction chapter.

NOTE

Be careful when modifying this register as improper settings can seriously degrade the performance.

29.6.2.5 System Secure Tick Calibration (SYSTEM_STICK_CALIB)

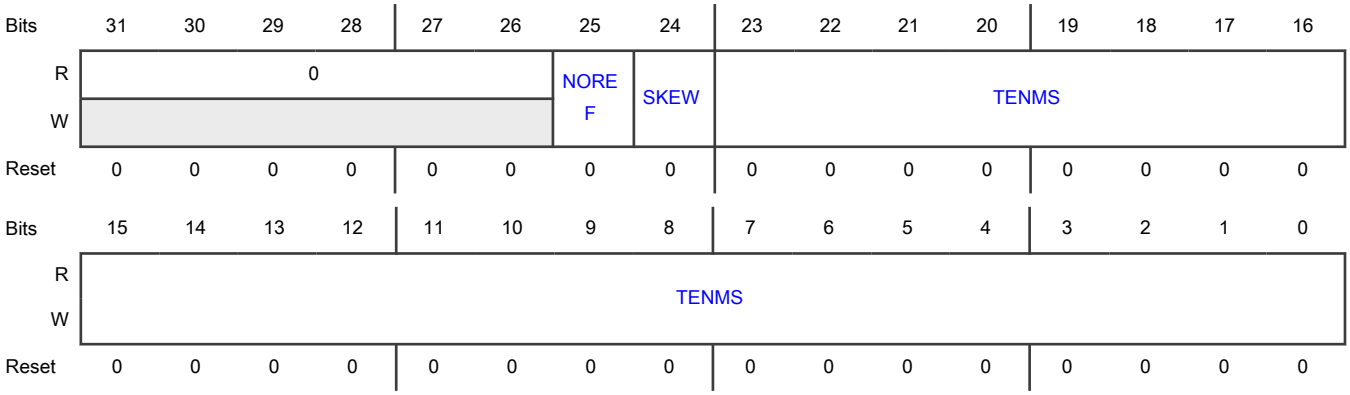
Offset

Register	Offset
SYSTEM_STICK_CALIB	90h

Function

Allows software to set up a default value for the SYST_CALIB register (see Arm documentation) in the System Tick Timer of secure part of CPU1.

Diagram



Fields

Field	Function
31-26 —	Reserved
25 NOREF	No Reference Clock Controls whether the device provides a reference clock to the processor. 0b - Provides 1b - Not provide
24 SKEW	SKEW Controls whether [TENMS] value is exact. 0b - Exact 1b - Inexact, or not given
23-0 TENMS	Ten Milliseconds Reload value for 10 ms (100 Hz) timing, subject to system clock skew errors. If the value reads as zero, the calibration value is not known.

29.6.2.6 System Non-Secure Tick Calibration (SYSTEM_NSTICK_CALIB)

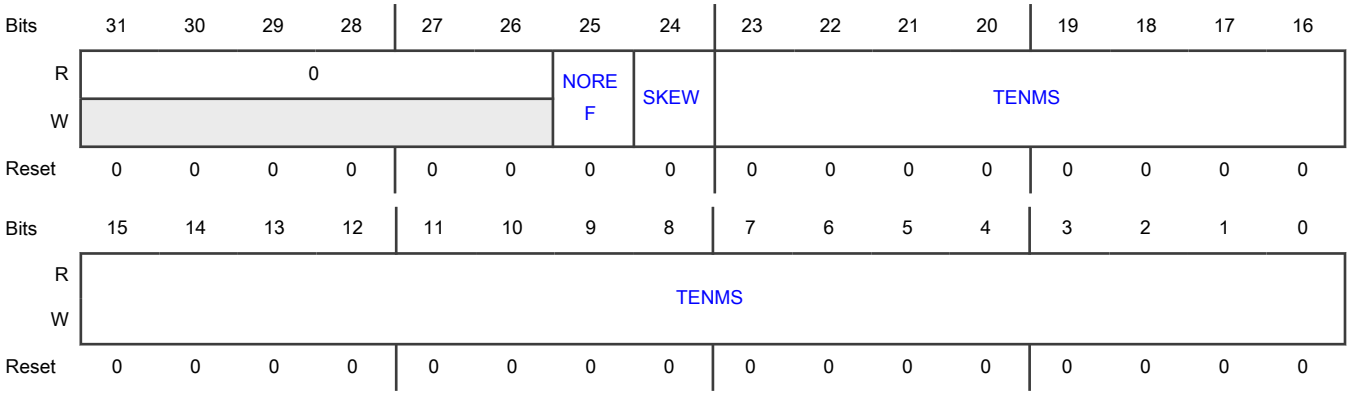
Offset

Register	Offset
SYSTEM_NSTICK_CALIB	94h

Function

Allows software to set up a default value for the SYST_CALIB register in the System Tick Timer of non-secure part of CPU1.

Diagram



Fields

Field	Function
31-26 —	Reserved
25 NOREF	No Reference Clock Controls whether the device provides a reference clock to the processor. 0b - Provides 1b - Not provide
24 SKEW	SKEW Controls whether [TENMS] value is exact. 0b - Exact 1b - Inexact, or not given
23-0 TENMS	Ten Milliseconds Reloads value for 10 ms (100 Hz) timing, subject to system clock skew errors. If the value reads as zero, the calibration value is not known.

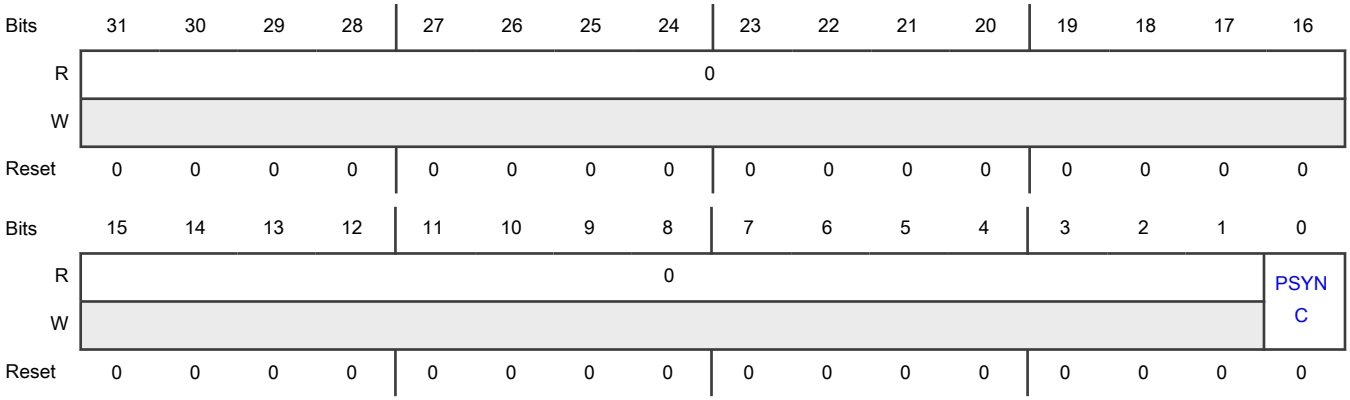
29.6.2.7 GPIO Synchronization Stages (GPIO_PSYNC)

Offset

Register	Offset
GPIO_PSYNC	D0h

Function
Selects the amount of synchronization stages in the GPIO inputs.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 PSYNC	Synchronization Stage Setting The PINT block has two flip-flop synchronizers on the interrupt and pattern match detect circuits based on data inputs from the pads. The first flip-flop stage of synchronization is clocked on the falling edge of the peripheral clock. The second flip-flop stage is clocked on the rising edge of the peripheral clock. The synchronizers can be configured to be 1-stage synchronizers to reduce the signal latency at low peripheral clock frequencies. 0b - 2-stage sync 1b - 1-stage sync

29.6.2.8 eDMA2 Memory Control (EDMA2_MEM_CTRL)

Offset

Register	Offset
EDMA2_MEM_CTRL	144h

Function

Configures input and power gating for eDMA2 memory.

NOTE

Ideally, [PWR_IG] and [PWR_STDBY] fields should be cleared before warm reset if the bits were set. If this is not possible, the application programmer should make sure that [PWR_IG] and [PWR_STDBY] fields are cleared after each warm reset.

Fields

Field	Function
31-9 —	Reserved
8 PWR_IG	Memory Input Gating When active, gates the selected memory inputs to reduce active power associated with input toggles. This bit can be set to reduce RAM power consumption if reads or writes are not needed for short periods of time. 0b - Inactive 1b - Active
7 PWR_STDBY	Memory Standby Mode When active, puts the memory into standby mode. This bit can be set to reduce RAM power consumption if the RAM is never used or will not be used for long periods of time. There is a brief increase in RAM power created by the shutdown sequence caused by a transition from regular mode to standby mode. Therefore, standby mode should only be used when the RAM array will not be accessed for long periods of time. 0b - Inactive 1b - Active
6-0 —	Reserved

29.6.2.9 eDMA3 Memory Control (EDMA3_MEM_CTRL)

Offset

Register	Offset
EDMA3_MEM_CTRL	148h

Function

Configures read and write characterization mode, input and power gating for eDMA3 memory.

NOTE

Ideally, [PWR_IG] and [PWR_STDBY] fields should be cleared before warm reset if the bits were set. If this is not possible, the application programmer should make sure that [PWR_IG] and [PWR_STDBY] fields are cleared after each warm reset.

29.6.2.10 SAI3 MCLK IO Direction Control (SAI3_MCLK_CTRL)

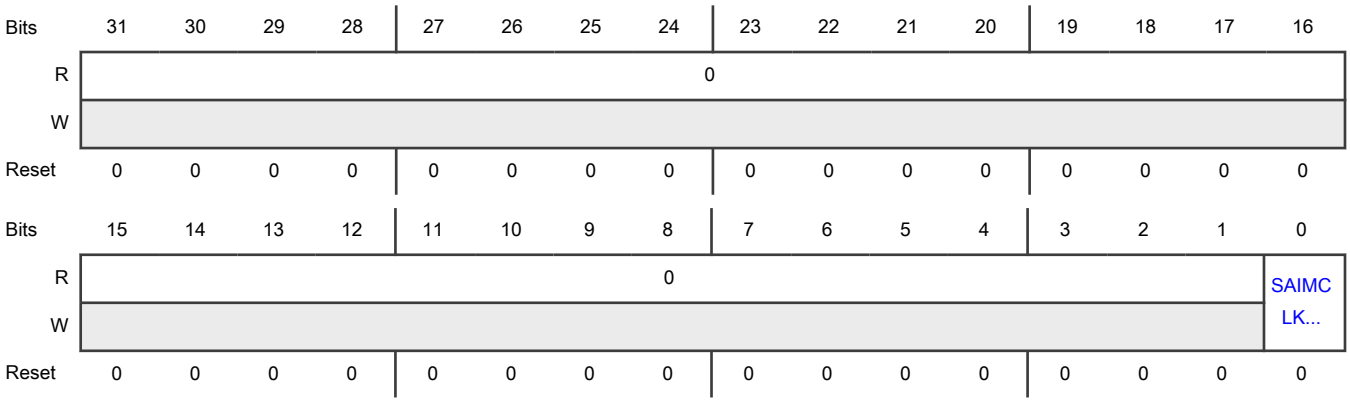
Offset

Register	Offset
SAI3_MCLK_CTRL	240h

Function

Controls MCLK input and output direction for Serial Audio Interface (SAI) 3.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 SAIMCLKDIR	SAI3 MCLK Direction Control Specifies whether MCLK is output or input signal. IOPCTL needs to select MCLK function.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Input 1b - Output

29.6.2.11 HiFi1 DSP Stall (DSPSTALL)

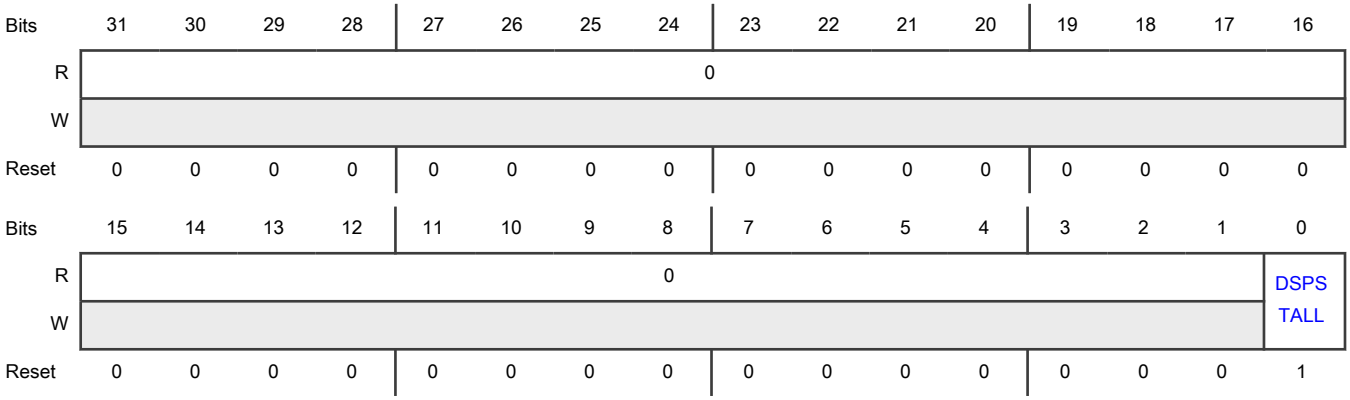
Offset

Register	Offset
DSPSTALL	300h

Function

Controls the operation of HiFi1 DSP.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 DSPSTALL	Run/Stall Control 0b - Run (normal mode) 1b - Stall mode

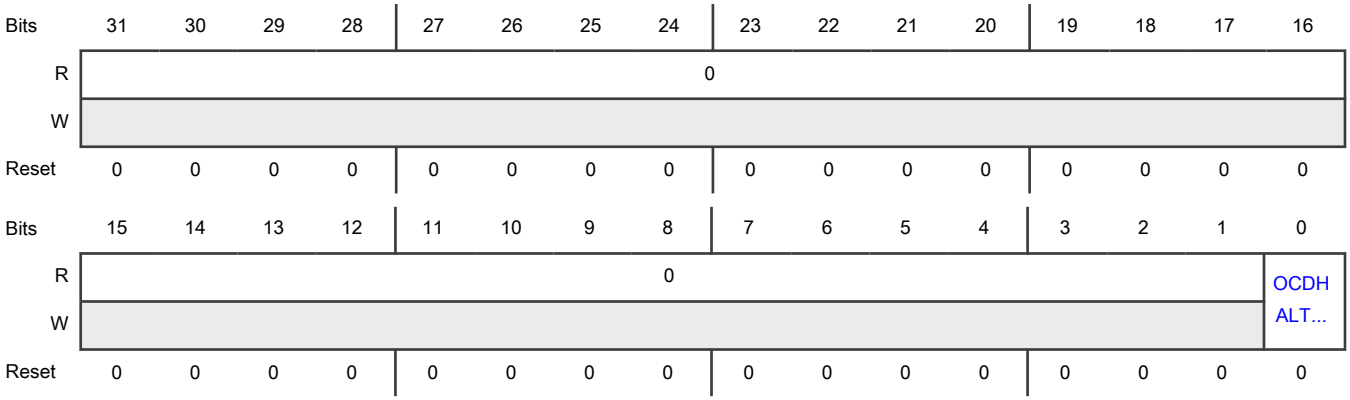
29.6.2.12 HiFi1 OCDHaltOnReset (OCDHALTONRESET)

Offset

Register	Offset
OCDHALTONRESET	304h

Function
HiFi1 enters OCD Halt mode if this signal is sampled asserted on reset.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 OCDHALTONRESET	OCDHaltOnReset 0b - Allow normal operation when HiFi1 exits reset (starts fetching and executing instructions from memory) 1b - Force HiFi1 to enter OCD Halt mode when HiFi1 exits reset

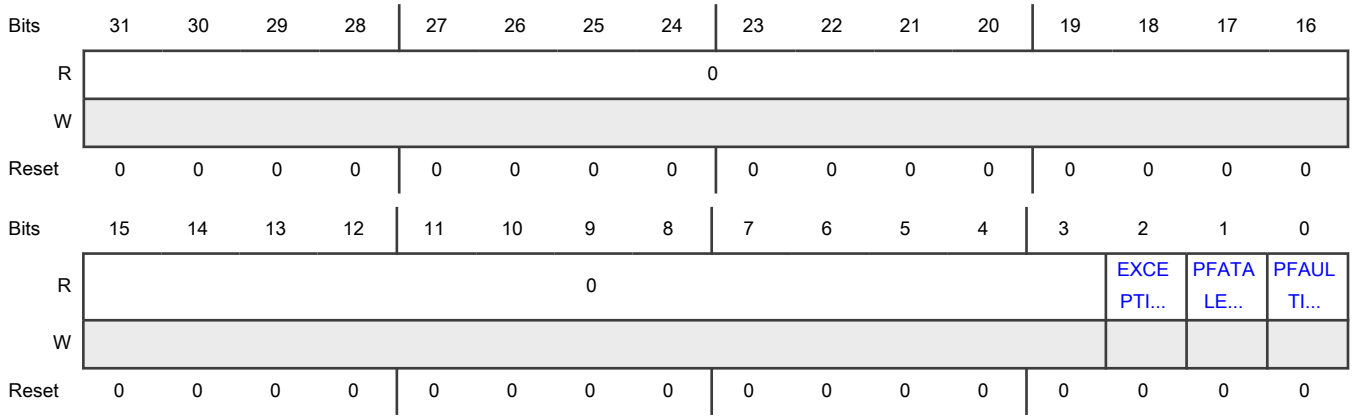
29.6.2.13 HiFi1 General Purpose Register 0 (HIFI1_GPR0)

Offset

Register	Offset
HIFI1_GPR0	308h

Function
General purpose register assigned to capture HiFi1 status signals.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 EXCEPTIONERR	DoubleExceptionError Single-cycle assertion every time double exception faults occur. Unlike [PFATALERR], this signal is not sticky. The system can use the information presented on [PFATALERR] and HIFI1_GPR1[PFAULTINFO] and decide whether to reset the HIFI1 core or the whole system. 0b - No error occurs 1b - Error occurs
1 PFATALERR	PFatalError Asserted when a fatal error condition occurs due to AXI parity or ECC errors. The PFatalError signal is sticky and is cleared by HiFi1 reset. 0b - No error occurs 1b - Error occurs
0 PFAULTINFOVLD	PFaultInfoValid Asserted when the PFaultInfo signal changes its value. The system can use its rising edge as an enabler to capture PFaultInfo. 0b - Not asserted 1b - Asserted

29.6.2.14 HiFi1 General Purpose Register 1 (HIFI1_GPR1)

Offset

Register	Offset
HIFI1_GPR1	314h

Function

General purpose register assigned to capture HiFi1 status signals.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	TIE_EXPSTATE															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TIE_EXPSTATE	GPIO32 Option TIE Output State Indicates the state of “tie_expstate” used to capture OSTIMER and to trigger EZH-V.

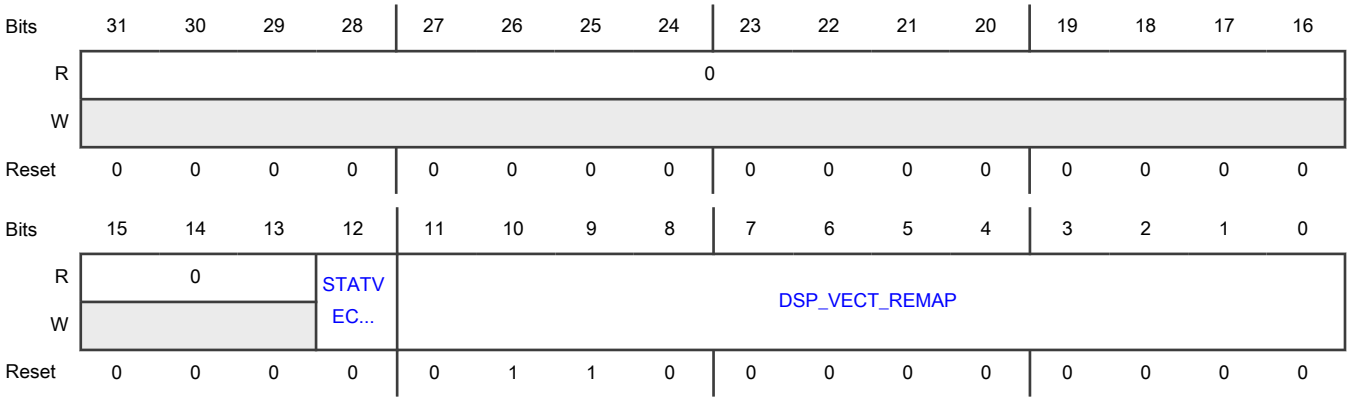
29.6.2.16 HiFi1 DSP Vector Remap (DSP_VECT_REMAP)

Offset

Register	Offset
DSP_VECT_REMAP	31Ch

Function
Configures HiFi1 DSP static vector remapping to shared SRAMs.

Diagram



Fields

Field	Function
31-13 —	Reserved
12 STATVECSELECT	Static Vector Select Selects the static vector address on HiFi1. 0b - Selects the primary static vector address (0058_0000h) 1b - No effect
11-0	DSP Vector Remap

Table continues on the next page...

Table continued from the previous page...

Field	Function
DSP_VECT_REMAP	Remaps ARADDR[21:10] when ARADDR hits 1 KB from [STATVECSELECT] selected base address. **NOTE** Remapping the vectors will leave a "hole" of 1 KB at the default vector location which the HiFi1 DSP will never be able to access (CPU1 and all other initiators will have access though). **RESTRICTION** When [STATVECSELECT] = 0, bit 11 and bit 10 of this field will not take effect.

29.6.2.17 eDMA2 Request Enable 0 (EDMA2_EN0)

Offset

Register	Offset
EDMA2_EN0	420h

Function

Enables request register 0 for eDMA2.

29.6.4.2 Receive Event Pulse Generator (RXEVPULSEGEN)

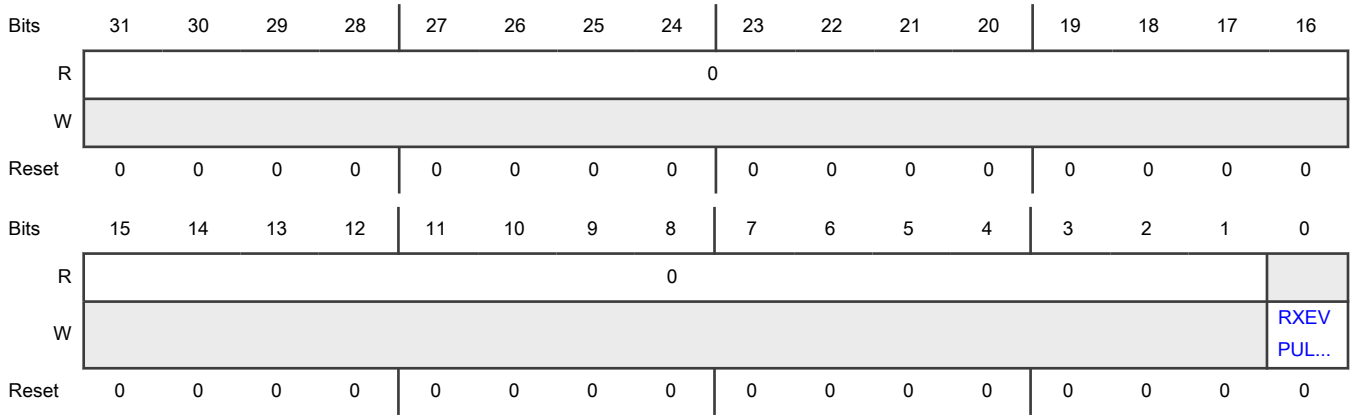
Offset

Register	Offset
RXEVPULSEGEN	80h

Function

Allows generating a pulse on CPU1 receive event input that will wake it up if it is stopped in a wait for event (WFE) instruction.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 RXEVPULSEGEN	Receive Event Pulse Generator Writing a 1 to this register will create a logic 1 pulse for one APB bus clock when set by HiFi1 and HiFi4. It is automatically cleared. 0b - No effect 1b - Pulse receive event high for one cycle

29.6.4.3 CPU Status (CPU_STATUS)

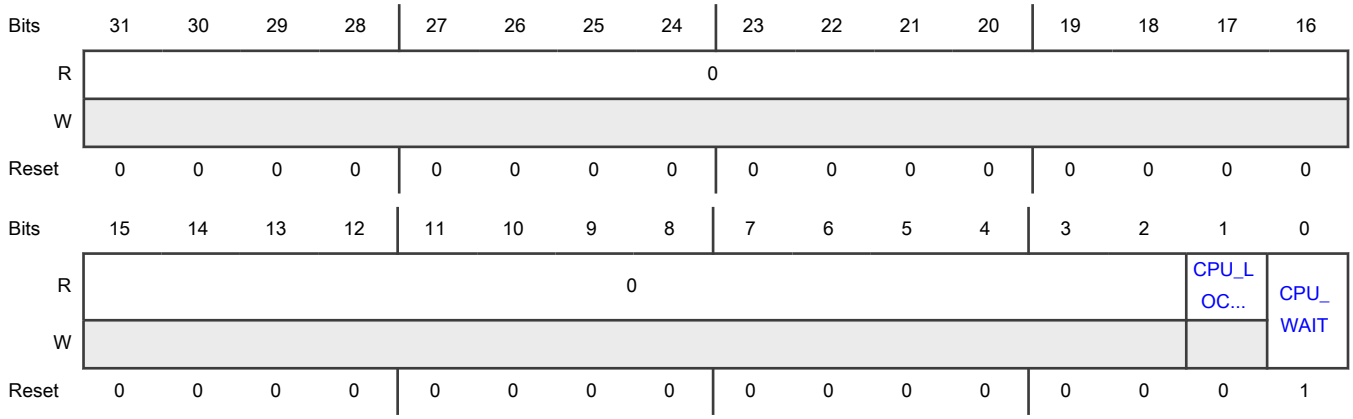
Offset

Register	Offset
CPU_STATUS	8Ch

Function

Indicates CPU1 status.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 CPU_LOCKUP	CPU1 Lockup State Indicates whether CPU1 is in lockup state. 0b - Not in lockup 1b - In lockup
0 CPU_WAIT	CPU1 Stall Stalls CPU1 out of reset. 0b - No stall 1b - Stall

29.6.4.4 CPU1 Secure Vector Table Offset (CPU1_SVTOR)

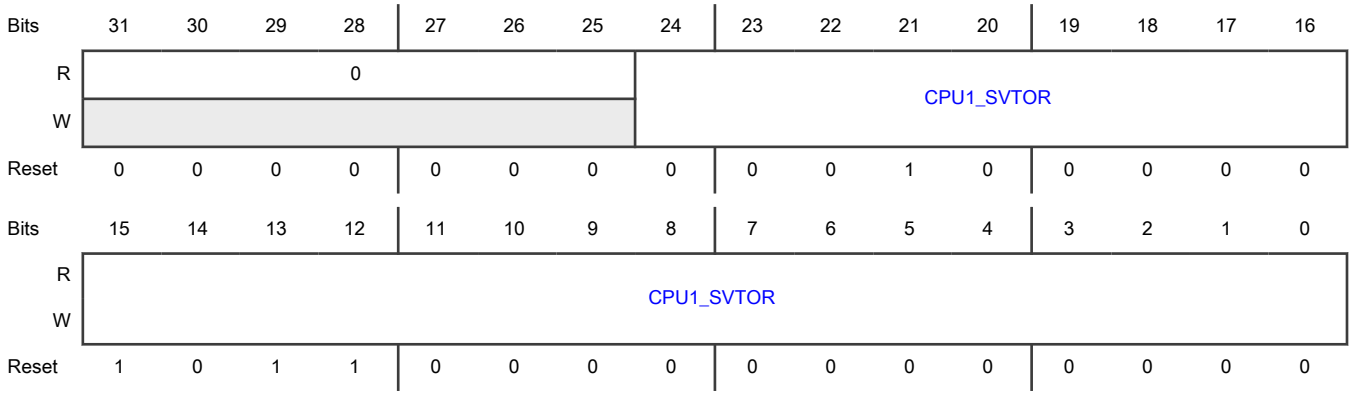
Offset

Register	Offset
CPU1_SVTOR	98h

Function

Indicates the offset of the secure vector table base address from the shared memory address.

Diagram



Fields

Field	Function
31-25 —	Reserved
24-0 CPU1_SVTOR	Secure Vector Table Offset Specifies the secure vector table offset register out of reset. This register controls INIT_SVTOR[31:7] of CPU1. For example, if secure vector is 32'h1058_0000, the register value will be 25'h020B000.

29.6.4.5 CPU1 Non-Secure Vector Table Offset (CPU1_NSVTOR)

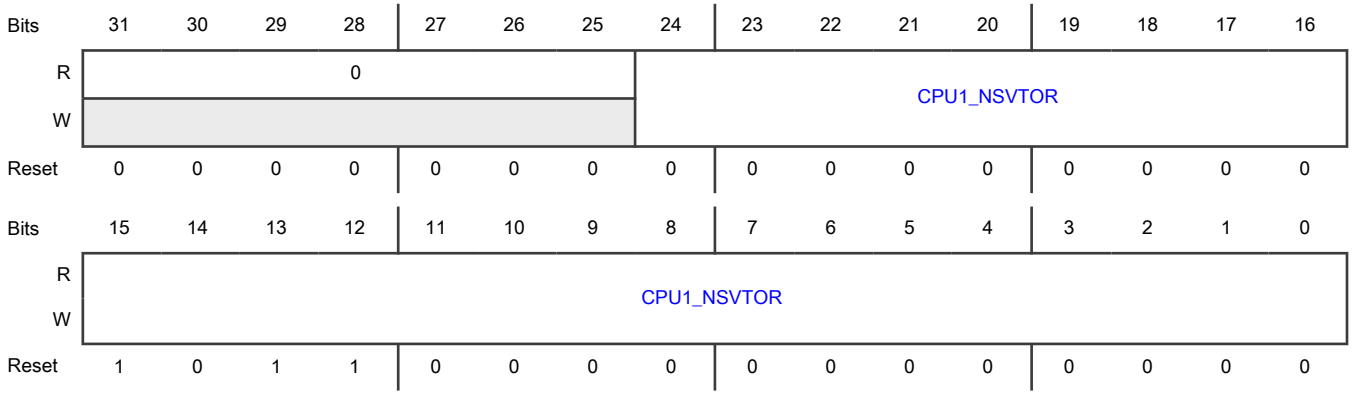
Offset

Register	Offset
CPU1_NSVTOR	9Ch

Function

Indicates the offset of the non-secure vector table base address from memory address.

Diagram



Fields

Field	Function
31-25 —	Reserved
24-0 CPU1_NSVTOR	Non-Secure Vector Table Offset Specifies the non-secure vector table offset register out of reset. This register controls INIT_NSVTOR[31:7] of CPU1.

29.6.4.6 Silicon Revision ID (SILICONREV_ID)

Offset

Register	Offset
SILICONREV_ID	C4h

Function

On the first silicon, the minor revision is 0h. Any subsequent metal mask change or update should result in the minor revision being upgraded to the next level.

On the first silicon, the major revision is Ah. Any subsequent full mask change or update should result in the major revision being upgraded to the next level.

29.6.4.7 Automatic Clock Gate Override (AUTOCLKGATEOVERRIDE0)

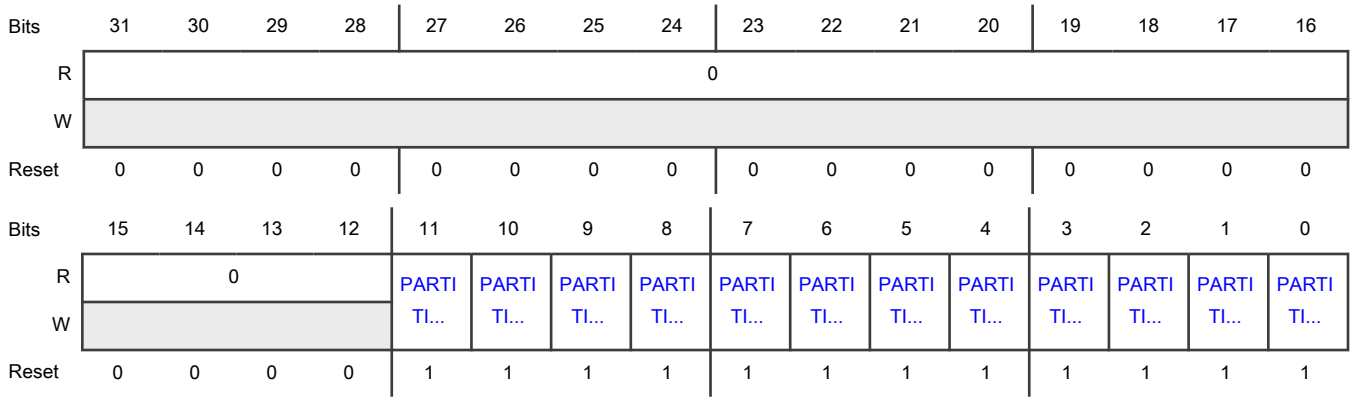
Offset

Register	Offset
AUTOCLKGATEOVERRIDE0	114h

Function

This register allows selectively disabling automatic clock gating for SRAM partitions. By default, automatic clock gating turns off clocks to each internal SRAM after 5 bus clocks with no activity. This saves power when the SRAMs are not used for a period of time. When turned off due to automatic clock gating, there is a 1- clock delay for the next access to an SRAM.

Diagram



Fields

Field	Function
31-12 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
11-0 PARTITIONn	Partition n Controls clock gating for Partition 18 (bit 0) to Partition 29 (bit 11). 0b - Enables clock gating 1b - Continuous clocking

29.6.4.8 SRAM Clock Gating Control (SRAM_CLKGATE_CTRL)

Offset

Register	Offset
SRAM_CLKGATE_CTRL	118h

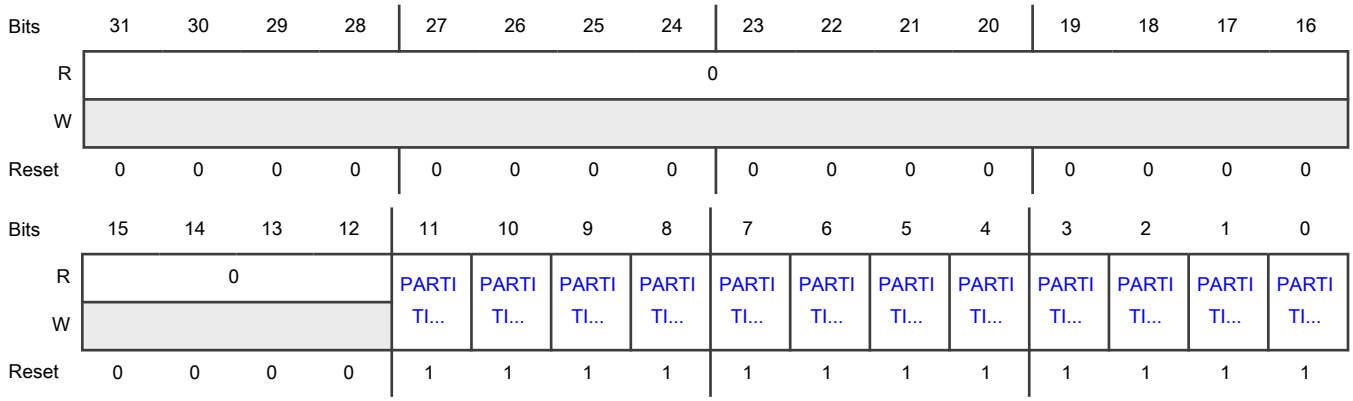
Function

If cleared, the corresponding SRAM partition input clock driven by SENSE_MAIN_CLK will be gated off. This provides means to save power if the corresponding partition is not planned to be used for a significant amount of time. To get the power saving, the Sense domain CPU (CPU1) needs to do a dummy read to the partition to switch the partition clock to SENSE_MAIN_CLK, and then clear this bit. While the bit for an associated partition is cleared, no bus initiators will be able to access that partition unless the bit is set again.

NOTE

When gated, any core will halt when accessing the partition, until CPU1 turns on the partition clock.

Diagram



Fields

Field	Function
31-12	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
11-0 PARTITIONn	Partition n Gates off the bus clock input in VDD1_SENSE domain for Partition 18 (bit 0) to Partition 29 (bit 11). 0b - Bus clock input gated 1b - No effects

29.6.4.9 VDD1_SENSE Auto Gating Enable (SENSE_AUTOGATE_EN)

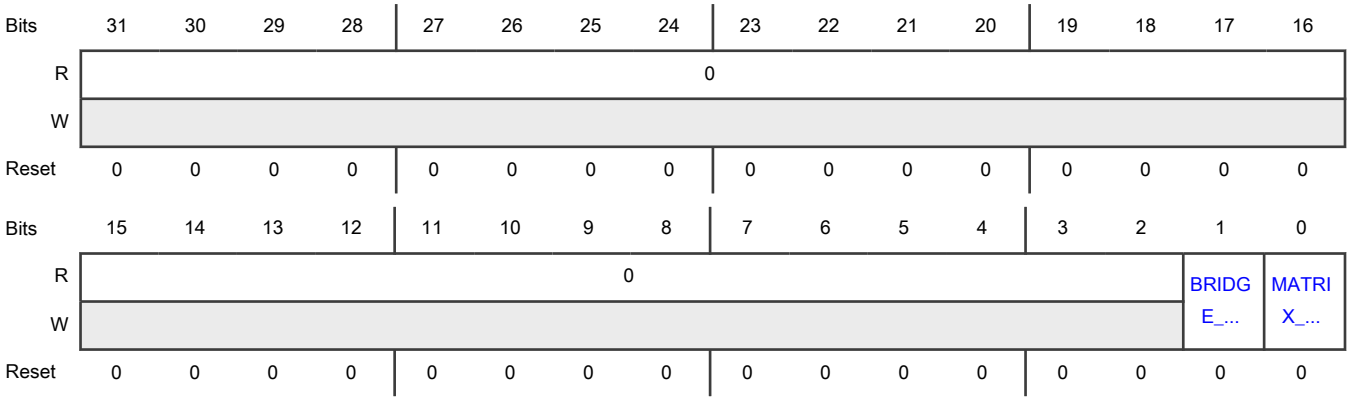
Offset

Register	Offset
SENSE_AUTOGATE_EN	280h

Function

Controls clock gating for S-bus, AHB2APB bridge, and the AIPS and AXBS in VDD1_SENSE domain. This register allows selectively enabling automatic clock gating for the modules. By default, automatic clock gating turns off clocks to the modules after 2 bus clocks with no bus transaction activity. This saves power when the corresponding modules are not used for a period of time.

Diagram



Fields

Field	Function
31-2 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 BRIDGE_EN	Automatic Clock Gating Enable for AHB to APB Bridge, AIPS and AXBS Controls clock gating for AHB2APB bridge, and the AIPS and AXBS in VDD1_SENSE domain. You can set it to disable the module's clock in order to save power when the module is not working. 0b - Disables clock gating (continuous clock) 1b - Enables clock gating
0 MATRIX_EN	Automatic Clock Gating Enable for S-Bus Controls clock gating for S-bus. You can set it to disable the module's clock in order to save power when the module is not working. **NOTE** Once CPU1 enters Deep Sleep when accessing RAM arbiter 1, if any other initiator needs to access RAM arbiter 1, you must disable this bit before CPU1 enters Deep Sleep. 0b - Disables clock gating (continuous clock) 1b - Enables clock gating

29.6.4.10 TEMPDETECT0 Control (TEMPDETECT0_CTRL)

Offset

Field	Function
MEM_IG	When active, gates the selected memory inputs to reduce active power associated with input toggles. This bit can be set to reduce RAM power consumption if reads or writes are not needed for short periods of time. **NOTE** When this bit is set, only memory inputs are gated and outputs still have data. For LCDIF, DONE flag might be observed. 0b - Inactive 1b - Active
7 MEM_STDBY	Memory Standby Mode When active, puts the memory into standby mode. This bit can be set to reduce RAM power consumption if the RAM is never used or will not be used for long periods of time. There is a brief increase in RAM power created by the shutdown sequence caused by a transition from regular mode to standby mode. Therefore, standby mode should only be used when the RAM array will not be accessed for long periods of time. 0b - Inactive 1b - Active
6-0 —	Reserved

29.6.5.6 JPEGDEC Memory Control (JPEGDEC_MEM_CTRL)

Offset

Register	Offset
JPEGDEC_MEM_CTRL	3Ch

Function

Configures read and write input gating and power gating for JPEGDEC memory.

1 DSI_CM	DSI Color Mode Control Color mode control for Type-4 display only. This feature is used to configure the display on Normal mode or Low color mode. When bit is configured to low-color mode, display works in 8-bit mode and display power is reduced. **NOTE** Both signals [DSI_SD] and [DSI_CM] are synchronized with the DPI clock (dpi_pclk) coming from display controller. Turn on the DPI mode of LCDIF to have [DSI_SD] and [DSI_CM] signals being propagated to DSI interface. 0b - Normal (full color) mode 1b - Low color mode (8-bit)
0 DSI_SD	DSI Shutdown Control Shutdown control for Type-4 display only. By specifying whether to send shutdown command to the Type-4 display, this feature triggers the display module to shut down the streaming video interface to reduce power consumption. **NOTE** Both signals [DSI_SD] and [DSI_CM] are synchronized with the DPI clock (dpi_pclk) coming from display controller. Turn on the DPI mode of LCDIF to have [DSI_SD] and [DSI_CM] signals being propagated to DSI interface. 0b - Do not send 1b - Send

29.6.5.18 VDD2_MEDIA Auto Gating Enable (MEDIA_AUTOGATE_EN)

Offset

Register	Offset
MEDIA_AUTOGATE_EN	280h

Function

Controls clock gating for AHB bus matrix, AHB to APB bridge, and the AIPS and AXBS in VDD2_MEDIA domain. This register allows selectively enabling automatic clock gating for the modules. By default, automatic clock gating turns off clocks to the modules after 2 bus clocks with no bus transaction activity. This saves power when the corresponding modules are not used for a period of time.

Diagram

Chapter 30
Sleep Controller (SLEEPCON)

30.1 Chip-specific SLEEPCON information

Table 253. Reference links to related information

Topic	Related module	Reference
Full description	SLEEPCON	SLEEPCON
Peripheral memory map		Memory map overview
Power management	PMC	Power overview PMC
Clocking		Clock overview Clock controller

NOTE

The SLEEPCON module includes some security functionality that is not described here. Refer to the i.MX RT700 Security Reference Manual for more details.

30.1.1 Module instances

This device has two instances of the SLEEPCON module: SLEEPCON0 and SLEEPCON1.

Table 254. SLEEPCON instances

Features	SLEEPCON0	SLEEPCON1
Located in	VDD2_COM	VDD1_SENSE
Access	CPU0, HiFi4, EZH-V, eDMA0, eDMA1	CPU1, HiFi1, EZH-V, eDMA2, eDMA3
Controls modules in	VDD2_COMP, VDD2_MEDIA, VDDN_MEDIA, VDDN_COM, VDD1P8_AON, VDD2_COM, VDD1_SENSE (shared)	VDD2_MEDIA, VDDN_MEDIA, VDDN_COM, VDD1P8_AON, VDD2_COM, VDD1_SENSE
pclk clock source	COMPUTE_MAIN_CLK	SENSE_MAIN_CLK
pclk_regbank clock source	COMPUTE_MAIN_CLK	SENSE_MAIN_CLK

30.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

30.2 Overview

SLEEPCON is a programmable low-power control module within the chip's overall power management and control system. Working with PMC and CLKCTL, SLEEPCON helps coordinate power mode transitions, especially the low-power transitions for individual modules.

30.2.1 Block diagram

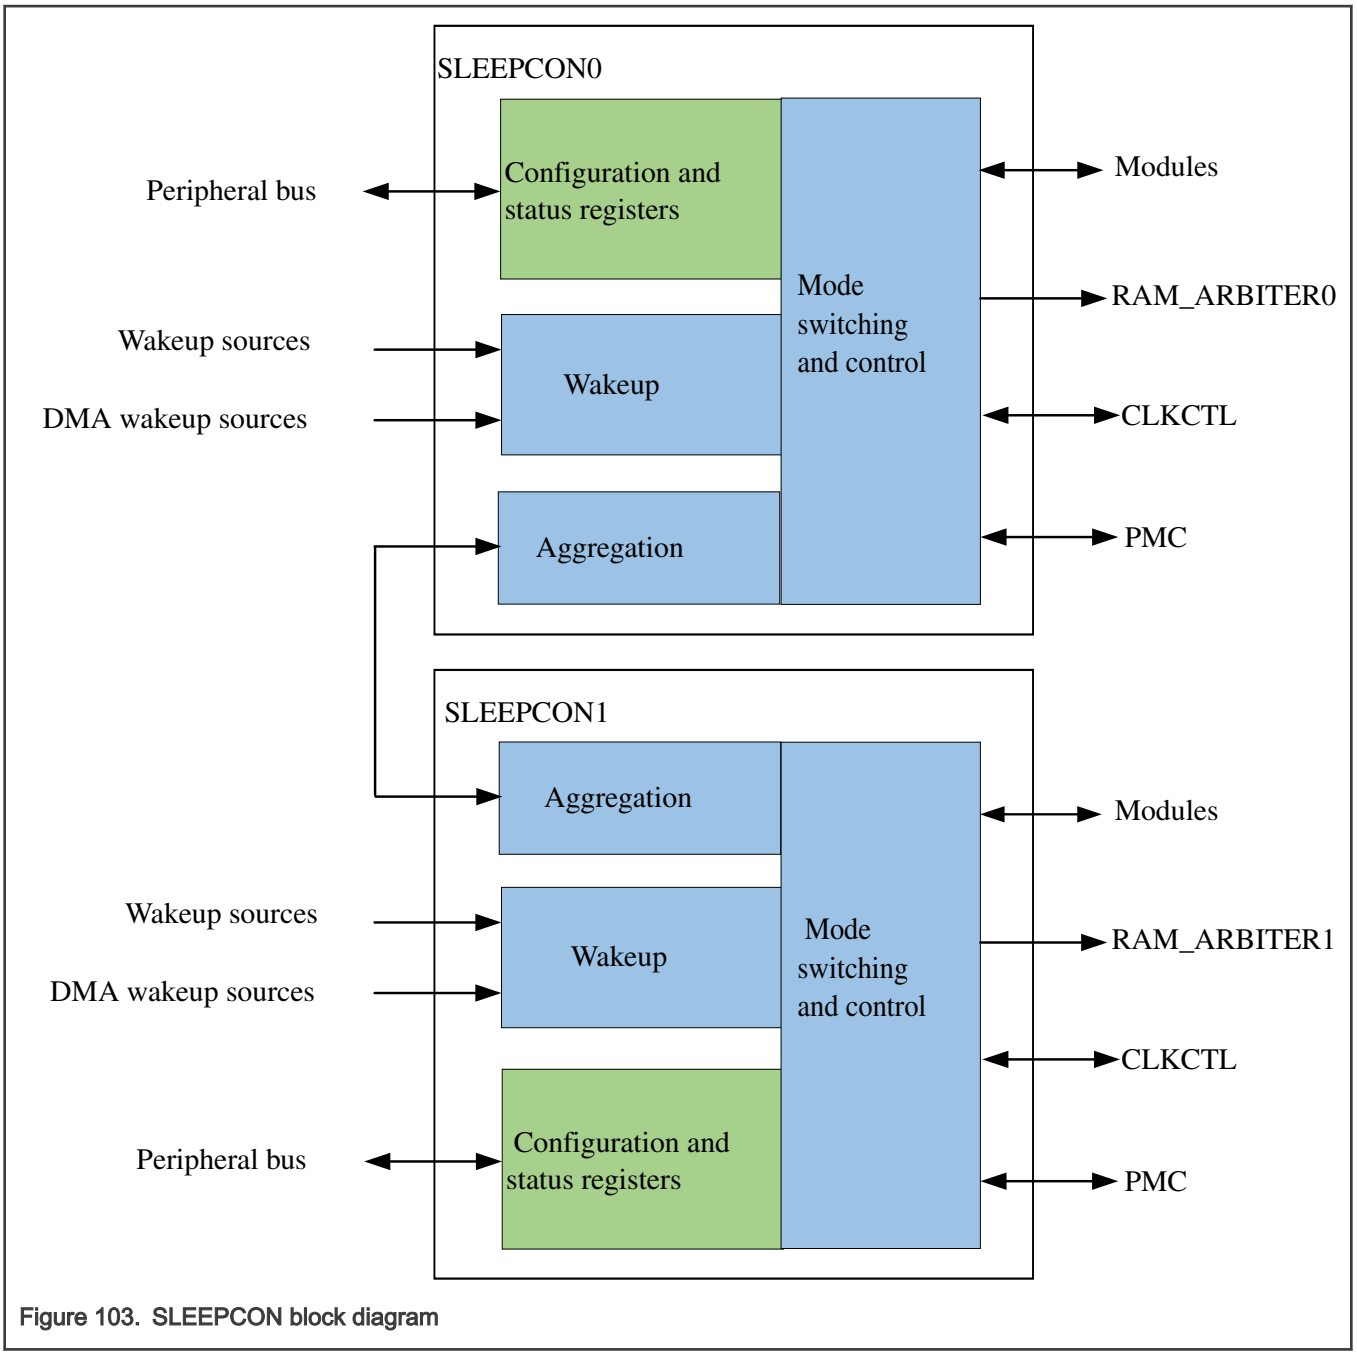

Figure 103. SLEEPCON block diagram

30.2.2 Features

SLEEPCON features include:

- Enables wakeup interrupts for on-chip modules
- Performs the low-power request handshake for individual modules to ensure safe transitioning to a low-power state
- Enables the DMA wakeup mechanism for supported modules
- Triggers CLKCTL to shut off associated clocks to modules, system components and memory
- Enables the low-power sequence interaction with PMC

30.3 Functional description

SLEEPCON provides for the following functions within the power management and control system:

- Requesting low-power for modules
- DMA wakeup

30.3.1 Aggregation for shared modules

Table 255 lists the shared modules that can be controlled by both SLEEPCONs. These modules are mainly clock sources and main clocks of different domains. These bits in RUNCFG and SLEEPCFG registers can power down the corresponding modules or gate the clock. SLEEPCON0 and SLEEPCON1 control them together. These bits are not relevant to the low-power requests. A shared module is powered down only when the related bit is configured as power down in both SLEEPCONs.

Table 255. Shared modules

Shared modules	Control bit in RUNCFG/SLEEPCFG
ADC0	ADC_PD
Audio PLL	AUDPLLLDO_PD
	AUDPLLANA_PD
Main PLL	PLLLDO_PD
	PLLANA_PD
LPOSC 1 MHz	LPOSC_PD
FRO2	FRO2_PD FRO2_GATE
Xtal Oscillator	XTAL_PD
Media domain main clock	MEDIA_MAINCLK_SHUTOFF
VDDN_COM domain main clock	COMN_MAINCLK_SHUTOFF
RAM Arbiter1 clock	RAM1_CLK_SHUTOFF
RAM Arbiter0 clock	RAM0_CLK_SHUTOFF
VDD1_SENSE domain main clock-shared modules	SENSES_MAINCLK_SHUTOFF
VDD1_SENSE domain main clock private modules	SENSEP_MAINCLK_SHUTOFF

30.3.2 Requesting low-power for modules

For modules that do not need to remain active, software can first execute a low-power request-and-acknowledge handshake to check for module activity before gating its clock in active mode/low-power modes. The handshake ensures modules have safely completed any current transactions before gating their clocks.

The general handshake with a module is as follows:

1. Make the request by configuring the relevant low-power control register (xxx_CCTRLn and xxx_TCTRLn).
2. Poll for acknowledgement by reading the corresponding low-power status register (xxx_CSTATn and xxx_TSTATn). If the value is 1b, go to the next step.

NOTE

Most modules can send back low-power accept signals to SLEEPCON, except the following modules that are in reset status or their related peripheral clocks are off:

- eDMA0-3
- XSPI2
- ADC0
- EZH-V
- VGPU

3. Gate the module's clock by configuring the relevant PSCCTLn register field in the CLKCTL.

Factors affecting the specific details of the overall handshake sequence are:

- Whether the module can initiate bus transactions: See Order of module requests
- Whether both CPUs can access the module: See Private versus shared modules

NOTE

For some peripherals like LP_FLEXCOMM, LPSPI and FLEXIO, low-power requests can be made for different logic parts separately. One part of the logic of these peripheral is driven by the bus clock, and the other part is driven by its function clock. Peripheral that is not being used in Deep Sleep mode should complete the low-power handshake process and detect an accept or acknowledge state. ADC0, ACMP0, MICFILF, GPIO, SAI and I3C low-power handshaking is mandatory to enable them to generate a wake-up signal in Deep Sleep mode. Peripherals with separated bus and function clock handshaking mechanisms such as LP_FLEXCOMM, LPSPI, LPI2C15, FLEXIO, the bus portion of the handshaking is mandatory, otherwise the module will not be able to generate a wake-up signal in Deep Sleep mode. Low-power handshaking process is also needed for DSR/Deep Power Down/Full Deep Power down modes.

30.3.2.1 Order of module requests

To ensure coherency of operations and data flow, the order in which modules should be clock-gated is as follows:

Table 256. Order of module requests

Step	Modules that can...	Use these request registers...	And these status registers...
1	Initiate bus transactions (bus controllers)	SHA_MED_CCTRL0 and PRIVATE_CCTRL0	SHA_MED_CSTAT0 and PRIVATE_CSTAT0
2	Respond to bus transactions (bus targets)[1]	SHA_MED_TCTRL0, SHA_SEN_TCTRL0, and PRIVATE_TCTRLn	SHA_MEDSEN_TSTAT0 and PRIVATE_TSTATn

1. If a module has both bus logic and function logic, make the bus low-power request first, followed by the function low-power request.

30.3.2.2 Private versus shared modules

Modules can be categorized as private or shared:

- Private modules can be controlled by one and only one of the CPUs.
- Shared modules can be controlled by both CPUs. Shared modules require arbitration because both CPUs could attempt to affect their power state. See Arbitrating low-power requests for shared modules. A shared module powers down only after both SLEEPCON0 and SLEEPCON1 require it to power down. The shared module is on if either or both SLEEPCON instances need it on.

  The list below is the shared modules for low power requests:

— NIC_MEDIA1
— NIC_MEDIA0
— FLEXIO
— LPSPI16
— LPSPI14
— XSPI2
— EZH-V
— VGPU
— RTC
— LPI2C15
— MICFIL
— ACMP0
— ADC0

30.3.2.3 Arbitrating low-power requests for shared modules

For shared modules jointly controlled by SLEEPCON0 and SLEEPCON1, a hardware arbiter determines whether a low-power request can be passed along to a target module. The arbiter drives the module to enter its low-power state only when both SLEEPCON instances make a low-power request. Otherwise, as long as at least one instance needs the module to keep running, the module does not enter the low-power state.

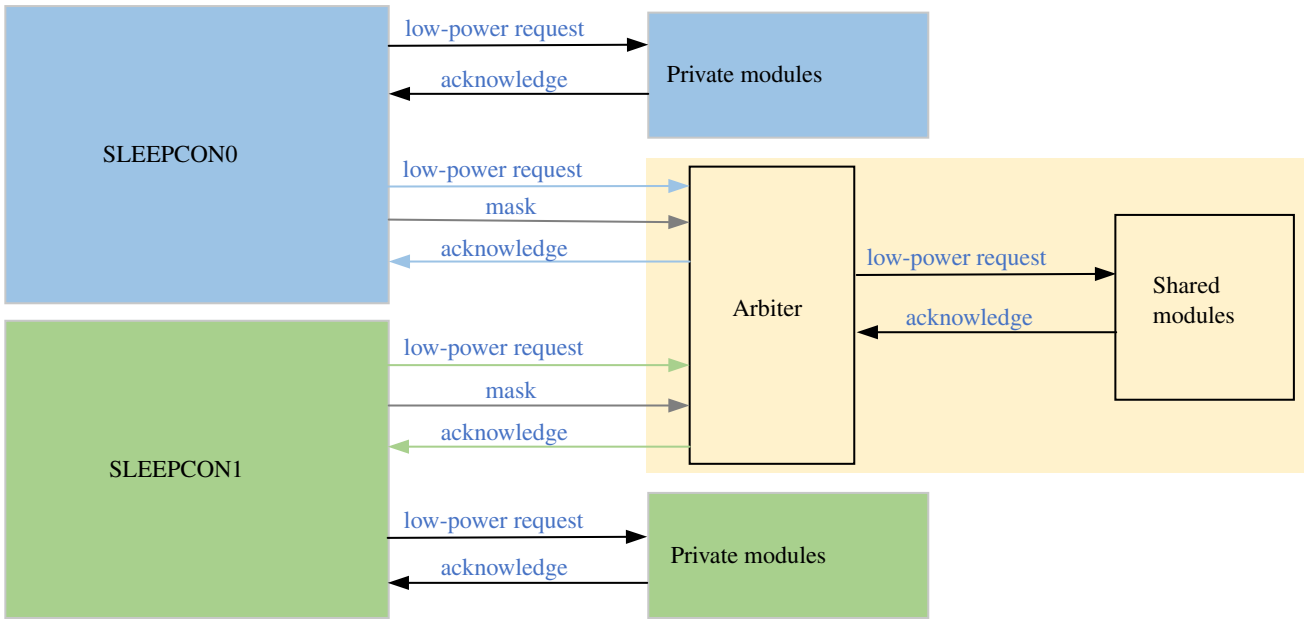

Figure 104. SLEEPCON low-power arbiter

30.3.2.4 Masking shared modules from arbitration

If software running on CPU0 or CPU1 does not require a shared module for an application, the software can remove itself from arbitration consideration by setting the module's mask bit in SHARED_MASK0 in the corresponding SLEEPCON instance. In this case, the other SLEEPCON instance has exclusive control over low-power requests to the module.

NOTE

A shared module's mask bit in SHARED_MASK0 must not be configured as 0b in both SLEEPCONs.

30.3.3 Clocking

Table 257. SLEEPCON clocks

Type of clock	Description
Module clock (pclk)	Functions the SLEEPCON module.
Module register clock (pclk_regbank)	Controls the access to the SLEEPCON registers.

See the chip-specific information for more details.

30.3.4 DMA wakeup

DMA wakeup is available for some modules in the VDD2_COMP, VDD1_SENSE and VDD2_MEDIA domains. It is an automatic hardware mechanism that handles DMA transactions for selected modules without core processing. Software can configure individual DMA channels to generate a wakeup when they receive a DMA request. The DMA wakeup triggers an exit from Deep Sleep mode except the core, which remains sleeping.

In order to use DMA wakeup, the modules which support this feature must complete the low-power handshake before entering the Deep Sleep mode.

- For DMA wakeup by eDMA0 or eDMA1: SAI0-2, LP_FLEXCOMM0-13, LPSPI14, LPSPI16, FLEXIO, eDMA0 and eDMA1 need to complete low-power handshake process.
- For DMA wakeup by eDMA2 or eDMA3: SAI3, LP_FLEXCOMM17-20, LPSPI14, LPSPI16, FLEXIO, eDMA2 and eDMA3 need to complete low-power handshake process.

If a module has seperate bus and function low-power handshake, the bus low-power handshake is needed to complete.

See Temporary wakeup for DMA for procedures.

An interrupt that occurs during a DMA wakeup causes an exit from the deep sleep mode without affecting the DMA transfer.

30.4 Memory map and register definition

This section includes the SLEEPCON0 and SLEEPCON1 module memory maps and detailed descriptions of all registers.

30.4.1 SLEEPCON0 register descriptions

30.4.1.1 SLEEPCON0 memory map

SLEEPCON0 base address: 4000_3000h

30.4.1.2 Sleep Configuration (SLEEPCFG)

Offset

Register	Offset
SLEEPCFG	0h

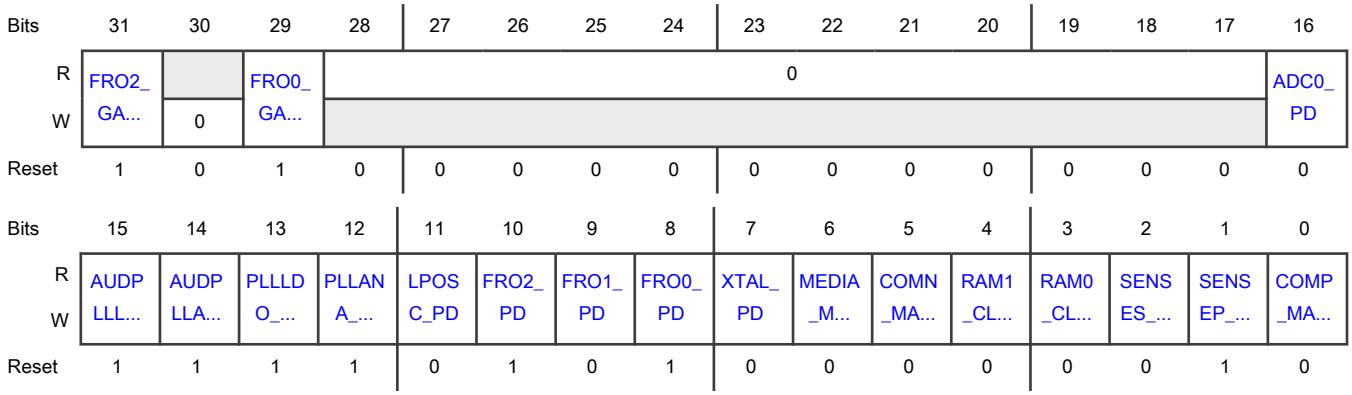
Function

Controls the power requests to various modules while CPU0 is in Deep Sleep mode. The power mode requests selected by this register are aggregated with the CPU1 requests to determine the actual settings. When the chip is in Deep Power Down mode or Full Deep Power Down mode, all the related modules are powered down.

NOTE

You need to clear FRO0_GATE and FRO2_GATE bits after POR and system reset.

Diagram



Fields

Field	Function
31 FRO2_GATE	FRO2 Gating Controls the gating of FRO2. 0b - Removes gating 1b - Applies gating
30 —	Reserved
29 FRO0_GATE	FRO0 Gating Controls the gating of FRO0. 0b - Removes gating 1b - Applies gating
28-17 —	Reserved
16 ADC0_PD	ADC0 Power Down Controls the power to ADC0. **NOTE** Write 1 to SHA_SEN_TCTRL0[ADC0_STOP] first and then write 1 to ADC0_PD to minimize the power consumption of ADC0. 0b - Powers on 1b - Powers down
15 AUDPLLLDO_PD	Audio PLL Internal Regulator Power Down Controls the power to audio PLL internal regulator.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Powers on 1b - Powers down
14 AUDPLLANA_PD	Audio PLL Analog Function Power Down Controls the power to audio PLL analog function. 0b - Powers on 1b - Powers down
13 PLLLDO_PD	Main PLL Internal Regulator Power Down Controls the power to main PLL internal regulator. 0b - Powers on 1b - Powers down
12 PLLANA_PD	Main PLL Analog Function Power Down Controls the power to main PLL analog function. 0b - Powers on 1b - Powers down
11 LPOSC_PD	LPOSC Power Down Controls the power to LPOSC. **NOTE** LPOSC is used by WWDT and RSTCTL. WWDT module can use MOD[LOCK] to lock SLEEPCON's control over power to the LPOSC. If MOD[LOCK] of either or both of WWDT0 and WWDT1 is configured as 1, the write to this field can change the filed value but does not take effect. 0b - Powers on 1b - Powers down
10 FRO2_PD	FRO2 Power Down Controls the power to FRO2. **NOTE** FRO2 power-down depends on both FRO2_PD and CSR[FROEN] of FRO2. To power down FRO2, you need to write 1 to FRO2_PD and write 0 to CSR[FROEN] of FRO2. To Power on FRO2, you need to write 0 to FRO2_PD or write 1 to CSR[FROEN] of FRO2. If SLEEPCON needs to wait power down ready from FRO2, then CSR[CLKGATE] of FRO2 must enable FRO divider 6 clock. Otherwise SLEEPCON will be blocked and PMC cannot entry low-power mode. 0b - Powers on 1b - Powers down

Table continues on the next page...

Table continued from the previous page...

Field	Function
9 FRO1_PD	FRO1 Power Down Controls the power to FRO1. **NOTE** FRO1 power-down depends on both FRO1_PD and CSR[FROEN] of FRO1. To power down FRO1, you need to write 1 to FRO1_PD and write 0 to CSR[FROEN] of FRO1. To Power on FRO1, you need to write 0 to FRO1_PD or write 1 to CSR[FROEN] of FRO1. If SLEEPCON needs to wait power down ready from FRO1, then CSR[CLKGATE] of FRO1 must enable FRO divider 6 clock. Otherwise SLEEPCON will be blocked and PMC cannot entry low-power mode. 0b - Powers on 1b - Powers down
8 FRO0_PD	FRO0 Power Down Controls the power to FRO0. **NOTE** FRO0 power-down depends on both FRO0_PD and CSR[FROEN] of FRO0. To power down FRO0, you need to write 1 to FRO0_PD and write 0 to CSR[FROEN] of FRO0. To Power on FRO0, you need to write 0 to FRO0_PD or write 1 to CSR[FROEN] of FRO0. If SLEEPCON needs to wait power down ready from FRO0, then CSR[CLKGATE] of FRO0 must enable FRO divider 6 clock. Otherwise SLEEPCON will be blocked and PMC cannot entry low-power mode. 0b - Powers on 1b - Powers down
7 XTAL_PD	Xtal Oscillator Power Down Controls the power to Xtal oscillator (osc_out). 0b - Powers on 1b - Powers down
6 MEDIA_MAINCLK_SHUTOFF	VDD2_MEDIA and VDDN_MEDIA Domains media_main_clk and media_vddn_clk Shut Off Controls the main clock shut-off of the VDD2_MEDIA and VDDN_MEDIA domains. 0b - Turns on 1b - Turns off
5 COMN_MAINCLK_SHUTOFF	VDDN_COM Domain common_vddn_clk Shut Off Controls the main clock shut-off of the VDDN_COM domain. 0b - Turns on 1b - Turns off

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 RAM1_CLK_SHUTOFF	RAM_ARBITER1 sense_ram_clk Shut Off Controls the clock shut-off of the RAM_ARBITER1 in VDD1_SENSE domain. 0b - Turns on 1b - Turns off
3 RAM0_CLK_SHUTOFF	RAM_ARBITER0 common_ram_clk Shut Off Controls the clock shut-off of the RAM_ARBITER0 in VDD2_COM domain. 0b - Turns on 1b - Turns off
2 SENSES_MAINCLK_SHUTOFF	VDD1_SENSE Domain sense_main_clk_1 Shut Off Controls the clock shut-off of the shared part in VDD1_SENSE domain. 0b - Turns on 1b - Turns off
1 SENSEP_MAINCLK_SHUTOFF	VDD1_SENSE Domain sense_main_clk Shut Off Controls the main clock shut-off of the private part in VDD1_SENSE domain. 0b - Turns on 1b - Turns off
0 COMP_MAINCLK_SHUTOFF	VDD2_COMP Domain compute_main_clk Shut Off Controls the main clock shut-off of the VDD2_COMP domain. 0b - Turns on 1b - Turns off

30.4.1.3 Run Configuration (RUNCFG)

Offset

Register	Offset
RUNCFG	10h

Function

Controls the power to various modules during normal operation. The power mode requests selected by this register are aggregated with the CPU1 requests to determine the actual settings.

To modify a RUNCFG bit, use RUNCFG_CLR and RUNCFG_SET:

- To make it 0, write a 1 to the corresponding bit position in RUNCFG_CLR.
- To make it 1, write a 1 to the corresponding bit position in RUNCFG_SET.

Using RUNCFG_CLR and RUNCFG_SET prevents unintentionally setting or clearing other bits and avoids the possibility of an interrupt changing the value of RUNCFG in the middle of a read-modify-write sequence. It also avoids accidentally changing bits that might have been modified by other software.

NOTE

After confirming that a specific FRO*/LPOSC/Xtal/PLLs is not used, you can configure FRO*_PD and *PLL*_PD bits in RUNCFG by RUNCFG_CLR. Then FRO*/LPOSC/Xtal/PLLs can power down on the fly.

You need to clear FRO0_GATE and FRO2_GATE bits after POR and system reset.

30.4.1.6 Wakeup Enable 0 (WAKEUPEN0)

Offset

Register	Offset
WAKEUPEN0	60h

Function

Enables the CPU0 to wake-up from deep sleep mode. If a module's wakeup field is enabled, the CPU0 will wake up when receiving the module's interrupt.

To modify a WAKEUPEN0 bit, use the corresponding WAKEUPEN0_CLR and WAKEUPEN0_SET registers:

- To make a bit 0, write a 1 to the corresponding bit position in WAKEUPEN0_CLR.
- To make a bit 1, write a 1 to the corresponding bit position in WAKEUPEN0_SET.

Using WAKEUPEN0_CLR and WAKEUPEN0_SET prevents unintentionally setting or clearing other bits

30.4.1.12 Wakeup Enable 1 Set (WAKEUPEN1_SET)

Offset

Register	Offset
WAKEUPEN1_SET	A4h

Function

Writing a 1 to a bit position sets the corresponding position in WAKEUPEN1. Writing a 0 to a bit position has no effect.

30.4.1.21 Power Down Wait (PWRDOWN_WAIT)

Offset

Register	Offset
PWRDOWN_WAIT	164h

Function

Controls the power down wait of FRO0-2 and LPOSC. Setting the ignore bits below will allow the CPU0 to continue entering a low-power mode without waiting for the corresponding clock to shut down first.

NOTE

If SLEEPCON needs to wait power down ready from FRO, then CSR[CLKGATE] of FRO must enable FRO divider 6 clock. Otherwise SLEEPCON will be blocked and PMC cannot entry low-power mode.

30.4.1.22 eDMA Wakeup Enable (HW_WAKE)

Offset

Register	Offset
HW_WAKE	190h

Function

Enables eDMA (eDMA0 and eDMA1) wakeup sources. To modify an HW_WAKE bit, use the HW_WAKE_CLR and HW_WAKE_SET registers:

- To make a bit 0, write a 1 to the corresponding bit position in HW_WAKE_CLR.
- To make a bit 1, write a 1 to the corresponding bit position in HW_WAKE_SET.

Using HW_WAKE_CLR and HW_WAKE_SET prevents unintentionally setting or clearing other bits.

Diagram

30.4.1.25 Shared Resources Mask (SHARED_MASK0)

Offset

Register	Offset
SHARED_MASK0	1A0h

Function

Enables the masking of SLEEPCON0 control for shared modules. To modify a SHARED_MASK0 bit, use the corresponding SHARED_MASK0_CLR and SHARED_MASK0_SET registers:

- To make a bit 0, write a 1 to the corresponding bit position in SHARED_MASK0_CLR.
- To make a bit 1, write a 1 to the corresponding bit position in SHARED_MASK0_SET.

Using SHARED_MASK0_CLR and SHARED_MASK0_SET prevents unintentionally setting or clearing other bits.

NOTE

The masking of a shared module must not be disabled in both SLEEPCON0 and SLEEPCON1.

30.4.2.2 Sleep Configuration (SLEEPCFG)

Offset

Register	Offset
SLEEPCFG	0h

Function

Controls the power requests to various modules while CPU1 is in Deep Sleep mode. The power mode requests selected by this register are aggregated with the CPU0 requests to determine the actual settings. When the CPU1 is in Deep Power Down mode or Full Deep Power Down mode, all the related modules are powered down.

NOTE

You need to clear FRO2_GATE bit after POR and system reset.

Diagram

Fields

Field	Function
31	FRO2 Gating

Table continues on the next page...

Table continued from the previous page...

Field	Function
FRO2_GATE	Controls the gating of FRO2. 0b - Removes gating 1b - Applies gating
30-17 —	Reserved
16 ADC0_PD	ADC0 Power Down Controls the power to ADC0. Write 1 to SHA_SEN_TCTRL0[ADC0_STOP] first and then write 1 to ADC0_PD to minimize the power consumption of ADC0. 0b - Powers on 1b - Powers down
15 AUDPLLLDO_PD	Audio PLL internal regulator Power Down Controls the power to audio PLL internal regulator. 0b - Powers on 1b - Powers down
14 AUDPLLANA_PD	Audio PLL Analog Function Power Down Controls the power to audio PLL analog function. 0b - Powers on 1b - Powers down
13 PLLLDO_PD	Main PLL internal regulator Power Down Controls the power to main PLL internal regulator. 0b - Powers on 1b - Powers down
12 PLLANA_PD	Main PLL Analog Function Power Down Controls the power to main PLL analog function. 0b - Powers on 1b - Powers down
11 LPOSC_PD	LPOSC Power Down Controls the power to LPOSC.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE LPOSC is used by WWDT and RSTCTL. WWDT module can use MOD[LOCK] to lock SLEEPCON's control over power to the LPOSC. If MOD[LOCK] of either or both of WWDT2 and WWDT3 is configured as 1, the write to this field can change the filed value but does not take effect. 0b - Powers on 1b - Powers down
10 FRO2_PD	FRO2 Power Down Controls the power to FRO2. **NOTE** FRO2 power-down depends on both FRO2_PD and CSR[FROEN] of FRO2. To power down FRO2, you need to write 1 to FRO2_PD and write 0 to CSR[FROEN] of FRO2. To Power on FRO2, you need to write 0 to FRO2_PD or write 1 to CSR[FROEN] of FRO2. If SLEEPCON needs to wait power down ready from FRO2, then CSR[CLKGATE] of FRO2 must enable FRO divider 6 clock. Otherwise SLEEPCON will be blocked and PMC cannot entry low-power mode. 0b - Powers on 1b - Powers down
9-8 —	Reserved
7 XTAL_PD	Xtal Oscillator Power Down Controls the power to Xtal oscillator (osc_out). 0b - Powers on 1b - Powers down
6 MEDIA_MAINCLK_SHUTOFF	VDD2_MEDIA and VDDN_MEDIA Domains media_main_clk and media_vddn_clk Shut Off Controls the main clock shut-off of the VDD2_MEDIA and VDDN_MEDIA domains. 0b - Turns on 1b - Turns off
5 COMN_MAINCLK_SHUTOFF	VDDN_COM Domain common_vddn_clk Shut Off Controls the main clock shut-off of the VDDN_COM domain. 0b - Turns on 1b - Turns off
4	RAM_ARBITER1 sense_ram_clk Shut Off

Table continues on the next page...

Table continued from the previous page...

2 SENSES_MAINCLK_SHUTOFF	VDD1_SENSE Domain sense_main_clk_1 Shut Off Controls the clock shut-off of the shared part in VDD1_SENSE domain. 0b - Turns on 1b - Turns off
1 SENSEP_MAINCLK_SHUTOFF	VDD1_SENSE Domain sense_main_clk Shut Off Controls the main clock shut-off of the private part in VDD1_SENSE domain. 0b - Turns on 1b - Turns off
0 —	Reserved

30.4.2.3 Run Configuration (RUNCFG)

Offset

Register	Offset
RUNCFG	10h

Function

Controls the power to various modules during normal operation. The power mode requests selected by this register are aggregated with the CPU0 requests to determine the actual settings.

To modify a RUNCFG bit, use RUNCFG_CLR and RUNCFG_SET:

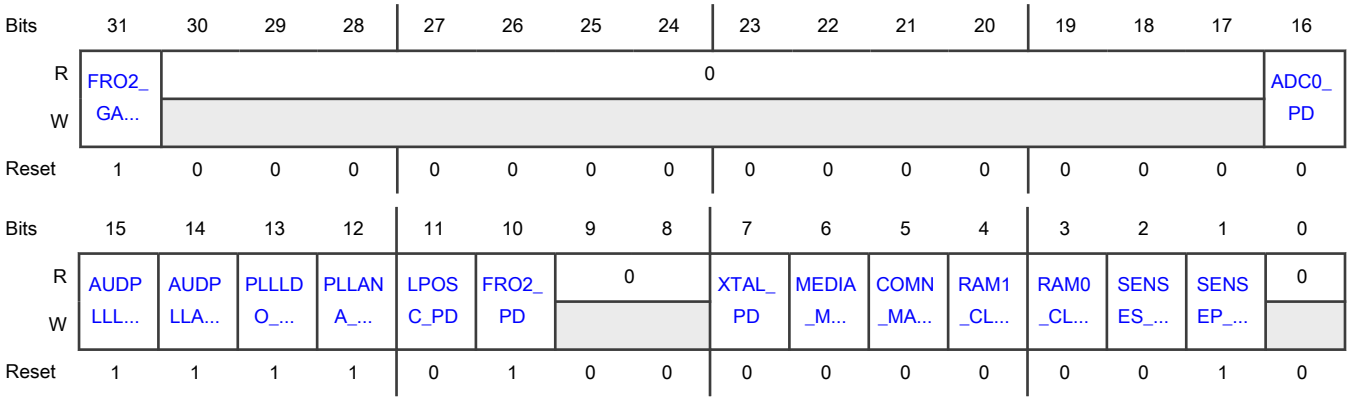
- To make it 0, write a 1 to the corresponding bit position in RUNCFG_CLR.
- To make it 1, write a 1 to the corresponding bit position in RUNCFG_SET.

NOTE

After confirming that a specific FRO*/LPOSC/Xtal/PLLs is not used, you can configure FRO*_PD and *PLL*_PD bits in RUNCFG by RUNCFG_CLR. Then FRO*/LPOSC/Xtal/PLLs can power down on the fly.

You need to clear FRO2_GATE bit after POR and system reset.

Diagram



Fields

Field	Function
31 FRO2_GATE	FRO2 Gating Controls the gating of FRO2. 0b - Removes gating 1b - Applies gating
30-17 —	Reserved
16 ADC0_PD	ADC0 Power Down Controls the power to the ADC0. Write 1 to SHA_SEN_TCTRL0[ADC0_STOP] first and then write 1 to ADC0_PD to minimize the power consumption of ADC0. 0b - Powers on 1b - Powers down
15 AUDPLLLDO_PD	Audio PLL Internal Regulator Power Down Controls the power to audio PLL internal regulator. 0b - Powers on 1b - Powers down
14 AUDPLLANA_PD	Audio PLL Analog Function Power Down Controls the power to audio PLL analog function. 0b - Powers on 1b - Powers down
13 PLLLDO_PD	Main PLL Internal Regulator Power Down Controls the power to main PLL internal regulator.

30.4.2.6 Wakeup Enable 0 (WAKEUPEN0)

Offset

Register	Offset
WAKEUPEN0	60h

Function

Enables the CPU1 to wake-up from deep-sleep mode. If a module's wakeup field is enabled, the CPU1 will wake up when receiving the module's interrupt.

To modify a WAKEUPEN0 bit, use the corresponding WAKEUPEN0_CLR and WAKEUPEN0_SET registers:

- To make a bit 0, write a 1 to the corresponding bit position in WAKEUPEN0_CLR.
- To make a bit 1, write a 1 to the corresponding bit position in WAKEUPEN0_SET.

Using WAKEUPEN0_CLR and WAKEUPEN0_SET prevents unintentionally setting or clearing other bits

30.4.2.7 Wakeup Enable 1 (WAKEUPEN1)

Offset

Register	Offset
WAKEUPEN1	64h

Function

Enables the CPU1 to wake-up from deep-sleep mode. If a module's wakeup field is enabled, the CPU1 will wake up when receiving the module's wakeup interrupt.

To modify a WAKEUPEN1 bit, use the corresponding WAKEUPEN1_CLR and WAKEUPEN1_SET registers:

- To make a bit 0, write a 1 to the corresponding bit position in WAKEUPEN1_CLR.
- To make a bit 1, write a 1 to the corresponding bit position in WAKEUPEN1_SET.

Using WAKEUPEN1_CLR and WAKEUPEN1_SET prevents unintentionally setting or clearing other bits

30.4.2.8 Wakeup Enable 2 (WAKEUPEN2)

Offset

Register	Offset
WAKEUPEN2	68h

Function

Enables the CPU1 to wake-up from deep-sleep mode. If a module's wakeup field is enabled, the CPU1 will wake up when receiving the module's wakeup interrupt.

To modify a WAKEUPEN2 bit, use the corresponding WAKEUPEN2_CLR and WAKEUPEN2_SET registers:

- To make a bit 0, write a 1 to the corresponding bit position in WAKEUPEN2_CLR.
- To make a bit 1, write a 1 to the corresponding bit position in WAKEUPEN2_SET.

Using WAKEUPEN2_CLR and WAKEUPEN2_SET prevents unintentionally setting or clearing other bits

15-0 LPOSCDELAY	Delay value for LPOSC output Controls the delay in units of LPOSC clock cycles. 0000h - No delay 0001h - 1 LPOSC clock cycle 0002h - 2 LPOSC clock cycles ..... FFFFh - 2^{16}-1 LPOSC clock cycles

30.4.2.16 Power Down Wait (PWRDOWN_WAIT)

Offset

Register	Offset
PWRDOWN_WAIT	164h

Function

Controls the power down wait of FRO2 and LPOSC. Setting the ignore bits below will allow the CPU1 to continue entering a low-power mode without waiting for the corresponding clock to shut down first.

NOTE

If SLEEPCON needs to wait power down ready from FRO, then CSR[CLKGATE] of FRO must enable FRO divider 6 clock. Otherwise SLEEPCON will be blocked and PMC cannot entry low-power mode.

2 IGN_FRO2PDR	Ignore FRO2 Power Down Ready Signal Ignores power-down ready signal from FRO2. 0b - Waits 1b - Ignores
1-0 —	Reserved

30.4.2.17 eDMA Wakeup Enable (HW_WAKE)

Offset

Register	Offset
HW_WAKE	190h

Function

Enables eDMA (eDMA2 and eDMA3) wakeup sources. To modify an HW_WAKE bit, use the HW_WAKE_CLR and HW_WAKE_SET registers:

- To make a bit 0, write a 1 to the corresponding bit position in HW_WAKE_CLR.
- To make a bit 1, write a 1 to the corresponding bit position in HW_WAKE_SET.

Using HW_WAKE_CLR and HW_WAKE_SET prevents unintentionally setting or clearing other bits.

30.4.2.18 eDMA Wakeup Set (HW_WAKE_SET)

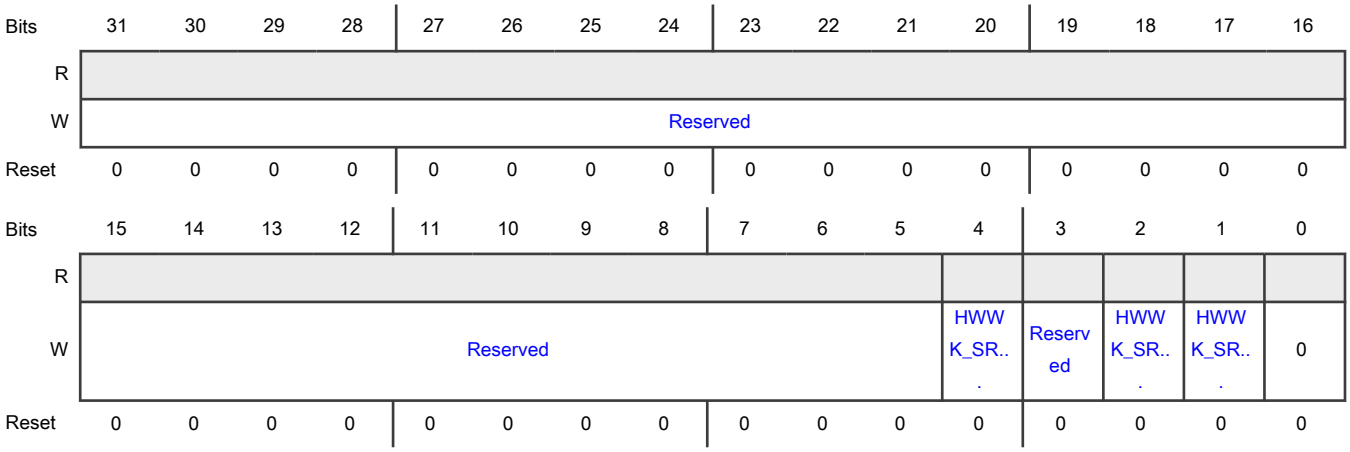
Offset

Register	Offset
HW_WAKE_SET	194h

Function

Writing a 1 to a bit position sets the corresponding position in HW_WAKE. Writing a 0 to a bit position has no effect.

Diagram



Fields

Field	Function
31-5 —	Reserved
4 HWWK_SRC4_SET	eDMA Wakeup Source 4 Enable Changes the corresponding bit to 1. 0b - No effect 1b - Sets the bit
3	Reserved

0 —	Reserved

30.4.2.20 Shared Resources Mask (SHARED_MASK0)

Offset

Register	Offset
SHARED_MASK0	1A0h

Function

Enables the masking of SLEEPCON1 control for shared modules. To modify a SHARED_MASK0 bit, use the corresponding SHARED_MASK0_CLR and SHARED_MASK0_SET registers:

- To make a bit 0, write a 1 to the corresponding bit position in SHARED_MASK0_CLR.
- To make a bit 1, write a 1 to the corresponding bit position in SHARED_MASK0_SET.

Using SHARED_MASK0_CLR and SHARED_MASK0_SET prevents unintentionally setting or clearing other bits.

NOTE

The masking of a shared module must not be disabled in both SLEEPCON0 and SLEEPCON1.
