57.7.15 Voice Activity Detector 0 Control (VAD0_CTRL_1)

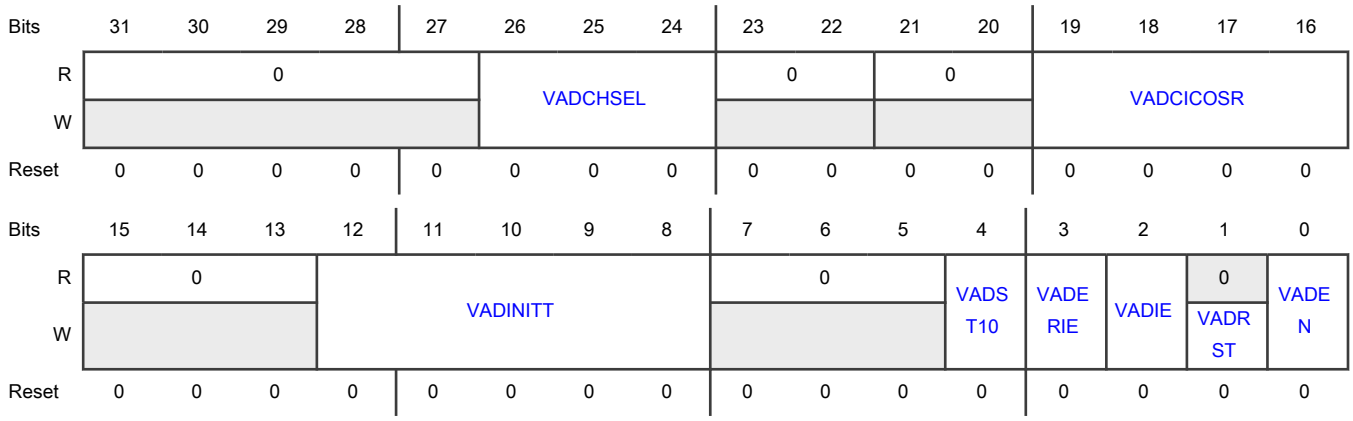
Offset

Register	Offset
VAD0_CTRL_1	90h

Function

Contains HWVAD configuration bits including the channel selector, CIC oversampling rate (OSR) and initialization time configuration, internal filters initialization, interrupt, reset, and HWVAD enable bits.

Diagram



Fields

Field	Function
31-27 —	Reserved
26-24 VADCHSEL	Channel Selector Selects the number of channels which HWVAD works with. **NOTE** You must not change the value of this field when STAT[BSY_FIL] = 1. 000b - PDM Microphone 0 Left 001b - PDM Microphone 0 Right 010b - PDM Microphone 1 Left 011b - PDM Microphone 1 Right 100b-101b - ... 110b - PDM Microphone 3 Left 111b - PDM Microphone 3 Right
23-22 —	Reserved
21-20 —	Reserved
19-16	CIC Oversampling Rate

Table continues on the next page...

Table continued from the previous page...

Field	Function
VADCICOSR	Defines the OSR of the CIC filter. The OSR is (16-CICOSR). **NOTE** You must not change the value of this field when STAT[BSY_FIL] = 1.
15-13 —	Reserved
12-8 VADINITT	Initialization Time Selects the number of frames to be used to initialize the voice detection. The initialization time is the time taken by {[VADINITT] + 1} frames. During this period the output of the voice activity detector is forced to inactive. For more information, see Initialization time. **NOTE** You must not change the value of this field when STAT[BSY_FIL] = 1. 0_0000b - 0 0_0001b - 1 0_0010b-1_1110b - ... 1_1111b - 31
7-5 —	Reserved
4 VADST10	Internal Filters Initialization Initializes the signal and noise filter with pre-filter value. When [VADST10] = 1, there is no voice activity detection. **NOTE** If the use of this bit is required, it should stay pulsed by more than 2 cycles of the system clock. 0b - Normal operation 1b - Filters initialized
3 VADERIE	Error Interruption Enable Enables Error Interrupts in MICFIL. This error could be caused by an overflow in the input of the HWVAD and it is signalized by the VADINSATF flag. 0b - Disables 1b - Enables
2 VADIE	Interruption Enable Enables interrupts in MICFIL when voice activity event has been detected by HWVAD. See the VADIF for more information.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disables 1b - Enables
1 VADRST	HWVAD Reset Provides the CPU with the capability to initialize HWVAD through the target-bus interface. This bit always reads zero. This bit is self-cleared. See VAD soft-reset.
0 VADEN	HWVAD Enable Enables the use of HWVAD. **NOTE** You must not change the value of this field when STAT[BSY_FIL] = 1. 0b - Disables 1b - Enables

57.7.16 Voice Activity Detector 0 Control (VAD0_CTRL_2)

Offset

Register	Offset
VAD0_CTRL_2	94h

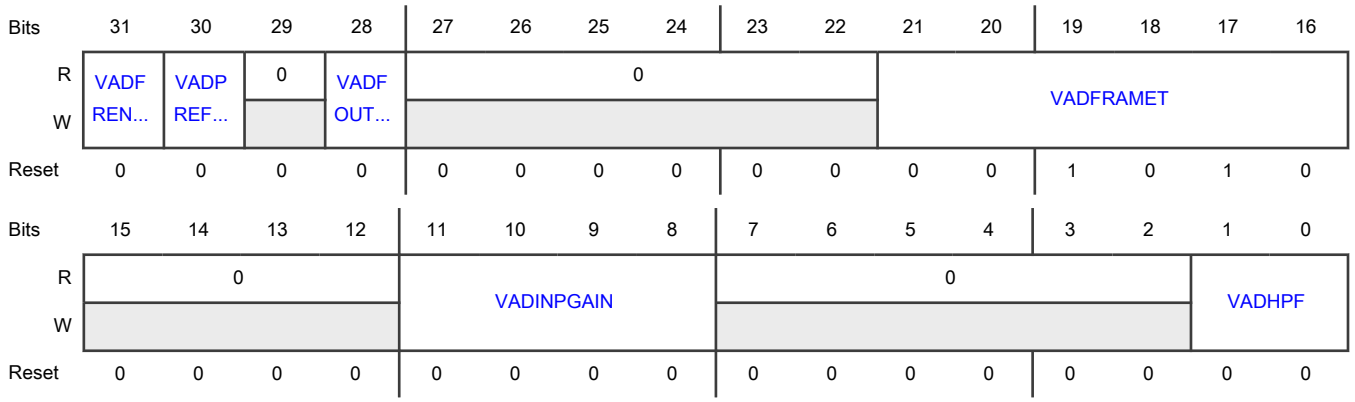
Function

Contains HWVAD configuration bits including the frame energy, pre-filter, force output, frame time, input gain, and high-pass filter configuration for the VAD.

NOTE

You must not change the value of this register when STAT[BSY_FIL] = 1.

Diagram



Fields

Field	Function
31 VADFRENDIS	Frame Energy Disable Disables the calculus of energy in a frame. For more information, see Noise filter. 0b - Enables 1b - Disables
30 VADPREFEN	Pre Filter Enable Enables a pre-filter in the input of noise and signal filters. For more information, see Pre-filter. 0b - Pre-filter bypassed 1b - Pre-filter enabled
29 —	Reserved
28 VADFOUTDIS	Force Output Disable Disables the output of the Energy and Envelope-based Detector. 0b - Enables 1b - Disables
27-22 —	Reserved
21-16 VADFRAMET	Frame Time Selects the scale value to control the frame time duration as described in Frame time setting. **NOTE** [VADFRAMET] = 0 is not allowed. 00_0000b - 1 00_0001b - 2 00_0010b-11_1110b - ... 11_1111b - 63
15-12 —	Reserved
11-8 VADINPGAIN	Input Gain Configures the gain value in the HWVAD input as a positive or negative (two's complement) number of bits to shift. 0000b - No shift 0001b - Shift 1 bit to the left

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0010b - Shift 2 bits to the left 0011b-0110b - ... 0111b - Shift 7 bits to the left 1000b - Shift 8 bits to the right 1001b - Shift 7 bits to the right 1010b-1110b - ... 1111b - Shift 1 bits to the right
7-2 —	Reserved
1-0 VADHPF	High-Pass Filter Configures the internal high-pass filter. 00b - Filter bypassed 01b - Cut-off frequency at 1750 Hz 10b - Cut-off frequency at 215 Hz 11b - Cut-off frequency at 102 Hz

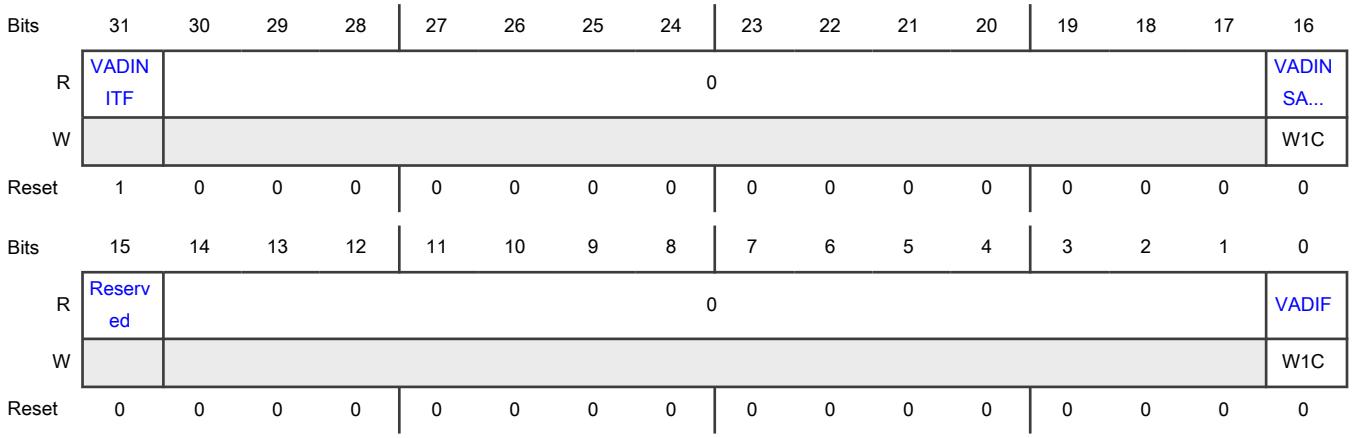
57.7.17 Voice Activity Detector 0 Status (VAD0_STAT)

Offset

Register	Offset
VAD0_STAT	98h

Function
Indicates the HWVAD status.

Diagram



Fields

Field	Function
31 VADINITF	Initialization Flag Signalizes when the HWVAD is being initialized according to VAD*n*_CTRL_1[VADINITT] value. 0b - Not being initialized 1b - Being initialized
30-17 —	Reserved
16 VADINSATF	Input Saturation Flag Indicates an exceptional saturation condition by an overflow or underflow in the HWVAD input. 0b - No exception 1b - Exception
15 —	Reserved
14-1 —	Reserved
0 VADIF	Interrupt Flag Indicates when voice activity has been detected by HWVAD. Write a logic 1 to this field to clear this flag. 0b - Not detected 1b - Detected

57.7.18 Voice Activity Detector 0 Signal Configuration (VAD0_SCONFIG)

Offset

Register	Offset
VAD0_SCONFIG	9Ch

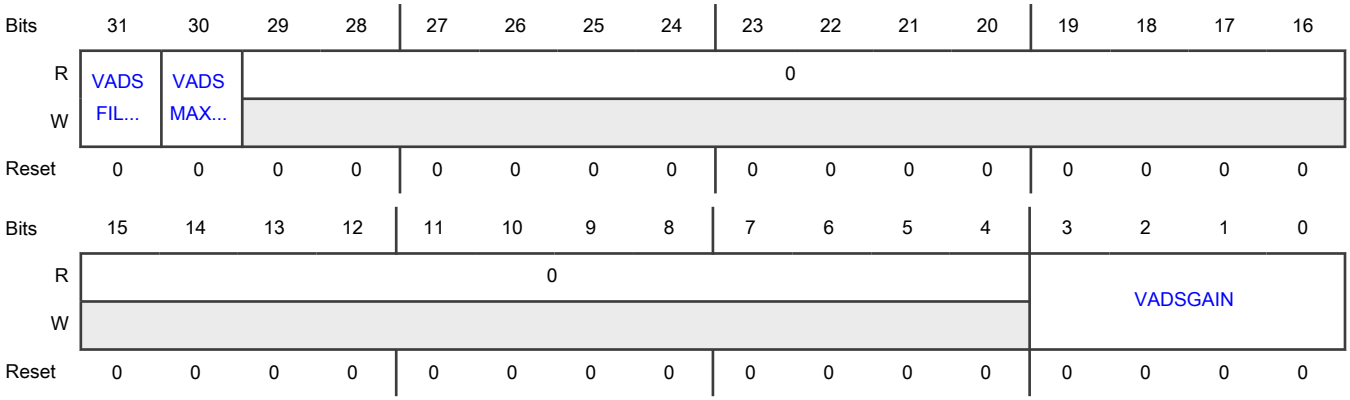
Function

Configures the HWVAD signal gain value and the signal filter.

NOTE

These fields must be configured when MICFIL is not running.

Diagram



Fields

Field	Function
31 VADSFILEN	Signal Filter Enable Enables the signal filter. For more information, see Signal filter. 0b - Disables 1b - Enables
30 VADSMAXEN	Signal Maximum Enable Selects whether or not a block to calculate the maximum value between the input and output of signal filter is used as signal estimation. For more information, see Signal filter. 0b - Maximum block bypassed 1b - Maximum block enabled
29-4 —	Reserved
3-0	Signal Gain

Table continues on the next page...

Table continued from the previous page...

Field	Function
VADSGAIN	Configures the gain value for the signal energy or envelope estimated. It is a unsigned value which is multiplied with the estimated signal data. **NOTE** When [VADSGAIN] = 0, the signal gain corresponds to 1. 0000b,0001b - Multiplier = 1 0010b - Multiplier = 2 0011b-1110b - ... 1111b - Multiplier = 15

57.7.19 Voice Activity Detector 0 Noise Configuration (VAD0_NCONFIG)

Offset

Register	Offset
VAD0_NCONFIG	A0h

Function

Configures the HWVAD noise gain value and the noise filter.

NOTE

These fields must be configured when MICFIL is not running.

Diagram

—	
11-8 VADZCDADJ	ZCD Adjustment Selects the adjustment value of the threshold estimator. For more information, see Zero-crossing detector (ZCD). 0000b - 0 0001b - 1 0010b-1110b - ... 1111b - 15
7-5 —	Reserved
4 VADZCDAND	ZCD AND Behavior Selects whether the ZCD results are combined with the energy-based detection using AND or OR to form the voice activity detection event. 0b - OR 1b - AND
3 —	Reserved
2 VADZCDAUTO	ZCD Automatic Threshold Disables the automatic estimation of the ZCD threshold. 0b - Disables 1b - Enables
1 —	Reserved
0 VADZCDEN	ZCD Enable Enables the ZCD in HWVAD. 0b - Disables 1b - Enables

Chapter 58
Synchronous Audio Interface (SAI)

58.1 Chip-specific SAI information

Table 573. Reference links to related information

Topic	Related module	Reference
Full description	SAI	SAI
Peripheral memory map		Memory map overview
Power management	PMC	Power overview PMC
Clocking		Clock overview Clock controller
Signal multiplexing	IOPCTL	External signals and pin multiplexing IO PAD controller

58.1.1 Module instances

This device has four instances of the SAI module, SAI0, SAI1, SAI2 and SAI3.

Table 574. SAI instances

	SAI0	SAI1	SAI2	SAI3
Located in	VDD2_COMP	VDD2_COMP	VDD2_COMP	VDD1_SENSE
Access	CPU0, HiFi4, EZH-V, eDMA0, eDMA1	CPU0, HiFi4, EZH-V, eDMA0, eDMA1	CPU0, HiFi4, EZH-V, eDMA0, eDMA1	CPU1, HiFi1, eDMA2, eDMA3

58.1.2 SAI TCR2, RCR2, and MCR configuration

Table 575. SAI configuration

Instance	Register bit	Configuration
SAI0-SAI2	TCR2[MSEL], RCR2[MSEL]	• 00b: compute_main_clk • 01b: MCLK from pin if the related pin is configured as input; or the clock configured by SAI012FCLKSEL and SAI012CLKDIV registers if the related pin is configured as output. • 10b: Reserved • 11b: Reserved
SAI3	TCR2[MSEL], RCR2[MSEL]	• 00b: sense_main_clk

Table continues on the next page...

Table 575. SAI configuration (continued)

Instance	Register bit	Configuration
		• 01b: MCLK from pin if the related pin is configured as input; or the clock configured by SAI3FCLKSEL and SAI3CLKDIV registers if the related pin is configured as output. • 10b: Reserved • 11b: Reserved
SAI0-SAI3	MCR[MSEL] MCR[DIVEN] MCR[DIV]	Reserved for this chip. Changes to these bit fields have no effect.

SAI1 and SAI2 bit clock, frame sync, and transmitter/receiver enable are synchronous with SAI0 in multiple SAI synchronous mode.

58.1.3 MCLK configuration

MCLK direction is configured by SYSCON register bits:

- SYSCON0.SAI0_MCLK_CTRL[SAIMCLKDIR] for SAI0, SAI1 and SAI2
- SYSCON1.SAI3_MCLK_CTRL[SAIMCLKDIR] for SAI3

Configure SAI register bit MCR[MOE]=1 whenever the SAI instance is using MCLK from any internal or external source.

If you want to use MCLK as the input, besides configuring the MCLK direction as input, you also need to configure MCLK as the clock source of audio controller clock for SAI as below:

- Select MCLK as the clock source of audio controller clock for SAI0, SAI1 and SAI2 by configuring
  1. CLKCTL0.AUDIOVDD2CLKCSEL[SEL] = 00b
  2. CLKCTL0.SAI012FCLKSEL[SEL] = 11b
- Select MCLK as the clock source of audio controller clock for SAI3 by configuring
  1. CLKTL1.AUDIOVDD1CLKSEL[SEL] =00b
  2. CLKCTL1.SAI3FCLKSEL[SEL] = 11b

58.1.4 Timestamp counter synchronization

This chip does not support timestamp counter synchronization between different SAI instances. See available timestamp select as below

Table 576. TSSEL configuration

Register bit	Configuration
TTCR[TSSEL]	• 00b: Increment when enabled • 01b: Increment when the receive timestamp counter is enabled • Others: Reserved
RTCR[TSSEL]	• 00b: Increment when enabled • 01b: Increment when the transmit timestamp counter is enabled • Others: Reserved

58.1.5 Initialization

1. Enable the clock to the SAI.
   - SAI*n* in compute domain via the CLKCTL0_PSCCTL2[SAI*n*] (*n* = 0-2)
   - SAI3 in sense domain via the CLKCTL1_PSCCTL1[SAI3]
2. Select a clock source and its divider for the SAI.
   - SAI*n* (*n* = 0-2) in compute domain via the CLKCTL0_SAI012FCLKSEL and CLKCTL0_SAI012CLKDIV registers
   - SAI3 in sense domain via the CLKCTL1_SAI3FCLKSEL and CLKCTL1_SAI3CLKDIV registers
3. Resets the internal transmitter logic and receiver logic by TCSR[SR] and RCSR[SR].

58.2 Overview

SAI provides an interface that supports full-duplex serial digital audio interfaces with frame synchronization formats such as I^2S, AC97, TDM, and Codec/DSP interfaces.

58.2.1 Block diagram

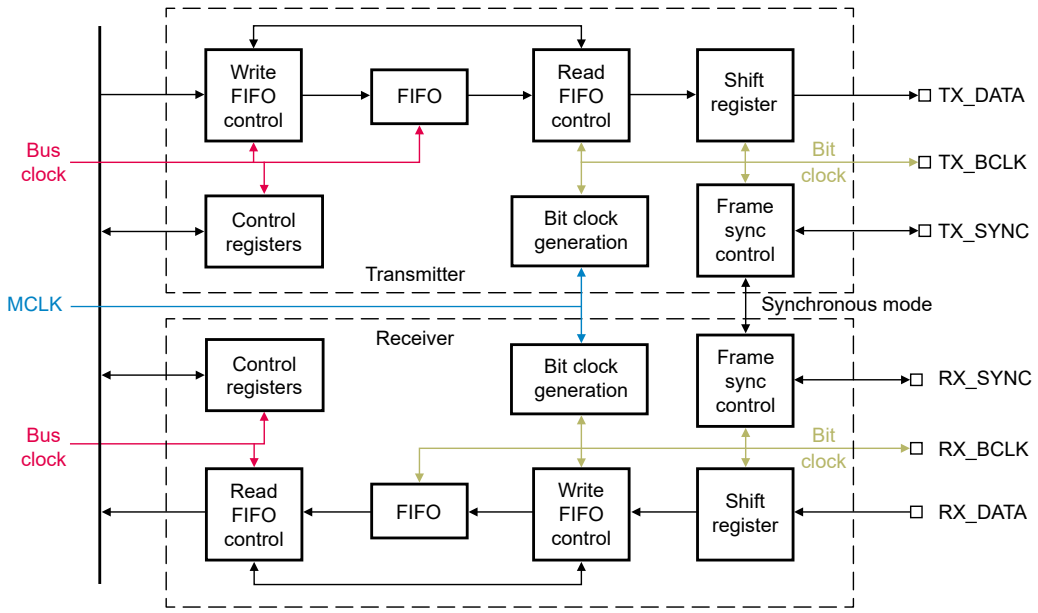

Figure 251. Block diagram

58.2.2 Features

Features can vary among chips and among SAI modules on the same chip. See the chip-specific SAI information at the beginning of this chapter.

- Transmitter with independent bit clock and frame synchronization supporting 1 data line
- Receiver with independent bit clock and frame synchronization supporting 1 data line
- Maximum frame size of 32 words per data line
- Word length of 8 to 32 bits
- Word length configured separately for the first word and remaining words in a frame
- Asynchronous 8 × 32-bit FIFO for each transmit and receive data line supports:

  - Graceful restart after FIFO error.
  - Automatic restart after FIFO error without software intervention.
  - 8-bit and 16-bit data packing into each 32-bit FIFO word.
- Independent 32-bit timestamp counters and bit counters for monitoring transmit and receive progress

58.3 Functional description

This section provides a complete functional description of SAI.

58.3.1 Modes of operation

- Run mode
- Stop mode
- Debug mode

58.3.1.1 Run mode

In Run mode, the SAI transmitter and receiver operate normally.

58.3.1.2 Stop mode

There are two situations in which you can configure the SAI transmitter or receiver to continue operating in Stop mode:

- The SAI transmitter or receiver uses an externally generated bit clock.
- The SAI transmitter or receiver uses an audio clock (MCLK) that operates when the chip is in Stop mode.

Write 1 to TCSR[STOPE] to configure the transmitter to run in Stop mode, and write 1 to RCSR[STOPE] to configure the receiver to run in Stop mode.

The SAI transmitter and receiver can generate an asynchronous interrupt to wake the CPU from Stop mode.

When the chip enters Stop mode, if TCSR[STOPE] = 0, the transmitter is disabled after completing the current transmit frame. Similarly, when the chip enters Stop mode, if RCSR[STOPE] = 0, the receiver is disabled after completing the current receive frame. Entry into Stop mode is blocked (not acknowledged) when waiting for the transmitter and receiver to be disabled at the end of the current frame.

58.3.1.3 Debug mode

You can configure either or both the SAI transmitter and receiver to continue operating in Debug mode:

- Write 1 to TCSR[DBGE] to configure the transmitter to run in Debug mode.
- Write 1 to RCSR[DBGE] to configure the receiver to run in Debug mode.

When TCSR[DBGE] and RCSR[DBGE] are 0 and the chip enters Debug mode, SAI is disabled after completing the current transmit or receive frame. Debug mode does not affect the transmitter and receiver bit clocks.

58.3.2 Synchronous modes

The SAI transmitter and receiver can operate synchronously to each other. You can configure the SAI transmitter and receiver to operate with a synchronous bit clock and frame sync (see TCR2[SYNC] and RCR2[SYNC]).

If both the transmitter and receiver use the transmitter bit clock and frame sync:

- Configure the transmitter for asynchronous operation and the receiver for synchronous operation.
- Enable the receiver in Synchronous mode only after configuring both the transmitter and receiver.
- Enable the transmitter last and disable the transmitter first.

If both the transmitter and receiver use the receiver bit clock and frame sync:

- Configure the receiver for asynchronous operation and the transmitter for synchronous operation.
- Enable the transmitter in Synchronous mode only after configuring both the receiver and transmitter.
- Enable the receiver last and disable the receiver first.

When operating in Synchronous mode, the transmitter and receiver share only the bit clock, frame sync, and transmitter and receiver enable. Otherwise, the transmitter and receiver operate independently, although the configuration register settings must be consistent across both the transmitter and receiver.

58.3.3 Frame sync configuration

When enabled, SAI continuously transmits and receives frames of data. Each frame consists of a fixed number of words, with each word consisting of a fixed number of bits. Within each frame, you can mask any word, causing the receiver to ignore that word and the transmitter to 3-state during that word.

The frame sync signal indicates the start of a frame. A valid frame sync requires the detection of a rising edge (if active high) or falling edge (if active low). The transmitter or receiver cannot be busy with a previous frame. SAI ignores a valid frame sync (in Target mode) or does not generate one (in Controller mode) for the first four bit-clock cycles after enabling the transmitter or receiver.

You can configure the transmitter and receiver frame sync independently by using any of the following options:

- Generate externally or internally
- Configure to be active high or active low
- Assert with the first bit in the frame or one bit early
- Assert for a duration between one bit-clock cycle and the first word length
- Configure the frame length from 1 to 32 words
- Configure the word length from 8 to 32 bits, with separate configurations for the length of the first word and that of the remaining words
- Transmit or receive words MSB first or LSB first

You cannot change these configuration options after enabling the SAI transmitter or receiver.

58.3.4 Data FIFO

Each transmit and receive channel includes a 8 × 32-bit FIFO. Use Transmit Data (TDR0) and Receive Data (RDR0) to access FIFO data.

58.3.4.1 Data alignment

Data in the FIFO can be aligned anywhere within the 32-bit-wide register via the First Bit Shifted (FBT) configuration field. This field selects the bit index (between 31 and 0) of the first bit shifted.

Examples of supported data alignment and the required FBT configuration are shown in Figure 252 for LSB-first configurations and Figure 253 for MSB-first configurations.

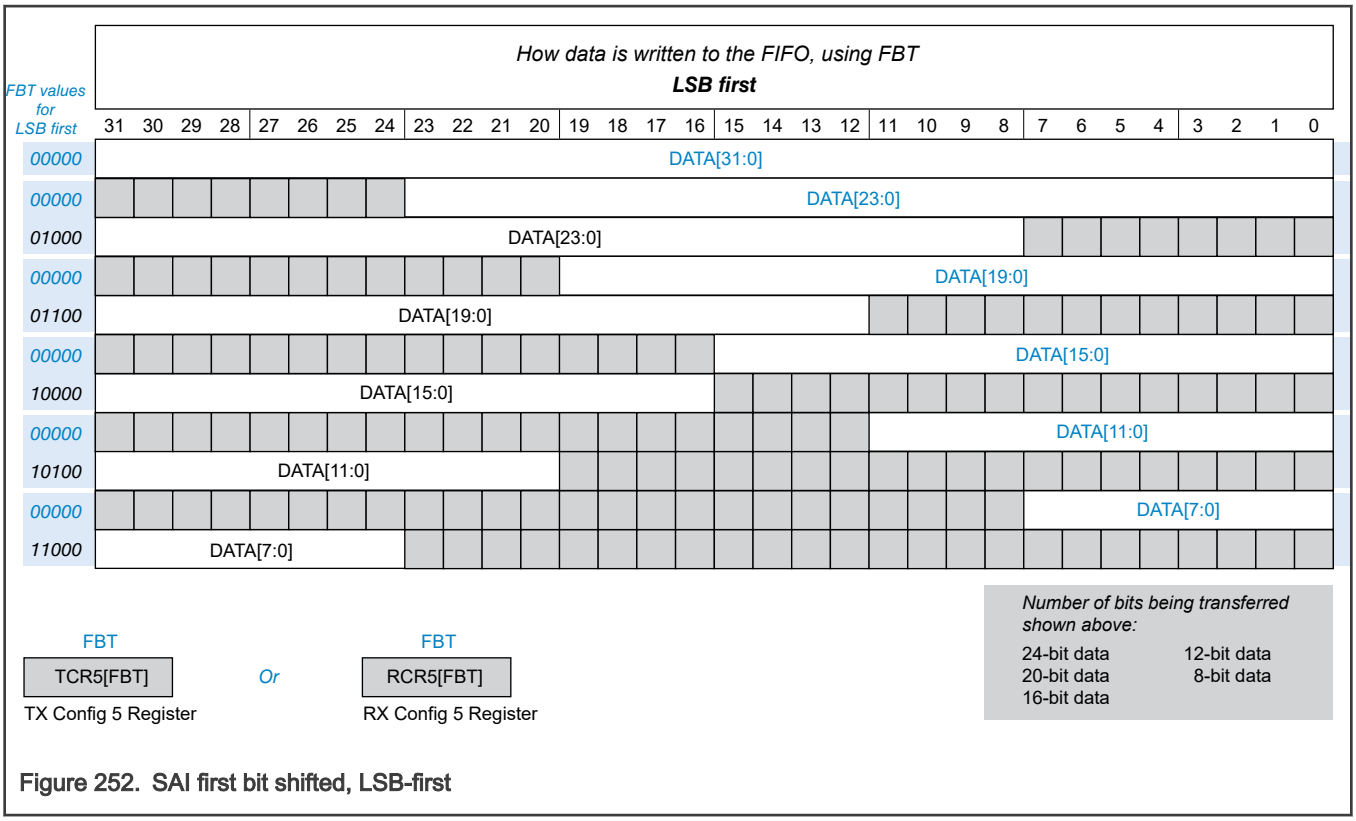

Figure 252. SAI first bit shifted, LSB-first

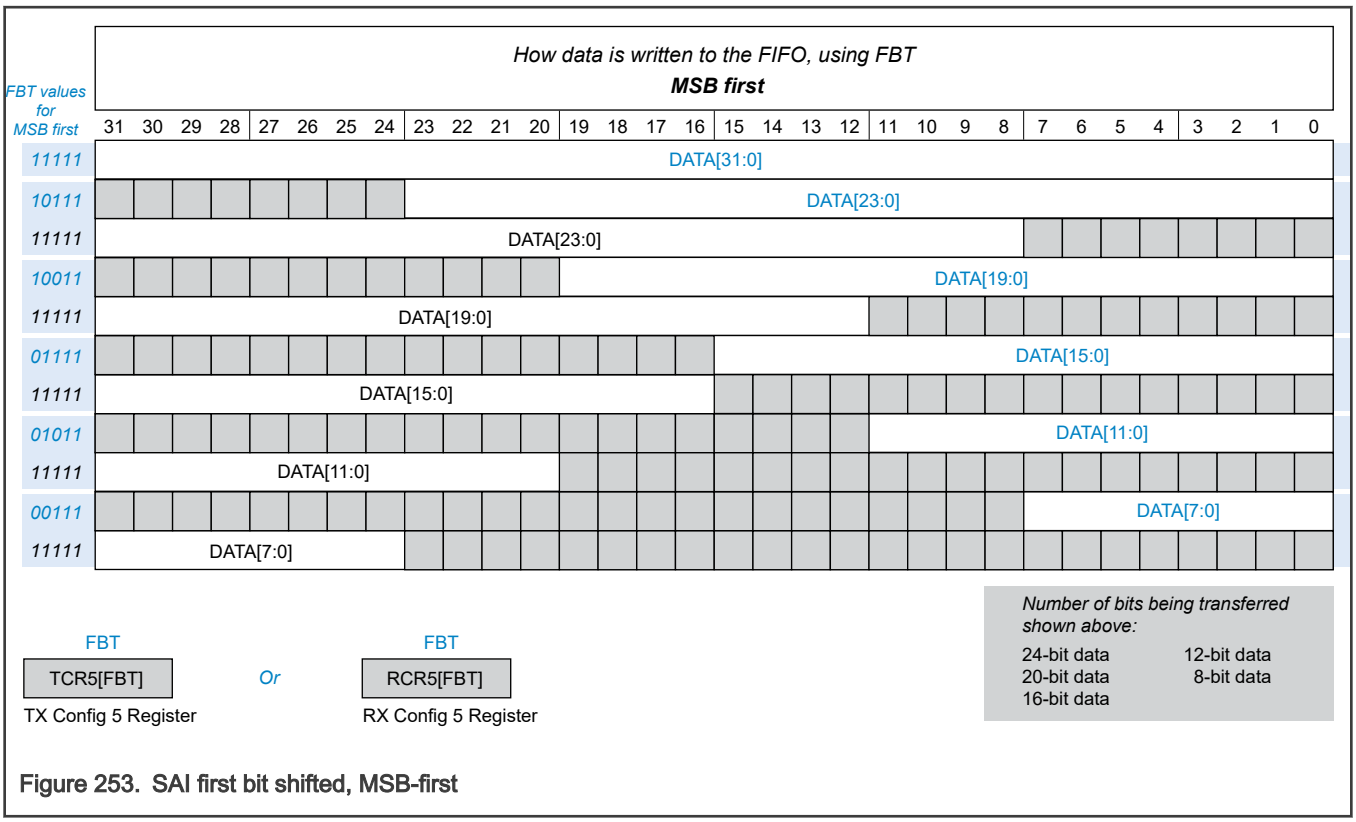

Figure 253. SAI first bit shifted, MSB-first

58.3.4.2 FIFO pointers

When writing to one of the Transmit Data (TDR0) registers, the write FIFO pointer of the corresponding Transmit FIFO register (TFR*n*[WFP]) increments after each valid write. SAI supports 8-bit, 16-bit, and 32-bit writes to TDR*n*, and the FIFO pointer increments after each individual write. Use only 8-bit writes when transmitting up to 8-bit data, and use only 16-bit writes when transmitting up to 16-bit data:

- If the transmit FIFO is full, SAI ignores writes to TDR*n*.
- If the transmit FIFO is empty, write to TDR*n* at least three bit-clock cycles before the start of the next unmasked word. This write avoids a FIFO underrun.
- Before enabling the transmitter, initialize the transmit FIFO with data. The transmitter starts a new frame after enabling the transmitter. If no data is in the FIFO, the transmitter immediately generates an error.

When reading one of the Receive Data (RDR0) registers, the read FIFO pointer of the corresponding Receive FIFO register (RFR*n*[RFP]) increments after each valid read. SAI supports 8-bit, 16-bit, and 32-bit reads from RDR*n*, and the FIFO pointer increments after each individual read. Use only 8-bit reads when receiving up to 8-bit data, and use only 16-bit reads when receiving up to 16-bit data:

- If the receive FIFO is empty, SAI ignores reads to RDR*n*.
- If the receive FIFO is full, read RDR*n* at least three bit-clock cycles before the end of an unmasked word. This read avoids a FIFO overrun.

58.3.4.3 FIFO packing

Using FIFO packing, you can store multiple 8-bit or 16-bit data words in one 32-bit FIFO word for the transmitter or receiver. You could emulate this feature by adjusting the number of bits per word and number of words per frame. FIFO packing, however, does not require even multiples of words per frame, and it fully supports word masking.

When FIFO packing is enabled, the FIFO pointers only increment when the full 32-bit FIFO word has been written (transmit) or read (receive). In this way, FIFO packing supports scenarios where different words within each frame are stored in different areas of memory.

Using 16-bit FIFO packing for transmitting, the transmit shift register loads at the start of each frame and after every second unmasked transmit word. The first transmitted word is taken from the 16-bit word at byte offset 0h. (The first bit is selected by TCR5[FBT], and you must configure it within this 16-bit word.) The second transmitted word is taken from the 16-bit word at byte offset 2h. (The first bit is selected by TCR5[FBT][3:0].) After the 16-bit word has been transmitted, the transmitter transmits logic zeroes until the start of the next word.

Using 16-bit FIFO packing for receiving, the receive shift register is stored after every second unmasked received word. If there is an odd number of unmasked-received words in each frame, the receive register is also stored, at the end of each frame. The first received word is stored in the 16-bit word at byte offset 0h. (The first bit is selected by RCR5[FBT], and you must configure it within this 16-bit word.) The second received word is stored in the 16-bit word at byte offset 2h. (The first bit is selected by RCR5[FBT][3:0].) The receiver ignores received data until the start of the next word after the 16-bit word has been received.

8-bit FIFO packing is similar to 16-bit packing, except four words are loaded or stored into each 32-bit FIFO word. The first word is stored in byte offset 0h, the second word in byte offset 1h, and so on. You must configure TCR5[FBT], RCR5[FBT], or both within byte offset 0h.

58.3.5 Word mask register

The SAI transmitter and receiver each have a word mask register (Transmit Mask (TMR) and Receive Mask (RMR)) that you can use to mask any word in the frame. The word mask register is double buffered. You can update it before the end of each frame to mask a particular word in the next frame.

TMR causes the transmit data pin to be 3-stated for the length of each selected word; the transmit FIFO is not read for masked words.

RMR causes the received data for each selected word to be discarded and not written to the receive FIFO.

58.3.6 Timestamp counter

The transmitter and receiver implement separate timestamp counters and bit counters. The bit counter increments at the end of each bit in a frame when the transmitter or receiver is enabled. The bit counter continues to increment if a word is masked or a FIFO underrun or overrun condition occurs. The bit counter does not increment if an external frame sync is configured and no frame sync is detected. You can reset the bit counter via software. Due to synchronization delays it can take up to 3 bit-clock cycles for the bit clock counter to continue incrementing after a bit counter reset.

The timestamp counter increments on the bus interface clock when it is enabled. You can configure it to synchronize to the bit counter by waiting for the bit counter to increment first (if configured, this synchronization is performed after the time counter is reset). The current value of the timestamp counter is latched whenever the bit counter increments. Reading the bit counter register causes the latched timestamp value to be saved in the bit counter timestamp register. You can reset the timestamp counter via software; a reset via software also resets the latched timestamp value and the bit counter timestamp register.

The timestamp counter can be synchronized between the transmitter and receiver; it can also be synchronized with the transmitter or receiver of another instance. When synchronizing timestamp counters, the controlling timestamp counter must be the last one enabled and the first one disabled. The timestamp counter software reset is not synchronized.

You can use the timestamp counter and bit counter to track the progress of the transmitter and receiver. You can also use it to calculate the relative frequency of the bit clock compared to the bus interface clock.

58.3.7 Clocking

- Audio clock
- Bit clock
- Bus clock

58.3.7.1 Audio clock

The audio clock (MCLK) generates the bit clock when you configure the receiver or transmitter for an internally generated bit clock. The transmitter and receiver can independently select between the bus clock and up to three audio clocks to generate the bit clock.

The SAI peripheral controls the pin direction and postdivider of an audio clock. The postdivider can divide down the clock output on the MCLK signal pin without affecting the audio clock that the transmitter and receiver use.

The audio clock generation and selection is chip-specific. See chip-specific clocking information about how the audio clocks are generated.

58.3.7.2 Bit clock

The SAI transmitter and receiver support asynchronous free-running bit clocks that an audio clock can generate internally or an external source can supply. SAI can also have synchronous bit clock and frame sync operation between the receiver and transmitter, or between multiple SAI peripherals. The transmitter and receiver configuration affects the bit clock and frame sync in the following ways:

- If you configure both the transmitter and receiver for asynchronous operation, each uses its own bit clock and frame sync.
- If you configure the transmitter for asynchronous operation and the receiver for synchronous operation, both use the transmitter bit clock and frame sync.
- If you configure the receiver for asynchronous operation and the transmitter for synchronous operation, both use the receiver bit clock and frame sync.

Your choice of synchronous or asynchronous operation selects the bit clock and frame sync used.

Externally generated bit clocks must be:

- Enabled before the SAI transmitter or receiver is enabled.
- Disabled after the SAI transmitter or receiver is disabled and completes its current frames.

In asynchronous operation, a SAI transmitter or receiver can use a bit clock externally generated by a SAI module instance that is disabled in Stop mode. In this case, disable the transmitter or receiver before entering Stop mode. This issue does not apply when the transmitter or receiver is in synchronous operation because all synchronous SAI modules are enabled and disabled simultaneously.

58.3.7.3 Bus clock

The control and configuration registers use the bus clock to generate synchronous interrupts and DMA requests.

NOTE

Although no minimum bus clock frequency is specified, the frequency must be fast enough (relative to the bit clock frequency) to serve the FIFOs. You must meet this requirement without generating a transmitter FIFO underrun or receiver FIFO overflow condition.

58.3.8 Reset

SAI is asynchronously reset on system reset. SAI has a Software reset and a FIFO reset.

58.3.8.1 Software reset

The SAI transmitter includes a software reset that resets all transmitter internal logic, including the bit clock generation, status flags, and FIFO pointers. The SAI receiver includes a software reset that resets all receiver internal logic, including bit clock generation, status flags, and FIFO pointers.

These software resets do not reset the configuration registers. The software resets remain asserted until you clear them via software.

58.3.8.2 FIFO reset

The SAI transmitter includes a FIFO reset that synchronizes the FIFO write pointer to the value of the FIFO read pointer. This FIFO reset empties the FIFO contents. Use this reset after TCSR[FEF] becomes 1, and before SAI reinitializes the FIFO and TCSR[FEF] becomes 0. SAI asserts the FIFO reset for one cycle only.

The SAI receiver includes a FIFO reset that synchronizes the FIFO read pointer to the value of the FIFO write pointer. This FIFO reset empties the FIFO contents. Use this reset after RCSR[FEF] becomes 1 and SAI reads any remaining data from the FIFO, and before RCSR[FEF] becomes 0. SAI asserts the FIFO reset for one cycle only.

58.3.9 Interrupts and DMA requests

In SAI, the transmitter and receiver generate separate interrupts and DMA requests, but use the same status flags. SAI generates asynchronous versions of the transmitter and receiver interrupts to wake the CPU from Stop mode. SAI only generates asynchronous interrupts when the system clock is gated but the corresponding BCLK signal is active.

58.3.9.1 FIFO request flag

SAI sets the transmit FIFO request flag (TCSR[FRF]) when the number of entries in any enabled transmit FIFO is less than or equal to the transmit FIFO watermark configuration (TCR1[TFW]). SAI clears this flag when the number of entries in each enabled transmit FIFO is greater than TCR1[TFW].

SAI sets the receive FIFO request flag (RCSR[FRF]) when the number of entries in any enabled receive FIFO is greater than the receive FIFO watermark configuration (RCR1[RFW]). SAI clears this flag when the number of entries in each enabled receive FIFO is less than or equal to RCR1[RFW].

The FIFO request flag can generate an interrupt when TCSR[FRIE] = 1. It can generate a DMA request when TCSR[FRDE] = 1.

58.3.9.2 FIFO warning flag

SAI sets the transmit FIFO warning flag (TCSR[FWF]) when the number of entries in any of the enabled transmit FIFOs is empty. SAI clears this flag when the number of entries in each enabled transmit FIFO is not empty.

SAI sets the receive FIFO warning flag (RCSR[FWF]) when the number of entries in any of the enabled receive FIFOs is full. SAI clears this flag when the number of entries in each enabled receive FIFO is not full.

The FIFO warning flag can generate an interrupt when TCSR[FWIE] = 1. The flag can generate a DMA request when TCSR[FWDE] = 1.

58.3.9.3 FIFO error flag

SAI sets the transmit FIFO error flag (TCSR[FEF]) when any enabled transmit FIFOs underrun. After the error flag is set, all enabled transmit channels transmit zero data before SAI clears TCSR[FEF].

When you write 1 to TCR4[FCONT], the FIFO continues transmitting data following an underrun without software intervention. To ensure that data transmits in the correct order, the transmitter continues from the same word number in the frame that caused the FIFO to underrun. It continues only after new data is written to the transmit FIFO. In this case, clear TCSR[FEF] without reinitializing the transmit FIFOs.

SAI sets the receive FIFO error flag (RCSR[FEF]) when any enabled receive FIFO overflows. After the flag is set, all enabled receive channels discard their received data until SAI clears RCSR[FEF] and the next receive frame starts. Empty all enabled receive FIFOs before SAI clears RCSR[FEF].

When you write 1 to RCR4[FCONT], the FIFO continues receiving data following an overflow without software intervention. To ensure that data is received in the correct order, the receiver continues from the same word number in the frame that caused the FIFO to overflow. It continues only after data has been read from the receive FIFO. In this case, clear RCSR[FEF] without emptying the receive FIFOs.

TCSR[FEF] and RSCR[FEF] can only generate an interrupt.

58.3.9.4 Sync error flag

SAI sets a sync error flag (TCSR[SEF] or RCSR[SEF]) when both of these conditions are true:

- The frame sync is generated externally.
- The external frame sync asserts when the transmitter or receiver is busy with the previous frame.

SAI ignores the external frame sync assertion and sets the sync error flag. When this flag is set, the transmitter or receiver continues checking for frame sync assertion when idle or at the end of each frame.

TCSR[SEF] and RCSR[SEF] can only generate an interrupt.

58.3.9.5 Word start flag

SAI sets the word start flag (TCSR[WSF]) at the start of the second bit-clock cycle for the selected word. You can select this word via TCR3[WDFL].

TCSR[WSF] can only generate an interrupt.

58.4 External signals

Name	Function	I/O
TX_BCLK	Transmit bit clock: the bit clock is an input when externally generated and an output when internally generated.	I/O
TX_SYNC	Transmit frame sync: the frame sync is an input sampled synchronously by the bit clock when externally generated. It is an output generated	I/O

Table continues on the next page...

Table continued from the previous page...

Name	Function	I/O
	synchronously by the bit clock when internally generated.	
TX_DATA	Transmit data: the bit clock synchronously generates the transmit data; this signal is 3-stated when not transmitting a word.	O
RX_BCLK	Receive bit clock: the bit clock is an input when externally generated and an output when internally generated.	I/O
RX_SYNC	Receive frame sync: the frame sync is an input sampled synchronously by the bit clock when externally generated. It is an output generated synchronously by the bit clock when internally generated.	I/O
RX_DATA	Receive data: the bit clock synchronously samples the receive data.	I
MCLK	Audio clock: the audio clock is an input when externally generated and an output when internally generated.	I/O

58.5 Initialization

To initialize SAI:

1. Enable the clock to SAI.
2. Reset the internal transmitter logic and receiver logic by writing 1 to TCSR[SR] and RCSR[SR], respectively.

58.6 Memory map and register definition

A read or write access to an address from offset 108h and above results in a bus error.

58.6.1 SAI register descriptions

SAI provides an interface that supports full-duplex serial digital audio interfaces with frame synchronization formats.

58.6.1.6 Transmit Configuration 2 (TCR2)

Offset

Register	Offset
TCR2	10h

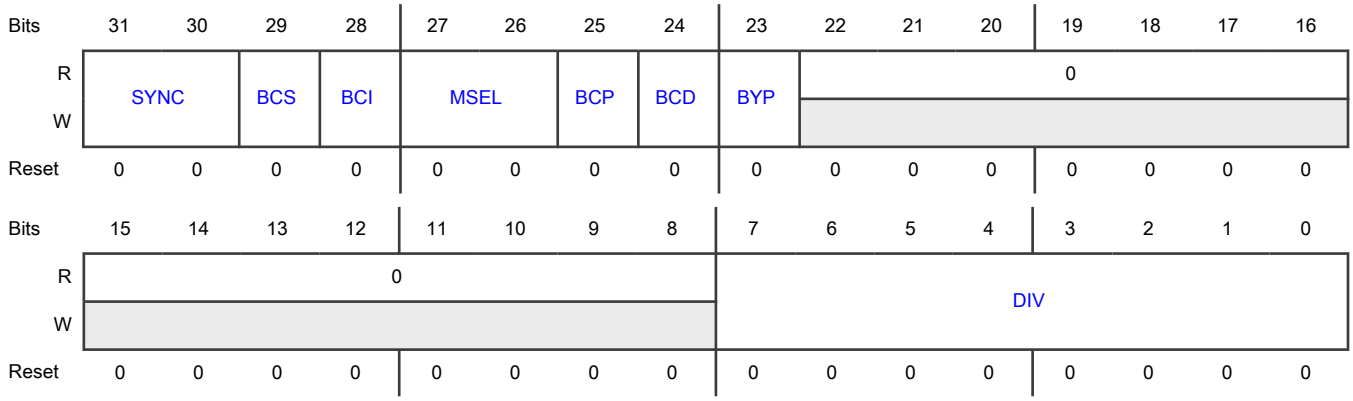
Function

Contains the SYNC mode and clock setting fields.

NOTE

Do not alter this register when TCSR[TE] is 1.

Diagram



Fields

Field	Function
31-30 SYNC	Synchronous Mode Configures Asynchronous and Synchronous modes of operation. When configured for Synchronous mode, you must configure the receiver for asynchronous operations.

NOTE

This field is not supported in every instance. The following table includes only supported registers.

Instance	Field supported in	Field not supported in
SAI0	TCR2[30]	TCR2[31]
SAI1	TCR2	—
SAI2	TCR2	—
SAI3	TCR2[30]	TCR2[31]

NOTE

The descriptions of the field settings vary by module instance.

Instance	Field value and description
SAI0 SAI3	0b - Asynchronous mode 1b - Synchronous with receiver
SAI1 SAI2	00b - Asynchronous mode 01b - Synchronous with receiver 10b - Synchronous with another SAI transmitter 11b - Synchronous with another SAI receiver

Table continued from the previous page...

Field	Function
29 BCS	Bit Clock Swap Swaps the bit clock used by the transmitter. When you configure the transmitter in Asynchronous mode and this field is 1, the receiver bit clock (RX_BCLK) clocks the transmitter. This configuration allows the transmitter and receiver to share a bit clock, while the transmitter continues to use the transmit frame sync (TX_SYNC). When you configure the transmitter in Synchronous mode, you must write the same value to the transmitter BCS field and the receiver BCS field. When both are 1, the transmitter and receiver are both clocked by the transmitter bit clock (TX_BCLK) but both use the receiver frame sync (RX_SYNC). 0b - Use the normal bit clock source 1b - Swap the bit clock source
28 BCI	Bit Clock Input Enables the internal logic to be clocked as if the bit clock is generated externally. When this field is 1 while using an internally generated bit clock in Synchronous or Asynchronous mode, the bit clock used by the transmitter is delayed by the pad output delay. (The pad input clocks the transmitter as if the clock is externally generated.) This setting decreases the data input setup time, but increases the data output valid time. Use the Target mode timing from the data sheet for the transmitter when this field is 1. In Synchronous mode, this field allows the transmitter to use the Target mode timing from the data sheet, while the receiver uses the Controller mode timing. This field has no effect when configured for an externally generated bit clock. **NOTE** When BCI = 1, both the input buffer and output buffer must be enabled for the BCLK pad. 0b - Disable 1b - Enable
27-26 MSEL	MCLK Select Selects the audio clock option used to generate an internally generated bit clock. This field has no effect when SAI is configured for an externally generated bit clock. **NOTE** Depending on the chip, some audio clock options might not be available. See the chip-specific information for the meaning of each option. 00b - Bus clock 01b - Audio clock (MCLK) option 1 10b - Audio clock (MCLK) option 2 11b - Audio clock (MCLK) option 3
25 BCP	Bit Clock Polarity

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Configures the polarity of the bit clock. If you write 0 to this field, the bit clock becomes active high with drive outputs on rising edge and sample inputs on falling edge. If you write 1 to this field, the bit clock becomes active low with drive outputs on falling edge and sample inputs on rising edge. 0b - Active high 1b - Active low
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0b - Generate externally in Target mode 1b - Generate internally in Controller mode
23 BYP	Bit Clock Bypass Bypasses the bit clock divider. When bypassed, the internal bit clock is divide-by-one of the audio clock. When not bypassed, the internal bit clock is generated from the bit clock divider. 0b - Disable 1b - Enable
22-8 —	Reserved
7-0 DIV	Bit Clock Divide Determines the value by which SAI divides down the audio clock to generate the bit clock (when configured for an internal bit clock). The division value is (DIV + 1) × 2.

58.6.1.7 Transmit Configuration 3 (TCR3)

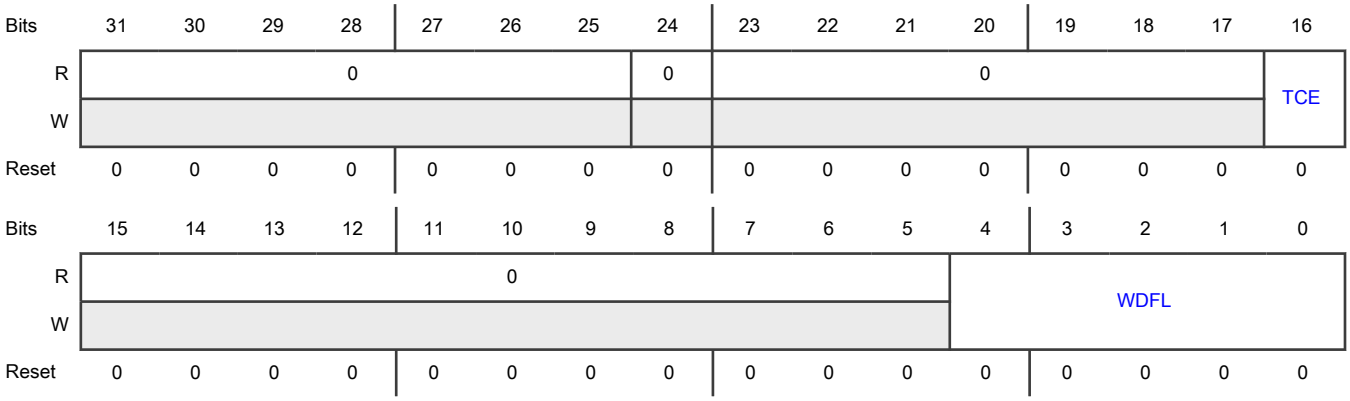
Offset

Register	Offset
TCR3	14h

Function

Contains the transmit channel settings.

Diagram



Fields

Field	Function
31-25 —	Reserved
24 —	Reserved
23-17 —	Reserved
16 TCE	Transmit Channel Enable Enables the corresponding data channel for transmit operations. Changing this field takes effect immediately for generating the FIFO request and warning flags. It takes effect at the end of each frame for transmit operations. The width of this field = the number of transmit channels (call it *n*). For example, if this field is two bits wide, bit position 16 refers to transmit channel 1 and bit position 17 refers to transmit channel 2. Writing 1 to bit 16 enables transmit channel 1, and setting bit 17 enables transmit channel 2. Writing 1 to bit *n* enables transmit channel *n*. For each transmit data channel: • 0b – Disable • 1b – Enable
15-5 —	Reserved
4-0 WDFL	Word Flag Configuration Selects the word that sets the word start flag (TCSR[WSF]). The value must be one less than the word number. For example, writing 0 selects the first word in the frame. When you configure this field with a value greater than TCR4[FRSZ], TCSR[WSF] is never set.

58.6.1.8 Transmit Configuration 4 (TCR4)

Offset

Register	Offset
TCR4	18h

Function

Contains the transmit fields for FIFO Combine mode, FIFO Packing mode, and frame sync settings.

NOTE

Do not alter this register when TCSR[TE] is 1.

Diagram

Fields

Field	Function
31-29 —	Reserved
28 FCONT	FIFO Continue on Error Configures when SAI must continue transmitting after a FIFO error is detected. When this field is 0 and a FIFO error occurs, SAI continues from the start of the next frame after the FIFO error flag clears. When this field is 1 and a FIFO error occurs, SAI continues from the same word that caused the FIFO error after the FIFO warning flag clears. 0b - Continue from the start of the next frame 1b - Continue from the same word that caused the FIFO error
27-26 —	Reserved
25-24	FIFO Packing Mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
FPACK	Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8 bits or 16 bits, only the first 8 bits or 16 bits are loaded from the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO write pointer only increments when you write the full 32-bit FIFO word. 00b - Disable FIFO packing 01b - Reserved 10b - Enable 8-bit FIFO packing 11b - Enable 16-bit FIFO packing
23-21 —	Reserved
20-16 FRSZ	Frame Size Configures the number of words in each frame. The value must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words.
15-13 —	Reserved
12-8 SYWD	Sync Width Configures the length of the frame sync in number of bit-clock cycles. The value must be one less than the number of bit-clock cycles. For example, write 0 for the frame sync to assert for one bit-clock cycle only. You cannot configure the sync width to be longer than the first word of the frame.
7-6 —	Reserved
5 CHMOD	Channel Mode Specifies the mode of transmit data pins. In TDM mode, transmit data pins are 3-stated when slots are masked or channels are disabled. In Output mode, transmit data pins are never 3-stated, and they output zero when slots are masked or channels are disabled. 0b - TDM mode 1b - Output mode
4 MF	MSB First Configures what is transmitted first: LSB or MSB. 0b - LSB 1b - MSB
3 FSE	Frame Sync Early Determines when frame sync is asserted.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - First bit of the frame 1b - One bit before the first bit of the frame
2 ONDEM	On-Demand Mode Determines when the internal frame sync is generated. When this field is 1, and the frame sync is generated internally, a frame sync is only generated after the FIFO warning flag is cleared. 0b - Generated continuously 1b - Generated after the FIFO warning flag is cleared
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0b - Active high 1b - Active low
0 FSD	Frame Sync Direction Configures the direction of the frame sync. 0b - Generated externally in Target mode 1b - Generated internally in Controller mode

58.6.1.9 Transmit Configuration 5 (TCR5)

Offset

Register	Offset
TCR5	1Ch

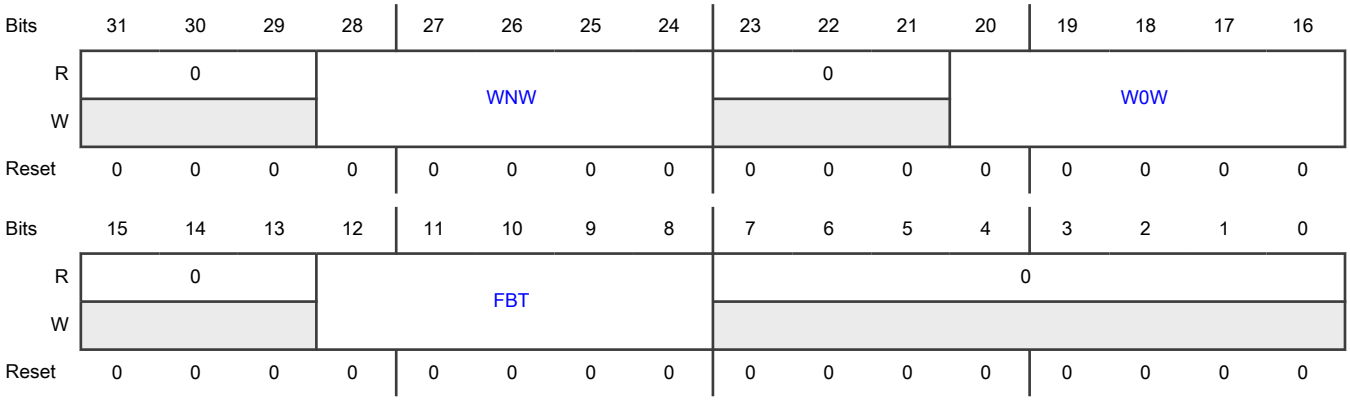
Function

Contains transmit word width and bit index settings.

NOTE

Do not alter this register when TCSR[TE] is 1.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-24 WNW	Word N Width Configures the number of bits in each word, except for the first one in the frame. The value written must be one less than the number of bits per word. SAI does not support word widths of less than 8 bits. SAI does not support bit settings 0–6 (0b–0_0110b). 0_0111b - 8 0_1000b - 9 0_1001b-1_1110b - (WNW value + 1) 1_1111b - 32
23-21 —	Reserved
20-16 W0W	Word 0 Width Configures the number of bits in the first word of each frame. The value written must be one less than the number of bits in the first word. SAI does not support word widths of less than 8 bits when there is only one word per frame. SAI does not support bit settings 0–6 (0b–0_0110b). 0_0111b - 8 0_1000b - 9 0_1001b-1_1110b - (W0W value + 1) 1_1111b - 32
15-13 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
12-8 FBT	First Bit Shifted Configures the bit index for the first bit transmitted for each word in the frame. If configured for MSB-first, the index of the next bit transmitted is one less than the current bit transmitted. If configured for LSB-first, the index of the next bit transmitted is one more than the current bit transmitted. The value written must be greater than or equal to the word width when configured for MSB-first. The value written must be less than or equal to 31-word width when configured for LSB-first. See Data alignment for details. 0_0000b - 0 0_0001b-1_1110b - FBT 1_1111b - 31
7-0 —	Reserved

58.6.1.10 Transmit Data (TDR0)

Offset

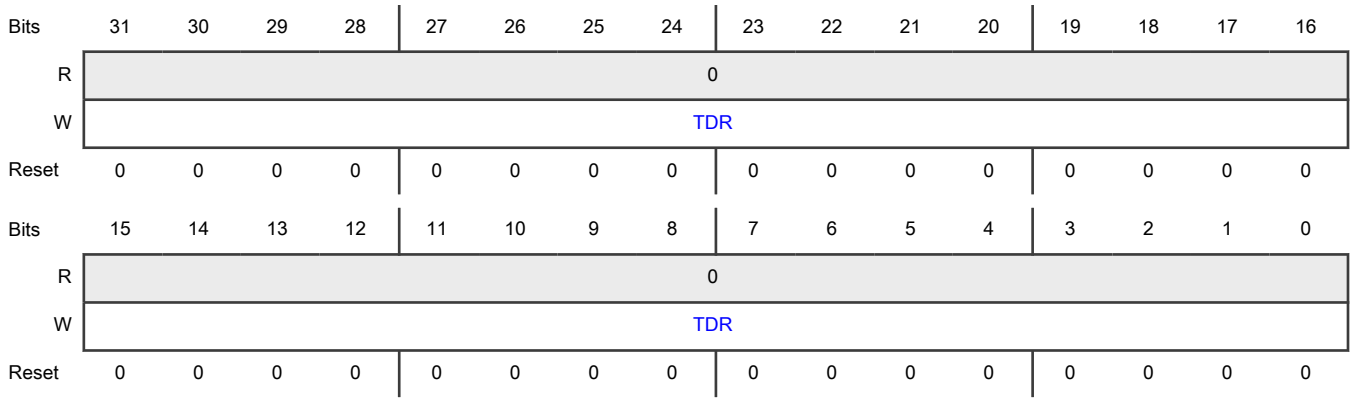
Register	Offset
TDR0	20h

Function

Contains transmit data.

When the transmit FIFO is not full, writes to this register push the data written into the transmit data FIFO. When the transmit FIFO is full, SAI ignores writes to this register.

Diagram



Fields

Field	Function
31-0 TDR	Transmit Data

58.6.1.11 Transmit FIFO (TFR0)

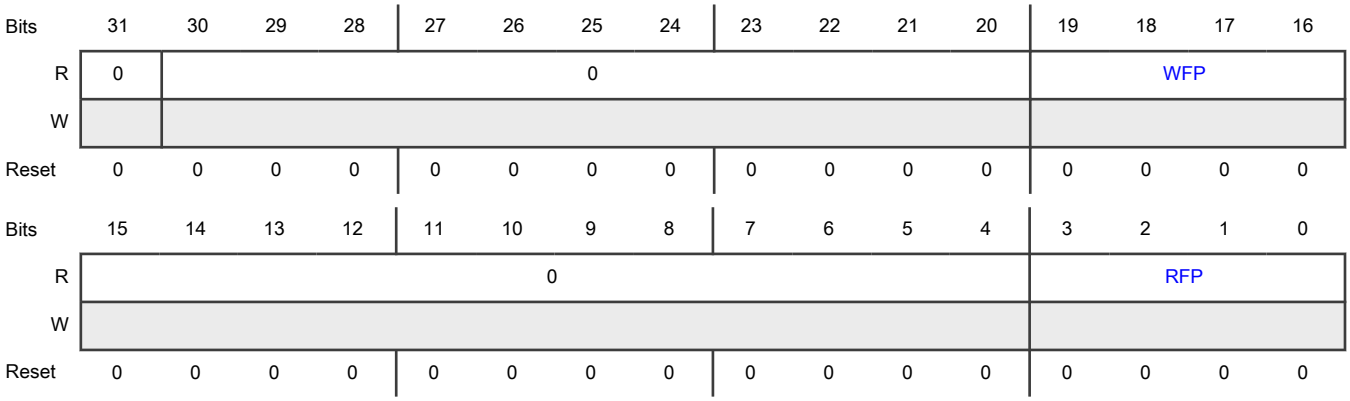
Offset

Register	Offset
TFR0	40h

Function

Contains the transmit FIFO pointers. The MSB of the read and write pointers distinguishes between FIFO full and empty conditions. If the read and write pointers are identical, the FIFO is empty. If the read and write pointers are identical except for the MSB, the FIFO is full.

Diagram



Fields

Field	Function
31 —	Reserved
30-20 —	Reserved
19-16 WFP	Write FIFO Pointer Indicates the FIFO write pointer for the transmit data channel.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-4 —	Reserved
3-0 RFP	Read FIFO Pointer Indicates the FIFO read pointer for the transmit data channel.

58.6.1.12 Transmit Mask (TMR)

Offset

Register	Offset
TMR	60h

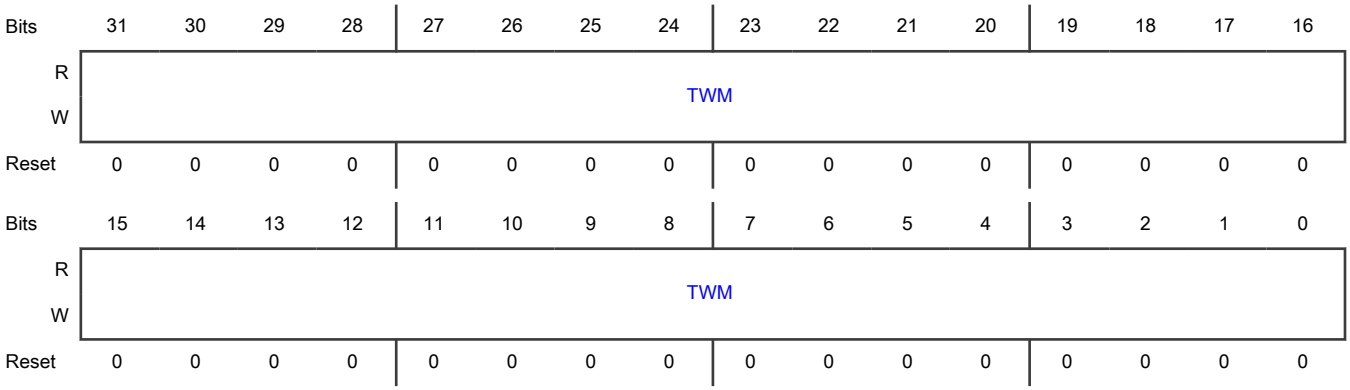
Function

Contains the mask for the transmit word. This register is double-buffered and updates:

- When TCSR[TE] first becomes 1.
- At the end of each frame.

This setup allows the masked words in each frame to change from frame to frame.

Diagram



Fields

Field	Function
31-0 TWM	Transmit Word Mask Configures whether the transmit word *n* is masked for the corresponding word in the frame. In this case, being masked means that transmit data pins are 3-stated or driven zero and transmit data is not read from the FIFO.

Table continues on the next page...

Field	Function
	0000_0000_0000_0000_0000_0000_0000_0000b - Enable 0000_0000_0000_0000_0000_0000_0000_0001b - Mask

58.6.1.13 Transmit Timestamp Control (TTCR)

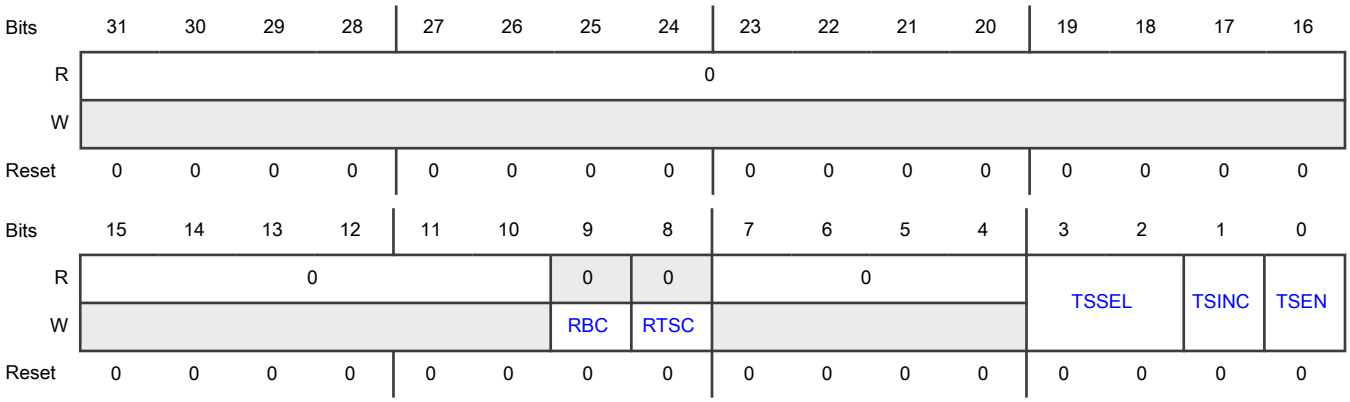
Offset

Register	Offset
TTCR	70h

Function

Controls the transmit timestamp counter and bit clock counter.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 RBC	Reset Bit Counter Resets the bit counter. 0b - No effect 1b - Reset
8 RTSC	Reset Timestamp Counter Resets the timestamp counter. 0b - No effect

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Reset
7-4 —	Reserved
3-2 TSSEL	Timestamp Select Configures whether the timestamp counter is synchronized with another timestamp counter. 00b - Increment when enabled 01b - Increment when the receive timestamp counter is enabled 10b - Increment when the transmit timestamp counter on another instance is enabled 11b - Increment when the receive timestamp counter on another instance is enabled
1 TSINC	Timestamp Increment Configures when the timestamp counter starts incrementing. 0b - When enabled and after the bit counter has incremented 1b - When enabled
0 TSEN	Timestamp Enable Enables the timestamp counter to increment on the bus interface clock. 0b - Disable 1b - Enable

58.6.1.14 Transmit Timestamp (TTSR)

Offset

Register	Offset
TTSR	74h

Function

Indicates the current value of the transmit timestamp counter.

Diagram

58.6.1.18 Receive Configuration 1 (RCR1)

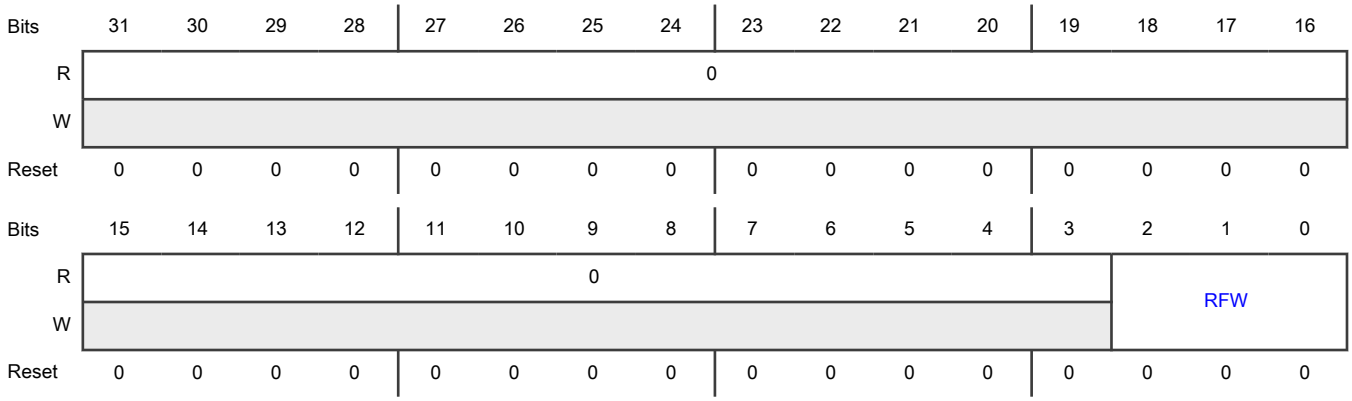
Offset

Register	Offset
RCR1	8Ch

Function

Configures the watermark level for all enabled receiver channels.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 RFW	Receive FIFO Watermark Configures the level of the receive FIFO watermark, in 32-bit FIFO words. 000b - 1 001b - 2 010b-110b - (RFW value + 1) 111b - 8

58.6.1.19 Receive Configuration 2 (RCR2)

Offset

Register	Offset
RCR2	90h

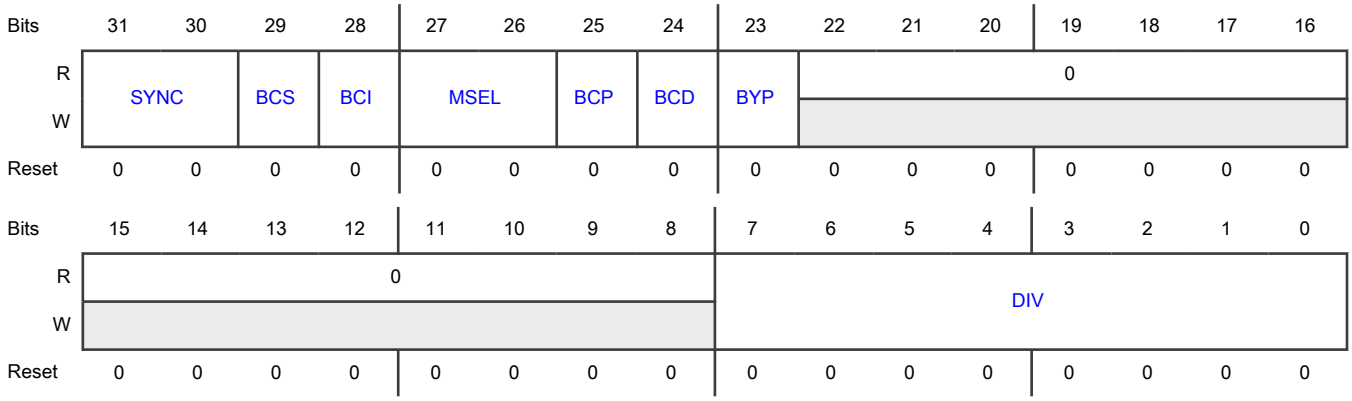
Function

Contains the SYNC mode and clock setting fields.

NOTE

Do not alter this register when RCSR[RE] is 1.

Diagram



Fields

Field	Function
31-30 SYNC	Synchronous Mode Configures Asynchronous and Synchronous modes of operation. When configured for a Synchronous mode of operation, you must configure the transmitter for asynchronous operation. **NOTE** This field is not supported in every instance. The following table includes only supported registers.

Instance	Field supported in	Field not supported in
SAI0	RCR2[30]	RCR2[31]
SAI1	RCR2	—
SAI2	RCR2	—
SAI3	RCR2[30]	RCR2[31]

NOTE
The descriptions of the field settings vary by module instance.

Instance	Field value and description
SAI0 SAI3	0b - Asynchronous mode 1b - Synchronous with transmitter
SAI1 SAI2	00b - Asynchronous mode 01b - Synchronous with transmitter 10b - Synchronous with another SAI receiver 11b - Synchronous with another SAI transmitter

Table continued from the previous page...

Field	Function
29 BCS	Bit Clock Swap Swaps the bit clock used by the receiver. When the receiver is configured in Asynchronous mode and this field is 1, the transmitter bit clock (TX_BCLK) clocks the receiver. This setting allows the transmitter and receiver to share one bit clock, while the receiver continues to use the receiver frame sync (RX_SYNC). When you configure the receiver in Synchronous mode, you must write the same value to the transmitter BCS field and receiver BCS field. When both are 1, the transmitter and receiver are both clocked by the receiver bit clock (RX_BCLK) but both use the transmitter frame sync (TX_SYNC). 0b - Use the normal bit clock source 1b - Swap the bit clock source
28 BCI	Bit Clock Input Enables the internal logic to be clocked as if the bit clock is generated externally. When this field is 1 and when using an internally generated bit clock in Synchronous or Asynchronous mode, the bit clock used by the receiver is delayed by the pad output delay. (The pad input clocks the receiver as if the clock is externally generated.) This setting decreases the data input setup time, but increases the data output valid time. Use the Target mode timing from the data sheet for the receiver when this field is 1. In Synchronous mode, this field allows the receiver to use the Target mode timing from the data sheet, while the transmitter uses the Controller mode timing. This field has no effect when configured for an externally generated bit clock. **NOTE** When this field is 1, both the input buffer and output buffer must be enabled for the BCLK pad. 0b - Disable 1b - Enable
27-26 MSEL	MCLK Select Selects the audio clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock. **NOTE** Some audio clock options are not available for some chips. See the chip-specific information for the availability and chip-specific meaning of each option. 00b - Bus clock 01b - Audio clock (MCLK) option 1 10b - Audio clock (MCLK) option 2 11b - Audio clock (MCLK) option 3
25 BCP	Bit Clock Polarity Configures the polarity of the bit clock. If you write 0 to this field, the bit clock becomes active high with drive outputs on the rising edge and sample inputs on the falling edge. If you write 1 to this field, the bit clock becomes active low with drive outputs on the falling edge and sample inputs on the rising edge.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Active high 1b - Active low
24 BCD	Bit Clock Direction Configures the direction of the bit clock. 0b - Generated externally in Target mode 1b - Generated internally in Controller mode
23 BYP	Bit Clock Bypass Enables the bypass of the bit clock divider. When enabled, the internal bit clock is divide-by-one of the audio clock. When disabled, the internal bit clock is generated from the bit clock divider. 0b - Disable 1b - Enable
22-8 —	Reserved
7-0 DIV	Bit Clock Divide Determines the value by which the audio clock is divided to generate the bit clock, when configured for an internal bit clock. The division value is (DIV + 1) × 2.

58.6.1.20 Receive Configuration 3 (RCR3)

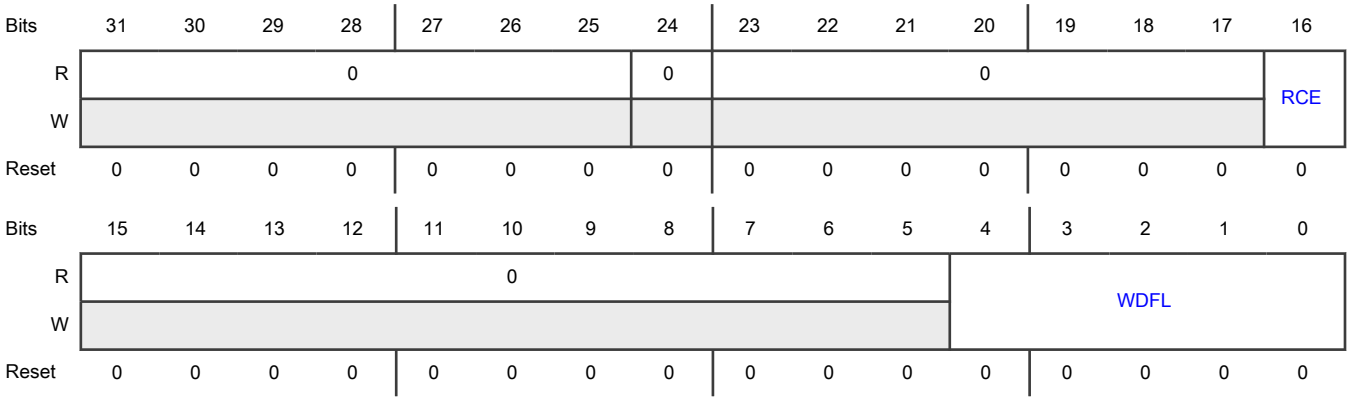
Offset

Register	Offset
RCR3	94h

Function

Contains the receive channel settings.

Diagram



Fields

Field	Function
31-25 —	Reserved
24 —	Reserved
23-17 —	Reserved
16 RCE	Receive Channel Enable Enables the corresponding data channel for receive operation. Changing this field takes effect immediately for generating the FIFO request and warning flags. It takes effect at the end of each frame for receive operations. The width of RCE = the number of receive channels (call it *n*). For example, if RCE is two bits wide, then bit position 16 refers to receive channel 1 and bit position 17 refers to receive channel 2. Writing 1 to bit 16 enables receive channel 1, and writing 1 to bit 17 enables receive channel 2. Writing 1 to bit *n* enables receive channel *n*. **NOTE** When there is only a single channel, you do not need an individual channel FIFO reset. In that case, use the global FIFO reset (RCSR[FR]). • 0b – Disable receive data channel *n* • 1b – Enable receive data channel *n*
15-5 —	Reserved
4-0 WDFL	Word Flag Configuration

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Configures which word sets the word start flag (RCSR[WSF]). The value must be one less than the word number (for example, write zero to select the first word in the frame). If you configure this field to a value greater than RCR4[FRSZ], RCSR[WSF] is never set. 0_0000b - Word 1 0_0001b - Word 2 0_0010b-1_1110b - Word (WDFL value + 1) 1_1111b - Word 32

58.6.1.21 Receive Configuration 4 (RCR4)

Offset

Register	Offset
RCR4	98h

Function

Contains the receive fields for FIFO Combine mode, FIFO Packing mode, and frame sync settings.

NOTE

Do not alter this register when RCSR[RE] is 1.

Diagram

31-29 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
28 FCONT	FIFO Continue on Error Configures when SAI continues receiving data after a FIFO error is detected. 0b - From the start of the next frame after the FIFO error flag is cleared 1b - From the same word that caused the FIFO error to become 1 after the FIFO warning flag is cleared
27-26 —	Reserved
25-24 FPACK	FIFO Packing Mode Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8 bits or 16 bits, only the first 8 bits or 16 bits are stored in the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO read pointer only increments when software reads the full 32-bit FIFO word. 00b - Disable 01b - Reserved 10b - Enable 8-bit FIFO packing 11b - Enable 16-bit FIFO packing
23-21 —	Reserved
20-16 FRSZ	Frame Size Configures the number of words in each frame. The value must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words. 0_0000b - 1 0_0001b - 2 0_0010b-1_1110b - (FRSZ value + 1) 1_1111b - 32
15-13 —	Reserved
12-8 SYWD	Sync Width Configures the length of the frame sync in number of bit-clock cycles. The value must be one less than the number of bit-clock cycles. For example, write 0 for the frame sync to assert for one bit-clock cycle only. You cannot configure this field to be longer than the first word of the frame. 0_0000b - 1 0_0001b - 2

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0_0010b-1_1110b - (SYWD value + 1) 1_1111b - 32
7-6 —	Reserved
5 —	Reserved Write only zero to this field.
4 MF	MSB First Configures what is received first: LSB or MSB. 0b - LSB 1b - MSB
3 FSE	Frame Sync Early Determines when frame sync is asserted. 0b - First bit of the frame 1b - One bit before the first bit of the frame
2 ONDEM	On-Demand Mode Determines when the internal frame sync is generated. When this field is 1, and the frame sync is generated internally, a frame sync is only generated when the FIFO warning flag is 0. 0b - Generated continuously 1b - Generated when the FIFO warning flag is 0
1 FSP	Frame Sync Polarity Configures the polarity of the frame sync. 0b - Active high 1b - Active low
0 FSD	Frame Sync Direction Configures the direction of the frame sync. 0b - Generated externally in Target mode 1b - Generated internally in Controller mode

58.6.1.22 Receive Configuration 5 (RCR5)

Offset

Register	Offset
RCR5	9Ch

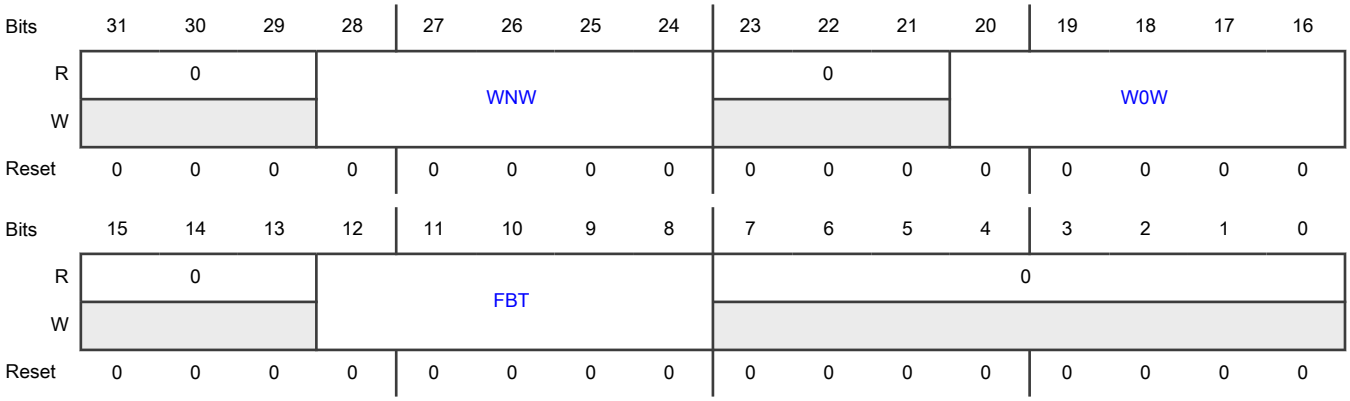
Function

Contains receive word and bit index settings.

NOTE

Do not alter this register when RCSR[RE] is 1.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-24 WNW	Word N Width Configures the number of bits in each word except for the first one in the frame. The value must be one less than the number of bits per word. SAI does not support word widths less than 8 bits. SAI does not support bit settings 0–6 (0b–0_0110b). 0_0111b - 8 0_1000b - 9 0_1001b-1_1110b - (WNW value + 1) 1_1111b - 32
23-21 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
20-16 W0W	Word 0 Width Configures the number of bits in the first word of each frame. The value must be one less than the number of bits in the first word. SAI does not support word widths less than 8 bits when there is only one word per frame. 0_0000b - 1 0_0001b - 2 0_0010b-1_1110b - (W0W value + 1) 1_1111b - 32
15-13 —	Reserved
12-8 FBT	First Bit Shifted Configures the bit index for the first bit received for each word in the frame. If configured for MSB-first, the index of the next bit received is one less than the current bit received. If configured for LSB-first, the index of the next bit received is one more than the current bit received. The value must be greater than or equal to the word width when configured for MSB-first. The value must be less than or equal to 31-word width when configured for LSB-first. See Data alignment for details. 0_0000b - 0 0_0001b-1_1110b - FBT value 1_1111b - 31
7-0 —	Reserved

58.6.1.23 Receive Data (RDR0)

Offset

Register	Offset
RDR0	A0h

Function

Contains receive data.

When the receive FIFO is not empty, reads from this register return the data from the top of the receive FIFO. When the receive FIFO is empty, SAI ignores reads from this register.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

3-0 RFP	Read FIFO Pointer Indicates the FIFO read pointer for the receive data channel.

58.6.1.25 Receive Mask (RMR)

Offset

Register	Offset
RMR	E0h

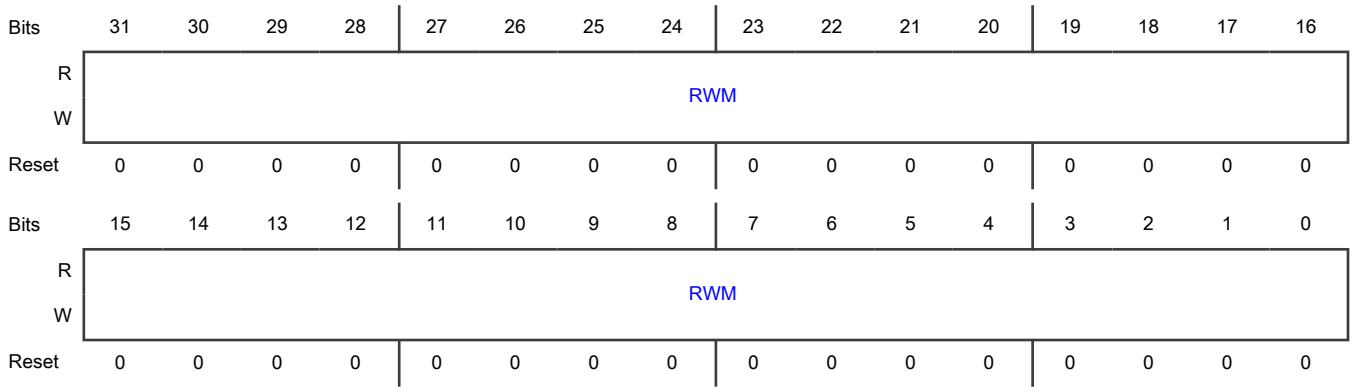
Function

Contains the mask for the receive word. This register is double-buffered and updates:

- When RCSR[RE] first becomes 1.
- At the end of each frame.

This setup allows the masked words in each frame to change from frame to frame.

Diagram



Fields

Field	Function
31-0 RWM	Receive Word Mask Configures whether the receive word is masked (received data ignored and not written to receive FIFO) for the corresponding word in the frame. 0000_0000_0000_0000_0000_0000_0000_0000b - Enable 0000_0000_0000_0000_0000_0000_0000_0001b - Mask

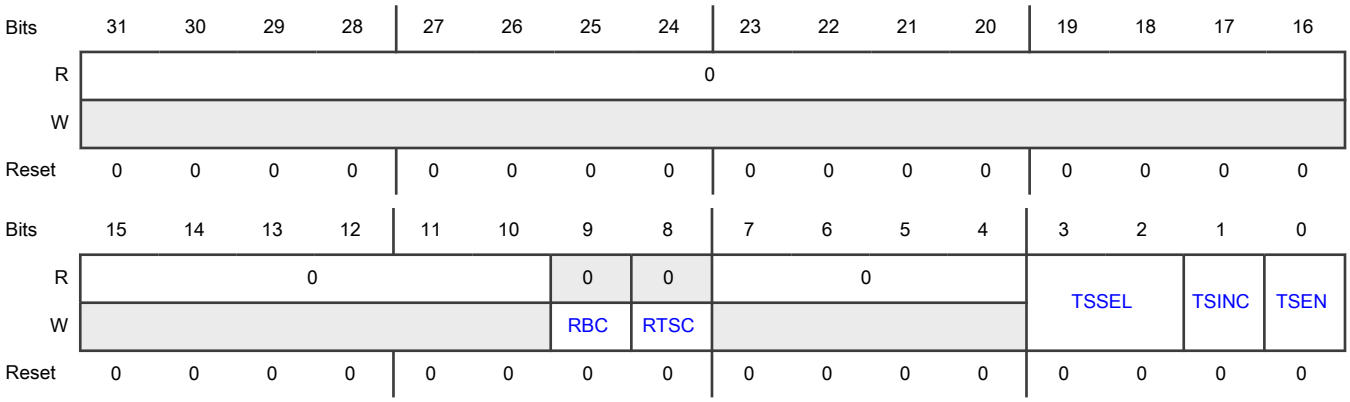
58.6.1.26 Receive Timestamp Control (RTCR)

Offset

Register	Offset
RTCR	F0h

Function
Controls the receive timestamp counter and bit clock counter.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 RBC	Reset Bit Counter Resets the receive bit counter. 0b - No effect 1b - Reset

Table continues on the next page...

Table continued from the previous page...

Field	Function
8 RTSC	Reset Timestamp Counter Resets the receive timestamp counter. 0b - No effect 1b - Reset
7-4 —	Reserved
3-2 TSSEL	Timestamp Select Configures whether the timestamp counter is synchronized with another timestamp counter. 00b - Increment when enabled 01b - Increment when the transmit timestamp counter is enabled 10b - Increment when the receive timestamp counter on another instance is enabled 11b - Increment when the transmit timestamp counter on another instance is enabled
1 TSINC	Timestamp Increment Configures when the timestamp counter starts incrementing. 0b - When enabled and after the bit counter has incremented 1b - When enabled
0 TSEN	Timestamp Enable Enables the timestamp counter to increment on the bus interface clock. 0b - Disable 1b - Enable

58.6.1.27 Receive Timestamp (RTSR)

Offset

Register	Offset
RTSR	F4h

Function
Indicates the current value of the receive timestamp counter.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

59.2 Overview

Cadence® Xtensa® HiFi 1 Audio DSP (HiFi1) runs at frequencies up to 250 MHz. It is a 2-slot machine with two-way single-instruction multiple-data (SIMD) arithmetic logic unit (ALU) or multiplier–accumulator (MAC) operations. All HiFi1 operations can be used as intrinsics in low-level applications.

59.2.1 Block diagram

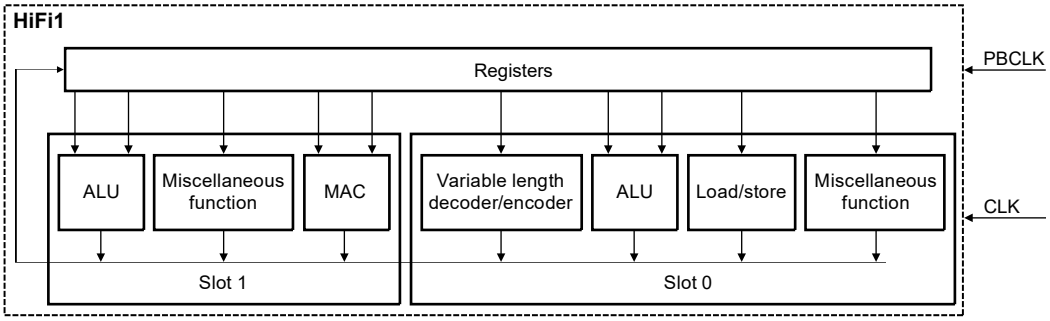

Figure 254. HiFi1 block diagram

59.2.2 Features

HiFi1 supports the following features:

- Vector floating-point unit (VFPU)
- Low-latency multiplier–accumulator (MAC)
- 256 bytes L0 loop buffer
- Memory protection: Region protection
- 32-bit integer divider
- Take exception on unaligned load and store address
- Normal L32R hardware support
- 5-stage pipeline
- 1 load and store unit

59.3 Functional description

59.3.1 Arithmetic logic unit (ALU) and multiplier–accumulator (MAC)

In HiFi1 DSP, MAC is a common process that computes the product of two numbers and adds the results to an accumulator. ALU performs arithmetic and logical operations on the operands. HiFi1 supports quad 16 x 16-bit, dual 32 x 16-bit, and single 32-bit MACs. 24 x 24-bit operations are emulated using 32 x 32 operations. It also supports CLAMPS operations and 32-bit integer divider.

59.3.2 Variable-length decoder and encoder

The HiFi1 bitstream engine supports both fixed-length and variable-length decoding and encoding. Variable-length (Huffman) decode instructions are specialized instructions, in which the elements with variable bit-widths are decoded.

59.3.3 Load and store operations

HiFi1 supports loading and storing scalars or vectors of 8, 16, 32, and 64 bits. Each scalar of load and store accesses 8, 16, 32, or 64 bits. Each vector accesses 64 bits.

59.3.4 Low-latency MAC

The low-latency MAC or FMA function reduces the latency fused multiply add (FMA) hardware and fixed-point MAC hardware to 1 cycle, and therefore improving MAC and FMA performance respectively.

The latencies of the below multi-cycle operations are reduced:

- Integer and fixed-point MAC: from 2 to 1 cycle
- Single-precision floating-point FMA: from 3 to 1 cycle
- Single-precision floating-point conversions: from 2 to 1 cycle

59.3.5 L0 loop buffer

L0 loop buffer captures instructions from the body of a Zero Overhead Loop, and then executes subsequent iterations of the loop from this buffer. This allows the instruction memories to be disabled during most of the loop execution. Power savings depend on what portion of code is being executed as Zero Overhead Loops.

59.3.6 Miscellaneous function

Miscellaneous functions in HiFi1 include:

- NSA/NSAU: Returns the number of contiguous sign bits in the most significant bits of a 32-bit signed/unsigned value
- MinMax: Performs a signed or unsigned integral minimum or maximum operation
- SEXT: Sign extend to 32 bits
- DEPBITS: Inferred automatically by the compiler from standard C code
- Density: Enable use of density (16-bit) instructions

59.3.7 PFaultInfo and Fault Information Register (FIR)

FIR provides information on the error condition and the PFaultInfo output signal mirrors this internal register.

Bit	Description	Notes
31:21	Deasserted	
20	Multiple Faults 0b - Only one fault has occurred so far 1b - Multiple faults have occurred*	* In this case, the FIR register has information only on the most severe fault.
19:16	User Bits These bits are zero by default. Software running on Xtensa can write to the user bits.	These bits are available only in configurations with both debug features (i.e. OCD at a minimum) and parity/ECC protection on the AXI bus interface.
15**:8	Fault Severity Level 0000b - Fault severity is not reset. The system can recover without resetting 0001b - Fault severity is core reset. Minimally, reset the Xtensa processor to recover from the fault 0010b - Fault severity is system reset. The whole system may need to be reset to recover from the fault	** CSR parity error sets the PFaultInfo[15] output signal. **NOTE** The suggested severity level and the recovery mechanism are recommendations and may not always work.
7:0	AXI Channel and AXI Port AXI channel [7:4]:	

Table continued from the previous page...

Bit	Description	Notes
	0000b - Read address AXI channel 0001b - Write address AXI channel 0010b - Write data AXI channel 0011b - Read data AXI channel 0100b - Write response AXI channel AXI port [3:0]: 0000b - Main AXI initiator port 0001b - Secondary (iDMA) AXI initiator port 0010b - AXI target port	

59.3.8 Clocking

Clock	Description
CLK	Main clock
PBCLK	APB interface clock

59.3.9 Interrupts

HiFi1 provides 32 interrupts with 4 priority levels, 2 timers, and 2 EXCM (exception mode) priority levels with highest priority of efficiently callable handlers.

59.4 Signals

Signal name	Description
OCDHaltOnReset	On-Chip Debug (OCD) halt on reset Tied low for normal operation. Alternatively, this signal can be tied high to force the processor to enable OCD and enter Stopped (halt) state at processor reset.
XOCDMode	Xtensa On-Chip Debug (XOCD) mode Indicates that the core is in Stopped (halt) or Stepping state.
DoubleExceptionError	Double exception error Indicates a double exception fault occurs.
PFatalError	Processor fatal error Indicates a fatal error condition occurs (e.g., CSR parity error).
PFaultInfo	Processor fault information PFaultInfo[31:0] mirrors the processor's internal FIR, using the same bit encoding to provide the source and severity of the fault. See PFaultInfo and Fault Information Register (FIR).
PFaultInfoValid	PFaultInfo valid

Table continues on the next page...

Table continued from the previous page...

Signal name	Description
	Asserted when PFaultInfo signal changes its value. The system can use its high level as an enabler to capture PFaultInfo.
TIE_EXPSTATE	Tensilica Instruction Extension (TIE) output state 32-bit set by instructions which can be connected to any system peripherals, independent of main system bus.

7	Configure the HiFi4 to Run mode	Write 0b to SYSCON0.DSPSTALL[DSPSTALL]

60.2 Overview

Cadence® Xtensa® HiFi 4 Audio DSP (HiFi4) is a highly optimized audio processor running at frequencies up to 325 MHz, for efficient execution of audio and voice codecs, and pre- and post-processing modules. There is a floating-point unit (FPU) included, providing up to four single-precision IEEE floating-point multiplier–accumulators (MAC) per cycle. All HiFi4 audio engine operations can be used as intrinsics in low-level applications.

60.2.1 Block diagram

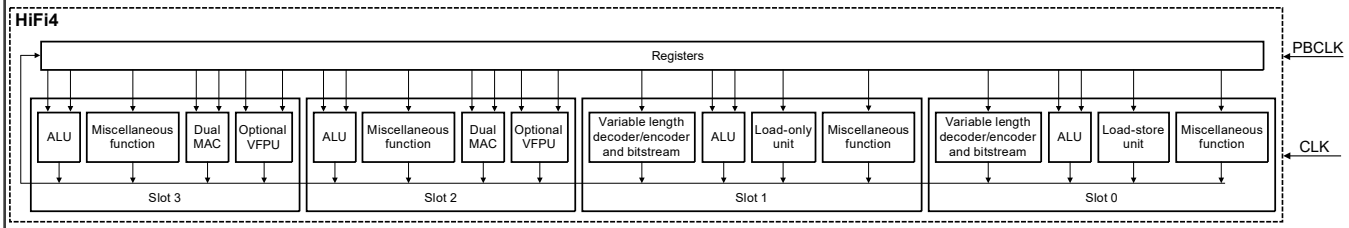

Figure 255. HiFi4 block diagram

60.2.2 Features

HiFi4 supports the following features:

- Vector floating-point unit (VFPU)
- 256 bytes L0 loop buffer
- Memory protection: Region protection
- Pipelined + UH/SH Multiplication (MUL) 32 implementation
- MUL 16
- 16-bit MAC with 40-bit accumulator
- 32-bit integer divider
- Non-IEEE double-precision FP accelerator
- Take exception on unaligned load and store address
- Normal L32R hardware support
- 7-stage pipeline
- 16 cache prefetch entries
- Instruction cache features:
  - 4-way instruction cache
  - Cache size: 32768
  - Line size: 256
  - Line locking
- Data cache features:
  - 4-way data cache
  - Cache size: 65536
  - Line size: 256
  - Write back
  - Line locking
  - 4 data banks
- Instruction RAM features:
  - Supports inbound processor interface
  - Size: 64 K

— Banks: 1

NOTE

The instruction RAM must be accessed in a 32-bit word unit. Each 32-bit word must have the contiguous four bytes all enabled or all disabled.

- Data RAM features:
  - Supports inbound processor interface
  - Size: 64 K
  - Banks: 4
- 2 load and store units

60.3 Functional description

60.3.1 Arithmetic logic unit (ALU) and multiplier–accumulator (MAC)

In HiFi4 DSP, MAC is a common process that computes the product of two numbers and adds the results to an accumulator. ALU performs arithmetic and logical operations on the operands. HiFi4 supports the following ALU and MAC functionalities:

- Four 32 x 32-bit MACs
- Limited support for 72-bit accumulators
- Ability to support eight 32 x 16-bit MACs
- 16-bit multiply and accumulate with 40-bit accumulator
- CLAMPS operations
- 32-bit integer divider

60.3.2 Vector floating-point unit (VFPU)

VFPU performs operations on floating-point numbers. HiFi4 provides up to four single-precision IEEE floating-point MACs per cycle.

60.3.3 Variable-length decoder and encoder

The HiFi4 bitstream engine supports fixed length and variable length decoding and encoding. Variable length (Huffman) decode instructions are specialized instructions, in which the elements with variable bit-widths are decoded.

60.3.4 Load and store operations

HiFi4 supports loading and storing scalars or vectors of 16, 24, 32, and 64 bits. Each scalar of load and store accesses 16, 24, 32, or 64 bits. Each vector accesses 64 bits or 48 bits for packed 24-bit data.

60.3.5 Non-IEEE double-precision floating-point (FP) accelerator

The double-precision FP accelerator adds a small set of TIE instructions and states to speed existing double-precision software execution of IEEE 754 double precision FP calculations. This implements IEEE 754 compliant 64-bit double-precision add, subtract, multiply, square root, and divide operations with the round to-nearest rounding mode. It also implements a complete set of comparison operations that allow for IEEE-compliant comparisons.

60.3.6 L0 loop buffer

L0 loop buffer captures instructions from the body of a Zero Overhead Loop, and then executes subsequent iterations of the loop from this buffer. This allows the instruction memories to be disabled during most of the loop execution. Power savings depend on what portion of code is being executed as Zero Overhead Loops.

60.3.7 Miscellaneous function

Miscellaneous functions in HiFi4 include:

- NSA/NSAU: Returns the number of contiguous sign bits in the most significant bits of a 32-bit signed/unsigned value
- MinMax: Performs a signed or unsigned integral minimum or maximum operation
- SEXT: Sign extend to 32 bits
- Density: Enable use of density (16-bit) instructions

60.3.8 PFaultInfo and Fault Information Register (FIR)

FIR provides information on the error condition and the PFaultInfo output signal mirrors this internal register.

Bit	Description	Notes
31:21	Deasserted	
20	Multiple Faults 0b - Only one fault has occurred so far 1b - Multiple faults have occurred*	* In this case, the FIR register has information only on the most severe fault.
19:16	User Bits These bits are zero by default. Software running on Xtensa can write to the user bits.	These bits are available only in configurations with both debug features (i.e. OCD at a minimum) and parity/ECC protection on the AXI bus interface.
15**:8	Fault Severity Level 0000b - Fault severity is not reset. The system can recover without resetting 0001b - Fault severity is core reset. Minimally, reset the Xtensa processor to recover from the fault 0010b - Fault severity is system reset. The whole system may need to be reset to recover from the fault	** CSR parity error sets the PFaultInfo[15] output signal. **NOTE** The suggested severity level and the recovery mechanism are recommendations and may not always work.
7:0	AXI Channel and AXI Port AXI channel [7:4]: 0000b - Read address AXI channel 0001b - Write address AXI channel 0010b - Write data AXI channel 0011b - Read data AXI channel 0100b - Write response AXI channel AXI port [3:0]: 0000b - Main AXI initiator port 0001b - Secondary (iDMA) AXI initiator port 0010b - AXI target port	

60.3.9 Clocking

Clock	Description
CLK	Main clock
PBCLK	APB interface clock
ATCLK	ATB clock

60.3.10 Interrupts

HiFi4 provides 32 interrupts with 4 priority levels, 2 timers, and 2 EXCM (exception mode) priority levels with highest priority of efficiently callable handlers.

60.4 Signals

Signal name	Description
OCDHaltOnReset	On-Chip Debug (OCD) halt on reset Tied low for normal operation. Alternatively, this signal can be tied high to force the processor to enable OCD and enter Stopped (halt) state at processor reset.
XOCDMode	Xtensa On-Chip Debug (XOCD) mode Indicates that the core is in Stopped (halt) or Stepping state.
DoubleExceptionError	Double exception error Indicates a double exception fault occurs.
PFatalError	Processor fatal error Indicates a fatal error condition occurs (e.g., parity error on AXI handshake signal or CSR parity error).
PFaultInfo	Processor fault information PFaultInfo[31:0] mirrors the processor's internal FIR, using the same bit encoding to provide the source and severity of the fault. See PFaultInfo and Fault Information Register (FIR).
PFaultInfoValid	PFaultInfo valid Asserted when PFaultInfo signal changes its value. The system can use its high level as an enabler to capture PFaultInfo.
ARADDR	AXI read address.
TIE_EXPSTATE	Tensilica Instruction Extension (TIE) output state 32-bit set by instructions which can be connected to any system peripherals, independent of main system bus.

Chapter 61
Micro-Tick Timer (UTICK)

61.1 Chip-specific UTICK information

Table 585. Reference links to related information

Clocking		Clock overview Clock controller
Signal multiplexing	IOPCTL	External signals and pin multiplexing IO PAD controller

61.1.1 Module instances

This device has two instances of the UTICK module, UTICK0 and UTICK1.

Table 586. UTICK instances

	UTICK0	UTICK1
Located in	VDD2_COMP	VDD1_SENSE
Access	CPU0, HiFi4, EZH-V, eDMA0, eDMA1	CPU1, HiFi1, EZH-V, eDMA2, eDMA3

61.1.2 UTICK clock source

The table below shows the UTICK clock source, see Clock Controller (CLKCTL) for details.

Table 587. UTICK clock source

UTICK clock	UTICK0	UTICK1
timer_clk	utick0_fclk	utick1_fclk
pclk	VDD2_COMP domain main clock	VDD1_SENSE domain main clock

61.1.3 Wakeup chip from low power mode

UTICK can run and wakeup this chip from the following low power modes:

- Sleep mode
- Deep sleep mode

61.2 Overview

UTICK is a 31-bit timer that counts down to 0 and then generates an interrupt. Thus, it provides a fixed time interval between interrupts. This is a simple, ultra-low-power timer that can run and wake up the chip from Low-power mode. See chip specific information for low power modes UTICK can wakeup.

61.2.1 Block diagram

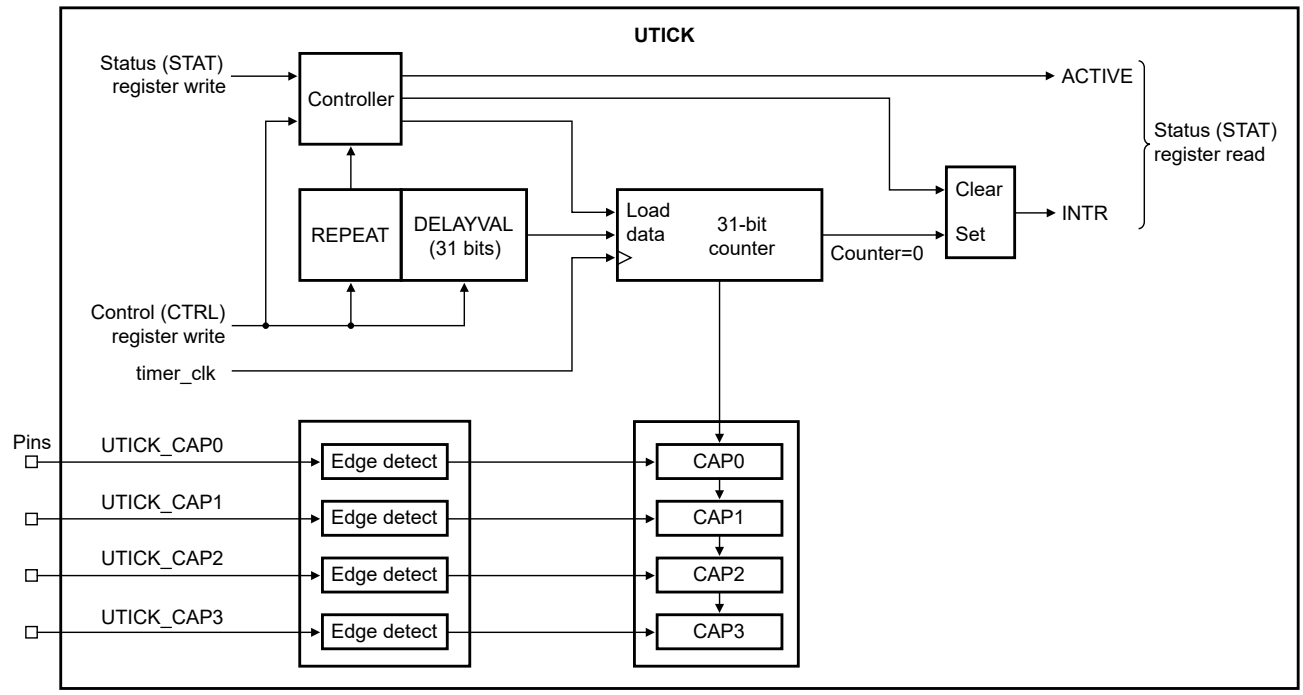

Figure 256. Block diagram

61.2.2 Features

- Wakes up the chip from Low-power mode.
- Starts with a nonzero value written to CTRL[DELAYVAL].
- Operates using interrupt or software polling mode.
- Includes Capture (CAP0 - CAP3) registers that use external pin transitions as a trigger.

61.3 Functional description

61.3.1 Operations

Perform the following procedure before using UTICK:

1. Configure CTRL[REPEAT] to either perform a one-time delay or continuous delay.
2. Configure CTRL[DELAYVAL] to specify the delay time value in terms of the timer clock.
3. Configure CFG[CAPEN*n*] to decide the number of events to capture (the maximum is four).
4. Configure CFG[CAPPOL*n*] to capture the polarity (whether to capture on a positive or negative edge of a signal).

61.3.2 Clocking

The UTICK clock is selectable from the following clock inputs:

Table 588. Clocking

Clock	Description
Global functional clock (timer_clk)	This clock is supposed to be on during normal operation. This clock is treated as asynchronous to pclk. **NOTE** See the Chip specific section for more details on UTICK clock.
System bus clock (pclk)	This clock is used only for register reads and writes.

61.3.3 Interrupts

The interrupt is generated when the tick_count reaches 1h so that on the next rising edge of timer_clk, it doesn't trigger again automatically. Its associated status field is STAT[INTR].

61.4 External signals

Signal	I/O	Description
UTICK_CAP0, UTICK_CAP1, UTICK_CAP2, UTICK_CAP3	I	Capture inputs. Configure the selected transition on a capture pin to load Capture (CAP0 - CAP3) with the counter value.

61.5 Initialization

To initialize UTICK:

1. Enable the clock to the UTICK register interface.
2. Enable UTICK interrupts for waking up from Low-power mode, configure Control (CTRL) register.
3. Configure Capture Configuration (CFG) register to enable UTICK capture functions and selects the polarity of capture triggers.
4. Enable the oscillator that provides the UTICK clock, after writing values corresponding registers UTICK timer works normally.

62.1.2 Signals

The tables below give a summary of each of the Timer/Counter related pins and the recommended PORT settings. Also note that different part number and package variations may provide different CTIMER related pin functions.

Table 591. Timer/Counter pin description

Pin	Type	Description
CTIMER0_CAP3:0 CTIMER1_CAP3:0 CTIMER2_CAP3:0 CTIMER3_CAP3:0	Input	Capture Signals- A transition on a capture pin can be configured to load one of the Capture Registers with the value in the Timer Counter and optionally generate an interrupt. Capture functionality can be selected from a number of pins.

Table continues on the next page...

Table 591. Timer/Counter pin description (continued)

Pin	Type	Description
CTIMER4_CAP3:0 CTIMER5_CAP3:0 CTIMER6_CAP3:0 CTIMER7_CAP3:0		Timer/Counter block can select a capture signal as a clock source instead of the APB bus clock. For more details, see CTCR register.
CTIMER0_MAT3:0 CTIMER1_MAT3:0 CTIMER2_MAT3:0 CTIMER3_MAT3:0 CTIMER4_MAT3:0 CTIMER5_MAT3:0 CTIMER6_MAT3:0 CTIMER7_MAT3:0	Output	External Match Output - When a match register (MR3:0) equals the timer counter (TC) this output can either toggle, go low, go high, or do nothing. The External Match Register (EMR) controls the functionality of this output. Match Output functionality can be selected on a number of pins in parallel.

62.1.3 Initialization

- Enable the clock to the CTIMER. This enables the register interface and the peripheral function clock.
  - CTIMER*n* in compute domain via the CLKCTL0_PSCCTL2[CTIMER*n*] (*n* = 0-4)
  - CTIMER*n* in sense domain via the CLKCTL1_PSCCTL1[CTIMER*n*] (*n* = 5-7)
- Select a clock source for the CTIMER.
  - CTIMER*n* in compute domain via the CLKCTL0_CT32BIT*n*FCLKSEL (*n* = 0-4) registers
  - CTIMER*n* in sense domain via the CLKCTL1_CT32BIT*n*FCLKSEL (*n* = 5-7) registers
- Each CTIMER provides interrupts to the NVIC. See MCR and CCR registers in the CTIMER register section for match and capture events. Interrupts are enabled in the NVIC using the appropriate Interrupt Set Enable register. For interrupt connections, see NVIC Interrupt Assignments (See Interrupts chapter).
- Select timer pins and pin modes as needed through the relevant PORT registers.
- The CTIMER DMA request lines are connected to the DMA trigger inputs via the DMAC0_ITRIG_INMUX registers. Note that timer DMA request outputs are connected to DMA trigger inputs.

62.1.4 External global enable

When the timer is enabled by the CTIMER global start enable register in SYSCON (CTIMERGLOBALSTARTEN), it is equivalent to writing 1 to the TCR[CEN] bit in CTIMER. The external global start register is used to enable multiple timers at the same time. This operation is allowed by writing a 1 to each Timer's TCR[AGCEN] bit. If the Timer control register's CEN bit is already 1, the external global start enable register has no effect.

See CTIMERGLOBALSTARTEN in SYSCON for more information about CTIMER global start enable register.

62.1.5 Peripheral input multiplexers

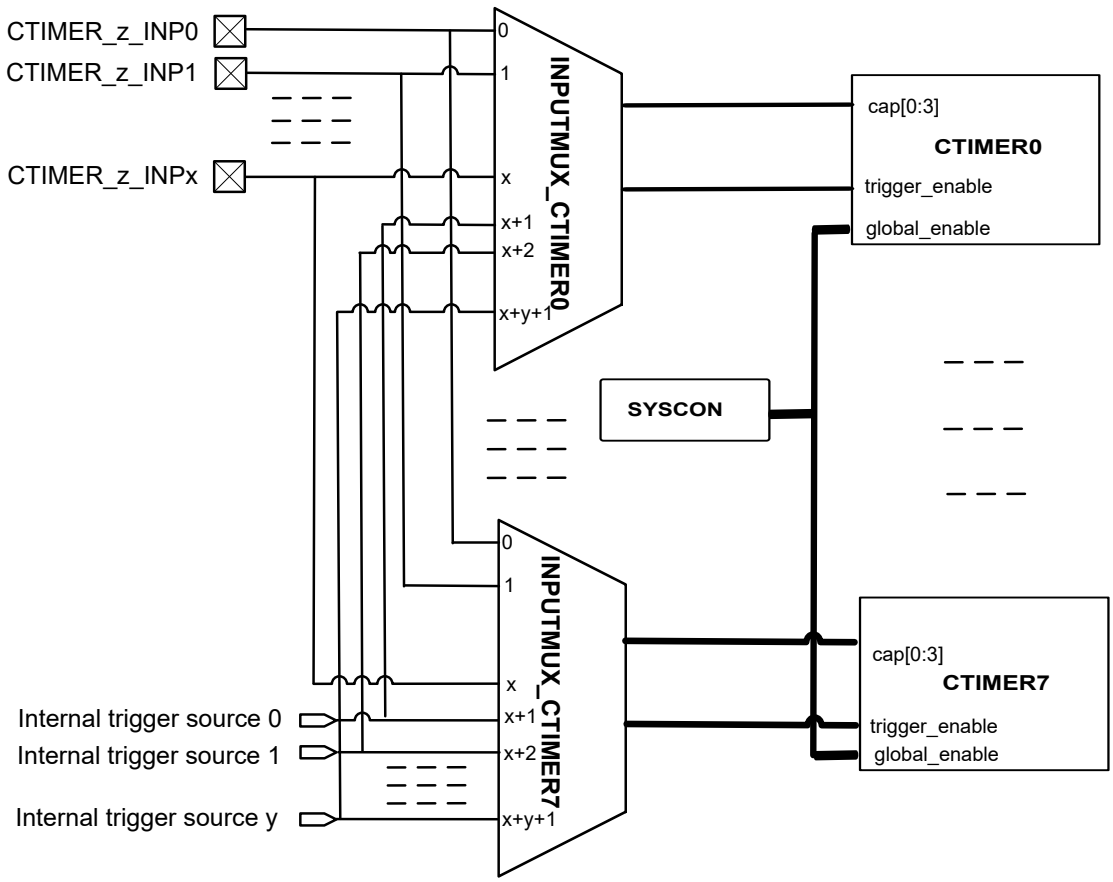

Figure 257. Peripheral input multiplexers for CTIMER

For CTIMER_z_INPx (z=C for CTIMER0 to CTIMER4, z=S for CTIMER5 to CTIMER7) and internal trigger sources, see CTIMERn_TRIG and CTIMERn_CAPm (n=0-7, m=0-3) registers in INPUTMUX for details.

62.2 Overview

Each CTIMER is designed to count cycles of the CTIMER function clock or an externally supplied clock. A CTIMER can optionally generate an interrupt or perform other actions at specified timer values based on the settings of Match (MR0 - MR3). Each CTIMER also includes capture input pins (see Capture mode) to capture the timer value when an input signal transitions, optionally generating an interrupt.

In PWM mode, three match registers can be used to provide a single-edge controlled PWM output on the match output pins. One match register is used to control the PWM cycle length. All match registers can optionally be auto-reloaded from a companion shadow register (see Match Shadow (MSR0 - MSR3)) whenever the counter is reset to zero. This feature permits modifying the match values for the next counter cycle without disrupting PWM waveforms during the current cycle. When enabled, match reload occurs whenever the counter is reset, either because of a match event or by writing 1 to TCR[CRST].

62.2.1 Block diagram

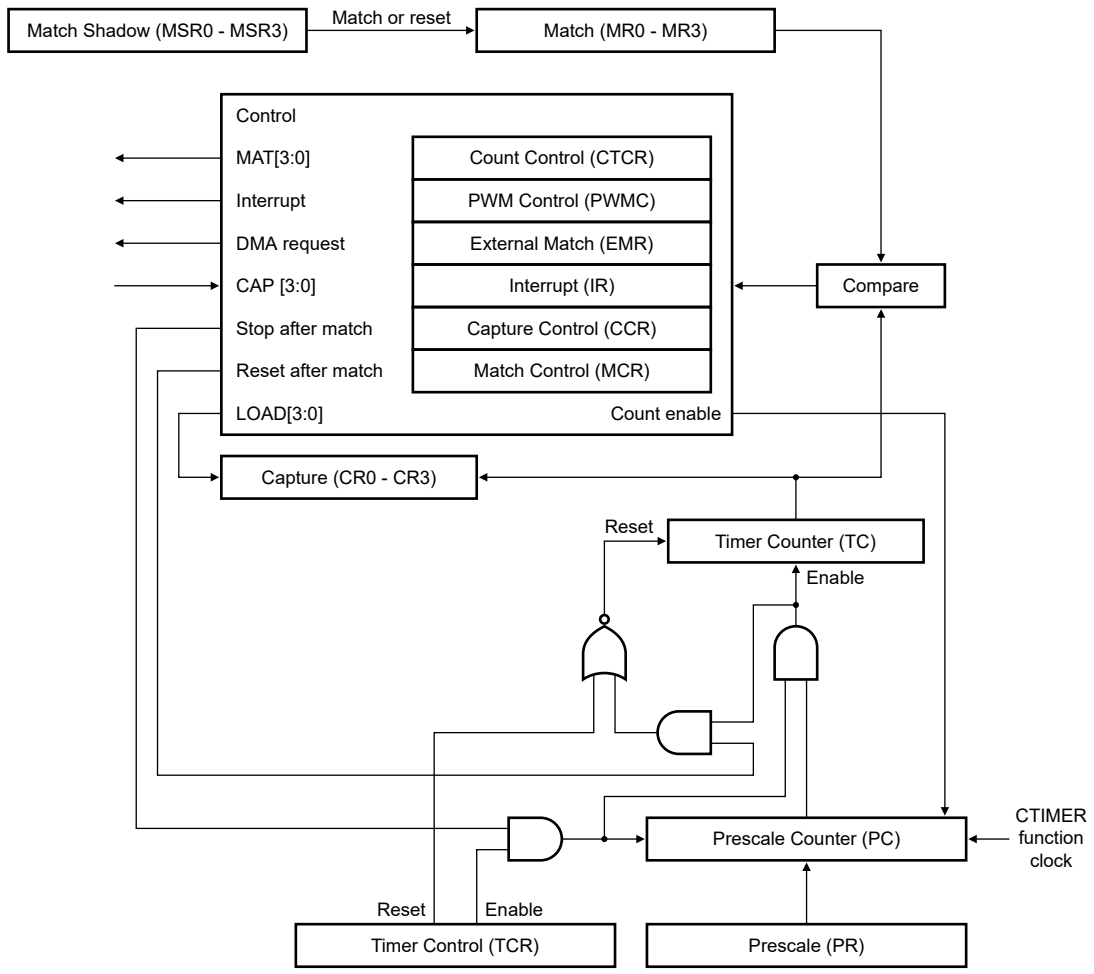

Figure 258. Block diagram

62.2.2 Features

- Contains a 32-bit CTIMER with a programmable 32-bit prescaler (the timers include external capture and match pin connections)
- Contains Timer Control (TCR) and External trigger enable, either of which you can use to enable each timer (you can also use an external global start enable register to globally enable one or more timers)
- Performs counter or timer operations
- Selects the function clocks that may be asynchronous to other system clocks
- Includes up to four 32-bit captures (see Capture mode) to take a snapshot of the timer value when an input signal transitions (a capture event may also optionally generate an interrupt, and the number of capture inputs available for each timer on a chip may vary)
- Enables you to configure the timer and prescaler to be cleared on a designated capture event (this feature permits easy pulse-width measurement by clearing the timer on the leading edge of an input pulse, capturing the timer value on the trailing edge)
- Includes Match (MR0 - MR3) to allow:
  - Continuous operation with optional interrupt generation after a match occurs

  - Optional auto-reload from Match Shadow (MSR0 - MSR3) when the counter is reset
  - Stop timer after a match with optional interrupt generation
  - Reset timer after a match with optional interrupt generation
- Generates up to four external outputs corresponding to Match (MR0 - MR3), for each timer, with the following capabilities (the number of match outputs available for each timer on a chip may vary):
  - Go low when matched
  - Go high when matched
  - Toggle when matched
  - Do nothing
- Enables you to configure up to four match registers for PWM operation, allowing up to three single-edged controlled PWM outputs (the number of match outputs available for each timer on a chip may vary)
- Uses up to two match registers to generate DMA requests

62.3 Functional description

Figure 259 shows a timer configured to reset the count and generate an interrupt after a match. The value of Prescale (PR) is 2 and the value of Match (MR0 - MR3) is 6. At the end of the timer cycle where the match occurs, the timer count is reset and gives a full-length cycle to the match value. The interrupt indicating that a match has occurred is generated in the next clock after the timer reaches the match value. Timer mode is selected in this case.

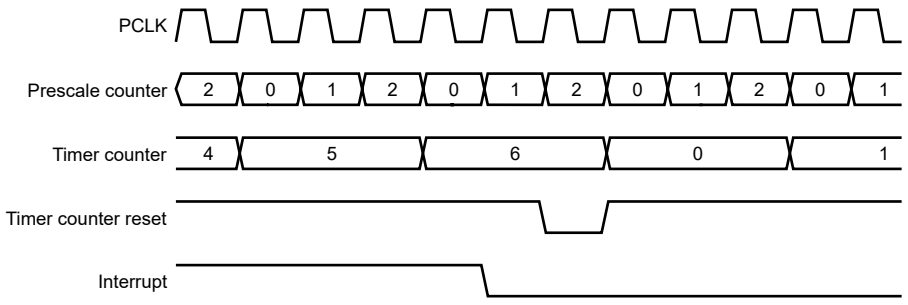

Figure 259. Timer cycle with PR = 2, MR*x* = 6, and both interrupt and reset enabled after match

Figure 260 shows a timer configured to stop and generate an interrupt after a match. The value of Prescale (PR) is 2 and the value of Match (MR0 - MR3) is 6. In the next clock after the timer reaches the match value, TCR[CEN] becomes 0 and the interrupt indicating that a match has occurred is generated.

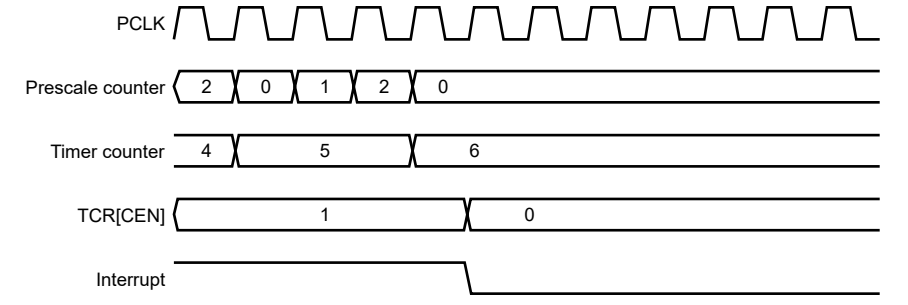

Figure 260. Timer cycle with PR = 2, MR*x* = 6, and both interrupt and stop enabled after match

62.3.1 Operation sections

All single-edge controlled PWM outputs go low at the beginning of each PWM cycle (timer is set to zero) unless their match value is zero.

Each PWM output goes high when its match value is reached. If no match occurs (that is, the match value is greater than the PWM cycle length), the PWM output remains continuously low.

If a match value larger than the PWM cycle length is written to Match (MR0 - MR3), and the PWM signal is already high, the PWM signal is cleared at the start of the next PWM cycle.

If a match register contains the same value as the timer reset value (the PWM cycle length), the PWM output is reset to low on the next clock tick after the timer reaches the match value. Therefore, the PWM output always consists of one clock tick wide positive pulse with a period that the PWM cycle length determines (that is, the timer reload value).

If Match (MR0 - MR3) = 0, the PWM output goes to high the first time the timer goes back to zero, and remains high continuously.

The following figure shows sample PWM waveforms with a PWM cycle length of 100 that MR3 specifies and PWM outputs that PWM Control (PWMC) enables. Counter mode is selected in this case.

NOTE

When you select match outputs to perform as PWM outputs, you must write 0 to MCR[MR*n*R] and MCR[MR*n*S], except to the match register setting the PWM cycle length. For this register, write 1 to MCR[MR*n*R] to enable the timer reset when the timer value matches the value of the corresponding match register.

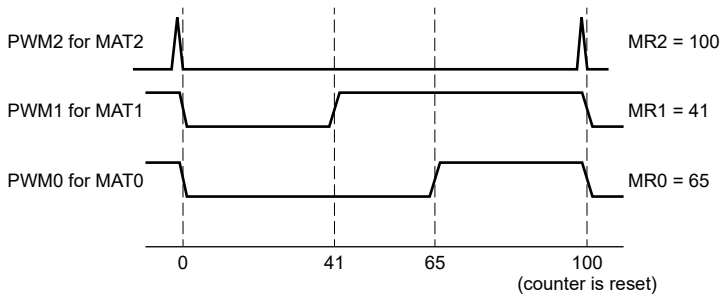

Figure 261. Sample PWM waveforms with a PWM cycle length of 100 (selected by MR3) and MAT3:0 enabled as PWM outputs by the PWM Control register.

62.3.2 Mode sections

62.3.2.1 Capture mode

You can configure a CAP to load Capture (CR0 - CR3) with the value in the counter or timer and optionally generate an interrupt. One of the pins generates the capture signal with a capture function. Each CAP is connected to one capture channel of the timer.

CTIMER can select a CAP as a clock source instead of selecting the APB CTIMER function clock. See Count Control (CTCR) for more information.

62.3.2.2 Match mode

When the value of a match register (Match (MR0 - MR3)) equals that of Timer Counter (TC), the corresponding match output can either toggle, go low, go high, or do nothing. External Match (EMR) and PWM Control (PWMC) control the functionality of this output.

62.3.3 External trigger enable

When trigger_enable is asserted (rising edge), it is equivalent to writing 1 to TCR[CEN]. If TCR[CEN] is already 1, trigger_enable rising edge events have no effect.

62.3.4 Clocking

Table 592. CTIMER clocks

Type of clock	Description
Functional Clock(ctclk)	Asynchronous to the bus clock, provide clock to perform counter or timer operations.
Bus Clock(pclk)	The bus clock is only used for bus accesses to the control and configuration registers.

62.3.5 Reset

TCR[CRST] resets Timer Counter (TC) and Prescale Counter (PC).

62.3.6 Interrupts

This module has capture and match interrupts. See the Interrupt (IR)

62.3.7 DMA

DMA requests are generated when the value of Timer Counter (TC) either matches the value of MR0 or MR1 (see Match (MR0 - MR3) for more information). This DMA request is not connected to the operation of the match outputs (see Match mode) controlled by External Match (EMR). Each match sets a DMA request flag, which is connected to the DMA controller. You must configure the DMA controller correctly.

When a timer is initially set up to generate a DMA request, the request may already be asserted before a match condition occurs. An initial DMA request may be avoided by writing 1 to the interrupt flag location twice, as if clearing a timer interrupt. See Interrupt (IR) for more information. A DMA request is cleared automatically when the DMA controller manages it.

NOTE

Timer DMA requests are generated whenever the timer value is equal to the related match register value. DMA requests are always generated when the timer is running, unless the match register value is higher than the upper count limit of the timer. It is important not to select and enable timer DMA requests in the DMA block unless you configure the timer correctly to generate valid DMA requests.

62.4 External signals

Table 593. CTIMER pin descriptions

Pin	Type	Description
CTIMER*m*_CAP*n*	Input	Capture signals—You can configure a transition on a capture pin to load one of the capture registers (Capture (CR0 - CR3)) with the value of Timer Counter (TC) and optionally generate an interrupt. You can select the capture functionality for a number of pins. CTIMER can select a capture signal as a clock source instead of the APB bus clock. See Count Control (CTCR) for more information.
CTIMER*m*_MAT*n*	Output	External match output—When the value of a match register (Match (MR0 - MR3)) equals the value of Timer Counter (TC), this output can either toggle, go low, go high, or do nothing. External Match (EMR) controls the functionality of this output. You can select the match output functionality for a number of pins in parallel.

62.4.1 Multiple capture (CAP) and match (MAT) pins

You can configure the pins of the chip to be used for this module. These pins are generally reused, and you can connect several internal module pins selectively. However, you can connect only one internal pin at a time.

NOTE

Match conditions may be used internally without the use of a chip's pin.

62.5 Initialization

See the Chip-specific CTIMER information for the initialization section for more details or steps.

62.6 Application information

CTIMER register descriptions discusses the following:

- Interval timer for counting internal events
- PWM outputs
- Pulse width demodulator via capture inputs
- Free running timer

62.7.2 Interrupt (IR)

Offset

Register	Offset
IR	0h

Function

Provides flags for match interrupts and capture interrupts. If an interrupt is generated, it sets the corresponding flag in this register. Otherwise, the flag remains cleared. Writing 1 to the corresponding IR field resets the interrupt. Writing 0 has no effect. Clearing an interrupt for a timer match also clears any corresponding DMA request. You can write to this register to clear interrupts, and can read this register to identify which interrupt sources are pending.

62.7.3 Timer Control (TCR)

Offset

Register	Offset
TCR	4h

Function

Controls timer counter functions. You can disable or reset Timer Counter (TC) by using this register.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-6 —	Reserved
5 ATCEN	Allow Trigger Count Enable Enables the input trigger. If this field is 1, it allows the input trigger_enable = 1 action to take effect (see External trigger enable). If this field is 0, the action is not allowed. 0b - Disable 1b - Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 AGCEN	Allow Global Count Enable Enables the global count. If this field is 1, it allows the input global_enable = 1 action to take effect. If this field = 0, the action is not allowed. 0b - Disable 1b - Enable
3-2 —	Reserved
1 CRST	Counter Reset Enable Enables the counter reset. If this field is 1, Timer Counter (TC) and Prescale Counter (PC) are synchronously reset after the next positive edge of the CTIMER function clock. The counters remain reset until this field becomes 0. If this field is 0, no effect takes place. 0b - Disable 1b - Enable
0 CEN	Counter Enable Enables the counters. If this field is 1, Timer Counter (TC) and Prescale Counter (PC) are enabled. When an external trigger enables the timer or the external global start enable register enables it, this field becomes 1 automatically. 0b - Disable 1b - Enable

62.7.4 Timer Counter (TC)

Offset

Register	Offset
TC	8h

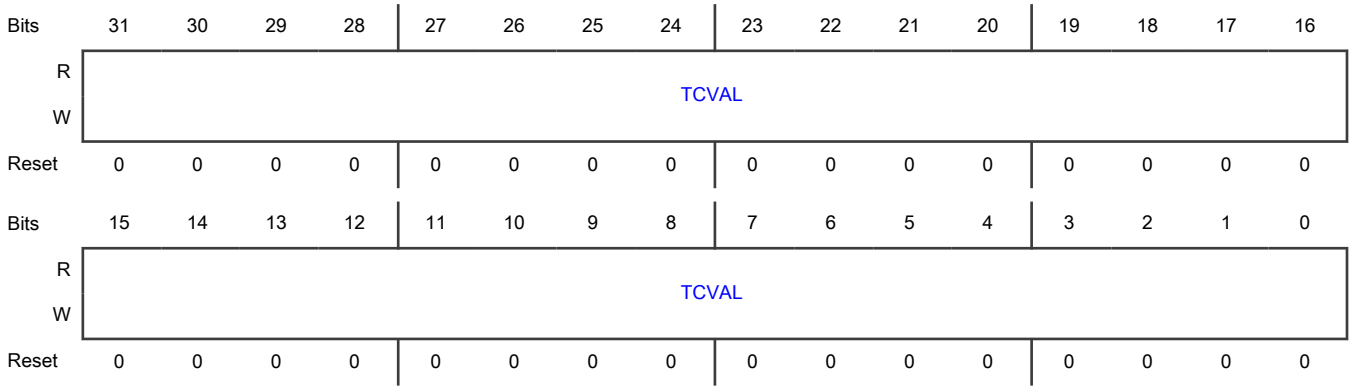
Function

Specifies the timer counter.

This register is incremented when Prescale Counter (PC) reaches its terminal count. Unless it is reset before reaching its upper limit, Timer Counter (TC) counts up through the value FFFF_FFFFh, and then wraps back to the value 0000_0000h. This event does not cause an interrupt, but you can use Match (MR0 - MR3) to detect an overflow if needed.

Timer Counter (TC) is incremented after every Prescale (PR) + 1 cycle of the CTIMER function clock. Timer Control (TCR) controls the functioning of this register.

Diagram



Fields

Field	Function
31-0 TCVAL	Timer Counter Value Specifies the value of the timer counter.

62.7.5 Prescale (PR)

Offset

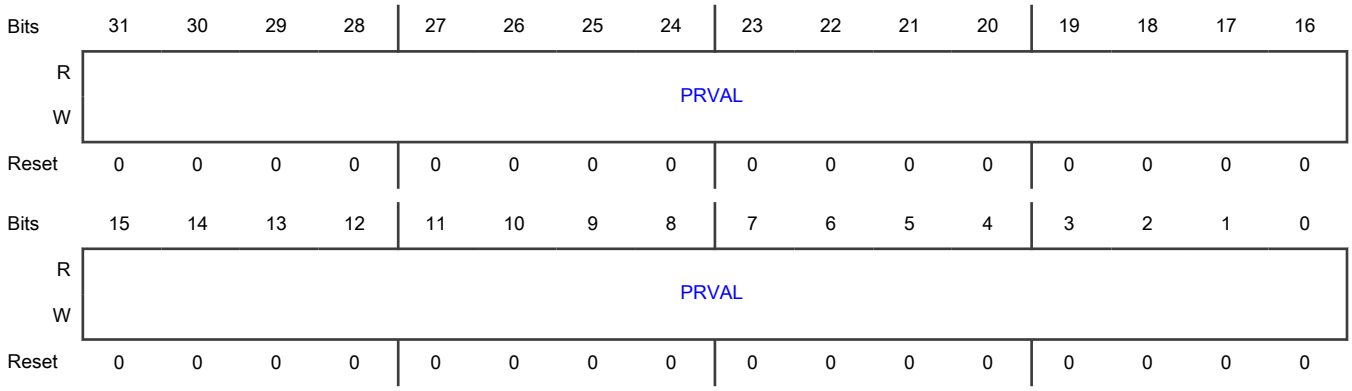
Register	Offset
PR	Ch

Function

Specifies the prescale value.

If Prescale Counter (PC) is equal to the prescale value, the next clock timer increments Timer Counter (TC) and turns the value of Prescale Counter (PC) to 0.

Diagram



Fields

Field	Function
31-0 PRVAL	Prescale Reload Value Specifies the value of the prescale reload.

62.7.6 Prescale Counter (PC)

Offset

Register	Offset
PC	10h

Function

Controls the division of the CTIMER function clock by some constant value before it is applied to Timer Counter (TC). This allows control of the relationship between the resolution of the timer and the maximum time before the timer overflows.

Prescale Counter (PC) is incremented on every CTIMER function clock. When it reaches the value stored in Prescale (PR), Timer Counter (TC) is incremented and Prescale Counter (PC) is reset on the next CTIMER function clock. This causes Timer Counter (TC) to increment on every CTIMER function clock when Prescale (PR) = 0, every two CTIMER function clocks when Prescale (PR) = 1, and so on.

You can use the bus interface to observe and control Prescale Counter (PC).

0 MR0I	Interrupt on MR0 Generates an interrupt when MR0 matches the value in Timer Counter (TC). 0b - Does not generate 1b - Generates

62.7.8 Match (MR0 - MR3)

Offset

Register	Offset
MR0	18h
MR1	1Ch
MR2	20h
MR3	24h

Function

Continuously compares the value of Match (MR0 - MR3) with the value of TC[TCVAL]. When both the values are equal, actions such as the following can be triggered automatically:

- Generation of an interrupt
- Resetting of Timer Counter (TC)
- Stopping of the timer

The settings defined in Match Control (MCR) control these actions.

If MCR[MRnRL] = 1, Match (MR0 - MR3) is automatically reloaded with the current contents of its corresponding Match Shadow (MSR0 - MSR3) whenever Timer Counter (TC) becomes 0. This transfer takes place on the same clock edge that advances Timer Counter (TC) to 0.

NOTE

Timer Counter (TC) resets in response to an occurrence of a match on MATCH being used to set the cycle counter rate. A reset can also occur if you write 1 to TCR[CRST].

Diagram

31-0 MATCH	Timer Counter Match Value Triggers an action automatically when the value of this field is the same as that of TC[TCVAL].

62.7.9 Capture Control (CCR)

Offset

Register	Offset
CCR	28h

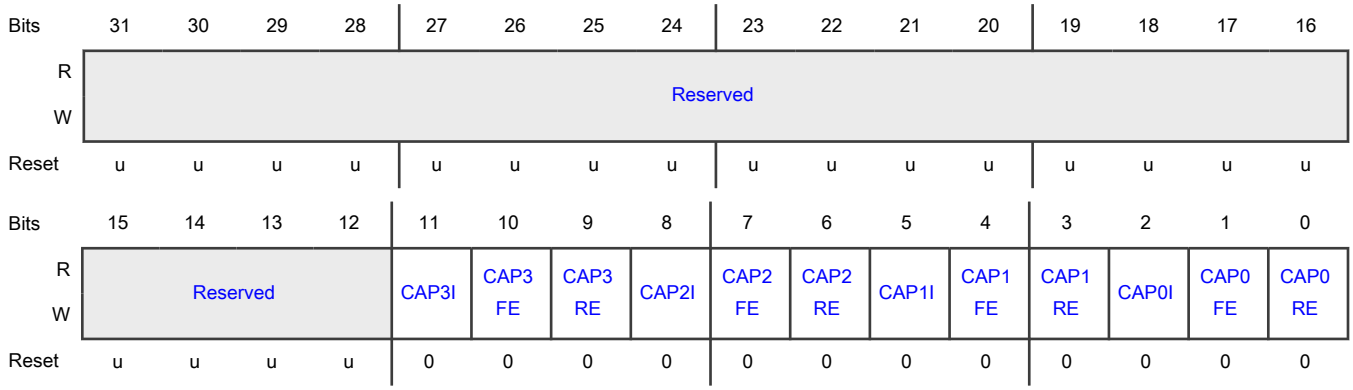
Function

Controls whether one of the capture registers (Capture (CR0 - CR3)) is loaded with the value in Timer Counter (TC) when the capture event occurs. The register also controls whether the capture event generates an interrupt. When you configure both the rising and falling bits at the same time, which is a valid configuration, it results into a capture event for both edges. In the description below, "*n*" represents the timer number, 0 or 1.

NOTE

If you select Counter mode for a particular CAP*n* input in Count Control (CTCR), you must program the fields in this register as 0. You can select both capture and interrupt for the other CAP*n* inputs.

Diagram



Fields

Field	Function
31-12 —	Reserved

62.7.10 Capture (CR0 - CR3)

Offset

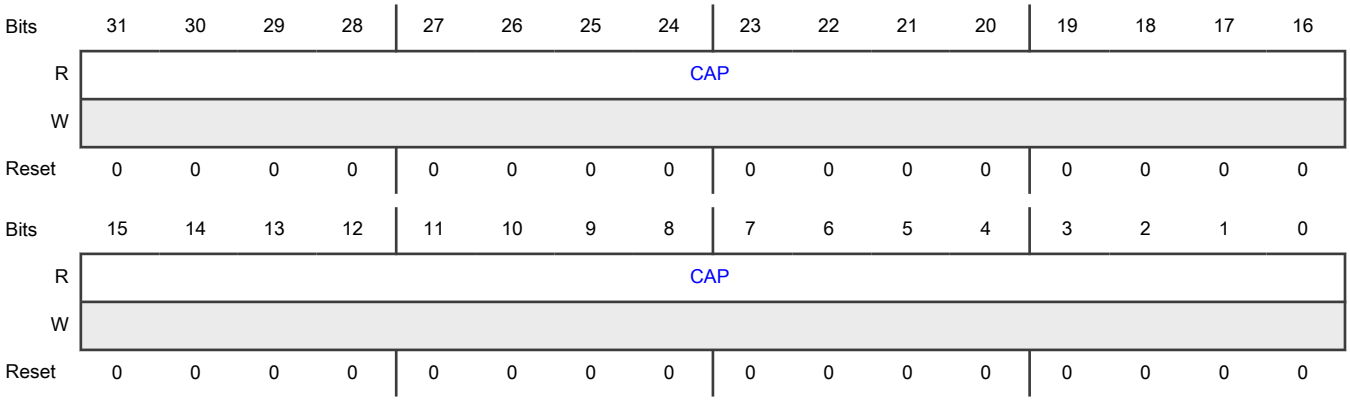
Register	Offset
CR0	2Ch
CR1	30h
CR2	34h
CR3	38h

Function

Works with a capture channel and may load with the value of Timer Counter (TC) when a specified event occurs on the signal defined for that capture channel. The signal could originate from an external pin or an internal source.

This register determines whether the capture function is enabled, and whether a capture event happens on the rising edge, falling edge, or on both edges of the associated signal. The register is loaded with the value of Timer Counter (TC) when there is an event on the CAP*n* input.

Diagram



Fields

Field	Function
31-0 CAP	Timer Counter Capture Value Determines whether the capture function is enabled and defines the edge on which the capture function occurs.

62.7.11 External Match (EMR)

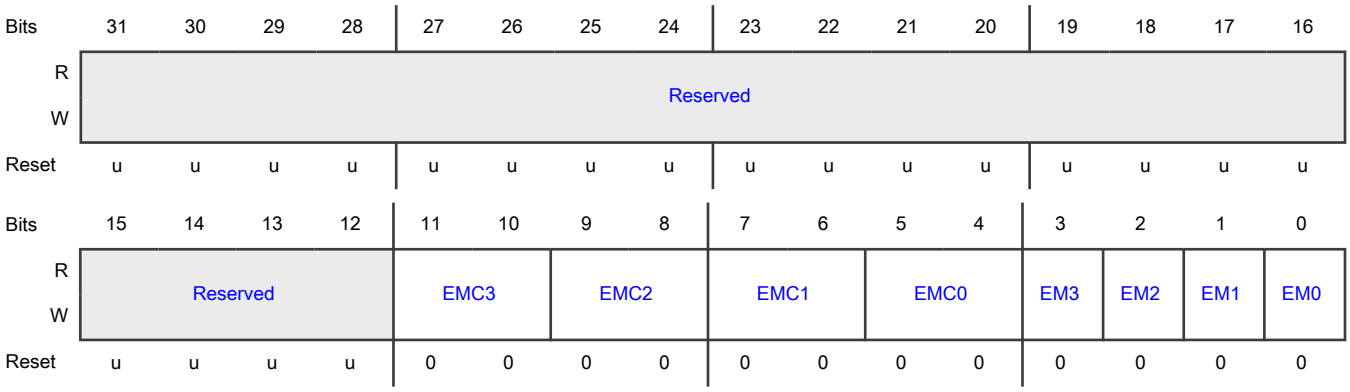
Offset

Register	Offset
EMR	3Ch

Function

Provides both control and status of the external match pins. If the match outputs (see Match mode) are configured as PWM outputs, PWM rules determine the function of this register.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-10 EMC3	External Match Control 3 Determines the functionality of EM3: • If this field is 1, the corresponding external match field or output becomes 0 (if pinned out MAT3 pin is low). • If this field is 10, the corresponding external match field or output becomes 1 (if pinned out MAT3 pin is high). • If this field is 11, it toggles the corresponding external match field or output. 00b - Does nothing 01b - Goes low 10b - Goes high 11b - Toggles
9-8 EMC2	External Match Control 2 Determines the functionality of EM2: • If this field is 1, the corresponding external match field or output becomes 0 (if pinned out MAT2 pin is low). • If this field is 10, the corresponding external match field or output becomes 1 (if pinned out MAT2 pin is high). • If this field is 11, it toggles the corresponding external match field or output. 00b - Does nothing

Field	Function
	do nothing, as selected by EMC2. This field is driven to the MAT pins if the match function is selected via IOPCTL. 0b - Low 1b - High
1 EM1	External Match 1 Reflects the state of output MAT1—whether this output is connected to a pin. If a match occurs between Timer Counter (TC) and MR1 (see Match (MR0 - MR3)), this field can either toggle, go low, go high, or do nothing, as selected by EMC1. This field is driven to the MAT pins if the match function is selected via IOPCTL. 0b - Low 1b - High
0 EM0	External Match 0 Reflects the state of output MAT0—whether this output is connected to a pin. If a match occurs between Timer Counter (TC) and MR0 (see Match (MR0 - MR3)), this field can either toggle, go low, go high, or do nothing, as selected by EMC0. This field is driven to the MAT pins if the match function is selected via IOPCTL. 0b - Low 1b - High

62.7.12 Count Control (CTCR)

Offset

Register	Offset
CTCR	70h

Function

Selects between Timer and Counter mode, and in Counter mode, selects the signal and edges for counting.

When Counter mode is selected as the mode of operation, the CAP input (selected by CINSEL) is sampled on every rising edge of the CTIMER function clock. After comparing two consecutive samples of this CAP input, one of the following four events is recognized:

- Rising edge
- Falling edge
- Either of the edges
- No change in the selected CAP input level

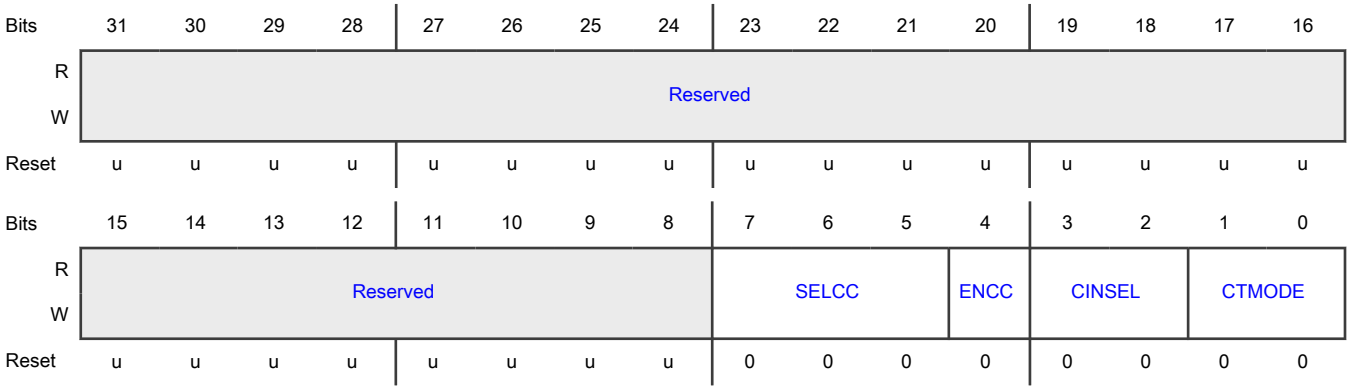
Only if the identified event occurs and the event corresponds to the one selected by CTMODE, Timer Counter (TC) is incremented.

Effective processing of the externally supplied clock to the counter has some limitations:

- Because two successive rising edges of the CTIMER function clock are used to identify only one edge on the CAP selected input, the frequency of the CAP input cannot exceed one half of the CTIMER function clock.
- Consequently, the duration of the high or low levels on the same CAP input in this case cannot be shorter than the CTIMER function clock duration.

You can also use ENCC and SELCC to enable and configure the capture-clears-timer feature. This feature allows for a designated edge on a particular CAP input to reset the timer to all zeros. Using this mechanism to clear the timer on the leading edge of an input pulse and perform a capture on the trailing edge permits direct pulse-width measurement using a single capture input without the need to perform a subtraction operation in software.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-5 SELCC	Edge Select Selects which input edge (rising or falling) causes the timer and prescaler to be cleared, when ENCC is 1. These fields have no effect when ENCC is 0. 000b - Capture channel 0 rising edge 001b - Capture channel 0 falling edge 010b - Capture channel 1 rising edge 011b - Capture channel 1 falling edge 100b - Capture channel 2 rising edge 101b - Capture channel 2 falling edge 110b - Capture channel 3 rising edge 111b - Capture channel 3 falling edge
4 ENCC	Capture Channel Enable Enables capture channel. Writing 1 to this field enables clearing of the timer and the prescaler when the capture-edge event specified in SELCC occurs.

Table continues on the next page...

Table continued from the previous page...

Field	Function
3-2 CINSEL	Count Input Select Selects which CAP pin is sampled for clocking when CTMODE is not 0. **NOTE** If Counter mode is selected for a particular CAP*n* input in Count Control (CTCR), you must program the corresponding fields for that input in Capture Control (CCR) as 0. However, you can select both capture and interrupt for the other three CAP*n* inputs in the same timer. 00b - Channel 0, CAPn[0] for CTIMERn 01b - Channel 1, CAPn[1] for CTIMERn 10b - Channel 2, CAPn[2] for CTIMERn 11b - Channel 3, CAPn[3] for CTIMERn
1-0 CTMODE	Counter Timer Mode Selects between Timer and Counter mode, and in Counter mode, selects the signal and edges for counting: • If this field is 0, every rising CTIMER function clock edge is incremented. • If this field is 1, Timer Counter (TC) is incremented on the rising edges of the CAP input selected by CINSEL. • If this field is 10, Timer Counter (TC) is incremented on the falling edges of the CAP input selected by CINSEL. • If this field is 11, Timer Counter (TC) is incremented on both edges of the CAP input selected by CINSEL. 00b - Timer mode 01b - Counter mode rising edge 10b - Counter mode falling edge 11b - Counter mode dual edge

62.7.13 PWM Control (PWMC)

Offset

Register	Offset
PWMC	74h

Function

Configures match outputs (see Match mode) as PWM outputs. You can independently set each match output to perform either as a PWM output or match output controlled by External Match (EMR).

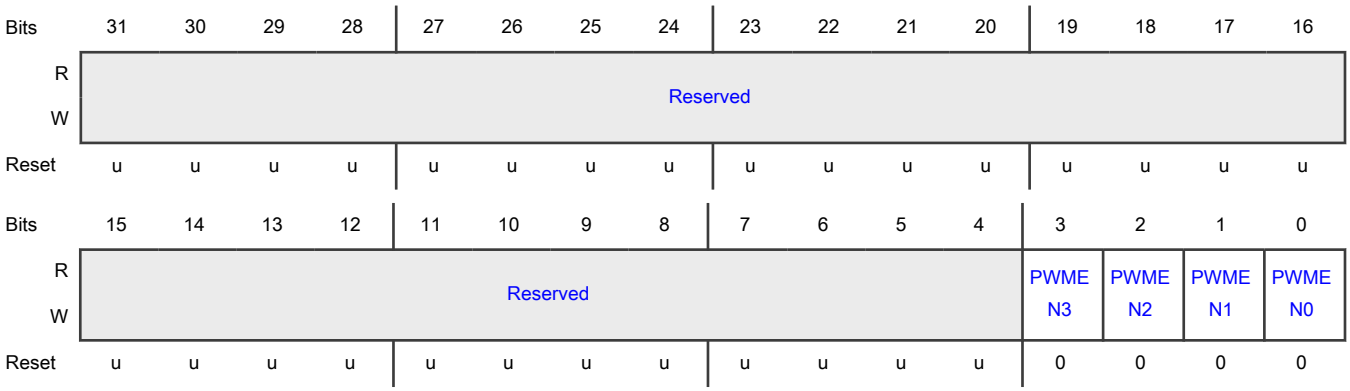
NOTE

Different part numbers and package variations may provide different match output pin functions.

For each timer, you can select a maximum of three single-edge controlled PWM outputs on the MAT*n*[2:0] outputs. One additional match register (see Match (MR0 - MR3)) determines the PWM cycle length. When a match occurs in any of the other match registers, the PWM output is set to high. The match register resets the timer that you can configure to set the PWM cycle length. When the timer is reset to zero, all currently high match outputs configured as PWM outputs are cleared.

This register enables PWM mode for the external match pins.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 PWMEN3	PWM Mode Enable for Channel 3 Enables PWM mode for channel 3. Use match channel 3 to set the PWM cycle length. If this field is 0, EM3 controls CTIMER*n*_MAT3. If this field is 1, PWM mode is enabled for CTIMER*n*_MAT3. 0b - Disable 1b - Enable
2 PWMEN2	PWM Mode Enable for Channel 2 Enables PWM mode for channel 2. If this field is 0, EM2 controls CTIMER*n*_MAT2. If this field is 1, PWM mode is enabled for CTIMER*n*_MAT2. 0b - Disable 1b - Enable
1 PWMEN1	PWM Mode Enable for Channel 1 Enables PWM mode for channel 1. If this field is 0, EM1 controls CTIMER*n*_MAT1. If this field is 1, PWM mode is enabled for CTIMER*n*_MAT1. 0b - Disable 1b - Enable
0	PWM Mode Enable for Channel 0

62.7.14 Match Shadow (MSR0 - MSR3)

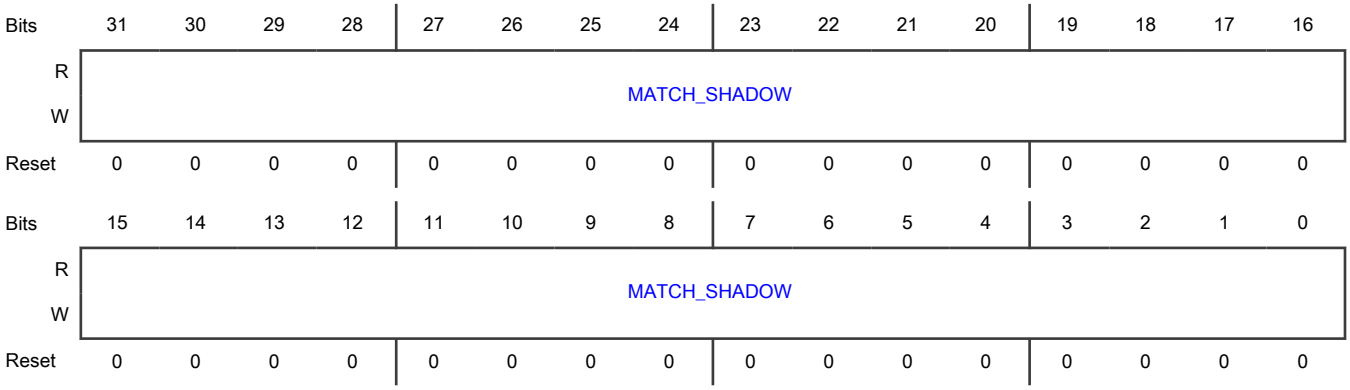
Offset

Register	Offset
MSR0	78h
MSR1	7Ch
MSR2	80h
MSR3	84h

Function

Contains the value that the corresponding Match (MR0 - MR3) are (optionally) reloaded with at the start of each new counter cycle. Typically, the match that causes the counter to be reset (and instigates the match reload) is also programmed to generate an interrupt or DMA request. Software or the DMA engine then has one full counter cycle to modify the contents of this register before the next reload occurs.

Diagram



Fields

Field	Function
31-0 MATCH_SHADOW	Timer Counter Match Shadow Value Reloads automatically with the contents of this register whenever Timer Counter (TC) is reset to zero.

63.2 Overview

OSTIMER includes a shared 64-bit timer and separate 64-bit match and capture functions for the Cortex-M33 core and DSP CPUs.

63.2.1 Block diagram

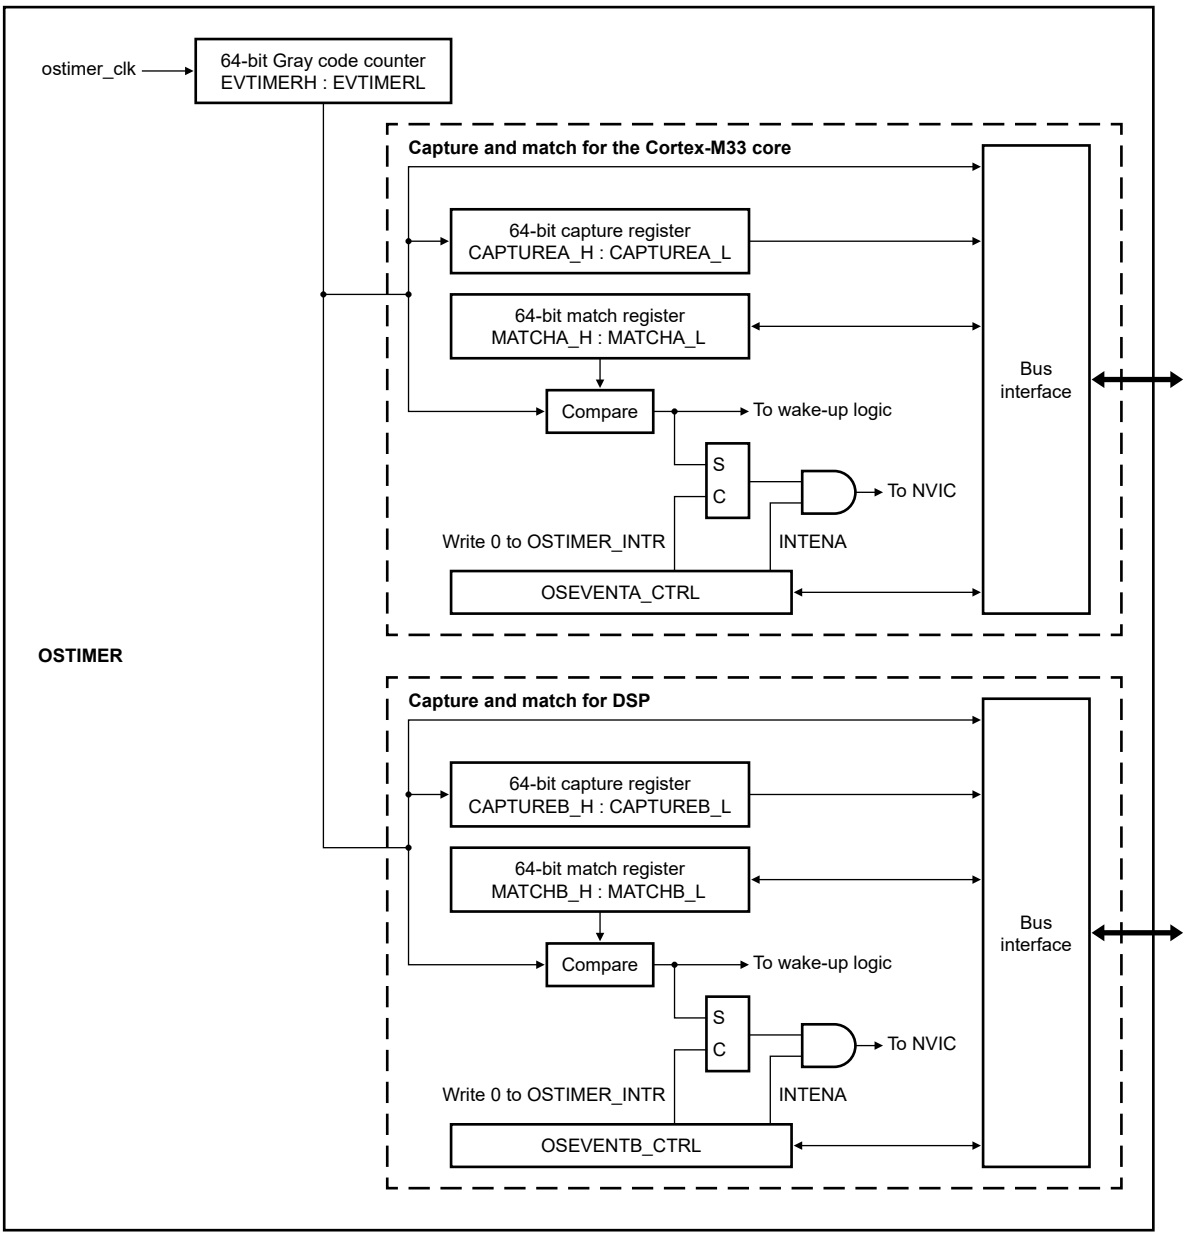

Figure 262. Block diagram

63.2.2 Features

- Provides a 64-bit Gray code counter (known as central EVTimer). Using Gray code means that the timer can run at a frequency unrelated to any CPU clock and can still be read by a CPU without a synchronization delay. Gray code is a reflected binary code that changes in a single-bit position for each increment.
- Supports separate functions for each CPU:
  - A capture register can copy the main counter value when triggered by a CPU request.
  - A match register can be compared to the main counter and can optionally generate an interrupt or wake-up event.

63.3 Functional description

The following sections describe the functional details of this module.

63.3.1 Shared event or timestamp timer

The 64-bit shared EVTimer initializes after chip power-up and then counts up continuously. The typical clock for this timer is the 1 MHz low-power oscillator.

This timer is implemented as a Gray code counter that enables the counter to be read asynchronously by any of the processing domains or captured by a capture register running on an asynchronous clock. The output of this shared EVTimer is connected to the processor-specific submodules.

63.3.2 CPU-specific match, capture, and interrupt generation

The submodules associated with each CPU include:

- A separate bus interface.
- 64 bits of capture values, available in CAPTURE_L and CAPTURE_H.
- 64 bits of match values, available in MATCH_H and MATCH_L.
- A control register, which includes an interrupt request flag and an interrupt enable field.

Capture registers	64 bits of capture values are available in CAPTURE_L and CAPTURE_H for each CPU. When the CPU issues a capture command, capture registers store the current value of the central EVTimer.
Match registers and interrupt request	64 bits of match values are available in MATCH_H and MATCH_L for each bus interface. The EVTimer output is compared against this combined value for interrupt or wake-up generation. A match to this register pair sets OSEVENT_CTRL[OSTIMER_INTRFLAG], which you can enable to generate an interrupt or wake-up request. You must write values to the match registers in Gray code. OSEVENT_CTRL[MATCH_WR_RDY] must be 0 before you write to the match registers. When you write a new value to the match registers, you must write to MATCH_L before the write to MATCH_H.

63.3.3 Clocking

The OSTIMER uses three clock signals: hclk, capture_clk, and ostimer_clk.

1. Hclk is the IPS interface clock for both the Arm and DSP sub-module, being used in all the registers and write/read operations.
2. Ostimer_clk is the counter clock, being used in the timer itself and in the intr_wakeup signals. It is expected to be running in a low frequency (~1MHz).
3. capture_clk is the Arm and DSP clock, it is used to register the capture signal “capture_load”.

63.3.4 Reset

For OSTIMER, the reset function is more complicated as compared to most other functions.

- Only the POR and software reset can reset the shared EVTimer. "Software reset" refers to a complete reset of the module.
- The capture and match registers are reset by a system reset. "System reset" refers to a reset from the RESET*n* pin, SYSRESETREQ from the CPU, a POR, or any other internal low-voltage resets.
- The control register (OSEVENT_CTL) is reset by the system reset or by software reset. However, the MATCH_WR_RDY bit can only be reset by system reset.

The following table shows a list of resets for OSTIMER registers.

Table 597. OSTIMER registers and their corresponding resets

Registers	POR	Software reset
EVTIMERL and EVTIMERH	Yes	Yes
CAPTURE_L and CAPTURE_H	Yes	No
OSEVENT_CTRL	Yes	Yes

63.3.5 Interrupts

If the interrupt request is enabled (i.e., OSEVENT_CTRL[OSTIMER_INTENA]= 1), the OSTIMER will generate interrupt when the central 64-bit EVTimer and the value programmed in MATCH_L and MATCH_H matches.

No interrupt generates if the interrupt request is disabled (i.e., OSEVENT_CTRL[OSTIMER_INTENA]= 0).

63.4 External signals

This module has no external signals.

63.5 Initialization

Perform this procedure to initialize OSTIMER:

1. Enable the OSTIMER clock. This enables the register interface and the peripheral function clock.
2. Select a clock source for OSTIMER.
3. Clear the OSTIMER peripheral reset.
4. Enable the interrupt that OSTIMER provides to the interrupt controller (set OSEVENT_CTRL[OSTIMER_INTRFLAG]= 1). This allows the chip to wake up from Deep Sleep mode. You can connect this interrupt to DSP alternatively.

63.6 Memory map and register definition

This section includes the module's memory map and detailed descriptions of all registers.

63.6.1 OSTIMER register descriptions

63.6.1.1 OSTIMER memory map

OSTIMER_CPU0 base address: 4020_7000h

Offset	Register	Width (In bits)	Access	Reset value
0h	EVTIMER Low (EVTIMERL)	32	R	0000_0000h
4h	EVTIMER High (EVTIMERH)	32	R	0000_0000h
8h	Local Capture Low for CPU (CAPTURE_L)	32	R	0000_0000h
Ch	Local Capture High for CPU (CAPTURE_H)	32	R	0000_0000h
10h	Local Match Low for CPU (MATCH_L)	32	RW	FFFF_FFFFh
14h	Local Match High for CPU (MATCH_H)	32	RW	FFFF_FFFFh
1Ch	OSTIMER Control for CPU (OSEVENT_CTRL)	32	RW	0000_0008h

63.6.1.2 EVTIMER Low (EVTIMERL)

Offset

Register	Offset
EVTIMERL	0h

Function

Contains the immediate value of the central EVTimer. This is a Gray encoded counter register that is not synchronized with the bus clock.

Because two 32-bit reads are required to retrieve the entire counter value, it is possible for the counter to roll over between the reads of EVTIMERL and EVTIMERH. Gray encoding ensures that even if this roll over occurs, the value read represents either the counter value immediately preceding or immediately following the rollover, if the bus clock rate is at least twice the module's clock rate (nominally 1 MHz), or if the bus is clocked by the same 1 MHz LP oscillator that provides the clock to the module.

R	EVTIMER_COUNT_VALUE															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 EVTIMER_COUNT_VALUE	EVTimer Count Value Specifies the current value of the lower 32 bits of the central 64-bit EVTimer when you read this register. **NOTE** Only one physical EVTimer exists and is readable from all domains.

63.6.1.3 EVTIMER High (EVTIMERH)

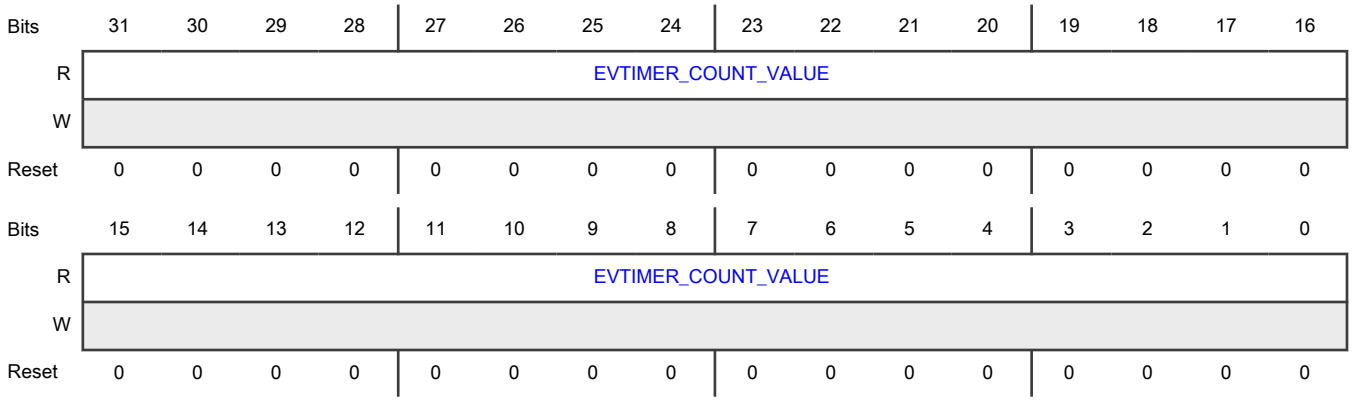
Offset

Register	Offset
EVTIMERH	4h

Function

Contains the higher value of the central EVTimer.

Diagram



Fields

Field	Function
31-0 EVTIMER_COUNT_VALUE	EVTimer Count Value Specifies the current value of the upper 32 bits of the central 64-bit EVTimer when you read this register. **NOTE** Only one physical EVTimer exists and is readable from all domains.

63.6.1.4 Local Capture Low for CPU (CAPTURE_L)

Offset

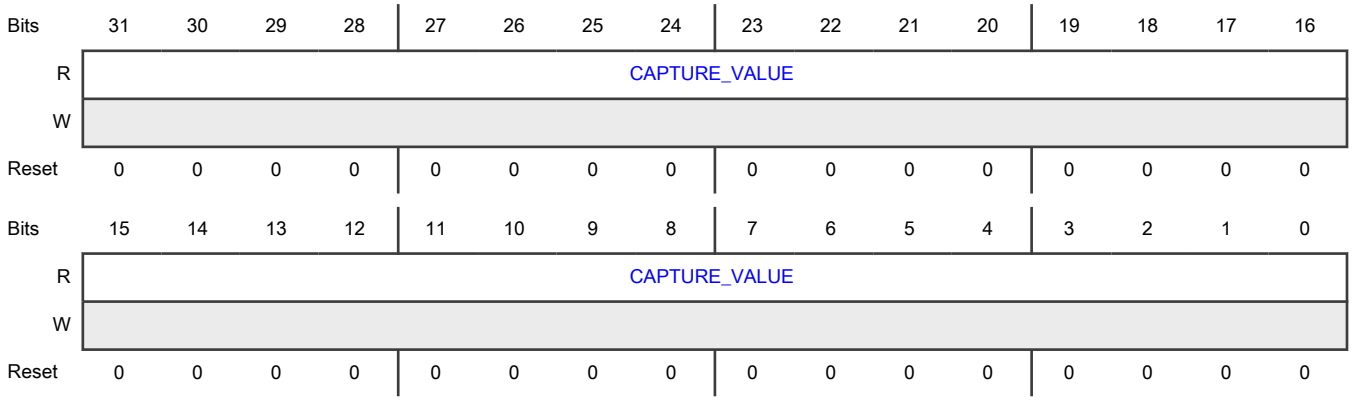
Register	Offset
CAPTURE_L	8h

Function

Contains the value of the central EVTimer when captured by the CPU. This register is Gray encoded to match EVTimer. A load is triggered by a load signal from the CPU (for example, an "arm_txev" pulse from the Cortex-M33 core CPU or a "tie_expstate" pulse from DSP). You must not execute a new capture command between reading CAPTURE_L and CAPTURE_H, to avoid retrieving incoherent results.

For the instance associated with the DSP CPU: If a read of CAPTURE_L and CAPTURE_H closely follows the command to implement a capture, then you should insert the `#pragma no_reorder` directive in the DSP code (to direct the compiler to not initiate the read operation until the capture command has executed).

Diagram



Fields

Field	Function
31-0 CAPTURE_VALUE	EVTimer Capture Value Specifies the value of the lower 32 bits of the central 64-bit EVTimer when you read this register, at the time that the CPU generated the last capture signal. A separate pair of CAPTURE_L and CAPTURE_H is implemented for each CPU. Each CPU reads its own capture value at the same pair of addresses.

63.6.1.5 Local Capture High for CPU (CAPTURE_H)

Offset

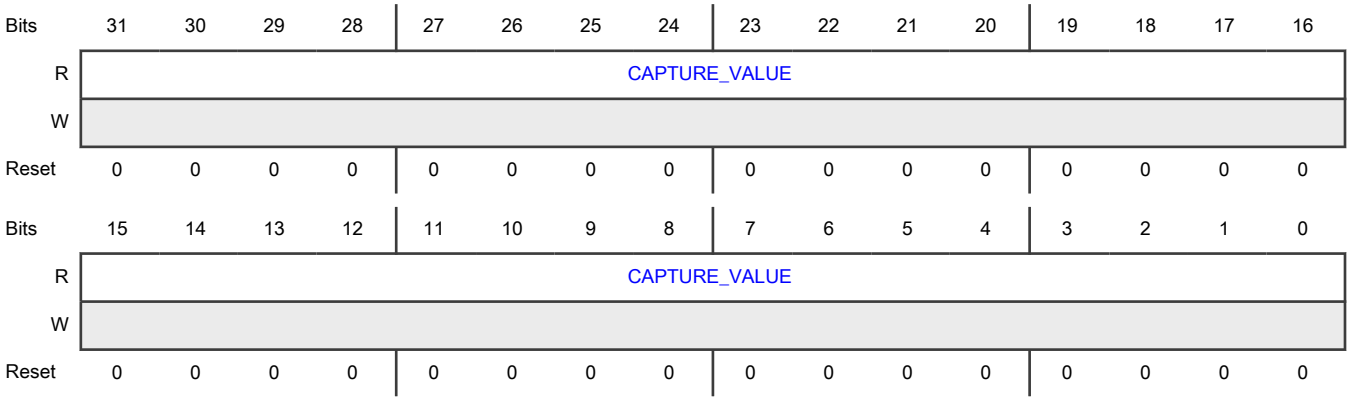
Register	Offset
CAPTURE_H	Ch

Function

Contains the value of the central EVTimer when captured by the CPU. This register is Gray encoded to match EVTimer. A load is triggered by a load signal from the CPU (for example, an "arm_txev" pulse from the Cortex-M33 core CPU or a "tie_expstate" pulse from DSP). You must not execute a new capture command between reading CAPTURE_L and CAPTURE_H, to avoid retrieving incoherent results.

For the instance associated with the DSP CPU: If a read of CAPTURE_L and CAPTURE_H closely follows the command to implement a capture, then you must insert the `#pragma no_reorder` directive in the DSP code (to direct the compiler to not initiate the read operation until the capture command has executed).

Diagram



Fields

Field	Function
31-0 CAPTURE_VALUE	EVTimer Capture Value Specifies the value of the upper 32 bits of the central 64-bit EVTimer when you read this register, at the time that the CPU generated the last capture signal. A separate pair of CAPTURE_L and CAPTURE_H is implemented for each CPU reading its own capture value at the same pair of addresses.

63.6.1.6 Local Match Low for CPU (MATCH_L)

Offset

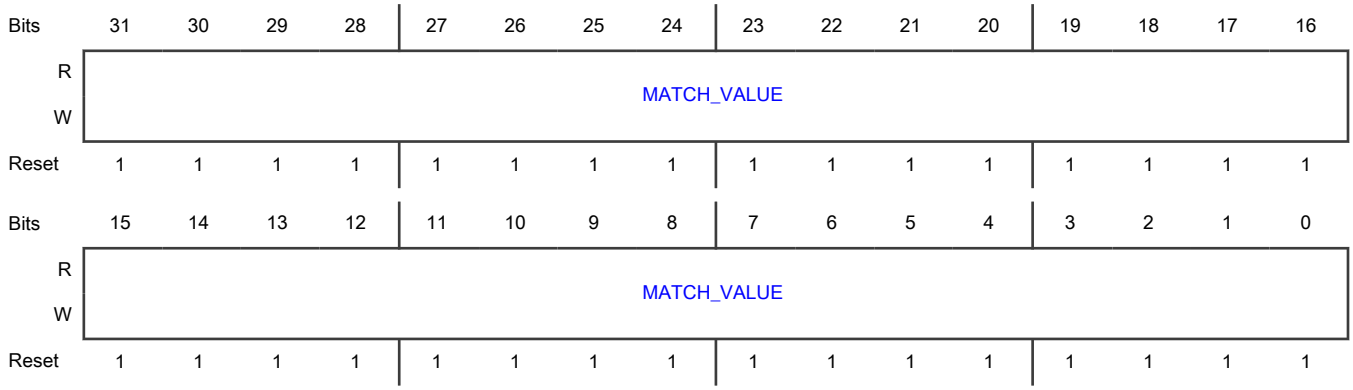
Register	Offset
MATCH_L	10h

Function

Compares the match value with the central EVTimer value. This register is Gray encoded to match EVTimer. The value in this pair of registers is stable, so there is no need for multiple reads. When writing to the match register pair, you must write to MATCH_L first, followed by the write to MATCH_H.

You must not initiate a second write to the match register pair until the first write is complete (which is a minimum of three bus clocks followed by a write to MATCH_H). OSEVENT_CTRL[MATCH_WR_RDY] indicates when it is safe to reload the match registers. You do not need to read OSEVENT_CTRL[MATCH_WR_RDY] if an interrupt has already occurred because of the previous match value, or the required time period has elapsed.

Diagram



Fields

Field	Function
31-0 MATCH_VALUE	EVTimer Match Value Compares the value (lower 32 bits) of the MATCH_L and MATCH_H register pair with the central EVTimer value. If both the values match, the CPU generates an interrupt request if the interrupt is enabled. A separate pair of MATCH_L and MATCH_H is implemented for each CPU reading its own local value at the same pair of addresses.

63.6.1.7 Local Match High for CPU (MATCH_H)

Offset

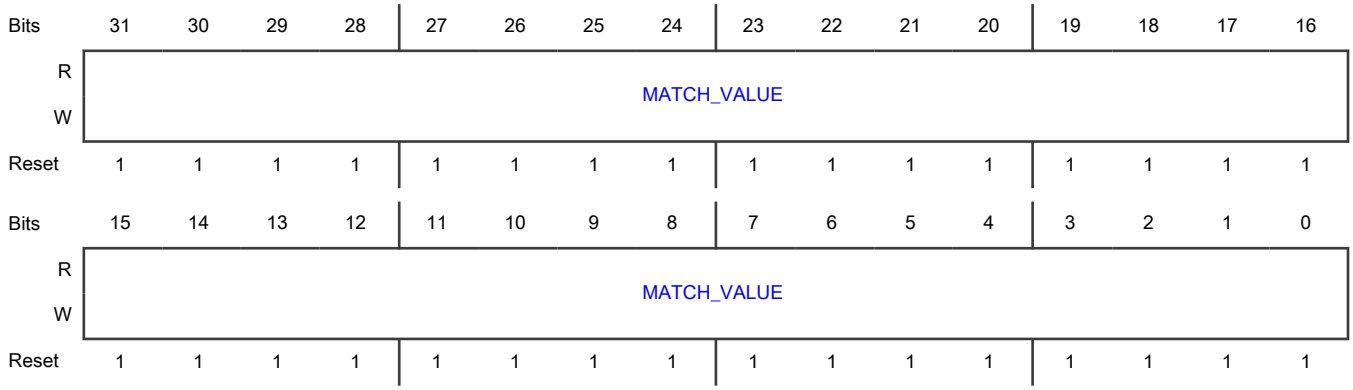
Register	Offset
MATCH_H	14h

Function

Compares the match value with the central EVTimer value. This register is Gray encoded to match EVTimer. The value in this pair of registers is stable, so there is no need for multiple reads. When writing to the match register pair, you must write to MATCH_L first, followed by the write to MATCH_H.

You must not initiate a second write to the match register pair until the first write is complete (which is a minimum of three bus clocks followed by a write to MATCH_H). OSEVENT_CTRL[MATCH_WR_RDY] indicates when it is safe to reload the match registers. You do not need to read OSEVENT_CTRL[MATCH_WR_RDY] if an interrupt has already occurred because of the previous match value, or the required time period has elapsed.

Diagram



Fields

Field	Function
31-0 MATCH_VALUE	EVTimer Match Value Compares the value (upper 32 bits) of the MATCH_L and MATCH_H register pair with the central EVTimer value. If both the values match, the CPU generates an interrupt request if the interrupt is enabled. A separate pair of MATCH_L and MATCH_H is implemented for each CPU reading its own local value at the same pair of addresses.

63.6.1.8 OSTIMER Control for CPU (OSEVENT_CTRL)

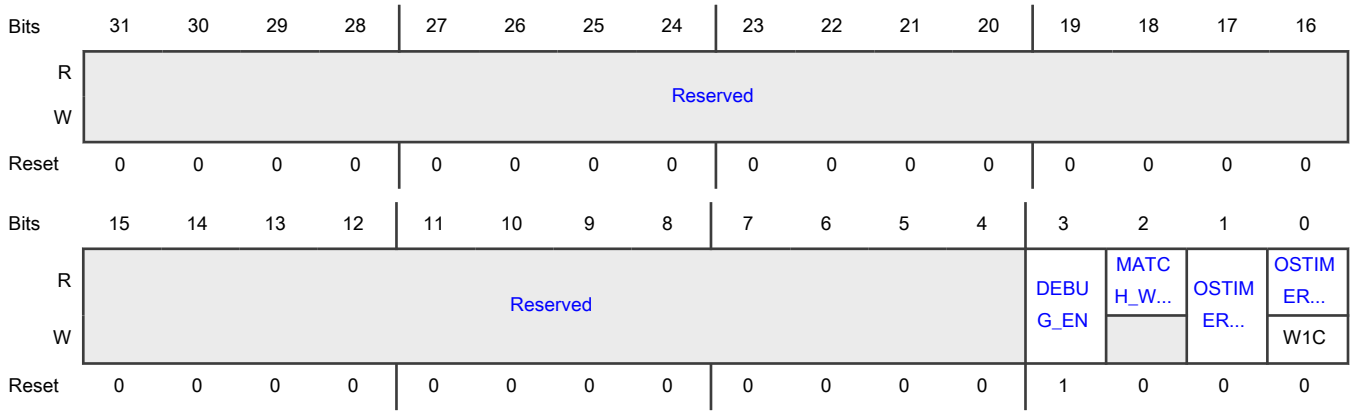
Offset

Register	Offset
OSEVENT_CTRL	1Ch

Function

Provides the interrupt flag and interrupt enable signals for each CPU. A separate OSEVENT_CTRL register is implemented for each CPU. Each CPU reads its own local value at the same address.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 DEBUG_EN	Debug Enable Enables OSTIMER to operate when the chip is in Debug mode. 0b - Disables 1b - Enables
2 MATCH_WR_RDY	EVTimer Match Write Ready Specifies that when this field is low, it is safe to reload (write) to the match registers. In typical applications, it is not necessary to read this field. The 64-bit match register value is transferred from a pair of shadow registers to the active match registers after you write to MATCH_H. You must not initiate a second write to MATCH_L and MATCH_H until after this transfer completes. This field becomes 0 after the transfer completes. It is not necessary to read this status field, if an interrupt has already occurred because of the first match value, or if it is certain (via some other means) that the required period of time (3 bus clocks) has elapsed.
1 OSTIMER_INTENA	Interrupt or Wake-Up Request This bit is to enable/disable interrupt request. If the value is 1, then this field asserts an interrupt or wake-up request to the domain processor. Otherwise, the interrupt or wake-up requests are blocked. 0b - Interrupts blocked 1b - Interrupts enabled
0 OSTIMER_INTRFLAG	Interrupt Flag Sets an interrupt flag when a match occurs between the central 64-bit EVTimer and the value programmed in the MATCH_L and MATCH_H register pair for the associated CPU. Writes to clear this field are asynchronous. You must write 1 to this field before writing a new match value into MATCH_L and MATCH_H.

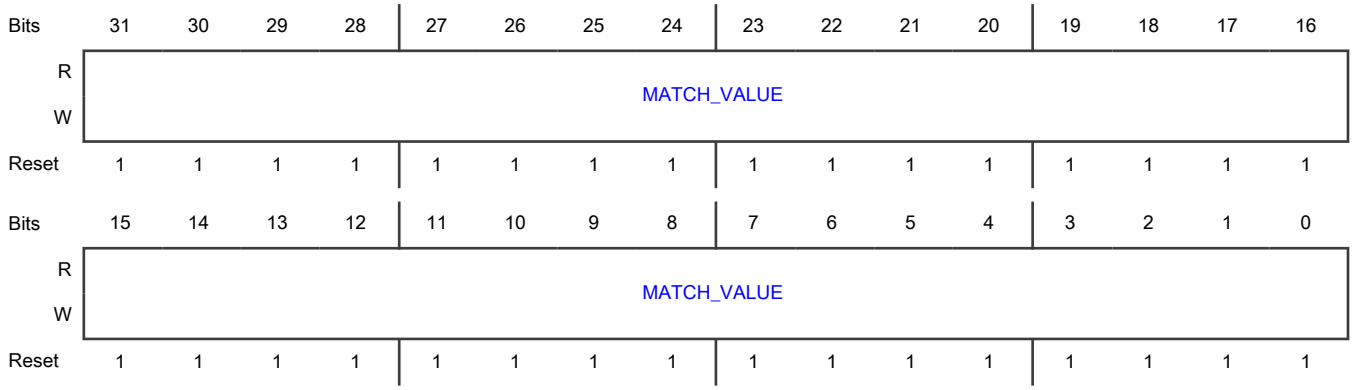
When writing to the match register pair, you must write to MATCH_L first, followed by the write to MATCH_H.

You must not initiate a second write to the match register pair until the first write is complete (which is a minimum of three bus clocks followed by a write to MATCH_H). OSEVENT_CTRL[MATCH_WR_RDY] indicates when it is safe to reload the match registers. You do not need to read OSEVENT_CTRL[MATCH_WR_RDY] if an interrupt has already occurred because of the previous match value, or the required time period has elapsed.

Diagram



Fields

Field	Function
31-0 MATCH_VALUE	EVTimer Match Value Compares the value (upper 32 bits) of the MATCH_L and MATCH_H register pair with the central EVTimer value. If both the values match, the CPU generates an interrupt request if the interrupt is enabled. A separate pair of MATCH_L and MATCH_H is implemented for each CPU reading its own local value at the same pair of addresses.

63.6.3.8 OSTIMER Control for CPU (OSEVENT_CTRL)

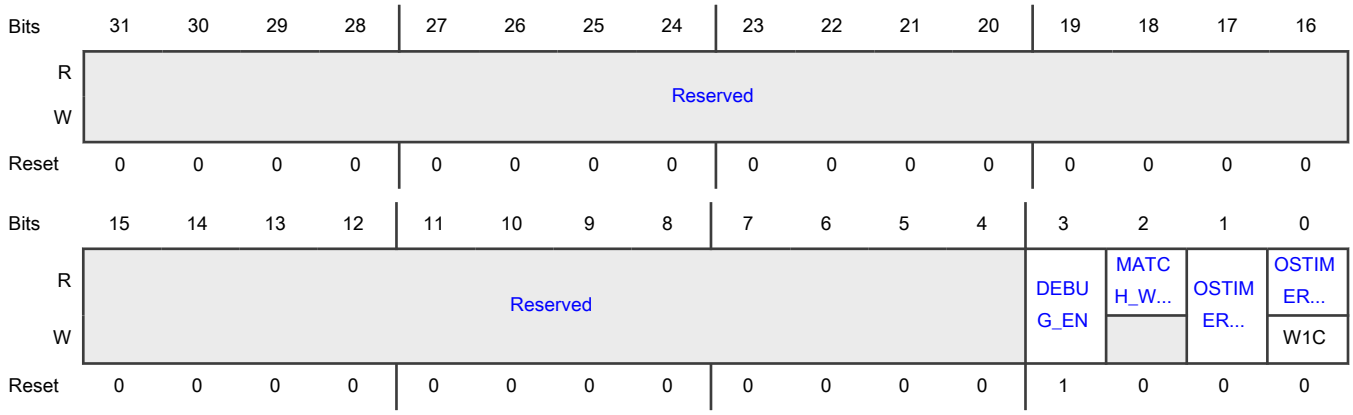
Offset

Register	Offset
OSEVENT_CTRL	1Ch

Function

Provides the interrupt flag and interrupt enable signals for each CPU. A separate OSEVENT_CTRL register is implemented for each CPU. Each CPU reads its own local value at the same address.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 DEBUG_EN	Debug Enable Enables OSTIMER to operate when the chip is in Debug mode. 0b - Disables 1b - Enables
2 MATCH_WR_RDY	EVTimer Match Write Ready Specifies that when this field is low, it is safe to reload (write) to the match registers. In typical applications, it is not necessary to read this field. The 64-bit match register value is transferred from a pair of shadow registers to the active match registers after you write to MATCH_H. You must not initiate a second write to MATCH_L and MATCH_H until after this transfer completes. This field becomes 0 after the transfer completes. It is not necessary to read this status field, if an interrupt has already occurred because of the first match value, or if it is certain (via some other means) that the required period of time (3 bus clocks) has elapsed.
1 OSTIMER_INTENA	Interrupt or Wake-Up Request This bit is to enable/disable interrupt request. If the value is 1, then this field asserts an interrupt or wake-up request to the domain processor. Otherwise, the interrupt or wake-up requests are blocked. 0b - Interrupts blocked 1b - Interrupts enabled
0 OSTIMER_INTRFLAG	Interrupt Flag Sets an interrupt flag when a match occurs between the central 64-bit EVTimer and the value programmed in the MATCH_L and MATCH_H register pair for the associated CPU. Writes to clear this field are asynchronous. You must write 1 to this field before writing a new match value into MATCH_L and MATCH_H.

63.6.4.2 EVTIMER Low (EVTIMERL)

Offset

Register	Offset
EVTIMERL	0h

Function

Contains the immediate value of the central EVTimer. This is a Gray encoded counter register that is not synchronized with the bus clock.

Because two 32-bit reads are required to retrieve the entire counter value, it is possible for the counter to roll over between the reads of EVTIMERL and EVTIMERH. Gray encoding ensures that even if this roll over occurs, the value read represents either the counter value immediately preceding or immediately following the rollover, if the bus clock rate is at least twice the module's clock rate (nominally 1 MHz), or if the bus is clocked by the same 1 MHz LP oscillator that provides the clock to the module.

63.6.4.4 Local Capture Low for CPU (CAPTURE_L)

Offset

Register	Offset
CAPTURE_L	8h

Function

Contains the value of the central EVTimer when captured by the CPU. This register is Gray encoded to match EVTimer. A load is triggered by a load signal from the CPU (for example, an "arm_txev" pulse from the Cortex-M33 core CPU or a "tie_expstate" pulse from DSP). You must not execute a new capture command between reading CAPTURE_L and CAPTURE_H, to avoid retrieving incoherent results.

For the instance associated with the DSP CPU: If a read of CAPTURE_L and CAPTURE_H closely follows the command to implement a capture, then you should insert the `#pragma no_reorder` directive in the DSP code (to direct the compiler to not initiate the read operation until the capture command has executed).

63.6.4.6 Local Match Low for CPU (MATCH_L)

Offset

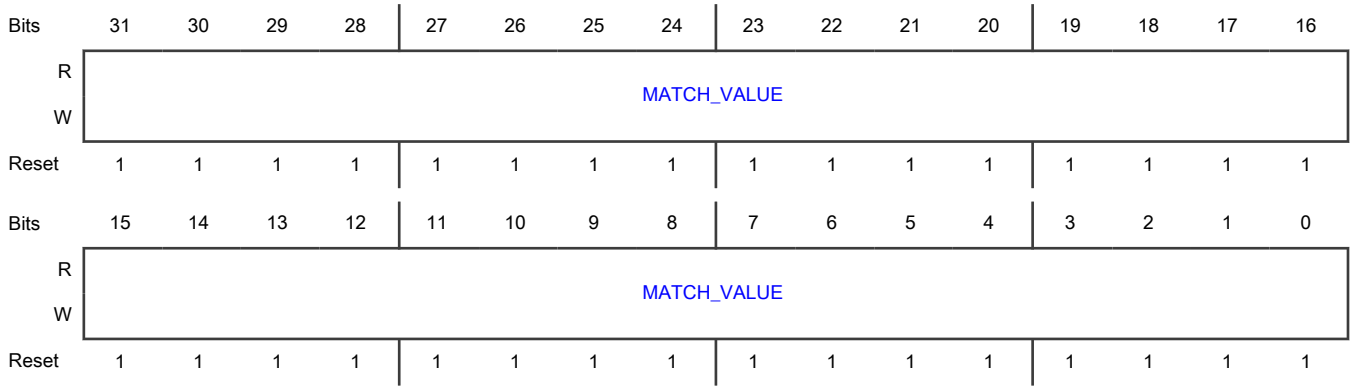
Register	Offset
MATCH_L	10h

Function

Compares the match value with the central EVTimer value. This register is Gray encoded to match EVTimer. The value in this pair of registers is stable, so there is no need for multiple reads. When writing to the match register pair, you must write to MATCH_L first, followed by the write to MATCH_H.

You must not initiate a second write to the match register pair until the first write is complete (which is a minimum of three bus clocks followed by a write to MATCH_H). OSEVENT_CTRL[MATCH_WR_RDY] indicates when it is safe to reload the match registers. You do not need to read OSEVENT_CTRL[MATCH_WR_RDY] if an interrupt has already occurred because of the previous match value, or the required time period has elapsed.

Diagram



Fields

Field	Function
31-0 MATCH_VALUE	EVTimer Match Value Compares the value (lower 32 bits) of the MATCH_L and MATCH_H register pair with the central EVTimer value. If both the values match, the CPU generates an interrupt request if the interrupt is enabled. A separate pair of MATCH_L and MATCH_H is implemented for each CPU reading its own local value at the same pair of addresses.

63.6.4.7 Local Match High for CPU (MATCH_H)

Offset

Register	Offset
MATCH_H	14h

Function

Compares the match value with the central EVTimer value. This register is Gray encoded to match EVTimer. The value in this pair of registers is stable, so there is no need for multiple reads. When writing to the match register pair, you must write to MATCH_L first, followed by the write to MATCH_H.

You must not initiate a second write to the match register pair until the first write is complete (which is a minimum of three bus clocks followed by a write to MATCH_H). OSEVENT_CTRL[MATCH_WR_RDY] indicates when it is safe to reload the match registers. You do not need to read OSEVENT_CTRL[MATCH_WR_RDY] if an interrupt has already occurred because of the previous match value, or the required time period has elapsed.

Input 7	clk_and_reset_pllclk (SCT_FCLK).

64.2 Overview

SCT is a powerful, flexible timer module capable of creating complex PWM waveforms and performing other advanced timing and control operations with minimal or no CPU intervention. It can operate as a single 32-bit counter or as two independent, 16-bit counters in Unidirectional or Bidirectional modes.

As with most timers, SCT supports:

- A selection of match registers against which you can compare the count value.
- Capture registers where you can record the current count value if a predefined condition is detected.

An additional feature contributing to the versatility of SCT is the concept of events. This module supports multiple separate events that you can define based on some combination of parameters, including all or some of the following:

- A match on one of the match registers
- A transition on one of the SCT inputs or outputs
- The direction of count

Every action that SCT performs occurs in direct response to the events that you define, without any software overhead. You can enable an event to:

- Start, stop, or halt the counter.
- Limit the counter, which refers to clearing the counter in Unidirectional mode, or changing the counter direction in Bidirectional mode.
- Set, clear, or toggle any SCT output.
- Force a capture of the count value into any of the capture registers.
- Generate an interrupt or DMA request.

SCT also allows you to group and filter events. A group of enabled and disabled events can be described as a state, and several states with different sets of enabled and disabled events are allowed. Changing from one state to another is event-driven and can therefore happen without your intervention. By defining these states, SCT provides the means to run state machines in hardware to accomplish complex waveform and timing tasks.

In a simple system such as a classical timer or counter with capture and match capabilities, all events that could cause the timer to capture the timer value or toggle a match output are enabled, and remain enabled, at all times while the counter is running. In this case, no events are filtered and the state that does not change describes the system. This is the default configuration for SCT.

In a more complex system, two states could be set up that allow some events in one state and not in the other. You can use an event that is enabled in both states to move from one state to the other and back while filtering out events in either of the states. In such a two-state system, you can create different waveforms at the SCT output, depending on the event history. Change of states is event-driven and happens without any CPU intervention.

Formally, you can program SCT as a state machine generator. With the unique ability to perform switching between groups of events, you can use SCT as a highly complex state machine engine. Events identify the occurrence of conditions that warrant state

changes and determine the next state to move to. This provides you with an extremely powerful control tool—particularly when SCT inputs and outputs are connected to other on-chip resources.

In addition to events and states, SCT provides other enhanced features:

- Four alternative clocking modes including a fully asynchronous mode
- Selection of any SCT input as a clock source or a clock gate
- Ability to define a fractional portion to certain match registers (fractional matching uses a “dither” approach to achieve average resolutions of up to 1/16th of a clock period when generating PWM edges)
- Ability to select a greater-than-or-equal-to match condition for the purpose of event generation

NOTE

In this chapter, the term "bus error" indicates an SCT response that makes the processor take an exception.

64.2.1 Block diagram

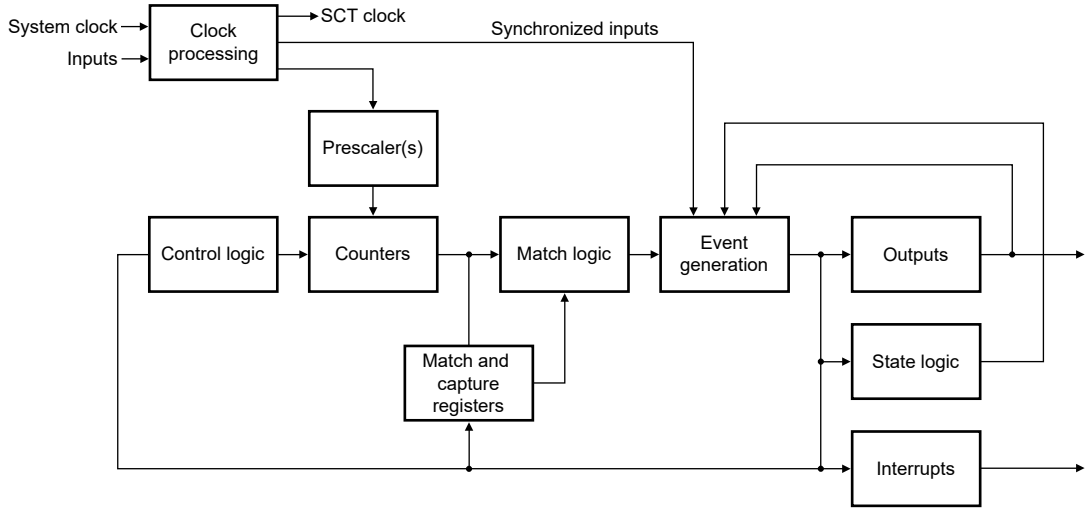

Figure 263. Block diagram

64.2.2 Features

SCT supports:

- 8 inputs
- 10 outputs
- 16 match and capture registers
- 16 events
- 32 states
- 6 dithers

Counter or timer features:

- Configurable as two 16-bit counters or one 32-bit counter (this configuration is possible for each SCT)
- Counters clocked by the system clock or a selected input
- Configurable as up counters or up-down counters
- Configurable number of match and capture registers

- Ability for the counter value to be loaded into capture registers, triggered by a match or I/O toggle
- Event creation possible for the following timer events for match and/or I/O transitions:
  - DMA request
  - Interrupt
  - Stop
  - Limit
  - Halt
  - Change counting direction
  - Toggle outputs
  - Change the state

PWM features:

- Ability to use counters with match registers to toggle outputs and create time-proportioned PWM signals (PWM waveforms can change based on the current state)
- Up to eight single-edge or four dual-edge PWM outputs with an independent duty cycle and a common PWM cycle length

Event creation features:

- Ability to enable events in Bidirectional mode, based on the count direction (the following conditions define an event):
  - A counter match condition
  - An input (or output) condition such as a rising or falling edge or level
  - A combination of match and/or I/O conditions
- Ability for selected events to limit, halt, start, or stop a counter or change direction
- Ability for events to trigger state changes, output transitions, timer captures, interrupts, and DMA transactions
- Ability to use match register 0 as an automatic limit
- Ability to hold match events until another qualifying event occurs

State control features:

- No pre-defined meaning (you determine these states entirely)
- Provision for a mechanism of context switching for SCT, including creation of complex state machines
- Defined by events that can happen in the state while the counter is running
- Ability to transition into another state as a result of an event
- Ability to be assigned to one or more states
- Ability for state variables to allow sequencing across multiple counter cycles

64.3 Functional description

64.3.1 SCT operation

In its simplest, single-state configuration, SCT operates as an event-controlled single or bidirectional counter. You can configure events as:

- Counter match events
- An input or output level
- Transitions on an input or output pin

- Combination of match and I/O behavior

In response to an event, SCT output (or outputs) can transition, or SCT can perform other actions such as creating an interrupt, and starting, stopping, or resetting the counter. You can perform multiple, simultaneous actions for each event. Furthermore, any number of events can trigger a specific SCT action.

A single or multiple SCT actions uniquely define an event. Events that you enable to trigger an SCT action or actions at any stage of the counter define a state, and the events not selected for this state are ignored.

In a multi-state configuration, states change in response to events. A state change is an additional action that SCT can perform when an event occurs. If you configure an event to change the state, the new state defines a new set of events resulting in different SCT actions. Through multiple cycles of the counter, events can change the state multiple times and thus create a large variety of event-controlled transitions on the SCT outputs and/or interrupts.

After configuration, SCT can run continuously, without your intervention, and can generate multiple output patterns entirely under the control of events. See the following sections to perform various SCT actions:

- Configuring SCT for multiple events and states to configure SCT
- Running SCT to start, run, and stop SCT
- Configuring SCT without using states to configure SCT as a simple, event-controlled counter or timer

64.3.2 Configuring SCT without using states

SCT can function as a standard counter or timer with external capture inputs and match outputs, without using the state logic. To use SCT without states, configure SCT as follows:

1. Write 0 to State Variable (STATE) (0 is the default).
2. Write 0 to EV*n*_CTRL[STATELD] and EV*n*_CTRL[STATEV] for each event.
3. Write 0x1 to EV*n*_STATE[STATEMSKn] for each event. This enables the event.

In effect, the event occurs in a single state that never changes when the counter is running.

64.3.3 Configuring SCT for multiple events and states

64.3.3.1 Configure the counter

1. Configure the low (L) and high (H) counters in SCT Configuration (CONFIG) by selecting two independent 16-bit counters (L and H) or one combined 32-bit counter in CONFIG[UNIFY].
2. Select the SCT clock source by using CONFIG[CLKMODE] and CONFIG[CKSEL] from any of the inputs or an internal clock.

64.3.3.2 Configure the match and capture registers

1. Select the number of match and capture registers that the application uses (not more than what is available on this chip), by using Match and Capture Register Mode (REGMODE). For each of the match and capture register pairs, you can select whether the register is used as a match register or capture register.
2. Define match conditions for each selected match register:
   - Each match register (Match Value (MATCH0 - MATCH15)) sets one match value, if a 32-bit counter is used, or two match values, if the L and H 16-bit counters are used.
   - Each match reload register (Match Reload Value (MATCHREL0 - MATCHREL15)) sets a reload value that is loaded into the match register when the counter reaches a limit condition or the value 0.

64.3.3.3 Configure events and event responses

State variables allow SCT control across more than one cycle of the counter. Counter matches, I/O edges, and state values are combined into a set of general-purpose events that can switch outputs, request interrupts, and change state values (see Figure 264). Perform this procedure to configure events and event responses:

1. Define what triggers each event, by using Event n Control (EV0_CTRL - EV15_CTRL) (one register per event):
   - Using EV*n*_CTRL[COMBMODE], select whether the event occurs:
     - On change of an input or output
     - On an input or output level
     - On a match condition of the counter
     - On a combination of match and I/O conditions
   - For a match condition:
     a. Select the match register that contains the match condition for the event to occur. Enter the number of the selected match register in EV*n*_CTRL[MATCHSEL].
     b. Define, by using EV*n*_CTRL[HEVENT], whether the event occurs on matching the L or the H counter (when using L and H counters).
   - For an SCT input or output level or transition:
     a. Select the input number or the output number that is associated with this event, using EV*n*_CTRL[IOSEL] and EV*n*_CTRL[OUTSEL].
     b. Define how the selected input or output triggers the event (edge- or level-sensitive) using EV*n*_CTRL[IOCOND].
2. Define the effect of each event on SCT outputs, by using Output n Set (OUT0_SET - OUT9_SET) or Output n Clear (OUT0_CLR - OUT9_CLR) (up to the maximum number of outputs on this chip, one register per output): For each SCT output, select the events that set or clear this output. More than one event can change the output, and each event can change multiple outputs.
3. Define how each event affects the counter:
   a. Write 1 to the corresponding LIMIT[LIMMSK_H] or LIMIT[LIMMSK_L] for the event to set an upper limit for the counter:
      - When a limit event occurs in Unidirectional mode, the counter is cleared to zero and begins counting up on the next clock edge.
      - When a limit event occurs in Bidirectional mode, the counter begins to count down from the current value on the next clock edge.
   b. Write 1 to the corresponding HALT[HALTMSK_H] or HALT[HALTMSK_L] for the event to halt the counter. If the counter is halted, it stops counting, and no new events can occur. You can restore the counter operation by writing 0 CTRL[HALT_H] and/or CTRL[HALT_L].
   c. Write 1 to the corresponding STOP[STOPMSK_H] or STOP[STOPMSK_L] for the event to stop the counter. If the counter is stopped, it stops counting. However, if you configure an event as a transition on an I/O, it can restart the counter.
   d. Write 1 to the corresponding START[STARTMSK_H] or START[STARTMSK_L] for the event to restart the counting. Only events that are defined by an input changing can be used to restart the counter.
4. Define the events that contribute to the SCT interrupt: write 1 to the corresponding EVEN[IEN*n*] and EVFLAG[FLAG*n*] to enable the event to contribute to the SCT interrupt.

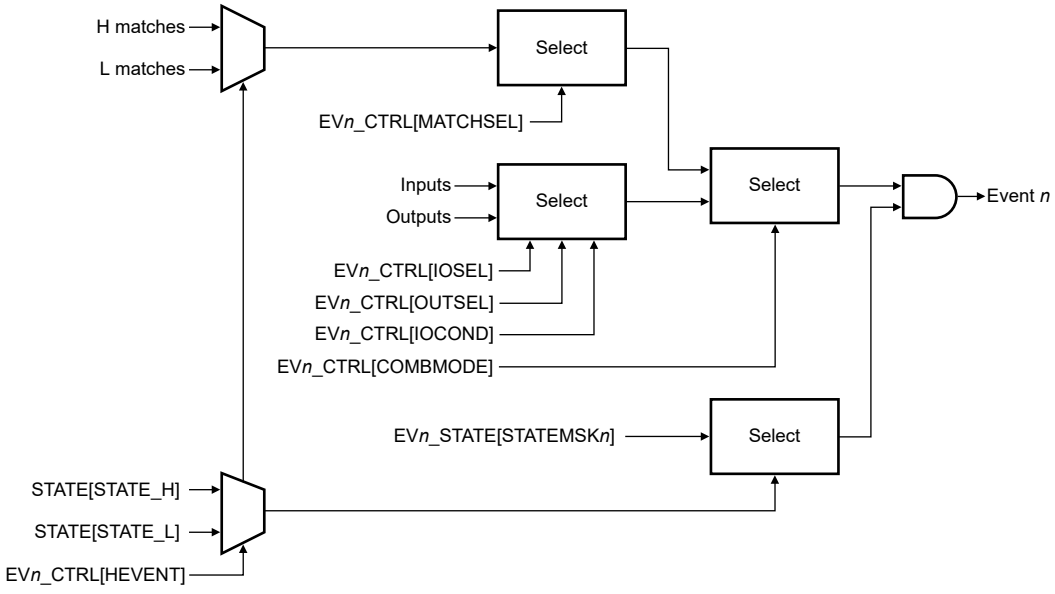

Figure 264. Event selection

64.3.3.4 Configure multiple states

1. Select the state or states (up to two), by using Event n State (EV0_STATE - EV15_STATE), for each event (up to the maximum number of events on this chip—one register per event), in which this event is allowed to occur. You can select each state for more than one event.
2. Determine how the event affects the system state: using Event n Control (EV0_CTRL - EV15_CTRL) (up to the maximum number of events on this chip—one register per event), set the new state value in EV*n*_CTRL[STATEV] for this event. If the event is the highest numbered in the current state, this value is either added to the existing state value or replaces it, depending on the configuration of EV*n*_CTRL[STATELD].

NOTE

If EV*n*_CTRL[STATEV] and EV*n*_CTRL[STATELD] are 0, the state does not change. If there are higher numbered events in the current state, this event cannot change the state.

64.3.3.5 Miscellaneous options

SCT includes a certain (selectable) number of capture registers that you can program to capture the counter contents when one or more events occur.

If the counter is in Bidirectional mode, you can configure Output Counter Direction Control (OUTPUTDIRCTRL) to determine the effect of setting and clearing of an output, based on whether the counter is counting up or down.

64.3.4 State logic

You can configure SCT as a timer or counter with multiple programmable states, which you can define through the events that can be captured in each particular state. A multi-state SCT can change from one state to another when an event that you define triggers a state change through each event's Event n Control (EV0_CTRL - EV15_CTRL) in one of the following ways:

- The event can increment the current state number by a new value.
- The event can write a new state value.

If an event increments the state number beyond the number of available states, SCT enters a locked state where all further events are ignored while the counter is still running. Software must interfere to change out of this state.

Software can capture the counter value (and potentially create an interrupt and write to all outputs) when an event that moves SCT into a locked state occurs. Later, when SCT is in the locked state, software can read the counter again to record the time passed since the locking event and can also read the state variable to obtain the current state number.

If SCT registers an event that forces an abort, putting SCT in a locked state can be a safe way to record the time that has passed since the abort event when no new events are allowed to occur. Because multiple states (any state number between the maximum implemented state and 31) are locked states, you can define multiple abort or error events, each incrementing the state number by a different value.

NOTE

When the implemented state is 32, which is equal to the maximum state number supported, there is no locked state available. In this case, ignore the locked state related description.

64.3.5 Clearing the prescaler

When enabled by a nonzero CTRL[PRE_L] and/or CTRL[PRE_H], the prescaler acts as a clock divider for the counter, like a fractional part of the counter value. The prescaler is cleared whenever the counter is cleared or loaded for any of the following reasons:

- Hardware reset
- When you write to Counter Value (COUNT)
- When you write 1 to CTRL[CLRCTR]
- An event selected by a 1 in the counter limit register when CTRL[BIDIR] = 0

When CTRL[BIDIR] = 0, a limit event caused by an I/O signal can clear a nonzero prescaler. However, a limit event caused by a match clears only a nonzero prescaler in a special case, as described in Match vs. I/O events.

A limit event, when CTRL[BIDIR] = 1, does not clear the prescaler. Instead, it writes 0 to CTRL[DOWN] and decrements the counter on the same clock if the counter is enabled in that clock.

64.3.6 Match vs. I/O events

The prescaler and clock mode 01 make the counter operation complex, in which the SCT clock is the bus clock. However, you can enable the prescaler and counter to count only when a selected edge is detected on a clock input:

- The prescaler is enabled when the clock mode is not 01, or when the input edge that CONFIG[CKSEL] selects is detected.
- The counter is enabled when the prescaler is enabled, and (PRELIM = 0 or the prescaler is equal to the value of PRELIM).

An I/O component of an event can occur in any SCT clock when its counter, CTRL[HALT], is 0. In general, a match component of an event can only occur in an SCT clock when its counter fields, CTRL[HALT] and CTRL[STOP], are both 0 and the counter is enabled.

The following table shows the conditions when various kinds of events can occur.

Table 601. Event conditions

EV*n*_CTRL[COMBMODE]	EV*n*_CTRL[IOCOND]	Event can occur on clock:
I/O	Any	Whenever CTRL[HALT] = 0.
MATCH	Any	When CTRL[HALT] = 0, CTRL[STOP] = 0, and the counter is enabled.
OR	Any	• From the I/O component, whenever CTRL[HALT] = 0.

Table continues on the next page...

Table 601. Event conditions (continued)

EV*n*_CTRL[COMBMODE]	EV*n*_CTRL[IOCOND]	Event can occur on clock:
		• From the match component, when CTRL[HALT] = 0, CTRL[STOP] = 0, and the counter is enabled.
AND	Low or High	When CTRL[HALT] = 0, CTRL[STOP] = 0, and the counter is enabled.
AND	Rise or Fall	Whenever CTRL[HALT] = 0.

64.3.7 Fractional matches

You can configure the first six match registers from Match Value (MATCH0 - MATCH15) to have a fractional portion to their match values. A higher average resolution is achievable on these registers, with an associated Fractional Match (FRACMAT0 - FRACMAT5), by using a dithering mechanism. The dither engine delays the assertion of a match by one counter clock every *n* (0 to 15) out of 16 counter cycles. The value of *n* is specified in Fractional Match (FRACMAT0 - FRACMAT5), associated with each of the first six match registers.

You can disable dithering on any of the match registers by loading all zeroes (the default value) into its corresponding Fractional Match (FRACMAT0 - FRACMAT5).

64.3.7.1 Dithering

At the start of each new SCT counter cycle (that is, when the counter counts down to zero in Bidirectional mode or is cleared to zero by a limit event), the dither engine determines which matches are to be delayed by one clock during the upcoming counter cycle. Delaying the match effectively adds 1 to the designated match value when up-counting or subtracts 1 when down-counting, during that particular counter cycle.

For each dither-enabled match register, the value that you program in its associated Fractional Match (FRACMAT0 - FRACMAT5) specifies for how many counter cycles, out of every 16 of them, its match is to be delayed. An algorithm applied to the FRACMAT value distributes this number as evenly as possible across the 16 counter cycles. This results in a unique dither pattern for each match register (see Table 602).

Dither Condition (DITHER) (event-mask register) provides you additional control over the dithering process. Typically, the dither engine advances though the match dither patterns at the start of every new SCT counter cycle. Dither Condition (DITHER) allows you to specify that advancement to the next element in the dither patterns occurs only if one or more designated events have happened during the previous cycle of the counter.

The dither algorithm is designed to spread out the cycles in which the matches are delayed as evenly as possible across the 16 counter cycles. The following table shows the dither pattern that is applied for each value of FRACMAT. "D" indicates the counter cycles where a match on the relevant match register is delayed.

Table 602. Dither pattern

	Counter cycle															
FRACMAT	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
0h	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-

64.4 External signals

SCT inputs can come from numerous places and are selected by the SCT input mux.

SCT outputs can be routed to multiple places and can be connected to both a pin and an ADC trigger at the same time.

Table 603. SCT signals

Signal	I/O	Description
SCT_IN*n*	I	SCT input. Signals come from GPIO sources, each from a variety of pins selected via IOPCTL muxing.
SCT_OUT*n*	O	SCT output. Signals go to IOPCTL muxing where they can be (optionally) output onto a selection of GPIO pins.

64.5 Initialization

To initialize SCT:

1. Enable the clock to SCT.
2. Clear the SCT peripheral reset.
3. Configure the interrupts.
4. Connect the SCT outputs to external pins.
5. Configure the DMA request lines to connect to the DMA trigger inputs.

64.6 Application information

64.6.1 Running SCT

1. Initialize SCT (see Initialization).
2. Write to State Variable (STATE) to define the initial state. By default, the initial state is 0.

3. To start SCT, write to SCT Control (CTRL):
    a. Clear the counters.
    b. Write 0 or 1 to CTRL[STOP_L] and/or CTRL[STOP_H].

    NOTE

    The counter starts counting after CTRL[STOP] becomes 0 as well. If CTRL[STOP] = 1, SCT, instead, waits for an event to occur that you can configure to start the counter.

    c. Select Unidirectional or Bidirectional counting mode (CTRL[BIDIR_L] and/or CTRL[BIDIR_H]) for each counter.
    d. Select the prescale factor for the counter clock (CTRL[PRE_L] or CTRL[PRE_H]).
    e. Write 0 to CTRL[HALT_L] and/or CTRL[HALT_H]. By default, the counters halt and no events can occur.
4. Stop or halt the counters at any time by using CTRL[STOP_L] and/or CTRL[STOP_H], or CTRL[HALT_L] and/or CTRL[HALT_H], respectively.
    - After the counters stop, both you and an event configured to write 0 to CTRL[STOP_L] and/or CTRL[STOP_H] can start the counter again.
    - After the counter halts, only writing 0 to CTRL[HALT_L] and/or CTRL[HALT_H] can start the counter again. No events can occur.
    - After the counters halt, you can set any SCT output as high or low by writing directly to the OUT register.

You can read the current SCT state at any time by using State Variable (STATE).

To change the current state (that is, independently of any event occurring), write 1 to CTRL[HALT] and write to State Variable (STATE) to change the state value. You are allowed to write to State Variable (STATE) only when the counter halts (CTRL[HALT_L] and/or CTRL[HALT_H] = 1) and no events can occur.

64.6.2 SCT configuration example

This section discusses SCT configuration by using an example, showing the simple application of SCT with two sets of match events (EV0/1 and EV3/4) to set and clear SCT output 0. The timer automatically resets whenever it reaches the MAT0 match value.

In the initial state 0, match event EV0 sets output 0 to high and match event EV1 clears output 0.

When monitoring SCT input 0:

- If input 0 is low at the next timer reset (EV2), the state changes to state 1, enabling events EV3 and EV4. This leads to the same output but with different match value triggers.
- If input 0 is high at the next timer reset, the associated event (EV5) causes the state to change back to the state enabling events EV0 and EV1.

Figure 265 uses this SCT configuration:

- One input
- One output
- Five match registers
- Six events, and match 0 used with the autolimit function
- Two states

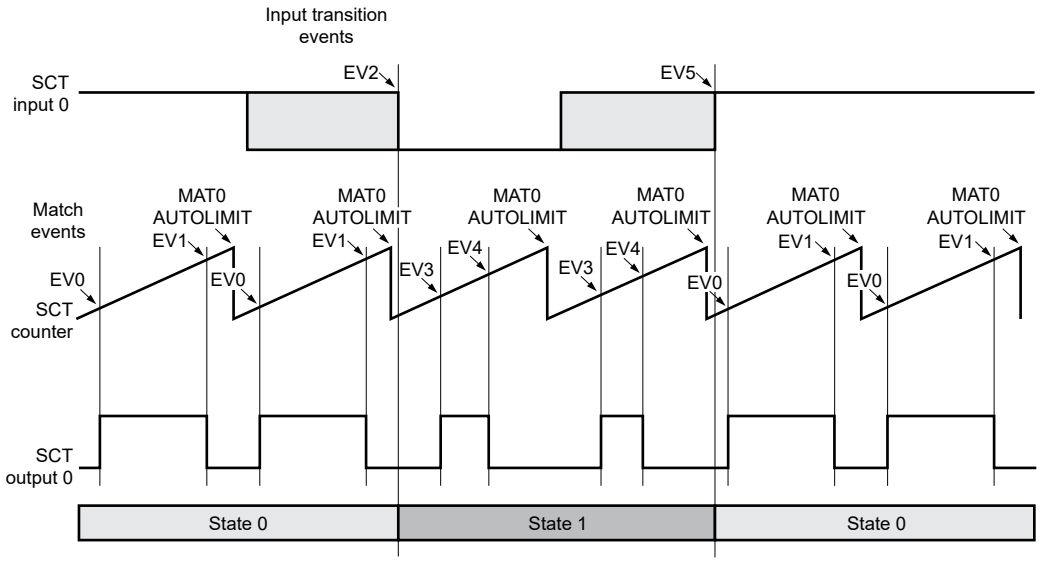

Figure 265. SCT configuration example: pictorial representation

This application of SCT uses the configuration listed in the following table (all register values not listed are their default values):

Table 604. SCT configuration example: settings

Configuration	Register	Setting
Counter	SCT Configuration (CONFIG)	Use a unified counter (CONFIG[UNIFY] = 1).
	SCT Configuration (CONFIG)	Enable the autolimit for MAT0 (CONFIG[AUTOLIMIT_L] = 1).
	SCT Control (CTRL)	Use a unidirectional counter (CTRL[BIDIR_L] = 0).
Clock base	SCT Configuration (CONFIG)	Use the default values for clock configuration.
Match and capture registers	Match and Capture Register Mode (REGMODE)	Configure one match register for each match event by writing 0 to bits 0, 1, 2, 3, and 4 of REGMODE[REGMOD_L*n*].
Define match values	MATCH (0/1/2/3/4)	Set a match value MATCH0/1/2/4_L in each register. The match register 0 serves as an automatic limit event that resets the counter, without using an event. To enable the automatic limit, write 1 to CONFIG[AUTOLIMIT].

Table continues on the next page...

Table 604. SCT configuration example: settings (continued)

Configuration	Register	Setting
Define match reload values	MATCHREL (0/1/2/3/4)	Set a match reload value RELOAD0/1/2/3/4_L in each register (same as the match value in this example).
Define when event 0 occurs	EV0_CTRL	• Set EV*n*_CTRL[COMBMODE] = 0x1. Event 0 uses match condition only. • Set EV*n*_CTRL[MATCHSEL] = 1. Select the match value of match register 1. The match value of MAT1 is associated with event 0.
Define when event 1 occurs	EV1_CTRL	• Set EV*n*_CTRL[COMBMODE] = 0x1. Event 1 uses match condition only. • Set EV*n*_CTRL[MATCHSEL] = 2. Select the match value of match register 2. The match value of MAT2 is associated with event 1.
Define when event 2 occurs	EV2_CTRL	• Set EV*n*_CTRL[COMBMODE] = 0x3. Event 2 uses match condition and I/O condition. • Set EV*n*_CTRL[IOSEL] = 0. Select input 0. • Set EV*n*_CTRL[IOCOND] = 0x0. Input 0 is low. • Set EV*n*_CTRL[MATCHSEL] = 0. This selects match register 0 to qualify the event = 0.
Define how event 2 changes the state	EV2_CTRL	Write 1 to EV*n*_CTRL[STATEV] and EV*n*_CTRL[STATELD]. Event 2 changes the state to state 1.
Define when event 3 occurs	EV3_CTRL	• Set EV*n*_CTRL[COMBMODE] = 0x1. Event 3 uses match condition only. • Set EV*n*_CTRL[MATCHSEL] = 0x3. Select match value of match register 3. The match value of MAT3 is associated with event 3.
Define when event 4 occurs	EV4_CTRL	• Set EV*n*_CTRL[COMBMODE] = 0x1. Event 4 uses match condition only. • Set EV*n*_CTRL[MATCHSEL] = 0x4. Select match value of match register 4. The match value of MAT4 is associated with event 4.
Define when event 5 occurs	EV5_CTRL	• Set EV*n*_CTRL[COMBMODE] = 0x3. Event 5 uses match condition and I/O condition. • Set EV*n*_CTRL[IOSEL] = 0. Select input 0. • Set EV*n*_CTRL[IOCOND] = 0x3. Input 0 is high. • Set EV*n*_CTRL[MATCHSEL] = 0. Chooses match register 0 to qualify the event.
Define how event 5 changes the state	EV5_CTRL	Write 0 to EV*n*_CTRL[STATEV] and 1 to EV*n*_CTRL[STATELD]. Event 5 changes the state to state 0.
Define by which events output 0 is set	OUT0_SET	Set SET0 bits 0 (for event 0) and 3 (for event 3) to one to set the output when these events 0 and 3 occur.
Define by which events output 0 is cleared	OUT0_CLR	Set CLR0 bits 1 (for events 1) and 4 (for event 4) to one to clear the output when events 1 and 4 occur.

Table continues on the next page...

Table 604. SCT configuration example: settings (continued)

Configuration	Register	Setting
Configure states to enable event 0	OUT0_STATE	Set STATEMSK0 bit 0 to 1, enabling event 0 in state 0. Set all other bits to 0.
Configure states to enable event 1	EV1_STATE	Set STATEMSK1 bit 0 to 1, enabling event 1 in state 0. Set all other bits to 0.
Configure states to enable event 2	EV2_STATE	Set STATEMSK2 bit 0 to 1, enabling event 2 in state 0. Set all other bits to 0.
Configure states to enable event 3	EV3_STATE	Set STATEMSK3 bit 1 to 1, enabling event 3 in state 1. Set all other bits to 0.
Configure states to enable event 4	EV4_STATE	Set STATEMSK4 bit 1 to 1, enabling event 4 in state 1. Set all other bits to 0.
Configure states to enable event 5	EV5_STATE	Set STATEMSK5 bit 1 to 1, enabling event 5 in state 1. Set all other bits to 0.

64.7 Memory map and register definition

64.7.1 Register configuration

For most of the SCT registers, the register function depends on the settings of certain other register fields:

- CONFIG[UNIFY] determines whether SCT is used as one 32-bit register (for operation as one 32-bit counter or timer) or as two 16-bit counters or timers named L and H.
  - If CONFIG[UNIFY] = 1, only one register is used (for operation as one 32-bit counter or timer).
  - If CONFIG[UNIFY] = 0, you can access the L and H registers using a 32-bit read or write operation, or you can read or write to them individually.

Typically, you configure CONFIG[UNIFY] by writing to SCT Configuration (CONFIG) before accessing any other registers.

- REGMOD[REGMOD_H*n*] and REGMOD[REGMOD_L*n*] determine whether each set of match and capture registers uses the match or capture functionality:
  - If REGMODE*n* = 0, registers operate as match and reload registers.
  - If REGMODE*n* = 1, registers operate as capture and capture control registers.

64.7.2 Register functional grouping

Most SCT registers either configure an event or select an event for a specific action of the counter (or counters) and outputs. The following figure shows the registers and register fields that you must configure for each event. In Figure 266, the following letters are used to represent the maximum quantity of certain SCT features:

- i = match and captures
- j = events
- k = states
- p = outputs
- q = inputs

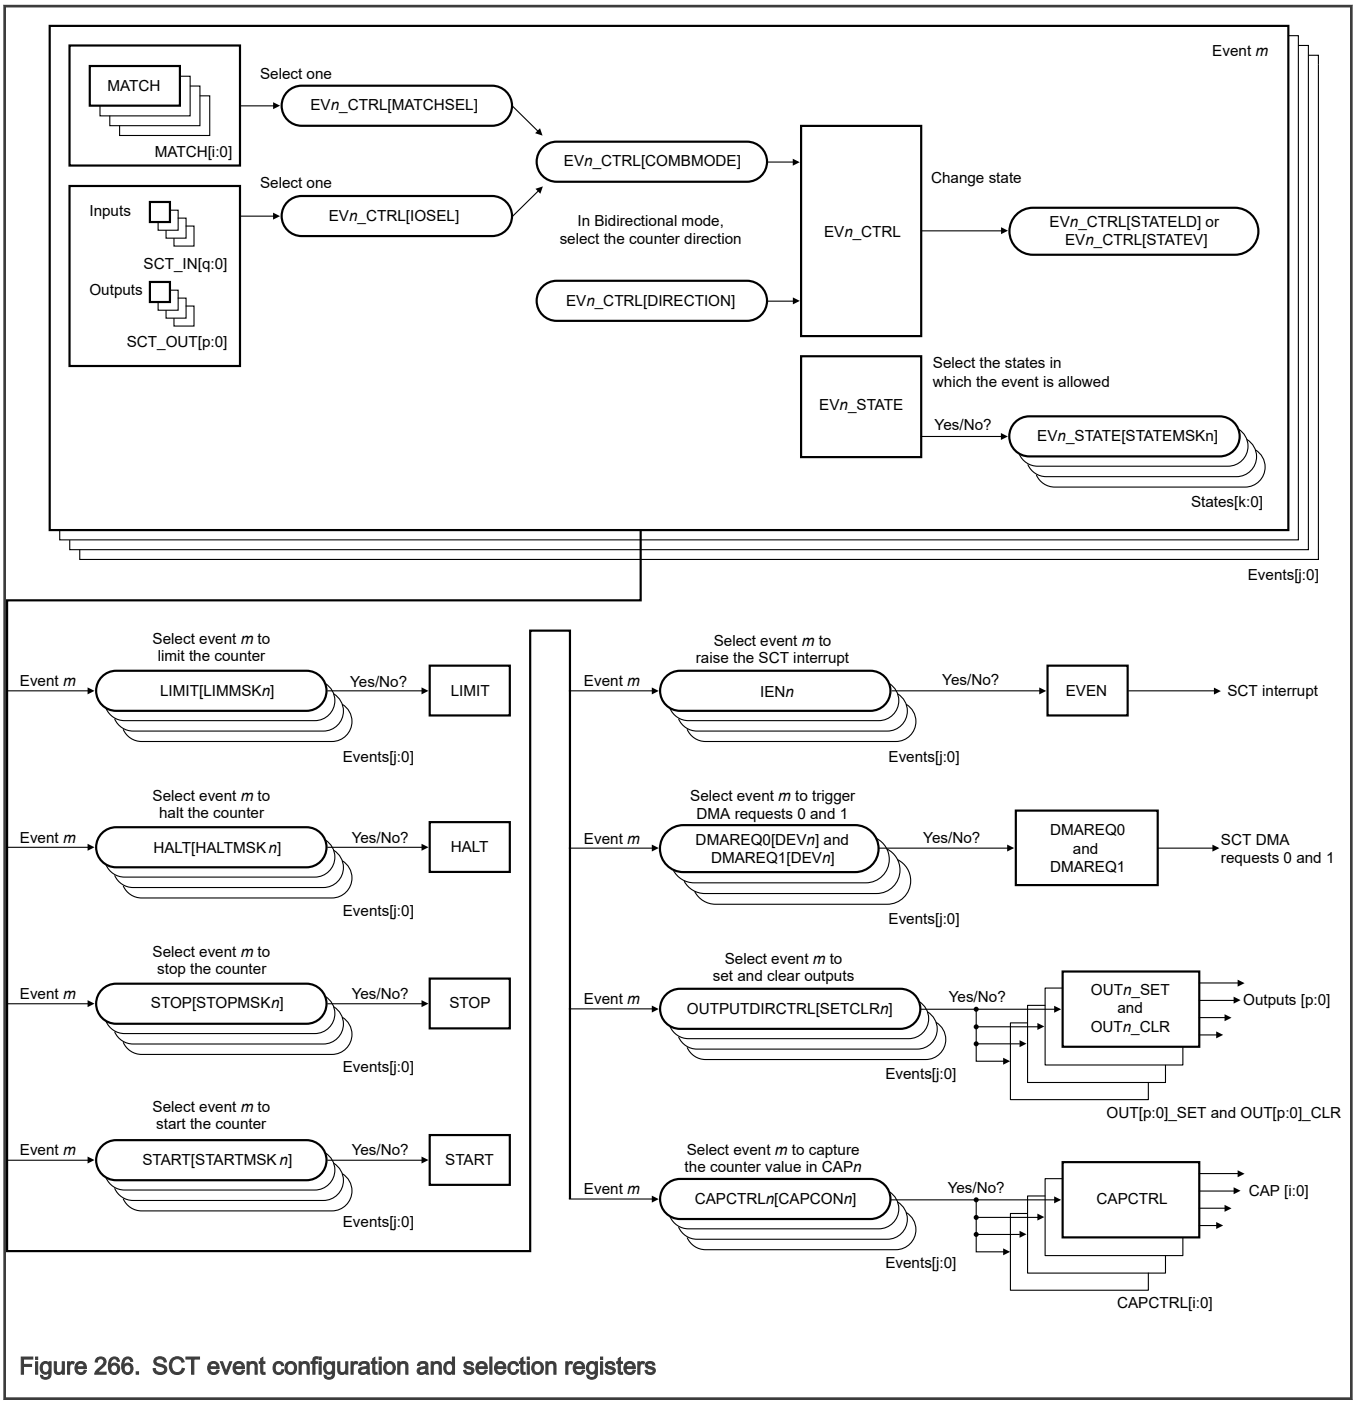

Figure 266. SCT event configuration and selection registers

64.7.2.1 Counter configuration and control registers

SCT contains these registers for configuration, monitoring, and control:

- SCT Configuration (CONFIG) configures SCT in a single, 32-bit counter mode or in dual, 16-bit counter mode. This register helps you perform clocking, clock synchronization, configure automatic limits, and use reload registers.
- SCT Control (CTRL) helps you monitor and set the counter direction. Additionally, using this register, you can clear, start, stop, or halt the 32-bit counter or individual 16-bit counters in Dual-Counter mode.

64.7.2.2 Event configuration registers

Each event is associated with these registers:

- Event n State (EV0_STATE - EV15_STATE) to enable the event
- Event n Control (EV0_CTRL - EV15_CTRL) to define what triggers the event

64.7.2.3 Match and capture registers

SCT includes a set of registers to store the SCT match or capture values:

- Each Match Value (MATCH0 - MATCH15) is associated with a corresponding Match Reload Value (MATCHREL0 - MATCHREL15), which automatically reloads Match Value (MATCH0 - MATCH15) at the beginning of each counter cycle.
- One Match and Capture Register Mode (REGMODE) to configure each match and capture register for either storing a match value or capture value.
- A set of match and capture registers with each register, depending on the setting of Match and Capture Register Mode (REGMODE), for either storing a match value or counter capture value.
- One Capture Control (CAPCTRL0 - CAPCTRL15) for each Capture Value (CAP0 - CAP15).

Figure 267 shows the match logic for SCT.

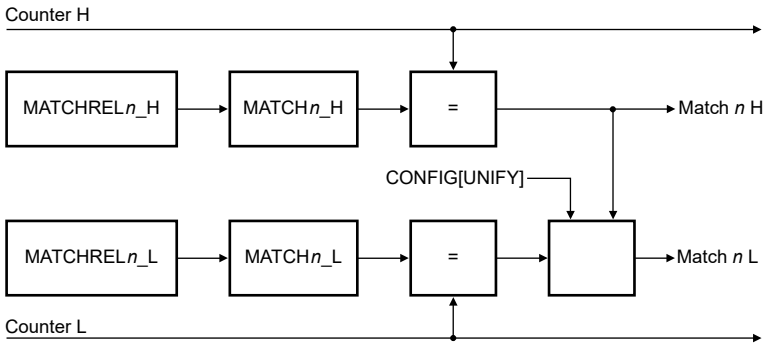

Figure 267. Match logic

Figure 268 shows the capture logic for SCT.

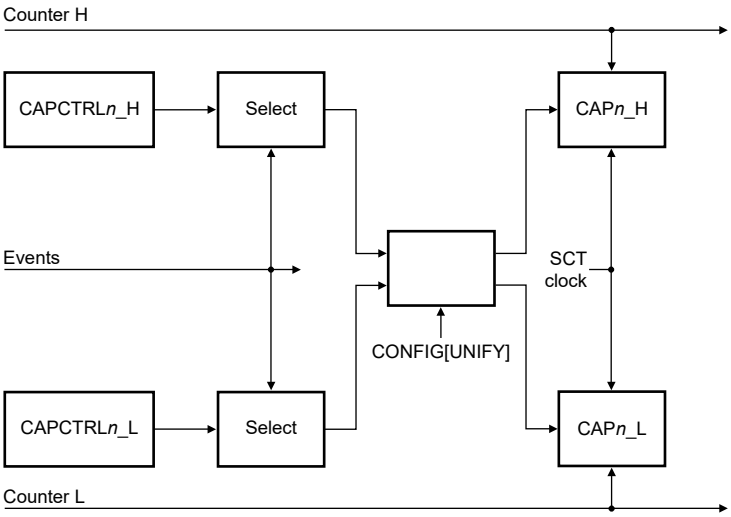

Figure 268. Capture logic

64.7.2.4 Event select registers for counter operations

This group of registers helps you select the events that affect the counter. The counter actions are limit, halt, start, and stop, which apply to the unified counter or to the two 16-bit counters:

- SCT Limit Event Select (LIMIT) selects the events that limit the counter.
- Start Event Select (START) and Stop Event Select (STOP) select the events that start or stop the counter.
- Halt Event Select (HALT) selects the events that halt the counter.
- Counter Value (COUNT) contains the counter value (or values) in the dual-counter setup.

All the aforementioned registers except Start Event Select (START) contain one field per event that selects whether each event limits, stops, starts, or halts the counter (or counters) in Dual-Counter mode. In this mode, you can select the events independently for each counter.

64.7.2.5 Event select registers for setting or clearing outputs

This group of registers helps you select the events that affect the level of each SCT output. Also included in this group are registers to manage conflicts that occur when events try to set or clear the same output:

- One Output n Set (OUT0_SET - OUT9_SET) for each output to select the events that set the output
- One Output n Clear (OUT0_CLR - OUT9_CLR) for each output to select the events that clear the output
- Output Conflict Resolution (RES) that defines an action when multiple events try to control an output at the same time
- Conflict Flag (CONFLAG) and Conflict Interrupt Enable (CONEN) that monitor interrupts arising from "output set and clear conflicts"
- Output Counter Direction Control (OUTPUTDIRCTRL) that interchanges the set and clear output operation caused by an event in Bidirectional mode

Output n Set (OUT0_SET - OUT9_SET) and Output n Clear (OUT0_CLR - OUT9_CLR) contain one field each per event that selects whether the event changes the state for a given output *n*.

In Dual-Counter mode, you can select the events independently for each output.

The following figure shows an SCT output slice.

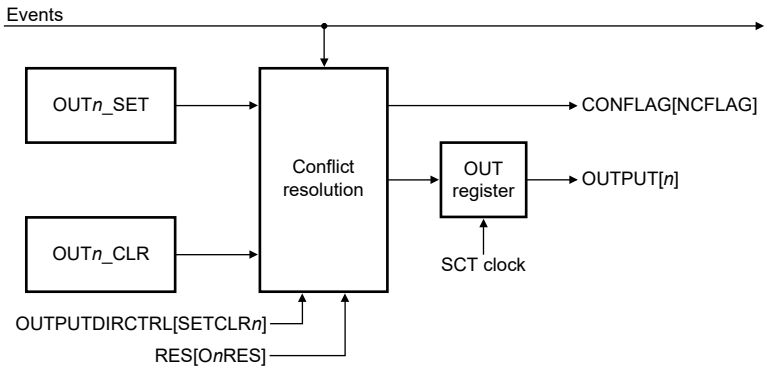

Figure 269. Output slice *n*

64.7.2.6 Event select registers for capturing a counter value

This group of registers helps you select events that capture the counter value and store it in one of Capture Value (CAP0 - CAP15). Each capture register *n* includes an associated Capture Control (CAPCTRL0 - CAPCTRL15), which in turn selects the events to capture the counter value.

64.7.2.7 Event select register for initiating DMA transfers

This register allows each of the two DMA requests to select the events that can generate a DMA request.

DMA Request 0 (DMAREQ0) and DMA Request 1 (DMAREQ1) contain a field for each event that selects whether the event generates a DMA request. An additional field enables the DMA trigger after the match registers are reloaded.

64.7.2.8 Interrupt handling registers

The following registers provide flags that are set by events and select the events that request an interrupt:

- Event Flag (EVFLAG) provides a flag for each event that is set when the event occurs.
- Event Interrupt Enable (EVEN) provides a field for each event to be enabled for the SCT interrupt.

This following figure shows an event triggering SCT to generate an interrupt.

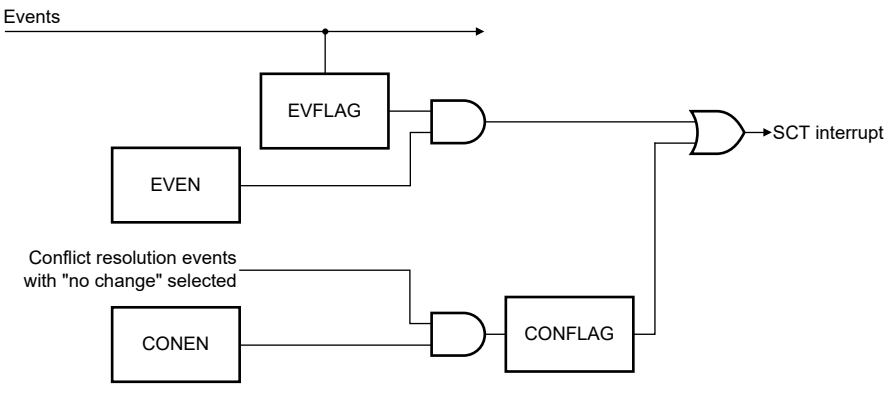

Figure 270. SCT interrupt generation

64.7.2.9 Registers for controlling SCT inputs and outputs

The following registers allow you (as opposed to events) to set SCT input and outputs:

- Input State (INPUT) to read the state of any of the SCT inputs
- Output State (OUTPUT) to set or clear any of the SCT outputs or to read their states

64.7.3 SCT register descriptions

SCT is a powerful, flexible timer module capable of creating complex PWM waveforms and performing other advanced timing and control operations with minimal or no CPU intervention.

64.7.3.2 SCT Configuration (CONFIG)

Offset

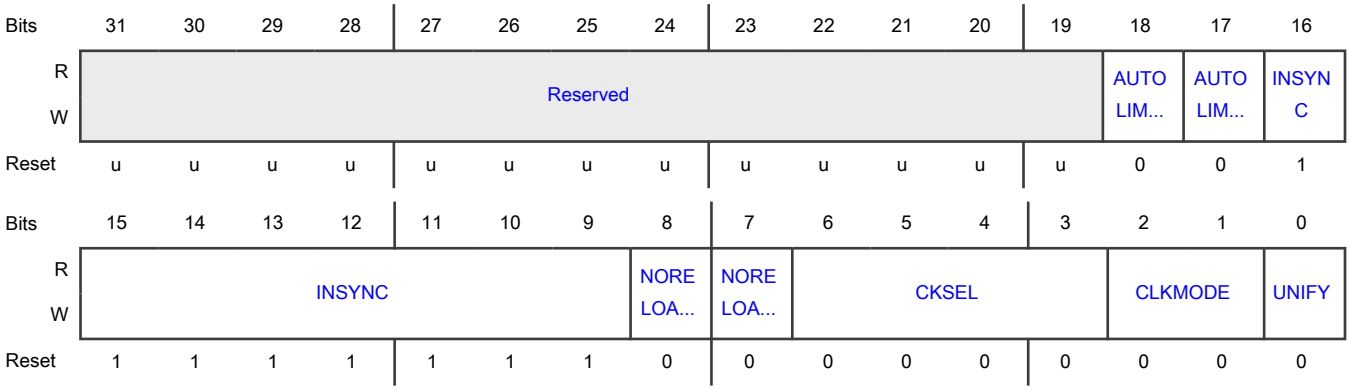
Register	Offset
CONFIG	0h

Function

Configures the overall SCT operation. You must write to this register before writing to any other registers.

Only word writes are permitted to this register. Attempting to write a halfword value results in a bus error.

Diagram



Fields

Field	Function
31-19 —	Reserved
18 AUTOLIMIT_H	Auto Limit Higher Enables the counter to be cleared to zero in Unidirectional mode or to change the direction of count in Bidirectional mode, as with any SCT Limit Event Select (LIMIT) event. You can write to this field at any time, except when CONFIG[UNIFY] = 1. If this field = 1, a match on match register 0 is considered as the limit condition without the need to define an associated event. 0b - Disables 1b - Enables
17 AUTOLIMIT_L	Auto Limit Lower Enables the counter to be cleared to zero in Unidirectional mode or to change the direction of count in Bidirectional mode, as with any SCT Limit Event Select (LIMIT) event. You can write to this field at any time, and the field applies to both the higher and lower registers when CONFIG[UNIFY] = 1. If this field = 1, a match on match register 0 is considered as the limit condition. You need not define an associated event. 0b - Disables 1b - Enables
16-9 INSYNC	Input Synchronization Specifies synchronization for input *n* (bit 9 = input 0, bit 10 = input 1, bit 16 = input 7, and so on). If you write 1 to any of these bits, it subjects the corresponding input to synchronization with the SCT clock, before it is used to create an event. If an input is already known to be synchronous with the SCT clock, you may write 0 to this field for a faster input response.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE SCT clock is the system clock for clock modes 0-2. It is the selected, asynchronous SCT input clock for clock mode 3. This field only affects inputs used for event generation, and does not apply to the clock input specified in CONFIG[CKSEL].
8 NORELOAD_H	No Reload Higher Match Specifies whether higher match registers are reloaded from their respective reload registers. Writing 1 to this field eliminates the need to write to Match Reload Value (MATCHREL0 - MATCHREL15) if the match values are fixed. It prevents the higher match registers to be reloaded from their respective reload registers. You can write to this field at any time, except when CONFIG[UNIFY] = 1. 0b - Reloaded 1b - Not reloaded
7 NORELOAD_L	No Reload Lower Match Specifies whether lower match registers are reloaded from their respective reload registers. Writing 1 to this field eliminates the need to write to Match Reload Value (MATCHREL0 - MATCHREL15) if the match values are fixed. It prevents the lower match registers to be reloaded from their respective reload registers. You can write to this field at any time, and the field applies to both the higher and lower registers when CONFIG[UNIFY] = 1. 0b - Reloaded 1b - Not reloaded
6-3 CKSEL	SCT Clock Select Specifies SCT clock. The specific functionality of the designated input or edge is dependent on the mode you select using CONFIG[CLKMODE]. 0000b - Rising edges on input 0 0001b - Falling edges on input 0 0010b - Rising edges on input 1 0011b - Falling edges on input 1 0100b - Rising edges on input 2 0101b - Falling edges on input 2 0110b - Rising edges on input 3 0111b - Falling edges on input 3 1000b - Rising edges on input 4

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1001b - Falling edges on input 4 1010b - Rising edges on input 5 1011b - Falling edges on input 5 1100b - Rising edges on input 6 1101b - Falling edges on input 6 1110b - Rising edges on input 7 1111b - Falling edges on input 7
2-1 CLKMODE	SCT Clock Mode Specifies SCT clock mode. • If this field = 0, SCT uses System Clock mode. In this mode, the system clock clocks the entire SCT module, including all counters and counter prescalers. • If this field = 1, SCT uses Sampled System Clock mode. In this mode, the system clock clocks the SCT module, but the counter and prescalers are only enabled to count when the designated edge is detected on the input that CONFIG[CKSEL] selects. The minimum pulse width on the selected clock-gate input is 1 bus clock period. This is a high-performance mode. • If this field = 10, SCT uses Input Clock mode. The input or edge that CONFIG[CKSEL] selects clocks the SCT module, including all counters and prescalers, after first being synchronized with the system clock. The minimum pulse width on the clock input is one bus clock period. This is a low-power, sampled-clock mode. • If this field = 11, SCT uses Asynchronous mode. In this mode, the input or edge that CONFIG[CKSEL] selects clocks the entire SCT module. The SCT outputs are switched synchronously to the SCT input clock, and not the system clock. The input clock rate must be at least half the system clock rate and can be the same or faster than the system clock. 00b - System Clock mode 01b - Sampled System Clock mode 10b - SCT Input Clock mode 11b - Asynchronous mode
0 UNIFY	SCT Operation Determines whether SCT is used as a single, unified 32-bit counter or timer or as dual, independent 16-bit counters or timers named low (L) and high (H). You must define the setting of this field before accessing other registers. 0b - Dual counters, COUNTER_L and COUNTER_H 1b - Unified counter

64.7.3.3 SCT Control (CTRL)

Offset

Register	Offset
CTRL	4h

Function

Allows SCT control.

You can use this register depending on the configuration of CONFIG[UNIFY]:

- If CONFIG[UNIFY] = 1, only the _L fields are used.
- If CONFIG[UNIFY] = 0, you can write to this register as two registers, CTRL_L and CTRL_H. You can read or write to both these registers, individually.

You can write to all fields in this register when the counter is stopped or halted. When the counter is running, the only fields that you can write to are STOP or HALT. You can write to the other fields in a subsequent write, after HALT becomes 1.

NOTE

- If you select CLKMODE = 0x3, wait for at least 12 system clock cycles between a write access to the H, L, or the unified version of this register and the next write access. This restriction does not apply when writing to the HALT field(s) and then writing to this register again to restart the counters (for example, you must update Match Value (MATCH0 - MATCH15), and this is allowed only when the counters are halted).
- If SCT is operating as two 16-bit counters, events can only modify the state of the outputs when no counter is halted. This is true regardless of what triggered the event.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved				PRE_H							BIDIR_H	CLRCTR_H	HALT_H	STOP_H	DOWN_H
Reset	u	u	u	0	0	0	0	0	0	0	0	0	0	1	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved				PRE_L							BIDIR_L	CLRCTR_L	HALT_L	STOP_L	DOWN_L
Reset	u	u	u	0	0	0	0	0	0	0	0	0	0	1	0	0

Fields

Field	Function
31-29 —	Reserved
28-21	Prescaler for High Counter

Table continues on the next page...

Table continued from the previous page...

Field	Function
PRE_H	Specifies the factor by which the SCT clock is prescaled to produce the high counter clock, which is clocked at the rate of SCT clock ÷ PREL_H + 1. **NOTE** Clear the counter (by writing 1 to CLRCTR) when changing the value of this field.
20 BIDIR_H	Bidirectional Select High Selects the direction of the high counter. If this field = 0, the high counter counts up to its limit condition, and is then cleared to zero. If this field = 1, the high counter counts up to its limit, and then counts down to a limit condition or to zero. 0b - Up 1b - Up-down
19 CLRCTR_H	Clear Counter High Clears the high counter. Writing 1 to this field clears the high counter. CLRCTR_H always reads as 0.
18 HALT_H	Halt Counter High Halts the high counter. When this field = 1, the H counter does not run and no events can occur. Also, CTRL[STOP_H] clears. You can remove the halt condition when SCT is not running (is in a stop condition), by using a single write to this register, to simultaneously clear the HALT and STOP fields. **NOTE** Once set, HALT_H can only be cleared by software to restore counter operation. HALT_H = 1 on reset. 0b - Disable 1b - Enable
17 STOP_H	Stop Counter High Stops the high counter from running. When STOP_H = 1 and HALT = 0, the H counter does not run but I/O events related to the counter can occur. If such an event matches the mask in Start Event Select (START), CTRL[STOP_H] is cleared and counting resumes. 0b - Disabled 1b - Enabled
16 DOWN_H	Down Counter High Specifies whether the high counter is counting up or down.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Hardware sets DOWN_H when the counter is counting up, a counter limit condition occurs, and BIDIR = 1. Hardware clears DOWN_H when the counter is counting down and a limit condition occurs, or when the counter reaches 0. 0b - Up 1b - Down
15-13 —	Reserved
12-5 PRE_L	Prescaler for Low Counter Specifies the factor by which the SCT clock is prescaled to produce the low or unified counter clock. The counter clock is clocked at the rate of SCT clock ÷ PRE_L + 1. **NOTE** You can clear the counter by writing 1 to CLRCTR when changing the value of this field.
4 BIDIR_L	Bidirectional Select Low Selects the direction of the low or unified counter. If this field = 0, the counter counts up to a limit condition and is then cleared to 0. If this field = 1, the counter counts up to a limit, and then counts down to a limit condition or to 0. 0b - Up 1b - Up-down
3 CLRCTR_L	Clear Counter Low Clears the low or unified counter. Writing 1 to this field clears the low or unified counter. The field always reads 0.
2 HALT_L	Halt Counter Low Specifies whether the L or unified counter is enabled. If this field = 1, the low or unified counter does not run and no events can occur. STOP_L also becomes 0. It is possible to remove the halt condition while SCT is in the stop condition (not running), with a single write to this register, to simultaneously clear the HALT field and set the STOP field. Once set, only software can clear HALT_L to restore counter operation. HALT_L = 1 on reset. 0b - Disabled 1b - Enabled
1 STOP_L	Stop Counter Low Specifies whether the low or unified counter is enabled. If STOP_L = 1 and HALT = 0, the low or unified counter does not run, but I/O events related to the counter can occur. If a designated start event occurs, STOP_L is cleared and counting resumes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
0 DOWN_L	Down Counter Low Specifies whether the low or unified counter is counting up or down. Hardware sets DOWN_L when the counter is counting up, counter limit occurs, and BIDIR = 1. Hardware clears this field when the counter is counting down and a limit condition occurs, or when the counter reaches 0. 0b - Up 1b - Down

64.7.3.4 SCT Limit Event Select (LIMIT)

Offset

Register	Offset
LIMIT	8h

Function

Selects the SCT limit event.

An event can limit a running counter. When any of the events selected in this register occur, the counter is cleared to zero from its current value or changes the counting direction, if it is in Bidirectional mode. Each field of this register is associated with a different event (bit 0 with event 0, and so on). Writing 1 to a field causes its associated event to serve as a LIMIT event, which whenever occurs, resets the counter to zero in Unidirectional mode, or changes the count direction in Bidirectional mode and keeps running. To define the actual limiting event (a match, an I/O pin toggle, and so on), see Event n Control (EV0_CTRL - EV15_CTRL).

NOTE

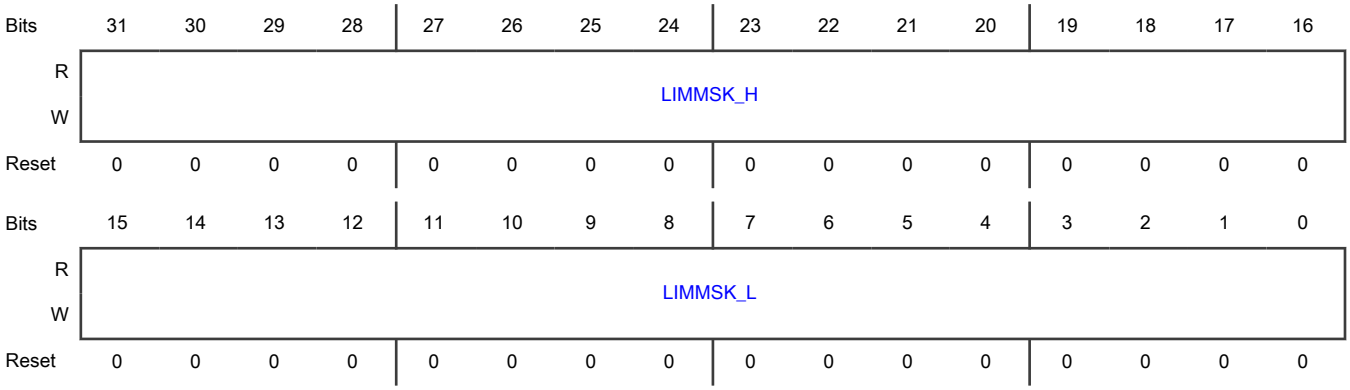
Counting up to all ones or counting down to zero is always equivalent to a limit event occurring.

In addition to using this register to specify events that serve as limits, it is also possible to automatically cause a limit condition whenever a match register 0 match occurs. This eliminates the need to define an event for the sole purpose of creating a limit. CONFIG[AUTOLIMIT_L] and CONFIG[AUTOLIMIT_H] enable or disable this feature.

You can use this register depending on the configuration of CONFIG[UNIFY]:

- If CONFIG[UNIFY] = 1, only the _L fields are used.
- If CONFIG[UNIFY] = 0, you can write to this register as two registers, LIMIT_L and LIMIT_H. You can read or write to both the _L and _H registers individually.

Diagram



Fields

Field	Function
31-16 LIMMSK_H	Limit Event Counter High Specifies the counter limit for the high counter. If bit *n* is 1, event *n* is used as a counter limit for the high counter (event 0 = bit 16, event 1 = bit 17, and so on). Number of bits = number of events in this SCT.
15-0 LIMMSK_L	Limit Event Counter Low Specifies the counter limit for the low counter. If bit *n* is 1, event *n* is used as a counter limit for the low or unified counter (event 0 = bit 0, event 1 = bit 1, and so on). Number of bits = number of events in this SCT.

64.7.3.5 Halt Event Select (HALT)

Offset

Register	Offset
HALT	Ch

Function

Halts high and low events.

A halt event can disable (or halt) a running counter. When any of the events selected in this register occur, the counter stops running and all further events are disabled.

Each field of this register is associated with a different event (bit 0 with event 0, and so on). Setting a bit causes the associated event to serve as a HALT event. To define the actual events that cause the counter to halt (a match, an I/O pin toggle, and so on), see Event n Control (EV0_CTRL - EV15_CTRL).

NOTE

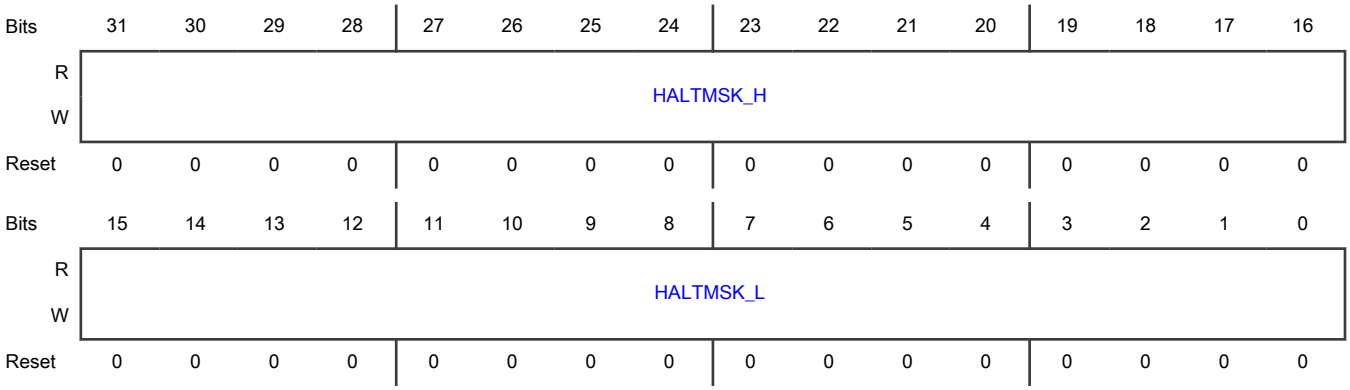
You can remove a HALT condition by clearing CTRL[HALT].

You can use this register depending on the configuration of CONFIG[UNIFY]:

- If CONFIG[UNIFY] = 1, only the _L fields are used.

- If CONFIG[UNIFY] = 0, you can write to this register as two registers, HALT_L and HALT_H. You can read or write to both the _L and _H registers individually.

Diagram



Fields

Field	Function
31-16 HALTMSK_H	Halt Event High Halts the high event. If bit *n* is 1, event *n* writes 1 to CTRL[HALT_H] (event 0 = bit 16, event 1 = bit 17, and so on). Number of bits = number of events in this SCT.
15-0 HALTMSK_L	Halt Event Low Halts the low event. If bit *n* is 1, event *n* writes 1 to CTRL[HALT_L] (event 0 = bit 0, event 1 = bit 1, and so on). Number of bits = number of events in this SCT.

64.7.3.6 Stop Event Select (STOP)

Offset

Register	Offset
STOP	10h

Function

Stops high and low events.

A stop event can stop a running counter. When any of the events selected in this register occur, counting is suspended. This means that the counter stops running and remains at its current value. Event generation remains enabled, and any event selected in Start Event Select (START), such as an I/O event or an event generated by the other counter, can restart the counter.

This register specifies the events that stop the counter. Each field of the register is associated with a different event (bit 0 with event 0, and so on). Setting a bit causes its associated event to serve as a STOP event. To define the actual event that causes the counter to stop (a match, an I/O pin toggle, and so on), see Event n Control (EV0_CTRL - EV15_CTRL).

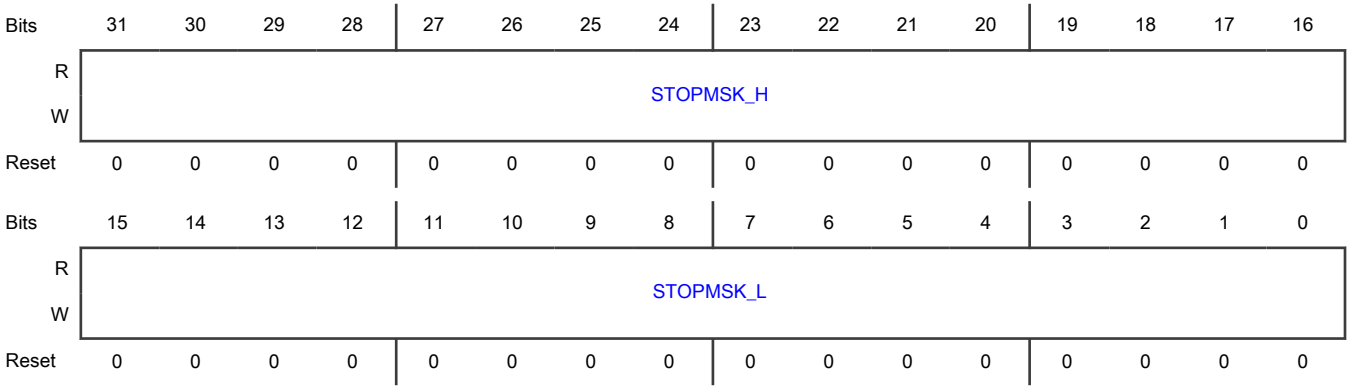
NOTE

You can stop and restart the counter by writing to SCT Control (CTRL).

You can use this register depending on the configuration of CONFIG[UNIFY]:

- If CONFIG[UNIFY] = 1, only the _L fields are used.
- If CONFIG[UNIFY] = 0, you can write to this register as two registers, STOP_L and STOP_H. You can read or write to both the _L and _H registers individually.

Diagram



Fields

Field	Function
31-16 STOPMSK_H	Stop Event High Stops the high event. If bit *n* is 1, the event *n* writes 1 to CTRL[STOP_H] (event 0 = bit 16, event 1 = bit 17, and so on). Number of bits = number of events in this SCT.
15-0 STOPMSK_L	Stop Event Low Stops the low event. If bit *n* is 1, the event *n* writes 1 to CTRL[STOP_L] (event 0 = bit 0, event 1 = bit 1, and so on). Number of bits = number of events in this SCT.

64.7.3.7 Start Event Select (START)

Offset

Register	Offset
START	14h

Function

Starts high and low events.

A start event can restart a stopped counter.

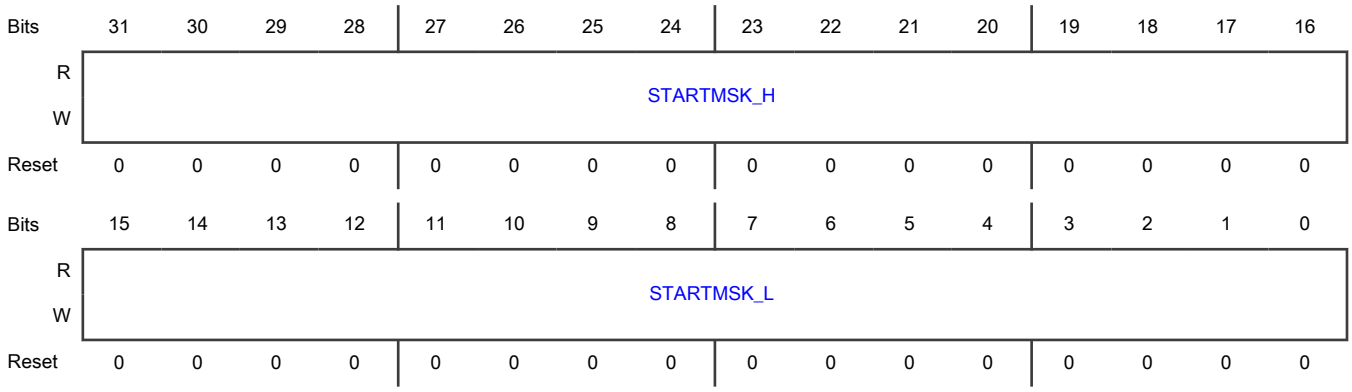
When any of the events selected in Start Event Select (START) occur, counting restarts from the current counter value.

Each field of this register associates with a different event (bit 0 with event 0, and so on). Setting a bit causes the associated event to serve as a START event. When a START event occurs, hardware clears CTRL[STOP]. A START event has no effect on CTRL[HALT]. Only software can remove a HALT condition. To define the actual event that starts the counter (an I/O pin toggle or an event generated by the other running counter in Dual-Counter mode), see Event n Control (EV0_CTRL - EV15_CTRL).

You can use this register depending on the configuration of CONFIG[UNIFY]:

- If CONFIG[UNIFY] = 1, only the _L fields are used.
- If CONFIG[UNIFY] = 0, you can write to this register as two registers, START_L and START_H. You can read or write to both the _L and _H registers individually.

Diagram



Fields

Field	Function
31-16 STARTMSK_H	Start Event High Starts the high event. If bit *n* is 1, event *n* writes 0 to CTRL[STOP_H] (event 0 = bit 16, event 1 = bit 17, and so on). Number of bits = number of events in this SCT.
15-0 STARTMSK_L	Start Event Low Starts the low event. If bit *n* is 1, event *n* writes 0 to CTRL[STOP_L] (event 0 = bit 0, event 1 = bit 1, and so on). Number of bits = number of events in this SCT.

64.7.3.8 Dither Condition (DITHER)

Offset

Register	Offset
DITHER	18h

Function

Enables the dither engine to advance to the next count in the dither pattern every time the SCT counter reaches zero (that is, at the start of every new SCT counter cycle). Using this register, you can alter this behavior by qualifying the advancement through the dither pattern with designated events. As with the other condition or mask registers (such as Halt Event Select (HALT), Stop Event Select (STOP), and SCT Limit Event Select (LIMIT)), each field of this register corresponds to an event.

Writing 1 to one or more fields in this register causes the dither engine to advance to the next element in the dither pattern (that is, increment the 16-state cycle counter) by only following SCT counter cycles during which one or more of the designated dither events have occurred.

There exists a global dither condition register per 16-bit SCT. This register controls advancement through the dither patterns for all the match registers associated with that half of SCT.

You can use this register depending on the configuration of CONFIG[UNIFY]:

- If CONGIG[UNIFY] = 1, only the _L bits are used.
- If CONFIG[UNIFY] = 0, you can write to this register as two registers, START_L and START_H. You can read and write to both the _L and _H registers individually or in a single 32-bit read or write operation.

For details on the dither engine and dither pattern, see Dithering.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	DITHER_L															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 DITHER_H	Dither High Dithers high events. If bit *n* is 1, event *n* writes 0 to CTRL[STOP_H] (event 0 = bit 16, event 1 = bit 17, and so on). Number of bits = number of events in this SCT.
15-0 DITHER_L	Dither Low Dithers low events. If bit *n* is 1, event *n* writes 0 to CTRL[STOP_L] (event 0 = bit 0, event 1 = bit 1, and so on). Number of bits = number of events in this SCT.

64.7.3.9 Counter Value (COUNT)

Offset

Register	Offset
COUNT	40h

Function

Defines high and low counters.

You can use this register depending on the configuration of CONFIG[UNIFY]:

- If CONFIG[UNIFY] = 1, this register acts as a unified 32-bit register and both the _L and _H fields are used.
- If CONFIG[UNIFY] = 0, you can write to this register as two registers, COUNT_L and COUNT_H. You can read and write to both the _L and _H registers individually. In this case, the _L and _H registers count independently under the control of other registers.

You are allowed to write to COUNT_L, COUNT_H, or the unified register only when the corresponding counter is halted (CTRL[HALT] = 1). In case you attempt to write to the counter when it is not halted, a bus error takes place. However, you can read the counter registers at any time.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	CTR_H															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R W	CTR_L															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 CTR_H	Counter High Allows reads and writes to the upper bits of the unified counter. If CONFIG[UNIFY] = 0, read or write the 16-bit H counter value, and if CONFIG[UNIFY] = 1, read or write the upper 16 bits of the 32-bit unified counter.
15-0 CTR_L	Counter Low Allows reads and writes to the lower bits of the unified counter. If CONFIG[UNIFY] = 0, read or write the 16-bit L counter value, and if CONFIG[UNIFY] = 1, read or write the lower 16 bits of the 32-bit unified counter.

64.7.3.10 State Variable (STATE)

Offset

Register	Offset
STATE	44h

Function

Specifies high and low state variables.

Each group of enabled and disabled events is assigned a number called the state variable. For example, a state variable with a value of 0 could have events 0, 2, and 3 enabled and all other events disabled. A state variable with the value of 1 could have events 1, 4, and 5 enabled and all others disabled.

NOTE

Event n State (EV0_STATE - EV15_STATE) defines the event that is enabled in each group.

You can read the state associated with a counter at any time, and are allowed to write to STATE[STATE_L], STATE[STATE_H], or the unified register only when the corresponding counter is halted (CTRL[HALT_L] and CTRL[HALT_H] = 1).

The state variable is the main feature that distinguishes SCT from other counters, timers, and PWM blocks. Events can be made to occur only in certain states, and these events can, in turn, perform the following actions:

- Set and clear outputs
- Limit, stop, and start the counter
- Cause interrupts and DMA requests
- Modify the state variable

The application completely controls the value of a state variable. If an application does not use states, the value of the state variable remains zero, which is the default value.

You can use a state variable to track and control multiple cycles of the associated counter in any desired operational sequence.

EV*n*_CTRL[STATEV] and EV*n*_CTRL[STATELD] of all defined events set all possible values for the state variable. The change of the state variable during multiple counter cycles reflects how the associated state machine moves from one state to the next.

You can use this register depending on the configuration of CONFIG[UNIFY]:

- If CONFIG[UNIFY] = 1, only the _L bits are used.
- If CONFIG[UNIFY] = 0, you can write to this register as two registers, STATE_L and STATE_H.

You can read or write to both the _L and _H registers individually.

64.7.3.11 Input State (INPUT)

Offset

Register	Offset
INPUT	48h

Function

Indicates the state and form of SCT inputs.

You can read the state of SCT inputs, in slightly different forms, using this register:

- The AIN fields of this register indicate the state of the inputs captured on the last rising edge of the SCT clock. This corresponds to a nearly direct read-out of the input but can cause spurious fluctuations in case of an asynchronous input signal.
- The SIN fields of this register indicate the form of the inputs used for event detection. This may include additional stages of synchronization, depending on what is specified for that input in CONFIG[INSYNC]:
  - If CONFIG[INSYNC] = 1, the input is triple-synchronized to the SCT clock, resulting in a stable signal that is delayed by three SCT clock cycles.

— If CONFIG[INSYNC] = 0, the value of SIN is identical to the value of AIN.

64.7.3.12 Match and Capture Register Mode (REGMODE)

Offset

Register	Offset
REGMODE	4Ch

Function

Specifies whether each register acts as a match register or capture register. SCT contains multiple match and capture registers, and each register includes an accompanying register that functions as a reload register when the primary register is used as a match or capture-control register.

You can use this register depending on the configuration of CONFIG[UNIFY]:

- If CONFIG[UNIFY] = 1, only REGMODE[REGMOD_L*n*] is used. REGMODE[REGMOD_H*n*] is used only when CONFIG[UNIFY] = 0.
- If CONFIG[UNIFY] = 0, you can write to this register as two registers, REGMODE_L and REGMODE_H. You can read or write to both the _L and _H registers individually. REGMODE[REGMOD_L*n*] controls the lower match and capture registers, and REGMODE[REGMOD_H*n*] controls the higher or upper match and capture registers.

Fields

Field	Function
31-16 REGMOD_Hn	Register Mode High Controls match and capture register *n*. If this field = 0, register *n* operates as a match register, and if this field = 1, register *n* operates as a capture register. 0b - Match 1b - Capture
15-0 REGMOD_Ln	Register Mode Low Controls match and capture register *n*. If this field = 0, register *n* operates as a match register, and if this field = 1, register *n* operates as a capture register. 0b - Match 1b - Capture

64.7.3.13 Output State (OUTPUT)

Offset

Register	Offset
OUTPUT	50h

Function

Determines SCT output state.

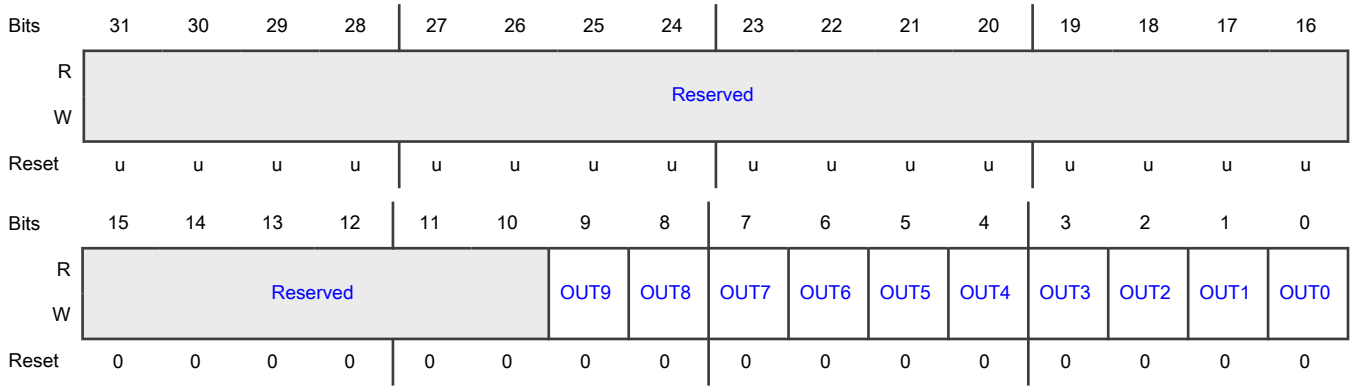
Each SCT output has a corresponding field in this register to allow you to control the output state directly or read its current state.

While the counter is running, only events can set, clear, and toggle these outputs. However, using this register, you can write to any of the output registers when both the counters are halted to control the outputs directly. Writing to the OUT register is only allowed when all counters (L-counter, H-counter, or unified counter) are halted (CTRL[HALT] = 1).

You can read this register at any time to sense the state of the outputs.

Only word writes are permitted to this register. Attempting to write a halfword value results in a bus error.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-10 —	Reserved
9-0 OUTn	Output Low and High Specifies the SCT output state. The number of bits equals the number of outputs in this SCT. 0b - Forces the corresponding output low 1b - Forces the corresponding output high

64.7.3.14 Output Counter Direction Control (OUTPUTDIRCTRL)

Offset

Register	Offset
OUTPUTDIRCTRL	54h

Function

Specifies, for each output, the impact of the counting direction on the meaning of set and clear operations on the output, when using Bidirectional mode. The purpose of this register is to facilitate the creation of center-aligned output waveforms without the need to define additional events.

Only word writes are permitted to this register; attempting to write a halfword value results in a bus error.

Diagram

64.7.3.15 Output Conflict Resolution (RES)

Offset

Register	Offset
RES	58h

Function

Specifies the action to be taken if multiple events (or even the same event) dictate that a given output must be both set and cleared at the same time.

To enable an event to toggle an output each time the event occurs, write 1 to the fields for that event in both Output n Set (OUT0_SET - OUT9_SET) and Output n Clear (OUT0_CLR - OUT9_CLR), and write 0x3 to RES[O*n*RES].

Only word writes are permitted to this register. Attempting to write a halfword value results in a bus error.

64.7.3.16 DMA Request 0 (DMAREQ0)

Offset

Register	Offset
DMAREQ0	5Ch

Function

Enables DMA requests to be generated when a particular event occurs or when counter match registers are loaded from the reload registers. SCT includes two DMA request outputs.

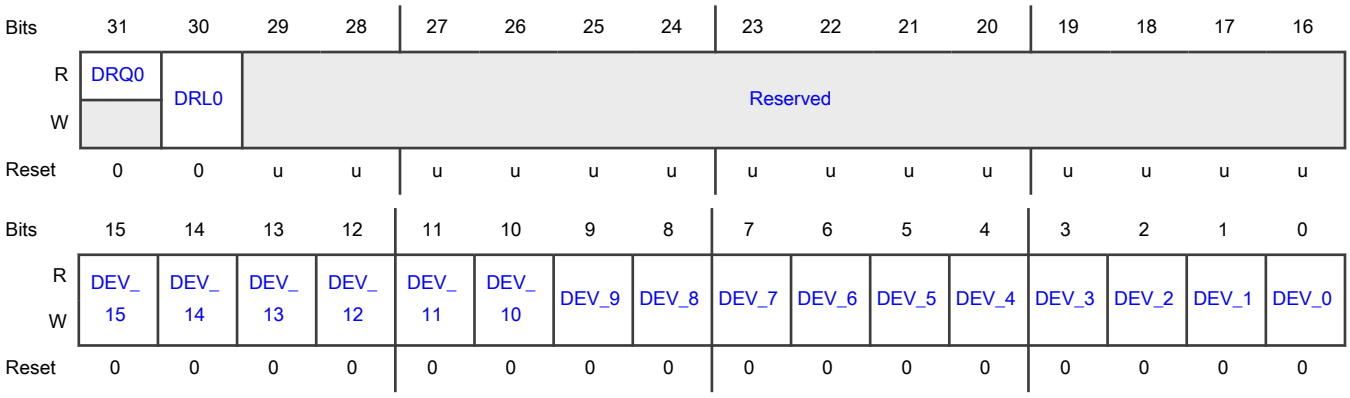
The DMA request registers are word-write only. Attempting to write a halfword value to these registers results in a bus error.

Event-generated DMA requests are particularly useful for launching DMA activity to or from other peripherals under SCT control.

NOTE

In this chip, SCT DMA requests are connected to the DMA trigger inputs, and the DMA trigger input mux registers control them.

Diagram



Fields

Field	Function
31 DRQ0	DMA Request 0 State Indicates the state of DMA request 0. **NOTE** If the related DMA channel is enabled and properly set up, it is unlikely for you to see this flag. The DMA service rapidly clears this field. If the flag remains set, there could be an issue with the DMA setup.
30 DRL0	DMA Request Low 0 Triggers DMA request 0. Writing 1 to this field triggers DMA request 0 when it loads MATCH*n*[MATCH_L] or the unified registers, using MATCHREL*n*[RELOAD_L] or the unified registers.
29-16 —	Reserved
15-0 DEV_n	DMA Request Event Triggers DMA request 0 using event *n*. If bit *n* = 1, event *n* triggers DMA request 0 (event 0 = bit 0, event 1 = bit 1, and so on). Number of bits = number of events in this SCT.

64.7.3.17 DMA Request 1 (DMAREQ1)

Offset

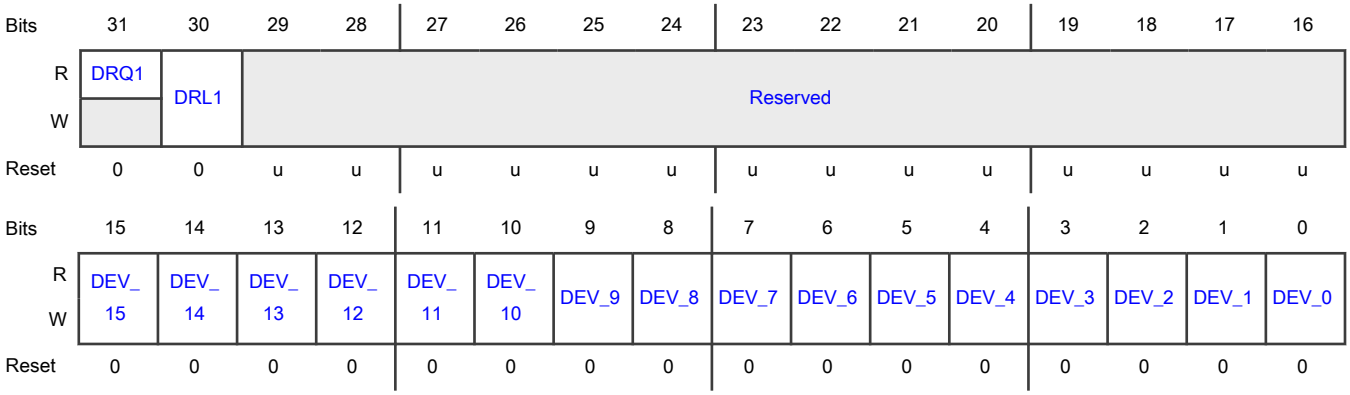
Register	Offset
DMAREQ1	60h

Function

Specifies DMA request 1.

Only word-writes are permitted to this register. Attempting to write a halfword value results in a bus error.

Diagram



Fields

Field	Function
31 DRQ1	DMA Request 1 State Specifies the state of DMA request 1. **NOTE** If the related DMA channel is enabled and properly set up, it is unlikely for you to see this flag, which the DMA service clears rapidly. If the flag remains set, there could be an issue with the DMA setup.
30 DRL1	DMA Request Low 1 Triggers DMA request 1. Writing 1 to this field triggers DMA request 1 when it loads MATCH*n*[MATCH_L] or the unified registers, using MATCHREL*n*[RELOAD_L] or the unified registers.
29-16 —	Reserved
15-0	DMA Request Event

Table continues on the next page...

Table continued from the previous page...

Field	Function
DEV_n	Triggers DMA request using event *n*. If bit *n* = 1, event *n* triggers DMA request 1 (event 0 = bit 0, event 1 = bit 1, and so on). Number of bits = number of events in this SCT.

64.7.3.18 Event Interrupt Enable (EVEN)

Offset

Register	Offset
EVEN	F0h

Function

Enables flags to request an interrupt if EVFLAG[FLAG*n*] = 1.

Only word-writes are permitted to this register. Attempting to write a halfword value results in a bus error.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

15-0 IENn	Event Interrupt Enable Enables event interrupts. 0b - Disables 1b - Enables

64.7.3.19 Event Flag (EVFLAG)

Offset

Register	Offset
EVFLAG	F4h

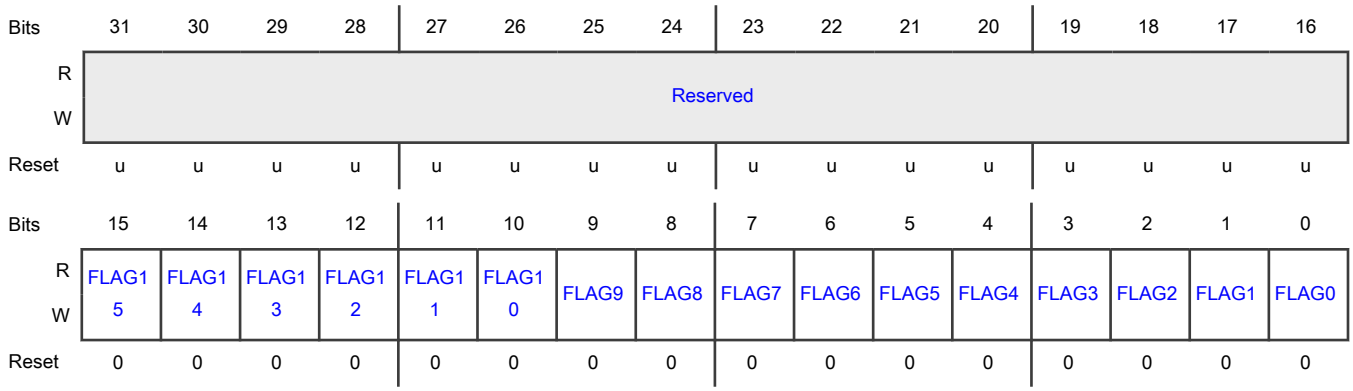
Function

Records events.

Writing 1 to this register clears the corresponding flags and negates the SCT interrupt request if all enabled flags are 0.

Only word-writes are permitted to this register. Attempting to write a halfword value results in a bus error.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 FLAGn	Event Flag Specifies event flag *n*. Bit *n* is 1 if event *n* has occurred since reset or a 1 was last written to this bit (event 0 = bit 0, event 1 = bit 1, and so on). Number of bits = number of events in this SCT. 0b - No flag 1b - Event n flag

64.7.3.20 Conflict Interrupt Enable (CONEN)

Offset

Register	Offset
CONEN	F8h

Function

Enables no-change conflict events specified in Output Conflict Resolution (RES) to generate an interrupt request.

Only word-writes are permitted to this register. Attempting to write a halfword value results in a bus error.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-10 —	Reserved
9-0 NCENn	No Change Conflict Event and Interrupt Enable Specifies whether an interrupt is generated. SCT requests an interrupt when bit *n* of this register and Conflict Flag (CONFLAG) are both = 1 (output 0 = bit 0, output 1 = bit 1, and so on). 0b - No interrupt 1b - Interrupt

64.7.3.21 Conflict Flag (CONFLAG)

Offset

Register	Offset
CONFLAG	FCh

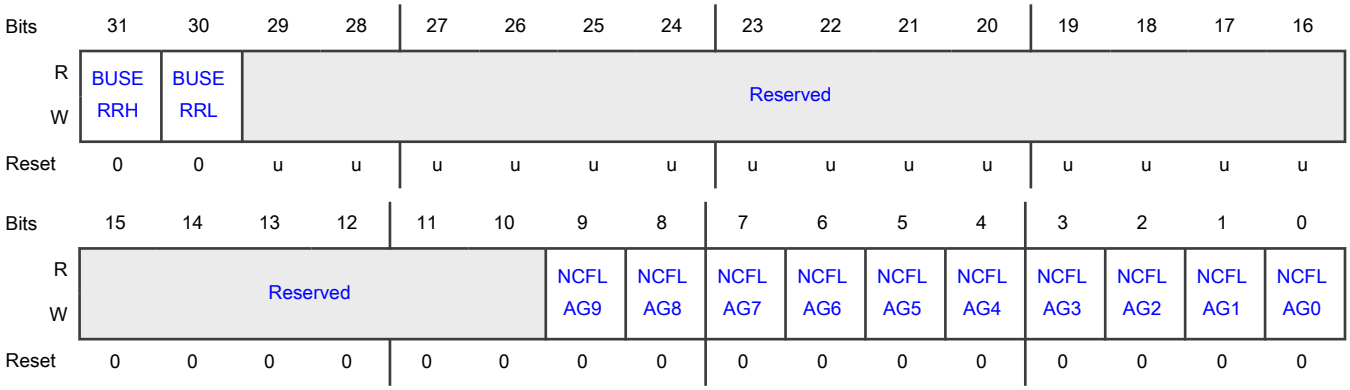
Function

Records a no-change conflict occurrence and also provides details of any bus errors.

Writing 1 to the fields of this register clears the corresponding read bits and negates the SCT interrupt request if all enabled flags are zero.

Only word-writes are permitted to this register. Attempting to write a halfword value results in a bus error.

Diagram



Fields

Field	Function
31 BUSERRH	Bus Error High Specifies whether the bus error is low or unified. The most recent bus error from this SCT involved writing CTR H, STATE H, MATCH H, or the Output register when the H counter was not halted.
30 BUSERRL	Bus Error Low or Unified Specifies whether the bus error is low or unified. The most recent bus error from this SCT involved writing to CTR L/Unified, STATE L/Unified, MATCH L/Unified, or the Output register when the L/U counter was not halted. A word write to certain L and H registers can be half successful and half unsuccessful.
29-10 —	Reserved
9-0 NCFLAGn	No Change Conflict Event Flag Specifies whether a no-change conflict event occurred. 0b - Did not occur 1b - Occurred

64.7.3.22 Capture Value (CAP0 - CAP15)

Offset

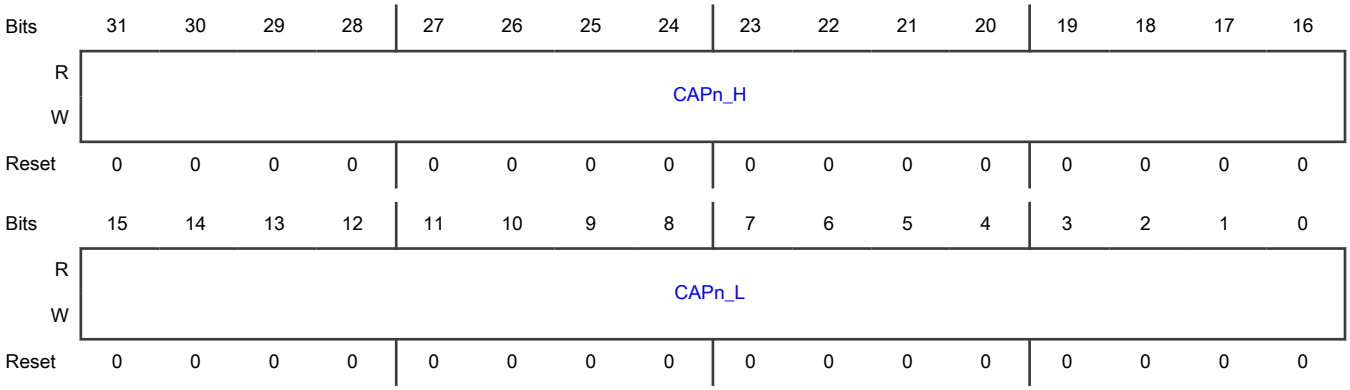
For n = 0 to 15:

Register	Offset
CAPn	100h + (n × 4h)

Function

Allows you to record counter values when the events selected by the corresponding capture control registers occur.

Diagram



Fields

Field	Function
31-16 CAPn_H	Capture High Captures the higher counter value. If CONFIG[UNIFY] = 0, read the 16-bit counter value at which this register was last captured, and if CONFIG[UNIFY] = 1, read the upper 16 bits of the 32-bit value at which this register was last captured.
15-0 CAPn_L	Capture Low Captures the lower counter value. If CONFIG[UNIFY] = 0, read the 16-bit counter value at which this register was last captured, and if CONFIG[UNIFY] = 1, read the lower 16 bits of the 32-bit value where this register was last captured.

64.7.3.23 Match Value (MATCH0 - MATCH15)

Offset

For n = 0 to 15:

Register	Offset
MATCHn	100h + (n × 4h)

Function

Is compared to counters to help create events.

You can use this register depending on the configuration of CONFIG[UNIFY]:

- If CONFIG[UNIFY] = 0, the L and H registers are independently compared to the L and H counters.
- If CONFIG[UNIFY] = 1, the combined L and H registers hold a 32-bit value that is compared to the unified counter. A match can only occur in a clock for which the counter is running (Stop Event Select (STOP) and Halt Event Select (HALT) are 0).

You can read this register at any time. Writing to MATCH[MATCH*n*_L], MATCH[MATCH*n*_H], or the unified register is only allowed when the corresponding counter is halted (CTRL[HALT_L] and CTRL[HALT_H] are 1). Match events occur in the SCT clock for which the counter is (or would be) incremented to the next value. When a match event limits its counter, the value in this register is the last value of the counter before it is cleared to zero (or decremented if BIDIR is 1).

There is no “write-through” from reload registers to match registers. Before starting a counter, you can write one value to this register, used in the first cycle of the counter, and a different value to the corresponding match reload register used in the second cycle.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	MATCHn_L															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 MATCHn_H	Match High Compares upper bits to the unified counter. If CONFIG[UNIFY] = 0, read or write the 16-bit value to be compared to the H counter. If CONFIG[UNIFY] = 1, read or write the upper 16 bits of the 32-bit value to be compared to the unified counter.
15-0 MATCHn_L	Match Low Compares lower bits to the unified counter. If CONFIG[UNIFY] = 0, read or write the 16-bit value to be compared to the lower counter. If CONFIG[UNIFY] = 1, read or write the lower 16 bits of the 32-bit value to be compared to the unified counter.

64.7.3.24 Fractional Match (FRACMAT0 - FRACMAT5)

Offset

Register	Offset
FRACMAT0	140h

Table continues on the next page...

Table continued from the previous page...

Register	Offset
FRACMAT1	144h
FRACMAT2	148h
FRACMAT3	14Ch
FRACMAT4	150h
FRACMAT5	154h

Function

Provides a higher average resolution over time by applying a dither pattern as described in Dithering. This dither pattern results in delaying recognition of a match for one counter clock for *n* (0 to 15) out of every 16 counter cycles. You must program the value of *n* in these fractional match registers, which are provided for up to first six of the match registers.

You can read fractional match registers at any time, but can write to FRACMAT*n*[FRACMAT_L], FRACMAT*n*[FRACMAT_H], or the unified register only when the corresponding counter is halted (CTRL[HALT_L] and CTRL[HALT_H] are 1).

Each fractional match register has an associated fractional match reload register. The contents of these reload registers are transferred into the fractional match registers at the start of every new SCT counter cycle unless CONFIG[NORELOAD] = 1 for the appropriate half counter.

You can write to the reload registers at any time, regardless of whether the counter is running.

There is no write-through from the fractional match reload registers to the fractional match registers. Before starting a counter, you can write a value to the fractional match register that is used in the first cycle or period of operation, and a different value to the corresponding fractional match reload register that is used in the second cycle or period.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	Reserved												FRACMAT_L			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-20 —	Reserved
19-16	Fractional Match High

Table continues on the next page...

Table continued from the previous page...

Field	Function
FRACMAT_H	Allows reads or writes to upper bits for fractional match. If CONFIG[UNIFY] = 0, read or write a 4-bit value specifying the dither pattern to be applied to the corresponding MATCH*n*[MATCH_H] field (*n* = 0 to 5).
15-4 —	Reserved
3-0 FRACMAT_L	Fractional Match Low Allows reads or writes to lower bits for fractional match. If CONFIG[UNIFY] = 0, read or write a 4-bit value specifying the dither pattern to be applied to the corresponding MATCH*n*[MATCH_L] field (*n* = 0 to 5). If CONFIG[UNIFY] = 1, the value applies to the unified, 32-bit fractional match register.

64.7.3.25 Capture Control (CAPCTRL0 - CAPCTRL15)

Offset

For n = 0 to 15:

Register	Offset
CAPCTRLn	200h + (n × 4h)

Function

Controls the events that cause loading of the corresponding capture register from the counter.

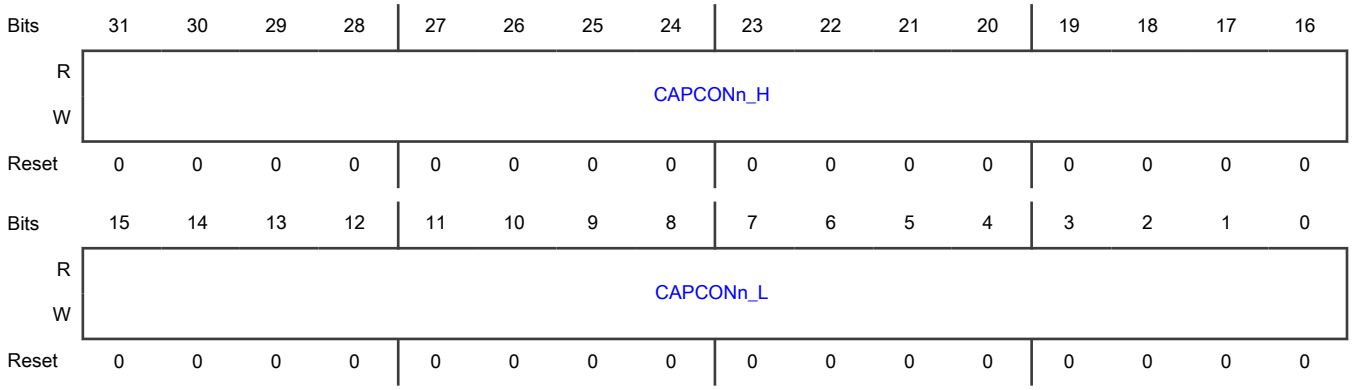
You can use this register depending on the configuration of CONFIG[UNIFY]:

- If CONFIG[UNIFY] = 1, only the _L fields are used.
- If CONFIG[UNIFY] = 0, you can write to this register as two registers, CAPCTRL*n*_L and CAPCTRL*n*_H. You can read both or write to the _L and _H registers individually.

Based on a selected event, the capture registers can be loaded with the current counter value when the event occurs.

Each capture control register (L, H, or unified 32-bit) controls which events cause the load of the corresponding capture register from the counter.

Diagram



Fields

Field	Function
31-16 CAPCONn_H	Capture Control High Captures higher bits. If bit *n* = 1, event *n* causes CAP*n*[CAP_H] (CONFIG[UNIFY] = 0) to be loaded (event 0 = bit 16, event 1 = bit 17, and so on). Number of bits = number of match and captures in SCT.
15-0 CAPCONn_L	Capture Control Low Captures lower bits. If bit *n* = 1, event *n* causes CAP*n*[CAP_L] (CONFIG[UNIFY] = 0) or CAP*n* (CONFIG[UNIFY] = 1) to be loaded (event 0 = bit 0, event 1 = bit 1, and so on). Number of bits = number of match and captures in SCT.

64.7.3.26 Match Reload Value (MATCHREL0 - MATCHREL15)

Offset

For n = 0 to 15:

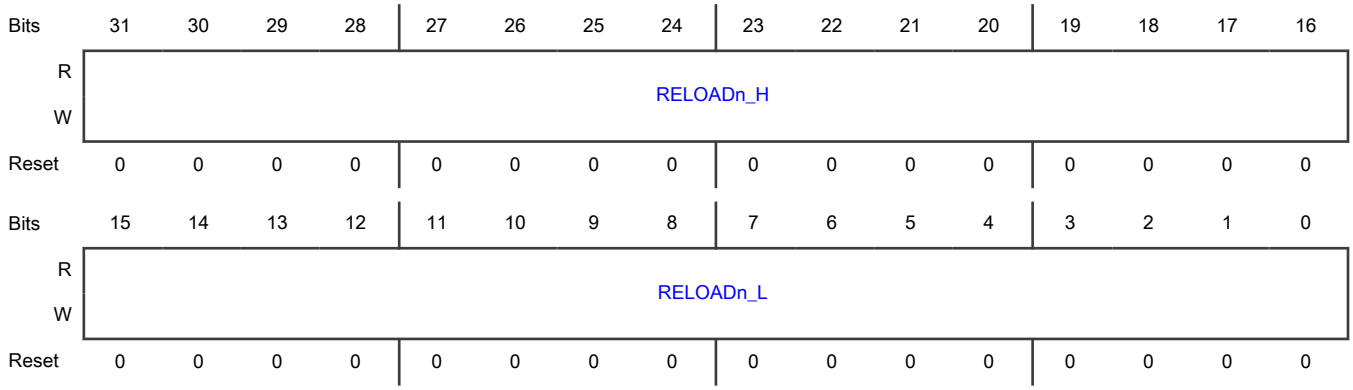
Register	Offset
MATCHRELn	200h + (n × 4h)

Function

Reloads a match register (L, H, or unified 32-bit counter) from its corresponding reload register at the start of each new counter cycle, which is when:

- CTRL[BIDIR_H] and CTRL[BIDIR_L] are 0 and the counter is cleared to zero upon reaching its limit condition.
- CTRL[BIDIR_H] and CTRL[BIDIR_L] are 1 and the counter counts down to 0, unless CONFIG[NORELOAD_H] and CONFIG[NORELOAD_L] are 1.

Diagram



Fields

Field	Function
31-16 RELOADn_H	Reload High Specifies the value to be loaded into MATCH*n*[MATCH_H]. If CONFIG[UNIFY] = 0, this field specifies the 16-bit value to be loaded into MATCH*n*[MATCH_H]. If CONFIG[UNIFY] = 1, the field specifies the upper 16 bits of the 32-bit value to be loaded into MATCH*n*[MATCH_H].
15-0 RELOADn_L	Reload Low Specifies the value to be loaded into MATCH*n*[MATCH_L]. If CONFIG[UNIFY] = 0, this field specifies the 16-bit value to be loaded into MATCH*n*[MATCH_L]. If CONFIG[UNIFY] = 1, the field specifies the lower 16 bits of the 32-bit value to be loaded into MATCH*n*[MATCH_L].

64.7.3.27 Fractional Match Reload (FRACMATREL0 - FRACMATREL5)

Offset

Register	Offset
FRACMATREL0	240h
FRACMATREL1	244h
FRACMATREL2	248h
FRACMATREL3	24Ch
FRACMATREL4	250h
FRACMATREL5	254h

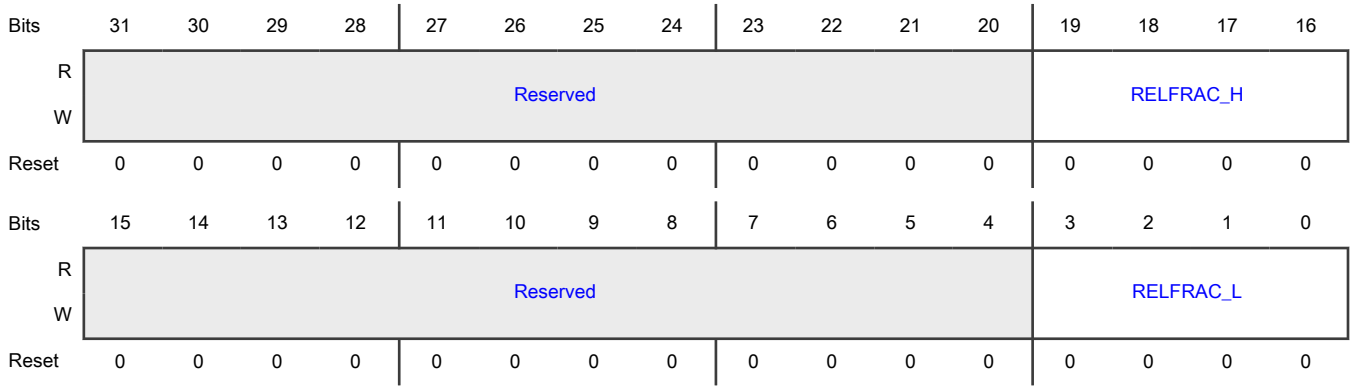
Function

Reloads a fractional match register (_L, _H, or the unified 32-bit counter) from the corresponding fractional match reload register at the start of each new counter cycle.

A fractional match register is loaded from the corresponding fractional match reload register at the start of each new counter cycle, which means when:

- CTRL[BIDIR] = 0 and the counter is cleared to zero upon reaching its limit condition.
- CTRL[BIDIR] = 1 and the counter counts down to 0, unless the appropriate CONFIG[NORELOAD] field = 1.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-16 RELFRAC_H	Reload Fractional Match High Specifies the value to be loaded into FRACMAT*n*[FRACMAT_H]. If CONFIG[UNIFY] = 0, read or write the 4-bit value to be loaded into FRACMAT*n*[FRACMAT_H]. If CONFIG[UNIFY] = 1, read or write the upper 4 bits with the 4-bit value to be loaded into FRACMAT*n*[FRACMAT_H].
15-4 —	Reserved
3-0 RELFRAC_L	Reload Fractional Match Low Specifies the value to be loaded into FRACMAT*n*[FRACMAT_L]. If CONFIG[UNIFY] = 0, read or write the 4-bit value to be loaded into FRACMAT*n*[FRACMAT_L]. If CONFIG[UNIFY] = 1, read or write the lower 4 bits to be loaded into FRACMAT*n*[FRACMAT_L].

64.7.3.28 Event n State (EV0_STATE - EV15_STATE)

Offset

For n = 0 to 15:

Register	Offset
EVn_STATE	300h + (n × 8h)

Function

Specifies event *n* state.

You can enable each event in some contexts (or states) and disable it in others. Each event defined in Event n Control (EV0_CTRL - EV15_CTRL) has an associated Event Interrupt Enable (EVEN) that can enable or disable the event for each available state.

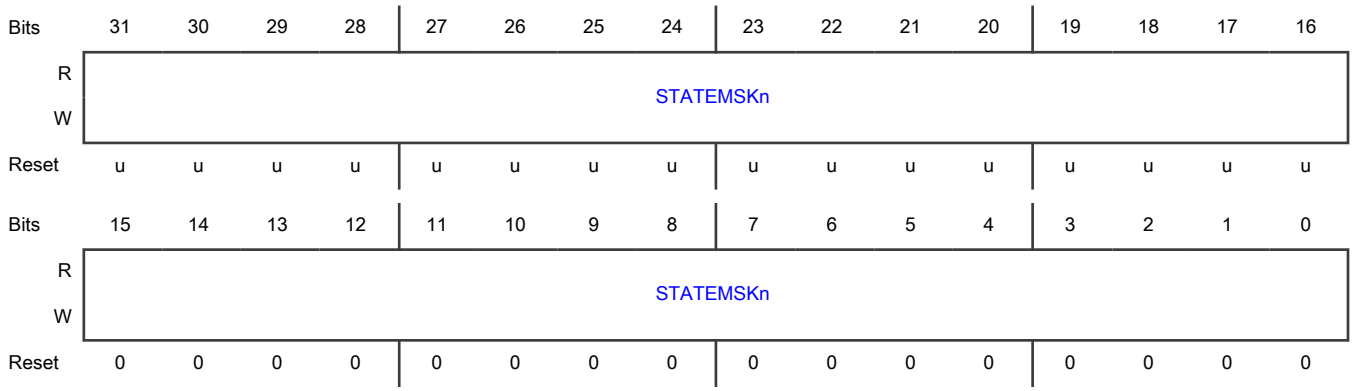
Each event also has an associated Event n State (EV0_STATE - EV15_STATE) that allows this event to happen in one or more states of the counter selected by the corresponding EV*n*_CTRL[HEVENT] field.

An event *n* is disabled when its corresponding Event n State (EV0_STATE - EV15_STATE) contains all zeros because it is masked regardless of the current state.

In simple applications that do not use states, write 0x01 to this register to enable each event in exactly one state. Because the state does not change (which means, the state variable always remains at its reset value of 0), writing 0x01 permanently enables this event.

Only word-writes are permitted to this register. Attempting to write a halfword value results in a bus error.

Diagram



Fields

Field	Function
31-0 STATEMSKn	Event State Mask Specifies the state in which event *n* happens. If bit *m* = 1, event *n* happens in state *m* of the counter selected by the HEVENT field (*n* = event number, *m* = state number; state 0 = bit 0, state 1= bit 1, and so on). Number of bits = number of states in this SCT.

64.7.3.29 Event n Control (EV0_CTRL - EV15_CTRL)

Offset

For n = 0 to 15:

Register	Offset
EVn_CTRL	304h + (n × 8h)

Function

Defines the conditions for an event to occur, based on the counter values or input and output states.

After you configure an event, it can be selected to trigger multiple actions (for example, stopping the counter and toggling an output) unless the event is blocked in the current SCT state, or the counter is halted. To block a particular event from occurring, use Event n State (EV0_STATE - EV15_STATE). To block all events for a given counter, write 1 to CTRL[HALT] or select an event to halt the counter.

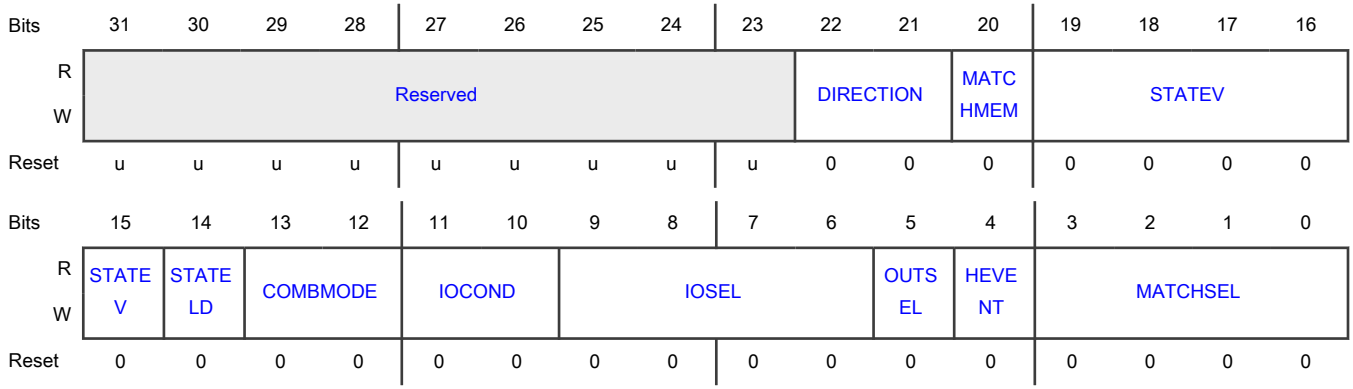
An event can be programmed to occur based on a selected input or output edge or level and/or based on its counter value, matching a selected match register. In Bidirectional mode, you can enable events based on the direction of count.

If CONFIG[UNIFY] = 0, each event is associated with a particular counter in EV*n*_CTRL[HEVENT]. An event is permanently disabled when its event state mask register contains all 0s.

Each event can modify its counter STATE value. If more than one event associated with the same counter occurs in a given clock cycle, only the state change specified for the highest-numbered event among them takes place. Other actions dictated by any simultaneously occurring events all take place.

Only word writes are permitted to this register. Attempting to write a halfword value results in a bus error.

Diagram



Fields

Field	Function
31-23 —	Reserved
22-21 DIRECTION	Direction Specifies the direction for event generation. This field only applies when the counters are operating in BIDIR mode. If CTRL[BIDIR] = 0, SCT ignores this field. 00b - Direction independent (event triggered regardless of the count direction) 01b - Counting up (event triggered only during up-counting when CTRL[BIDIR] = 1) 10b - Counting down (event triggered only during down-counting when CTRL[BIDIR] = 1) 11b - Reserved
20 MATCHMEM	Match Mem If this field = 1 and EV*n*_CTRL[COMBMODE] specifies a match component to the triggering of this event, a match is considered to be active whenever the counter value is greater than or equal to the value specified

Table continues on the next page...

Table continued from the previous page...

Field	Function
	in the match register when counting up, and less than or equal to the match value when counting down. If this field = 0, a match is only active during the cycle when the counter is equal to the match value.
19-15 STATEV	State Value Specifies the state value. The state value is loaded into or added to the state that EV*n*_CTRL[HEVENT] selects, depending on EV*n*_CTRL[STATELD], when this event is the highest-numbered event occurring for that state. If both the STATELD and STATEV fields are 0, there is no change to the value of STATE.
14 STATELD	State Load Controls how EV*n*_CTRL[STATEV] modifies the state that EV*n*_CTRL[HEVENT] selects when this event is the highest-numbered event occurring for that state. 0b - Value of STATEV added to that of STATE (the carry out is ignored) 1b - Value of STATEV loaded into that of STATE
13-12 COMBMODE	Combination Mode Selects how the specified match and I/O condition are used and combined. 00b - OR (the event occurs when either the specified match or I/O condition occurs) 01b - MATCH (uses the specified match only) 10b - IO (uses the specified I/O condition only) 11b - AND (the event occurs when the specified match and I/O condition occur simultaneously)
11-10 IOCOND	Input or Output Condition Selects the I/O condition for event *n*. The detection of edges on outputs lags the conditions that switch the outputs by one SCT clock. To guarantee proper edge and state detection, an input must have a minimum pulse width of at least one SCT clock period. 00b - Low 01b - Rise 10b - Fall 11b - High
9-6 IOSEL	Input or Output Signal Select Selects the input or output signal number associated with this event, if any. Do not select an input in this register if CONFIG[CLKMODE] is 1x. In this case, the clock input is an implicit ingredient of every event.
5 OUTSEL	Input and Output Select Selects the inputs or outputs that EV*n*_CTRL[IOSEL] specifies.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Inputs 1b - Outputs
4 HEVENT	High Event Selects the low and high counters. Do not write 1 to this field if CONFIG[UNIFY] = 1. 0b - Low counter (selects the L state and the L match register that the MATCHSEL field specifies) 1b - High counter (selects the H state and the H match register that the MATCHSEL field specifies)
3-0 MATCHSEL	Match Select Selects the match register associated with this event, if any. A match can occur only when the counter that EV*n*_CTRL[HEVENT] selects is running.

64.7.3.30 Output n Set (OUT0_SET - OUT9_SET)

Offset

For n = 0 to 9:

Register	Offset
OUTn_SET	500h + (n × 8h)

Function

Selects the events that can set each SCT output.

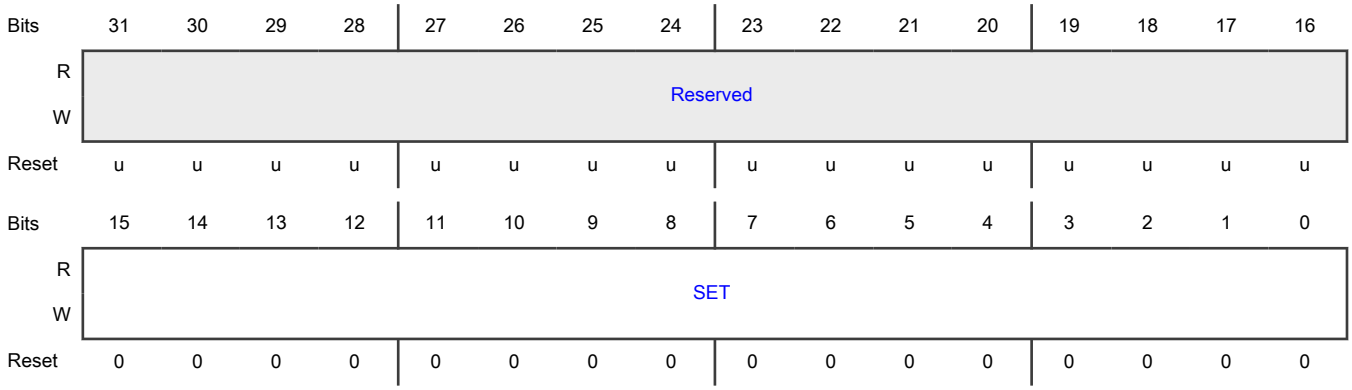
Based on a selected event, each SCT output can be set. There is one output set register for each SCT output. Each bit of an output set register is associated with a different event (bit 0 with event 0, and so on). The selected event can set or clear the output depending on the setting of OUTPUTDIRCTRL[SETCLR*n*]. To define the actual event that sets the output (a match, an I/O pin toggle, and so on), see Event n Control (EV0_CTRL - EV15_CTRL).

Only word-writes are permitted to this register. Attempting to write a halfword value results in a bus error.

NOTE

If SCT is operating as two 16-bit counters, events can modify output states only when no counter is halted. This is true regardless of what triggered the event.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 SET	Set Output Selects events to set outputs. If bit *m* = 1, it selects event *m* to set output *n* (or clear it if OUTPUTDIRCTRL[SETCLR*n*] = 0x1 or 0x2). Output 0 = bit 0, output 1 = bit 1, and so on. Number of bits = number of events in this SCT. If the counter is used in Bidirectional mode, it is possible to reverse the action that the output set and clear registers specify when counting down (see Output Counter Direction Control (OUTPUTDIRCTRL) for more information).

64.7.3.31 Output n Clear (OUT0_CLR - OUT9_CLR)

Offset

For n = 0 to 9:

Register	Offset
OUTn_CLR	504h + (n × 8h)

Function

Selects the events that can clear each SCT output.

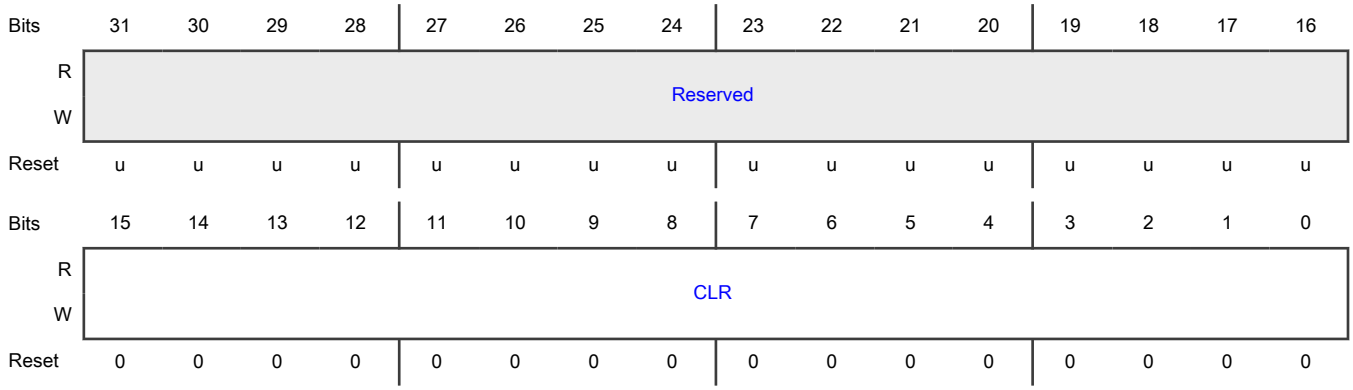
Based on a selected event, each SCT output can be cleared. There is one register for each SCT output that selects which events can clear that output. Each bit of an output clear register is associated with a different event (bit 0 with event 0, and so on). A selected event can clear or set the output depending on the setting of OUTPUTDIRCTRL[SETCLR*n*]. To define the actual event that clears the output (a match, an I/O pin toggle, and so on), see Event n Control (EV0_CTRL - EV15_CTRL).

Only word-writes are permitted to this register. Attempting to write a halfword value results in a bus error.

NOTE

If SCT is operating as two 16-bit counters, events can modify output states only when no counter is halted. This is true regardless of what triggered the event.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 CLR	Clear Output Selects events to clear outputs. If bit *m* = 1, it selects event *m* to clear output *n* (or set it if OUTPUTDIRCTRL[SETCLR*n*] = 0x1 or 0x2). Event 0 = bit 0; event 1 = bit 1, and so on. Number of bits = number of events in this SCT. If the counter is used in Bidirectional mode, it is possible to reverse the action specified by the output set and clear registers when counting down (see Output Counter Direction Control (OUTPUTDIRCTRL) for more information).

Multi-Rate Timer (MRT)

65.1 Chip-specific MRT information

Table 605. Reference links to related information

Topic	Related module	Reference
Full description	MRT	MRT
Peripheral memory map		Memory map overview
Clocking		Clock overview Clock controller
Signal multiplexing	IOPCTL	External signals and pin multiplexing IO PAD controller

65.1.1 Module instances

This device has two instances of the MRT module, MRT0 and MRT1.

Table 606. MRT instances

	MRT0	MRT1
Located in	VDD2_COMP	VDD1_SENSE
Access	CPU0, HiFi4, EZH-V, eDMA0, eDMA1	CPU1, HiFi1, EZH-V, eDMA2, eDMA3

65.1.2 Chip-specific MRT initialization

To initialize the MRT module:

1. Enable the clock to MRT0 via CLKCTL0_PSCCTL2 register and enable the clock to MRT1 via CLKCTL1_PSCCTL1 register.
2. Clear the MRT0 reset via RSTCTL0_PRSTCTL3[MRT0] and clear the MRT1 reset via RSTCTL2_PRSTCTL0[MRT1].
3. Ensure that the MRT can issue an interrupt in the chip. See registers in INPUTMUX:
   - MRT0: HIFI4_INTERRUPT0 - HIFI4_INTERRUPT26, EZH_TRIG0 - EZH_TRIG7 in INPUTMUX0
   - MRT1: HIFI1_INTERRUPT0 - HIFI1_INTERRUPT26 in INPUTMUX1

65.2 Overview

MRT provides a repetitive interrupt timer with 4 channels.

65.2.1 Block diagram

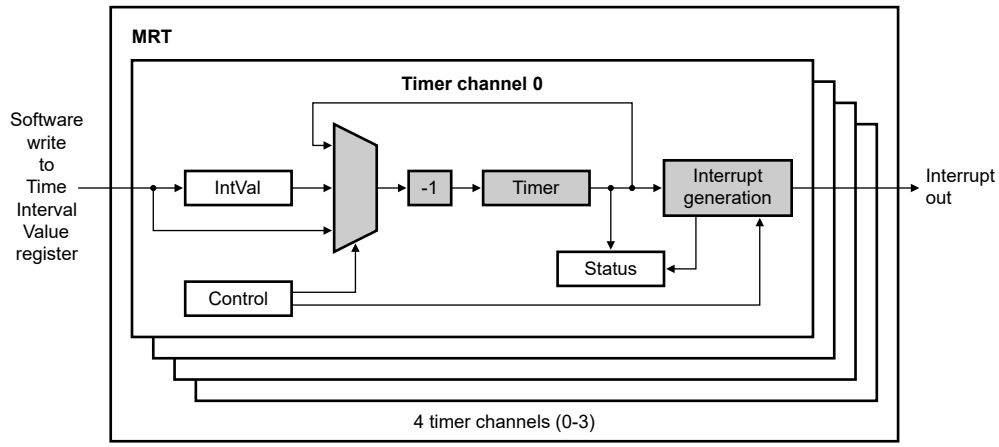

Figure 271. Block diagram

65.2.2 Features

- 24-bit interrupt timer.
- There are 4 channels independently counting down from individually set values.
- Repeat Interrupt, One-Shot Interrupt, and One-Shot Stall modes.
- You can program individual time intervals for each channel.
- Each channel operates independently of the other channels.

65.3 Functional description

The following sections discuss various modes that affect the functionality of MRT.

65.3.1 Operating modes

MRT has the following three operating modes:

- Repeat Interrupt mode
- One-Shot Interrupt mode
- One-Shot Stall mode

65.3.1.1 Repeat Interrupt mode

• Generates repeated interrupts after a selected time interval.

• Gets used for application-based Pulse Width Modulation (PWM) or Pulse Position Modulation (PPM).

When TIMER*n* is in idle state, writing a nonzero value (IVALUE) to INTVAL*n* immediately loads the time interval value (IVALUE -1). Then the timer begins to count down from this value.

After the timer reaches 0

- an interrupt is generated.
- the value in INTVAL*n* (IVALUE -1) is automatically reloaded, and
- the timer starts to count down again.

When the timer is running in Repeat Interrupt mode, you can perform various interval timer actions (change or stop):

Table 607. Possible actions in Repeat Interrupt mode

Action	To perform action	Timer does this	Interrupt
Change the interval value on the next interval timer cycle.	• Write new value (>0) to INTVAL*n*. • Write 0 to LOAD.	On the next cycle, the timer counts down from the new value.	An interrupt is generated when the timer reaches 0.
Change the interval value immediately (also called "change on-the-fly") in the interval timer.	• Write new value (>0) to INTVAL*n*. • Write 1 to LOAD.	The timer immediately starts to count down from the new timer interval value.	An interrupt is generated when the timer reaches 0.
Stop the interval timer at the end of the time interval.	• Write 0 to INTVAL*n*. • Write 0 to LOAD.	The timer stops at the end of the time interval.	An interrupt is generated when the timer reaches 0.
Stop the interval timer immediately.	• Write 0 to INTVAL*n*. • Write 1 to LOAD.	The timer stops immediately.	No interrupt is generated when INTVAL*n* is written.

65.3.1.2 One-Shot Interrupt mode

• In this mode, the timer generates one interrupt after a one-time count.

• This mode allows you to generate an interrupt at any time.

• Using this mode, you can introduce a specific delay in a software task.

When the timer is in an idle state, writing a nonzero value (IVALUE) to INTVAL*n* immediately loads the time interval value (IVALUE -1), and the timer starts to count down. As soon as the timer reaches 0, the timer stops and an interrupt is generated (and then enters the idle state).

When the timer is running in One-Shot Interrupt mode, you can perform the following interval timer actions (load or stop):

Table 608. Possible actions in One-Shot Interrupt mode

Action	To perform action	Timer does this	Interrupt
Load a timer interval value.	• Write a new time interval value (>0) to INTVAL*n*. • Write 1 to LOAD.	The timer immediately reloads the new time interval, and starts counting down from the new value.	An interrupt is generated when the timer reaches 0.
Stop the interval timer.	• Write a 0 to INTVAL*n*. • Write 1 to LOAD.	The timer immediately stops counting and moves to the idle state.	No interrupt is generated when INTVAL*n* is updated.

65.3.1.3 One-Shot Stall mode

• Used for very short delays (for example, when the delay needed is less than the time it takes to arrive at an interrupt service routine).

• Designed for very low software overhead that requires only a single write to INTVAL*n* (if the channel is already configured for One-Shot stall mode). MRT counts the requested delay when stalling the bus write operation, and then concluding the write operation when the delay has finished. No interrupt or status polling is needed.

Use this mode:

- when a short delay is needed between two software-controlled events.
- when a delay is expected before your application can continue.

The CPU consumes a minimum amount of power during One-Shot Stall mode, because no bus transactions occur during that period.

One-Shot Stall mode provides a minimum amount of time between the execution of the instruction that performs the write to INTVAL*n* and the time that your software resumes execution. Other system events, such as interrupts or other bus managers accessing the APB bus where MRT resides, can cause the delay to be longer.

65.3.2 Clocking

Table 609. MRT clocks

Type of clock	Description
Bus clock (vpb_clk)	Controls the access to the MRT registers and functions the MRT module.

65.3.3 Interrupts

A channel provides 3 different interrupts modes listed below and can select the interrupt mode individually per channel. This interrupt can be programmed with an independent time interval.

- Repeat interrupt
- Shot interrupt
- Shot bus stall interrupt

65.4 External signals

This module has no external signals.

65.5 Initialization

To initialize:

1. Enable the clock to MRT.
2. Deassert MRT reset.
3. Ensure that MRT can issue an interrupt in the chip.

See the Chip-specific section for more details.

65.6.1.2 Time Interval Value (INTVAL0 - INTVAL3)

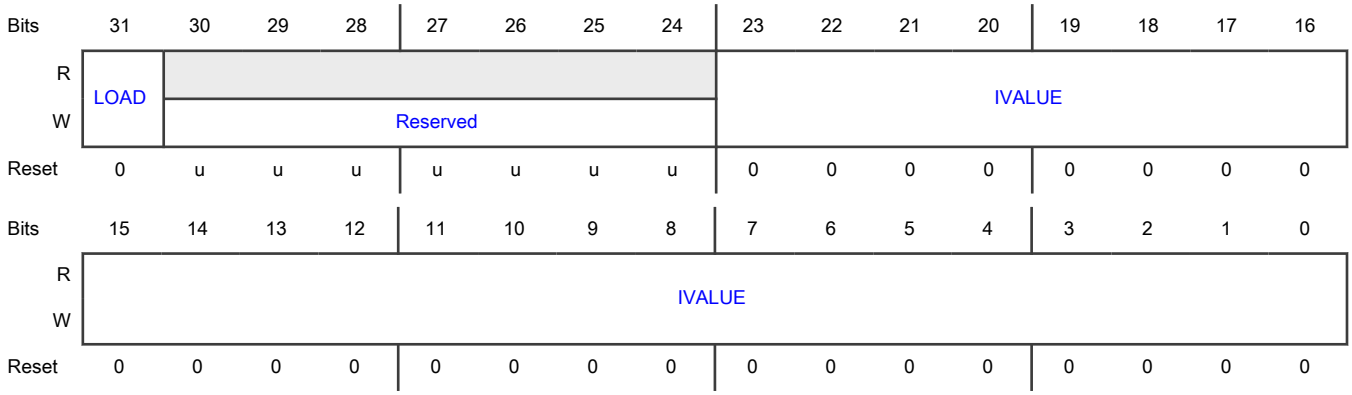
Offset

Register	Offset
INTVAL0	0h
INTVAL1	10h
INTVAL2	20h
INTVAL3	30h

Function

Contains MRT load value and controls how the timer is reloaded. The load value is IVALUE -1.

Diagram



Fields

Field	Function
31 LOAD	Force Load Enable Determines how the timer interval value (IVALUE -1) is loaded into the TIMER*n*. LOAD is write only. Reading LOAD always returns 0. If the repeat mode is selected, the load from the INTVAL*n* to the TIMER*n* is processed at the end of the time interval. The INTVAL*n* interval value (IVALUE -1) is immediately loaded into the TIMER*n* when it is running. 0b - No force load 1b - Force load
30-24 —	Reserved Reserved. Read value is undefined; only 0 should be written.
23-0 IVALUE	Time Interval Load Value. INTVAL*n*[IVALUE] is loaded into TIMER*n*, and MRT channel *n* starts counting down from IVALUE -1. If the timer is idle, then writing a nonzero value to INTVAL*n*[IVALUE] starts the timer immediately. If the timer is running, then writing a 0 to INTVAL*n*[IVALUE] does the following: if LOAD = 1, then the timer stops immediately; if LOAD = 0, then the timer stops at the end of the time interval.

65.6.1.3 Timer (TIMER0 - TIMER3)

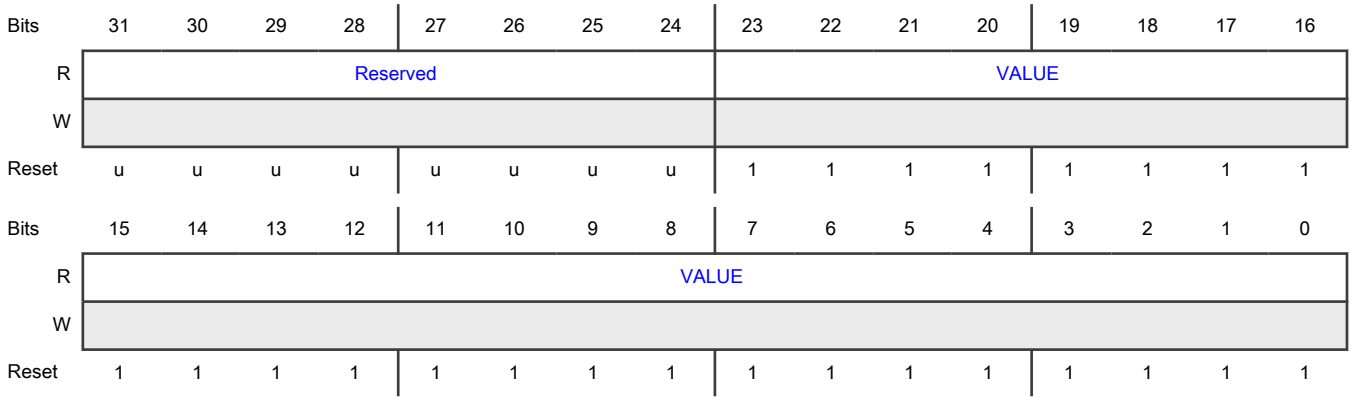
Offset

Register	Offset
TIMER0	4h
TIMER1	14h
TIMER2	24h
TIMER3	34h

Function

Holds the current timer value (the TIMER*n* reads the value of the down counter). TIMER*n* registers are read only.

Diagram



Fields

Field	Function
31-24 —	Reserved Reserved. Read value is undefined; only 0 should be written.
23-0 VALUE	Current Timer Value Holds the current timer value of the down counter. The initial value of TIMER*n* is loaded as (IVALUE -1) from INTVAL*n*, either at the end of the time interval or immediately in the following cases: INTVAL*n* is updated in the idle state or INTVAL*n* is updated with LOAD = 1. When the timer is in an idle state, reading TIMER*n*[VALUE] fields returns -1 (00FF FFFFh).

65.6.1.4 Control (CTRL0 - CTRL3)

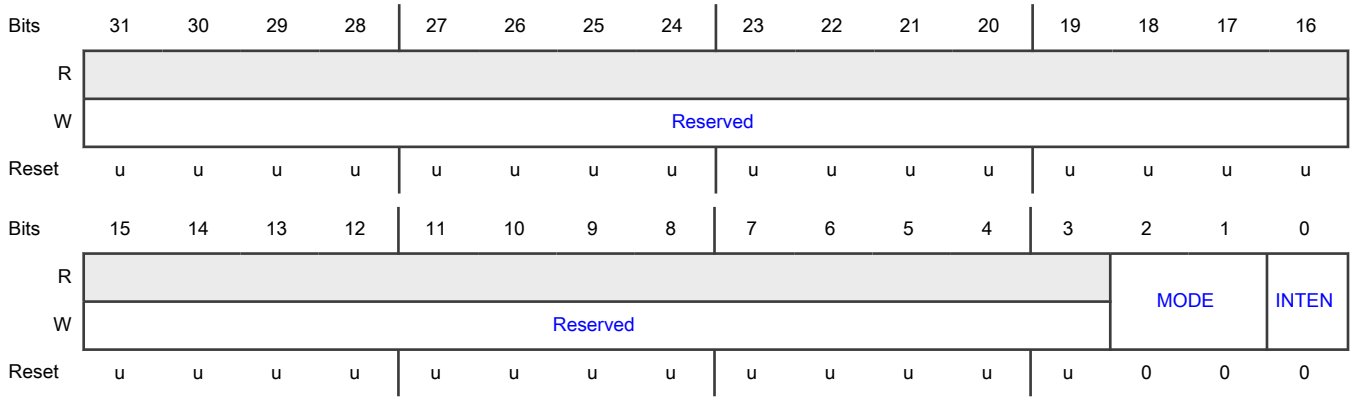
Offset

Register	Offset
CTRL0	8h
CTRL1	18h
CTRL2	28h
CTRL3	38h

Function

Controls the modes and enables the interrupt for each MRT.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-1 MODE	MRT Operating mode Selects the timer mode. 00b - Repeat Interrupt mode 01b - One-Shot Interrupt mode 10b - One-Shot Stall mode 11b - Reserved
0 INTEN	Interrupt request Enables the TIMER*n* interrupt. 0b - Disabled 1b - Enabled

65.6.1.5 Status (STAT0 - STAT3)

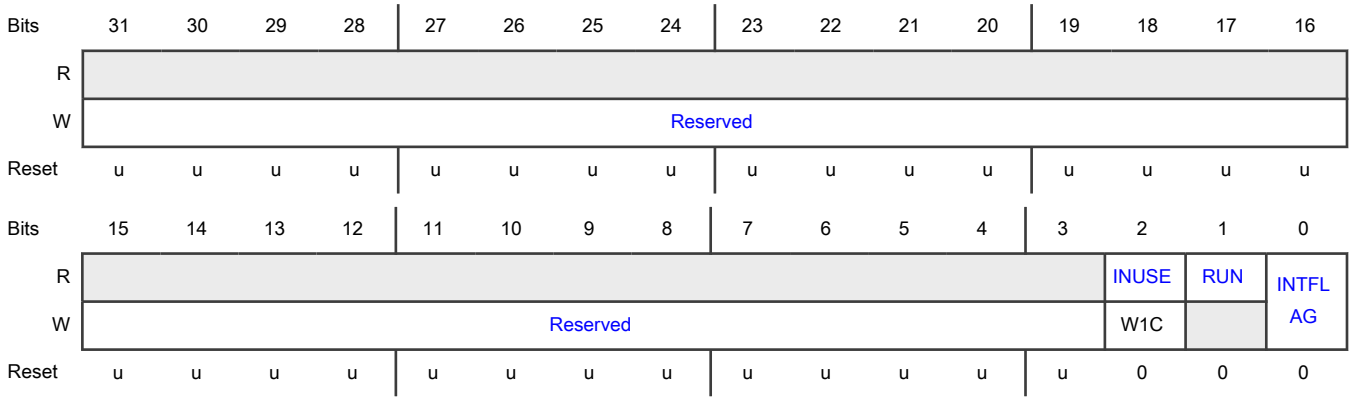
Offset

Register	Offset
STAT0	Ch
STAT1	1Ch
STAT2	2Ch
STAT3	3Ch

Function

Indicates the status of each MRT timer channel.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 INUSE	Channel-In-Use flag Affects the use of Idle Channel (IDLE_CH); the operating details depend on the operating mode bit in MODCFG[MULTITASK]. Writing 1 to this bit clears the status. 0b - This timer channel is not in use. 1b - This timer channel is in use.
1 RUN	Timer n State Indicates the state of TIMER*n*. STAT*n*[RUN] is read only. TIMER*n* stops in idle state and runs in running state. 0b - Idle state. 1b - Running.
0 INTFLAG	Interrupt Flag Monitors the interrupt flag. If the INTEN bit in the CONTROLn is also set to 1, then the interrupt for timer channel n and the global interrupt are generated. Writing a 1 to INTFLAG bit clears the interrupt request. 0b - No pending interrupt. 1b - Pending interrupt.

65.6.1.6 Module Configuration (MODCFG)

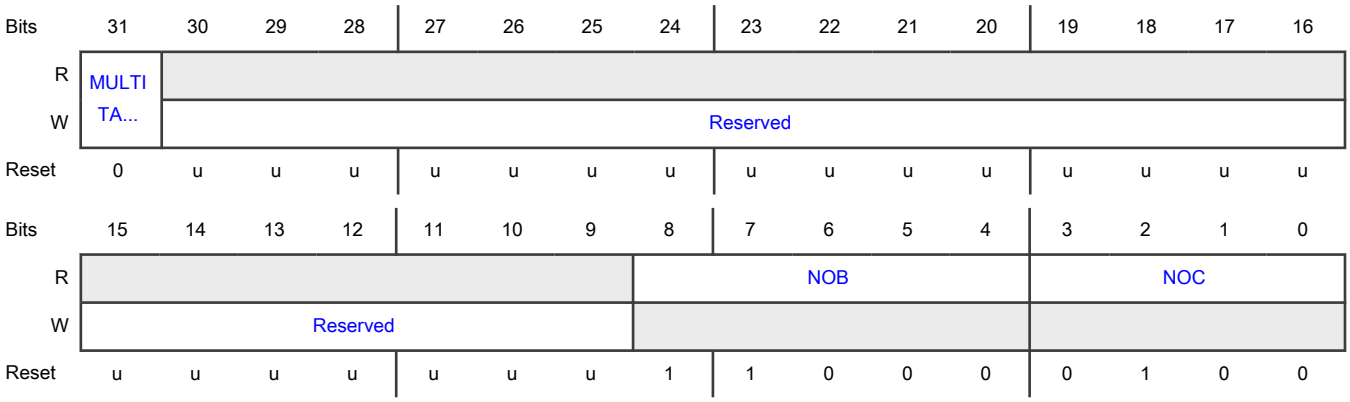
Offset

Register	Offset
MODCFG	F0h

Function

Provides information about this particular MRT instance. It also allows selecting an overall mode for the idle channel feature. MODCFG[MULTITASK] provides the configuration (number of channels and timer width) for this MRT. A reset of the INUSE(n) flags for all channels happens in Hardware Status mode.

Diagram



Fields

Field	Function
31 MULTITASK	MULTITASK Selects the operating mode for STAT*n*[INUSE] and Idle Channel (IDLE_CH). 0b - Hardware status mode. 1b - Multitask mode
30-9 —	Reserved Read value is undefined; only 0 should be written.
8-4 NOB	Number of Bits Identifies the number of timer bits in this MRT (24 bits on this chip).
3-0 NOC	Number of Channels Identifies the number of channels in this MRT.

65.6.1.7 Idle Channel (IDLE_CH)

Offset

Register	Offset
IDLE_CH	F4h

Function

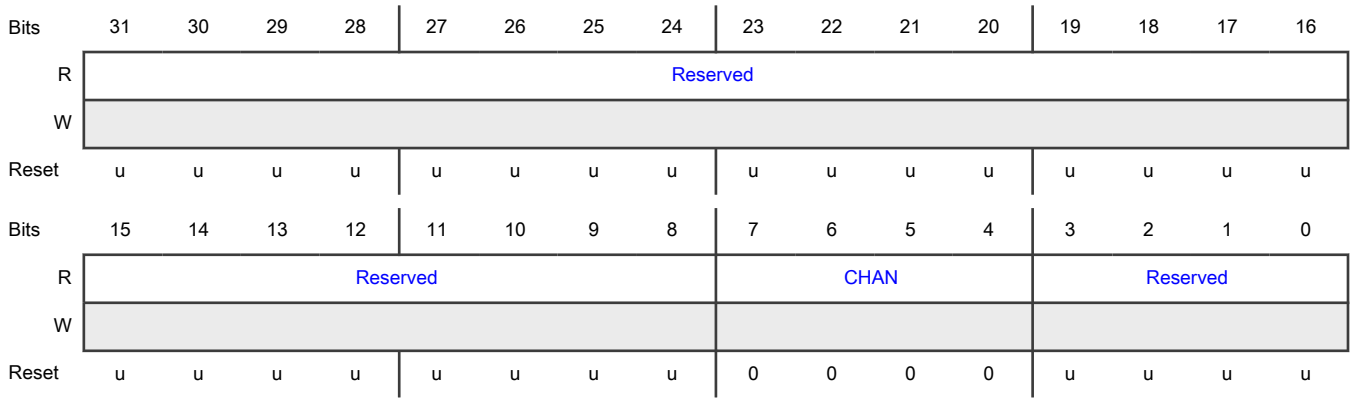
Returns the number of the first Idle Channel.

Use Idle Channel (IDLE_CH) for finding available channels in MRT. This allows you more flexibility when using MRT—no fixed channel assignments are required, and you do not need to search for an available channel. Generally, Idle Channel (IDLE_CH) returns the lowest available channel number.

MODCFG[MULTITASK] allows you to use Idle Channel (IDLE_CH) in two ways. MODCFG[MULTITASK] affects both the functions of Idle Channel (IDLE_CH), and the function of STAT*n*[INUSE] for each MRT channel:

- MULTITASK = 0: Hardware status mode. The STAT*n*[INUSE] for all MRT channels are reset. Idle Channel (IDLE_CH) returns the lowest idle channel number. A channel is considered idle if its RUN flag = 0, and there is no interrupt pending for that channel.
- MULTITASK = 1: Multitask mode. In Multitask mode, the STAT*n*[INUSE] allow more control over when MRT channels are released for further use. When Idle Channel (IDLE_CH) is read, returning a channel number of an idle channel, the STAT*n*[INUSE] for that channel is set by hardware. That channel is not considered idle until its RUN flag = 0, and there is no interrupt pending, and its INUSE flag = 0. This allows reserving an MRT channel with a single register read, and there is no need to start the channel before that channel is no longer considered idle by Idle Channel (IDLE_CH). It also allows you to identify a specific MRT channel. Then you can use that channel more than once without releasing it, removing the need to ask for an available channel for every use.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-4 CHAN	Idle Channel Helps in reading IDLE_CH[CHAN] and returns the lowest idle timer channel. The number is positioned so that you can use it as an offset from MRT base address. This provides access to the registers for the allocated channel. If all timer channels are running, then CHAN = Fh.
3-0 —	Reserved

65.6.1.8 Global Interrupt Flag (IRQ_FLAG)

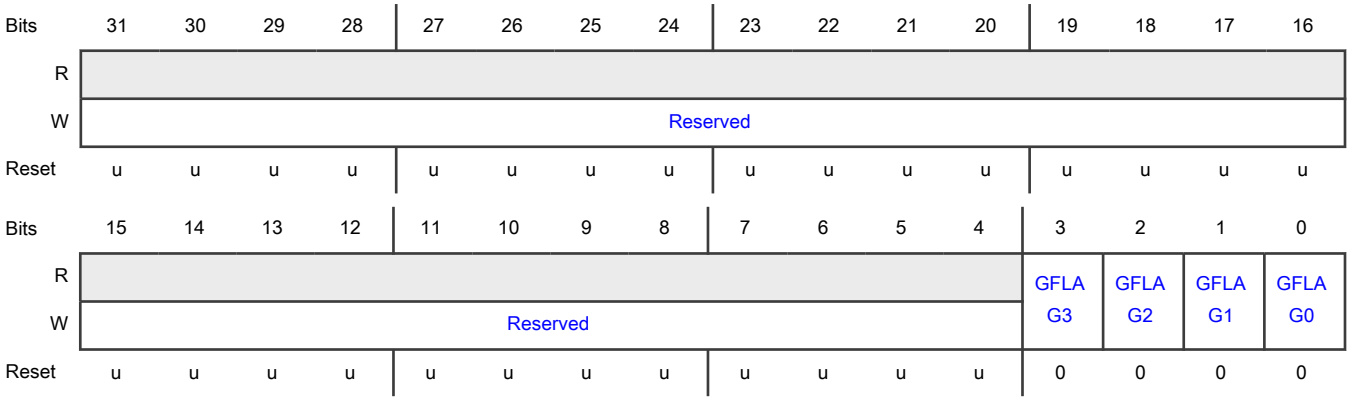
Offset

Register	Offset
IRQ_FLAG	F8h

Function

Combines the interrupt flags from the individual timer channels into one register. Setting and clearing each flag behaves in the same way as setting and clearing STAT*n*[INTFLAG] in each of the STATUS*n* registers.

Diagram



Fields

Field	Function
31-4 —	Interrupt Flag Reserved. Read value is undefined; only 0 should be written.
3 GFLAG3	Interrupt Flag Monitors the interrupt flag of TIMER3 and acts similar to channel 0.
2 GFLAG2	Interrupt Flag Monitors the interrupt flag of TIMER2 and acts similar to channel 0.
1 GFLAG1	Interrupt Flag Monitors the interrupt flag of TIMER1 and acts similar to channel 0.
0 GFLAG0	Interrupt Flag Monitors the interrupt flag of TIMER0. Writing 0 is equivalent to no operation. In the pending interrupt state, Timer (TIMER0 - TIMER3) has reached the end of the time interval. If CTRL*n*[INTEN] in CONTROL*n* also gets 1, then there is a timer channel *n* interrupt and a global interrupt. Writing 1 to IRQ_FLAG[GFLAG0] clears the interrupt request.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No pending interrupt. 1b - Pending interrupt

Chapter 66
Windowed Watchdog Timer (WWDT)

66.1 Chip-specific WWDT information

Table 610. Reference links to related information

Topic	Related module	Reference
Full description	WWDT	WWDT
Peripheral memory map		Memory map overview
Power management	PMC	Power overview PMC
Clocking		Clock overview Clock controller

NOTE

A watchdog reset resets the chip. See Reset Control for details.

66.1.1 Module instances

This device has four instances of the WWDT module, numbered WWDT0 through WWDT3.

Table 611. WWDT instances

	WWDT0, WWDT1	WWDT2, WWDT3
Located in	VDD2_COMP	VDD1_SENSE
Access	CPU0, HiFi4, EZH-V, eDMA0, eDMA1	CPU1, HiFi1, EZH-V, eDMA2, eDMA3

66.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

66.1.3 MOD[LOCK] behavior

- When MOD[LOCK] of WWDT0 or/and WWDT1 is set to 1b, the write to the SLEEPCFG[LPOSC_PD] and RUNCFG[LPOSC_PD] fields of the SLEEPCON0 instance changes fields configuration but does not take effect.
- When MOD[LOCK] of WWDT2 or/and WWDT3 is set to 1b, the write to the SLEEPCFG[LPOSC_PD] and RUNCFG[LPOSC_PD] fields of the SLEEPCON1 instance changes fields configuration but does not take effect.

After MOD[LOCK] is set to 1b and a Watchdog feed is performed, hardware prevents disabling or powering down of the lposc, which is used as watchdog oscillator. That is, in order to keep lposc running for any WWDT instance, enable the lposc and set the MOD[LOCK] of related WWDT instances to 1b.

MOD[LOCK] can be configured once by software and is cleared by any reset.

66.1.4 Watchdog clock (WDCLK) source

For this chip, 1m_lposc is the clock source for all the WWDT instances, see Clock Controller (CLKCTL) for details.

66.2 Overview

WWDT helps you reset or interrupt a microcontroller within a programmable time, if the microcontroller (or core) is stuck in an infinite loop or is executing an unintended code. If an application fails to reload or feed a watchdog timer within the predefined duration of time, it generates a watchdog reset (if enabled).

66.2.1 Block diagram

In the following WWDT block diagram, the synchronization logic (APB bus clock to WDCLK) is not shown. See the chip-specific WWDT information section or clocking chapter for more details.

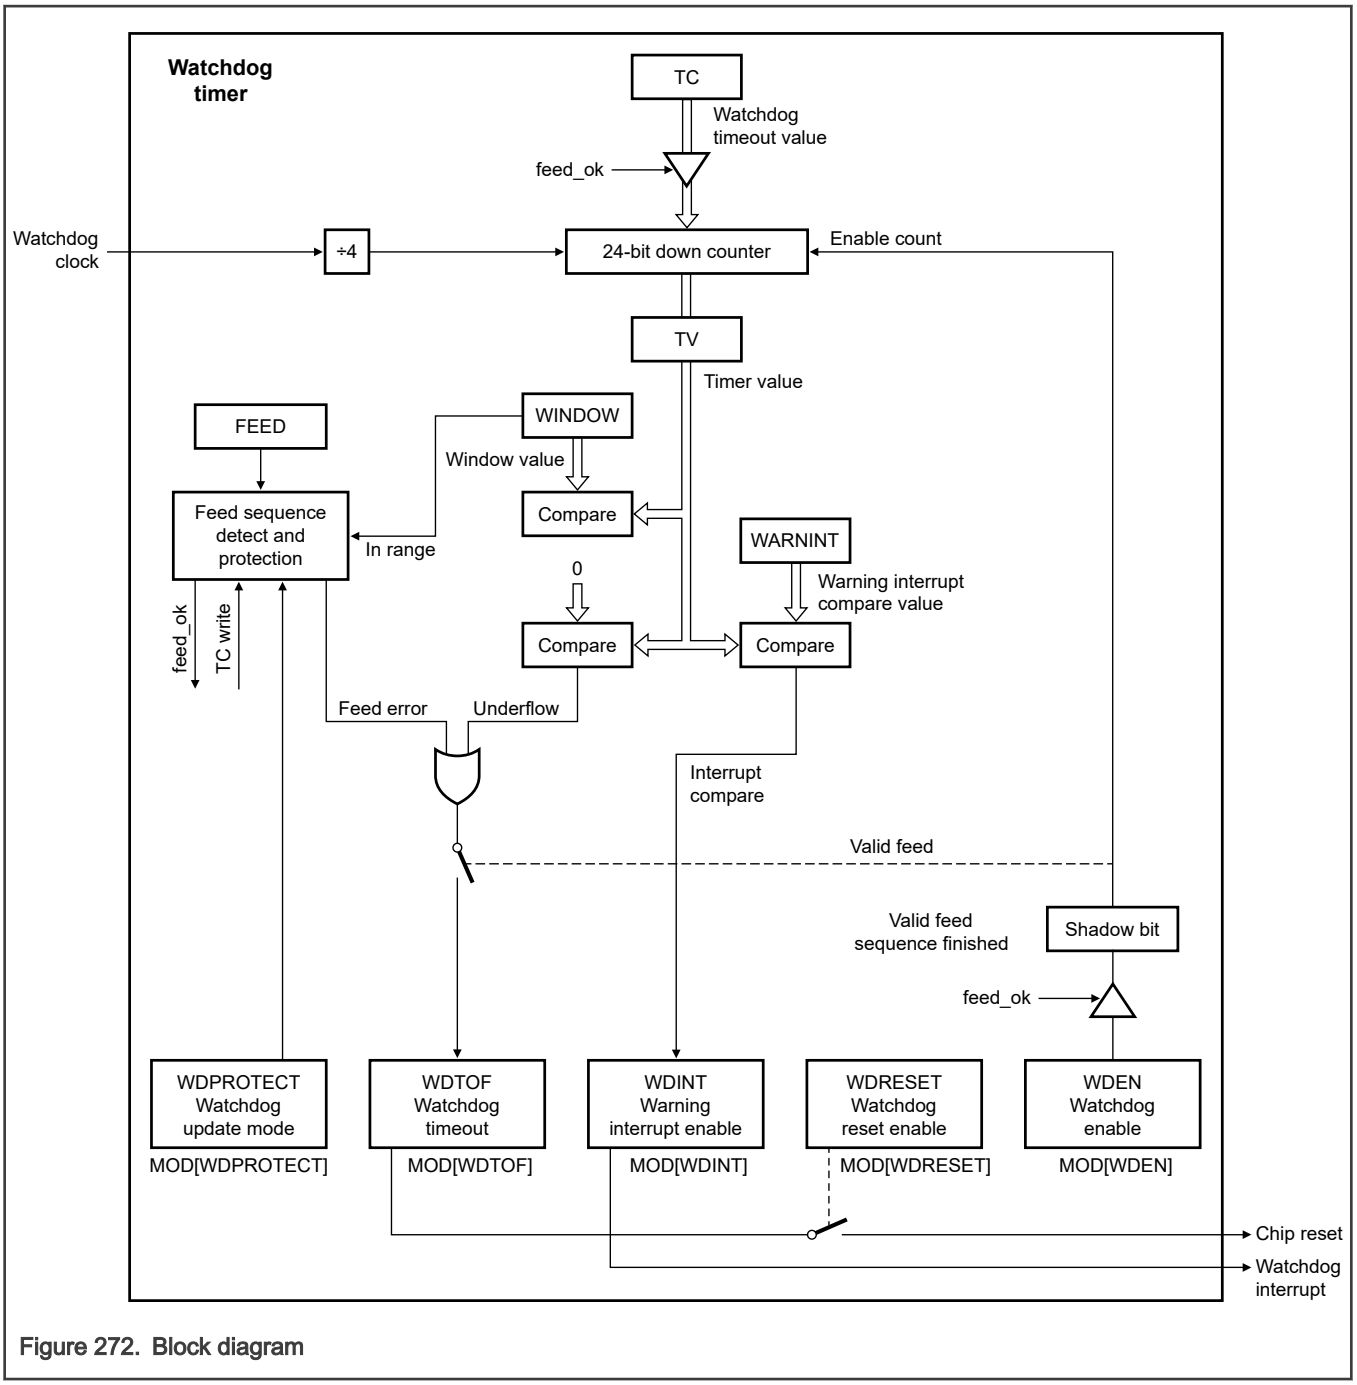


Figure 272. Block diagram

66.2.2 Features

- Can reset or interrupt the microcontroller within a programmable time
- Watchdog reset indication flag
- Clocking features:
  - Programmable 24-bit timer with an internal fixed (divided by 4) prescaler
  - Selectable time period in increments of four watchdog clocks: From 1024 watchdog clocks (T_{WDCLK} x 256 x 4) to over 67 million watchdog clocks (T_{WDCLK} x 2^{24} x 4)

  - Watchdog clock (WDCLK) source having a selectable frequency in the range of 6 kHz to 1.5 MHz (see the chip-specific information section and the Clocking chapter for detailed setting in this device)
- Can be configured to run in Low-Power mode (see the chip-specific information section and the Power Management chapter for detailed setting in this device)
- Other configurable features:
  - Windowed operation requiring a watchdog reload to occur between a programmable minimum and maximum timeout period
  - Generation of a warning interrupt at a programmable time before watchdog timeout
  - Protection of the watchdog reload value so that you can change it only after the warning interrupt time is reached

66.3 Functional description

When you program a watchdog window (a timing window), an early watchdog reload is also treated as a watchdog event, which prevents situations where a system failure may still reload the watchdog timer. For example, the application code could be stuck in an interrupt service that contains a watchdog reload (feed). You must set the timing window in a way that this situation causes an early watchdog timer reload, which generates a watchdog event, and then enables the system to recover from this situation.

WWDT consists of a fixed (divided by 4) prescaler and a 24-bit counter. The minimum value of the counter is FFh; if you write a value lower than FFh, the counter automatically loads with the value FFh.

- Minimum watchdog interval is (T_{WDCLK} X 256 X 4).
- Maximum watchdog interval is (T_{WDCLK} X 2^{24} X 4) in multiples of (T_{WDCLK} X 4).

66.3.1 Operating modes

This section describes all functional operating modes of the WWDT module: Disabled, Watchdog Interrupt, and Watchdog Reset.

Table 612. Watchdog operating modes selection

MOD[WDEN]	MOD[WDRESET]	Mode	Mode description
0	X (0 or 1)	Disabled	Debugs or operates without the watchdog running.
1	0	Watchdog Interrupt	Generates a watchdog warning interrupt but does not enable the watchdog reset. A watchdog counter equal to the value of WARNINT[WARNINT] sets MOD[WDINT] and generates a watchdog interrupt request.
1	1	Watchdog Reset	Enables both the watchdog interrupt and watchdog reset: • A watchdog counter equal to the value of WARNINT[WARNINT] sets MOD[WDINT] and generates a watchdog interrupt request. • A watchdog counter equal to 0 resets the microcontroller. • A watchdog feed before reaching the value of WINDOW[WINDOW] also causes a watchdog reset.

66.3.2 Example timing diagrams to show WWDT in operation

A feed is correct when both of the following conditions are true:

- A valid feed sequence completes, writing AAh followed by 55h to FEED[FEED].
- The value of TV[COUNT] is not greater than the value of WINDOW[WINDOW].

If either of these conditions is not true, a feed error occurs.

In the correct watchdog feed with Windowed mode enabled, the sequence of writing AAh followed by 55h occurs when the counter value (11FCh) is not greater than the value of WINDOW[WINDOW] (1200h). It is a correct feed (reload) event. After the correct feed event occurs, the watchdog counter reloads with the TC[COUNT] value (2000h).

In addition to the above two conditions, when MOD[WDPROTECT] = 1, the watchdog counter must not be greater than the value of WARNINT[WARNINT] for a correct feed to occur. See the following figure for a pictorial representation.

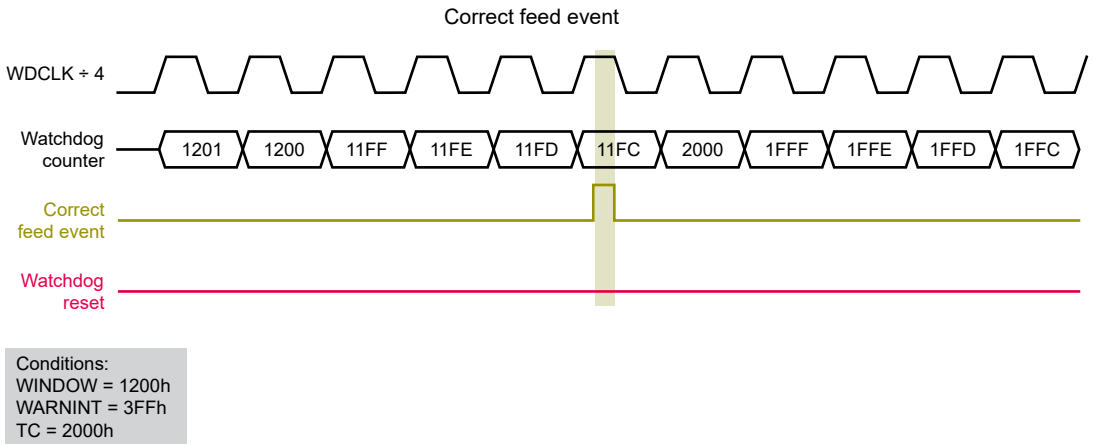

Figure 273. Correct watchdog feed with Windowed mode enabled

A correct feed sequence can only occur when the value of TV[COUNT] is not greater than the value of WINDOW[WINDOW] (1200h). Otherwise, a feed error occurs.

The following figure shows a reset trigger when you feed the watchdog too early.

An early feed event occurs if the feed sequence occurs when the watchdog counter value (1257h) is greater than the value of WINDOW[WINDOW] (1200h). This feed error can generate a reset if MOD[WDRESET] = 1.

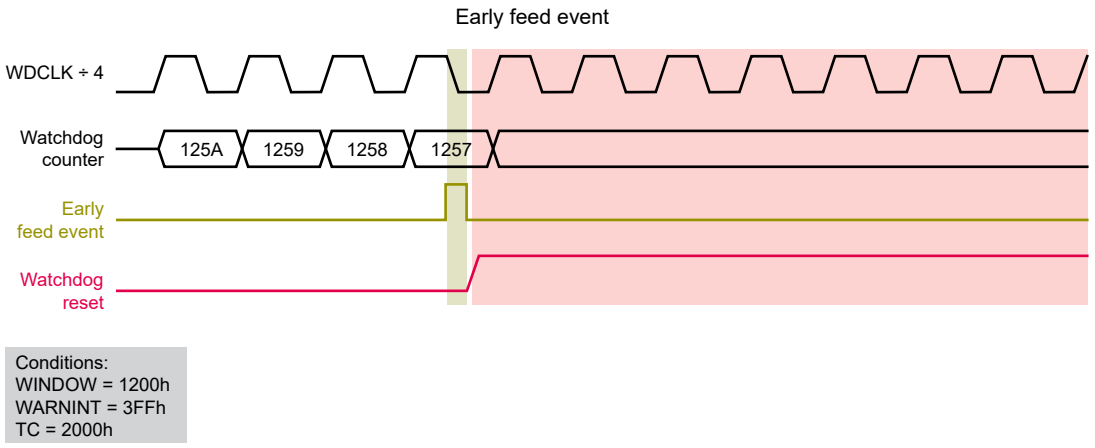

Figure 274. Early watchdog feed with Windowed mode enabled

The following figure shows WWDT generating a warning.

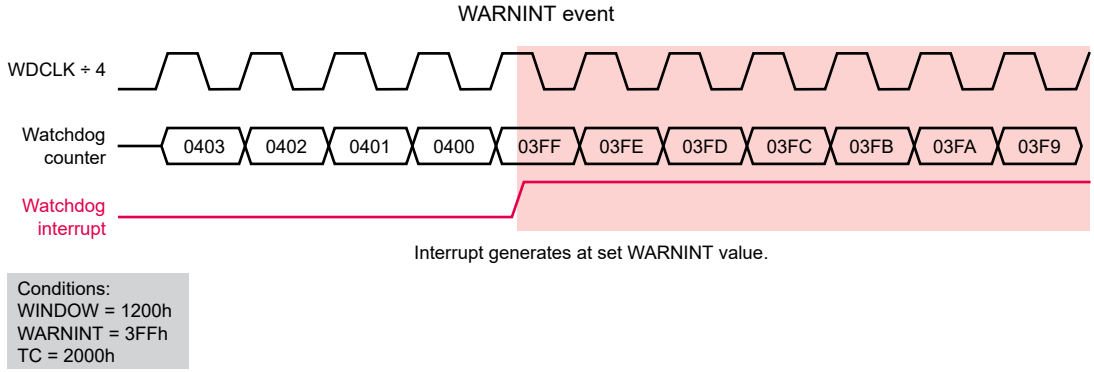

Figure 275. Watchdog warning interrupt

66.3.3 Clocking

WWDT uses two clocks: APB bus clock and WDCLK.

- The system clock derives the APB bus clock that is used for APB accesses to the watchdog registers.
- The watchdog oscillator derives WDCLK that is used for watchdog timer counting.

The synchronization logic between the two clock domains works as follows:

- When updating Mode (MOD) and Timer Constant (TC), the new value takes effect in three WDCLK cycles on the logic in the WDCLK clock domain.
- When the watchdog timer is counting on WDCLK, the synchronization logic first locks the value of the counter on WDCLK and then synchronizes it with the APB bus clock, so that the CPU can read Timer Value (TV).

NOTE

Because of the synchronization step, you must add a delay of three WDCLK clock cycles between the feed sequence and the time that you take to enable the functionality of MOD[WDPROTECT]. The length of the delay depends on the selected watchdog clock, WDCLK.

66.3.4 Using the WWDT lock

WWDT supports lock features to ensure continuous operation. These features prevent:

- The disabling of the WWDT clock source.
- The changing of the WWDT reload value.

66.3.4.1 Preventing the disabling of the WWDT clock source

If MOD[LOCK] = 1, the WWDT clock source is locked. You cannot disable the clock source when entering Sleep or Deep-Sleep modes. Therefore, enable the watchdog oscillator for each Power mode before writing 1 to MOD[LOCK].

66.3.4.2 Preventing the changing of the WWDT reload value

If MOD[WDPROTECT] = 1, then any attempt to change the value of TC[COUNT] with a feed sequence, before the watchdog counter value becomes less than the values of WARNINT[WARNINT] and WINDOW[WINDOW], sets MOD[WDTOF] and causes a watchdog reset.

Any type of reset disables the reload overwrite lock mechanism.

66.4 External signals

This module has no external signals.

66.5 Initialization

Perform the following steps to initialize WWDT:

1. Enable and configure the watchdog oscillator.
2. Set the watchdog timer constant reload value using TC[COUNT].
3. Set the watchdog timer operating mode using MOD[WDPROTECT].
4. Set a value for the watchdog window time using WINDOW[WINDOW], if the windowed operation is desired.
5. Set a value for the watchdog warning interrupt using WARNINT[WARNINT] and configure the system interrupt controller, if a warning interrupt is desired.
6. Enable the watchdog by writing AAh followed by 55h to FEED[FEED].

To prevent a watchdog event, you must feed or reload WWDT again before the watchdog counter reaches 0. If you set a value for the watchdog window time, then the feed or reload must also occur after the watchdog counter passes the value of WINDOW[WINDOW].

After you configure WWDT in a way that a watchdog event causes a reset (MOD[WDRESET] = 1), or when the counter reaches 0 (it causes a reset), then the microcontroller (or core) is also reset (loading the stack pointer and program counter from the vector table, just like the way it happens for an external reset).

66.6 Memory map and register definition

This section includes the WWDT module memory map and detailed descriptions of all registers.

66.6.1 WWDT register descriptions

66.6.1.1 WWDT memory map

WWDT0 base address: 4000_E000h

WWDT1 base address: 4002_E000h

WWDT2 base address: 4005_0000h

WWDT3 base address: 4005_1000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Mode (MOD)	32	RW	0000_0000h
4h	Timer Constant (TC)	32	RW	0000_00FFh
8h	Feed Sequence (FEED)	32	W	See section
Ch	Timer Value (TV)	32	R	0000_00FFh
14h	Warning Interrupt Compare Value (WARNINT)	32	RW	0000_0000h
18h	Window Compare Value (WINDOW)	32	RW	00FF_FFFFh

66.6.1.2 Mode (MOD)

Offset

Register	Offset
MOD	0h

Function

Controls the operation of WWDT. You must perform a watchdog feed before any changes to this register take effect.

NOTE

After you write 1 to MOD[WDEN], MOD[WDPROTECT], or MOD[WDRESET], you can return those fields to 0 only with an external reset or a WWDT reset. Until those resets occur, writing 0 to the aforementioned fields has no effect.

Fields

Field	Function
31-7 —	Reserved
6 —	Reserved
5 LOCK	Lock Prevents disabling or powering down of the watchdog oscillator after you write 1 to this field and perform a watchdog feed. You can write 1 to this field, which can become 0 only with a reset. 0b - No Lock 1b - Lock
4	Watchdog Update Mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
WDPROTECT	Protects the value of TC[COUNT] from changing at any time. In Flexible mode (when this field is 0), you can change the value of TC[COUNT] at any time. In Threshold mode (when this field is 1), you can change the value of TC[COUNT] only after the counter is less than the individual values of WARNINT[WARNINT] and WINDOW[WINDOW]. Any attempt to change the value of TC[COUNT] with a feed sequence, before the watchdog counter value becomes less than the values of WARNINT[WARNINT] and WINDOW[WINDOW], sets MOD[WDTOF] and causes a watchdog reset. You can write 1 to this field, which can become 0 only with a reset (see the note in MOD register). 0b - Flexible 1b - Threshold
3 WDINT	Warning Interrupt Flag Sets the flag when the timer is at or below the value defined in WARNINT[WARNINT]. Note that you cannot clear this flag while the value of WARNINT[WARNINT] is equal to the value of TV[COUNT]. This can occur if the value of both WARNINT[WARNINT] and MOD[WDRESET] is 0 when TV[COUNT] decrements to 0. When you configure WWDT to generate a warning interrupt, the interrupt occurs when the counter is no longer greater than the value defined by WARNINT[WARNINT]. If a feed sequence occurs when the watchdog counter value is greater than the value of WINDOW[WINDOW], this flag is set. Any reset clears this flag. 0b - No flag 1b - Flag
2 WDTOF	Watchdog Timeout Flag The bit could be set if: • Watchdog timer timeout has occurred • Feed error has occurred You must clear this flag by writing 0 to it. An external reset or POR clears this flag too. 0b - Watchdog event has not occurred. 1b - Watchdog event has occurred (causes a chip reset if WDRESET = 1).
1 WDRESET	Watchdog Reset Enable Allows a watchdog timeout to cause a chip reset, if this field = 1. After you write 1 to this field, you cannot write 0 to it (see the note in MOD register). **NOTE** If you write 0 to this field, and after an interrupt occurs, do not write 1 to this field immediately unless you refresh the watchdog. 0b - Interrupt 1b - Reset

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 WDEN	Watchdog Enable Enables or disables the watchdog timer. After writing 1 to this field, perform a watchdog feed (reload) to enable the watchdog timer. After you write 1 to this field, you cannot write 0 to it (see the note in MOD register). 0b - Timer stopped 1b - Timer running

66.6.1.3 Timer Constant (TC)

Offset

Register	Offset
TC	4h

Function

Specifies the desired timeout value. Transferring the value of this register into the watchdog counter requires a feed sequence. The register resets to 00_00FFh. Writing a value below FFh causes 00_00FFh to load into the register. Therefore, the minimum timeout interval is T_{WDCLK} X 256 X 4.

If MOD[WDPROTECT] = 1, then any attempt to change the value of this register with a feed sequence, before the watchdog counter value becomes less than the individual values of WARNINT[WARNINT] and WINDOW[WINDOW], sets MOD[WDTOF] and causes a watchdog reset.

Table continued from the previous page...

Field	Function
—	
23-0 COUNT	Watchdog Timeout Value Specifies the desired timeout value for WWDT.

66.6.1.4 Feed Sequence (FEED)

Offset

Register	Offset
FEED	8h

Function

Reloads the watchdog timer with the TC[COUNT] value, if you write AAh followed by 55h to FEED[FEED]. This operation also starts WWDT, if the watchdog timer is enabled by writing 1 to MOD[WDEN].

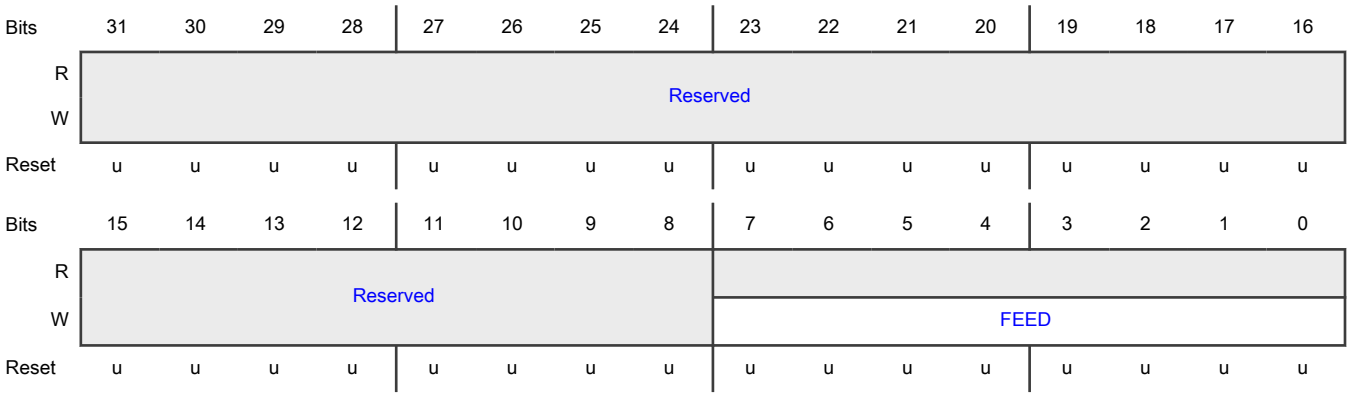
However, writing 1 to MOD[WDEN] is not sufficient to enable WWDT. Before the watchdog can generate a reset, MOD[WDEN] must be 1, followed by a valid feed sequence that completes itself. Until then, the watchdog ignores feed errors.

After writing AAh to FEED[FEED], access to any watchdog register other than writing 55h to FEED[FEED] causes an immediate reset or interrupt when WWDT is enabled and sets MOD[WDTOF]. An incorrect access to a watchdog register during a feed sequence generates the reset during the second APB bus clock.

To avoid an unintended interrupt, it is a good practice to disable interrupts around a feed sequence. Disable interrupts if they may result in rescheduling processor control away from the current task in the middle of the feed, and then lead to some other access to WWDT before control returns to the interrupted task.

If the value of WINDOW[WINDOW] is less than the default value, it may limit the time for which a watchdog feed is allowed.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 FEED	Feed Value Specifies feed value. The value must be AAh followed by 55h.

66.6.1.5 Timer Value (TV)

Offset

Register	Offset
TV	Ch

Function

Contains the current value of the WWDT counter. When the core (or CPU) reads this register, the value of this register is older than the actual value of the timer. Reading the timer using the lock and synchronization procedure takes up to six WDCLK cycles plus six APB bus clock cycles.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-24 —	Reserved
23-0 COUNT	Counter Timer Value Specifies the current value of the watchdog timer.

66.6.1.6 Warning Interrupt Compare Value (WARNINT)

Offset

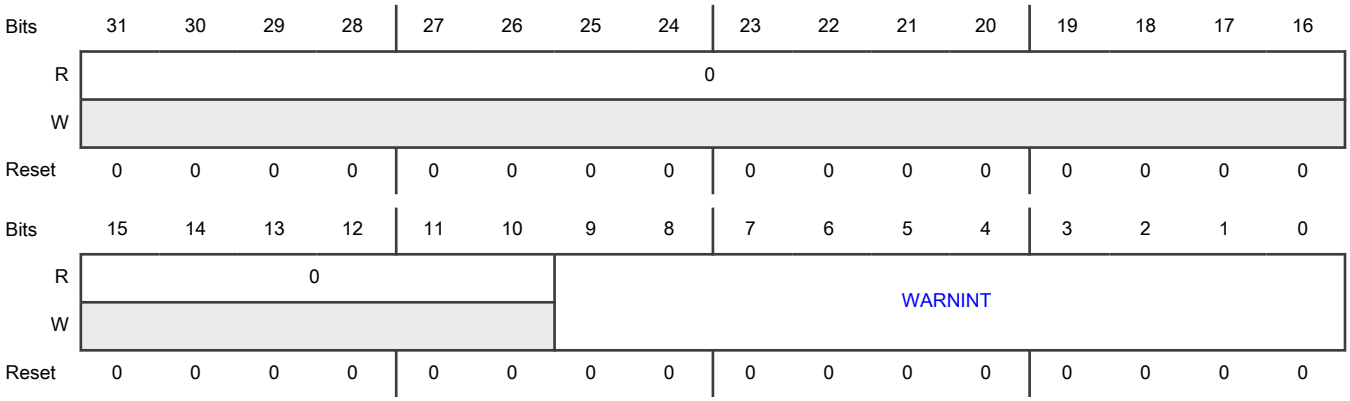
Register	Offset
WARNINT	14h

Function

Determines the value of TV[COUNT] that generates a watchdog interrupt. When this value is less than or equal to the value defined by WARNINT, an interrupt generates after the subsequent WDCLK.

A match of the WWDT counter to WARNINT occurs when the lower 10 bits of the timer counter have the same value as the lower 10 bits of WARNINT, and the remaining upper bits of the counter are all 0. This gives a maximum time of 1023 watchdog timer counts (4096 watchdog clocks) for the interrupt to occur before a watchdog event. If WARNINT is 0, then the interrupt occurs at the same time as the watchdog event.

Diagram



Fields

Field	Function
31-10 —	Reserved
9-0 WARNINT	Watchdog Warning Interrupt Compare Value Specifies a timer value that generates a warning interrupt.

66.6.1.7 Window Compare Value (WINDOW)

Offset

Register	Offset
WINDOW	18h

Function

Determines the highest timer value (TV[COUNT]) allowed during a watchdog feed. If a feed sequence occurs when the value of TV[COUNT] is greater than the value in WINDOW[WINDOW], a watchdog event occurs.

WINDOW[WINDOW] resets to the maximum value of TV[COUNT], where windowing is not in effect.

67.1.1 Module instances

This device has one instance of the FLEXIO module.

Table 614. FLEXIO instance

	FLEXIO
Located in	VDD2_MEDIA
Access	CPU0, CPU1, HiFi4, EZH-V, eDMA0, eDMA1, eDMA2, eDMA3

NOTE

Both CPU0 and CPU1 can operate FLEXIO. You need to use CPU0 to configure FLEXIO ports by IOPCTL0 registers before either CPU to operate the FLEXIO.

67.1.2 FLEXIO external trigger connections

The FLEXIO external trigger inputs come from various sources within the chip and are selected by the FLEXIO peripheral input muxes residing at INPUTMUX_BASE address plus offsets 0x760h – 0x76Ch. See FLEXIO_TRIG registers in the INPUTMUX.

67.2 Overview

FLEXIO is a highly configurable module that provides:

- Emulation of various serial or parallel communication protocols.
- Flexible 16-bit timers with support for various trigger, reset, enable, and disable conditions.

- Programmable logic blocks that allow the implementation of digital logic functions on-chip and configurable interaction of internal and external modules.
- Programmable state machine for offloading basic system control functions from the CPU.

67.2.1 Block diagram

The following diagram provides a high-level overview of the FLEXIO timer and shifter configuration.

FLEXIO uses shifters, timers, and external triggers to shift data into or out of FLEXIO. As shown in the block diagram, timers control the timing of this data shift. You can configure the timers to use generic timer functions, external triggers, or various other conditions to determine the control.

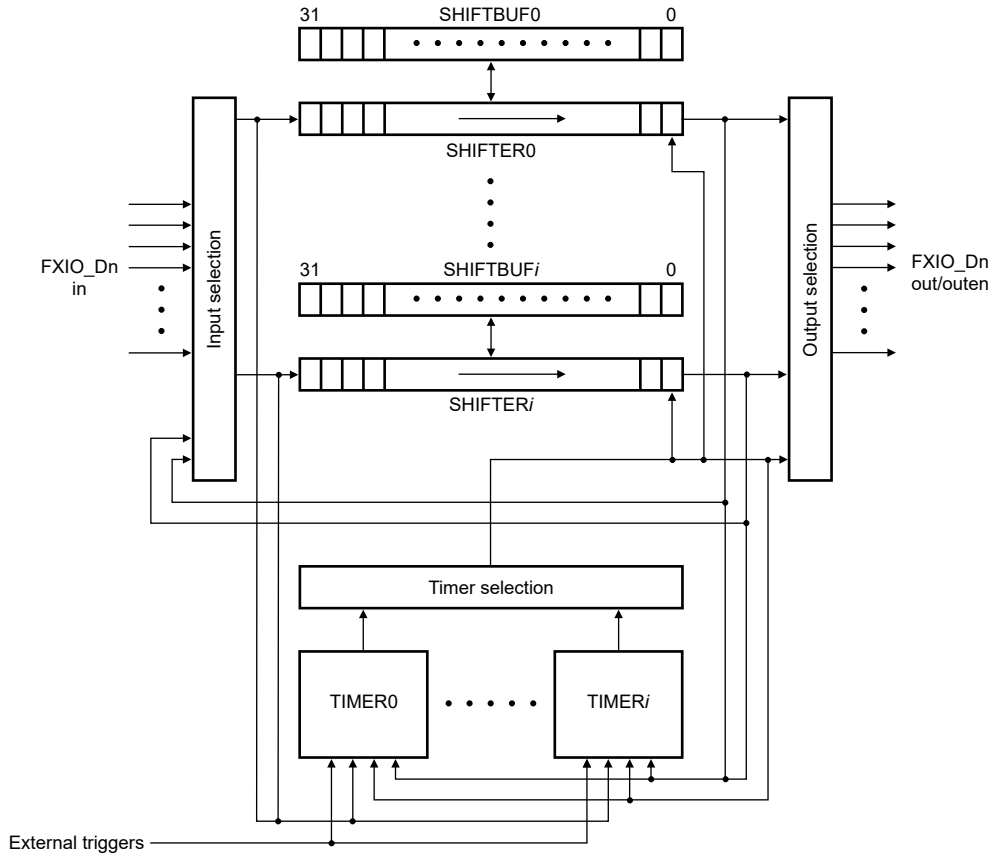

Figure 276. Block diagram

67.2.2 Features

- Array of 32-bit shift registers with transmit, receive, data match, logic, and state modes:
  - Double-buffered shifter operation for continuous data transfer
  - Shifter concatenation to support large transfer sizes
  - Automatic start and stop bit generation
  - 1, 2, 4, 8, 16, or 32 multi-bit shift widths for parallel interface support
  - Interrupt, DMA, or polled transmit and receive operation
- Highly flexible 16-bit timers with support for various internal or external triggers, reset, enable, and disable conditions:

— Programmable baud rates independent of bus clock frequency, with support for asynchronous operation during Stop mode

— Programmable logic mode for integrating external digital logic functions on-chip, or combining pin, shifter, or timer functions to generate complex outputs

— Programmable state machine for offloading basic system control functions from CPU, with support for up to eight states, eight outputs, and three selectable inputs per state

- Integrated general-purpose I/O registers and pin rising or falling edge interrupts to simplify software support
- Support for a wide range of protocols, including but not limited to:
  - — UART
  - — I2C
  - — SPI
  - — I2S
  - — Camera IF
  - — Motorola 68K or Intel 8080 bus
  - — PWM or waveform generation
  - — Input-capture (pulse-edge interval measurement), such as SENT

67.3 Functional description

67.3.1 Shifter operation

Shifters are responsible for buffering and shifting data into or out of FLEXIO. The timer assigned to the shifter controls the timing of shift, load, and store events via SHIFTCTL*n*[TIMSEL]. Shifters are designed to support either DMA, interrupt, or polled operations. The following figure provides a detailed view of the shifter microarchitecture.

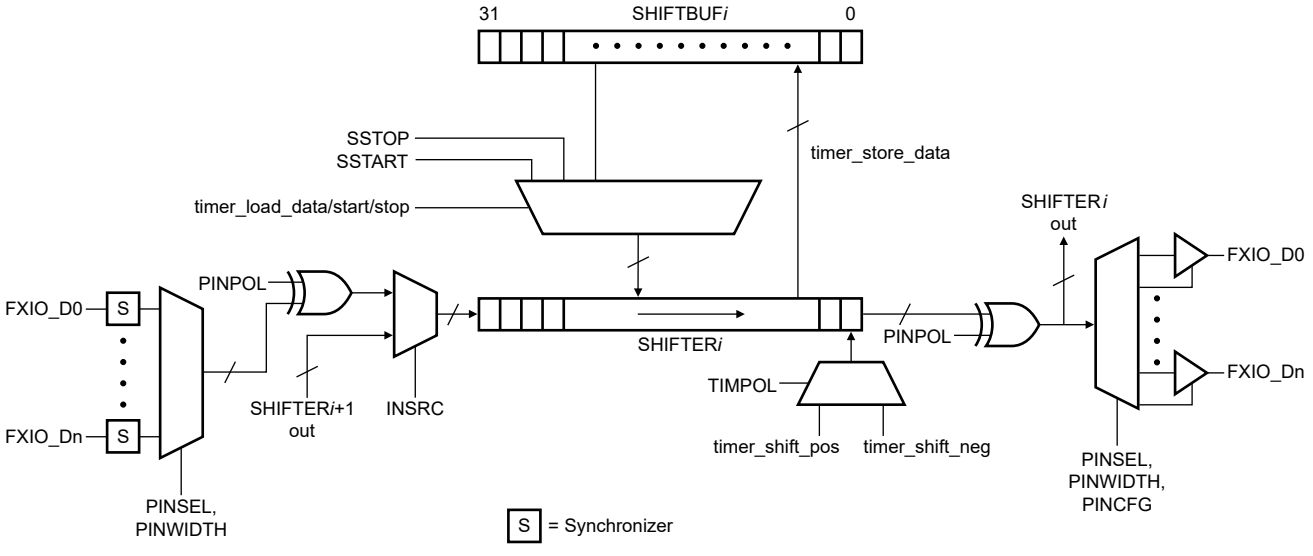

Figure 277. Shifter microarchitecture

67.3.1.1 Transmit mode

In Transmit mode (SHIFTCTL*n*[SMOD] = 010b), the shifter loads data from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) and shifts data out when the assigned timer signals a load event. An optional start and stop bit can be automatically loaded before or

after SHIFTBUF register data by configuring either SHIFTCFG[SSTART] and TIMCFG[TSTART], or SHIFTCFG[SSTOP] and TIMCFG[TSTOP] in the shifter and timer.

NOTE

If a stop bit is enabled, the shifter immediately loads a stop bit when it is initially configured for Transmit mode.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when data has either been loaded from the SHIFTBUF register into the shifter or when the shifter is initially configured for Transmit mode. To clear the flag, write 1 or write new data to SHIFTBUF. In Transmit mode, write any value to the SHIFTBUF register to clear the corresponding shifter status flag, which is cleared regardless of what is writing to the register (DMA or interrupt), or the state of the DMA or interrupt enables. See the functional description of SHIFTSTAT[SSF] for information on how the flag is set and cleared for each mode.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to load data from an empty SHIFTBUF register occurs (buffer underrun). Clear the flag by writing 1.

67.3.1.2 Receive mode

When the assigned timer signals a store event in Receive mode (SHIFTCTL*n*[SMOD] = 001b), the shifter shifts and stores data in Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). You can check for a start and stop bit before or after the shifter data is sampled by configuring either SHIFTCFG[SSTART] and TIMCFG[TSTART], or SHIFTCFG[SSTOP] and TIMCFG[TSTOP] in the shifter and timer.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when data is stored in the SHIFTBUF register from the shifter. To clear the flag, write 1 to or read the data from SHIFTBUF. Any read of the SHIFTBUF register clears the corresponding shifter status flag when the shifter is in Receive mode. The flag is cleared regardless of what is reading the register (DMA or interrupt) or the state of the DMA or interrupt enables. See the functional description of SHIFTSTAT[SSF] for information on how the flag is set or cleared for each mode.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set either when an attempt to store data into a full SHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start or stop bit check. Write 1 to clear the flag.

67.3.1.3 Match Store mode

In Match Store mode (SHIFTCTL*n*[SMOD] = 100b), the shifter shifts data in, checks for a match result, and stores matched data in Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) when the assigned timer signals a store event. By configuring either SHIFTCFG[SSTART], TIMCFG[TSTART], and SHIFTCFG[SSTOP], or TIMCFG[TSTOP] in the shifter and timer, you can check for a start and stop bit before or after the shifter data is sampled. You can compare up to 16 bits of data using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when a match occurs and the matched data is stored in the SHIFTBUF register from the shifter. To clear the flag, read the matched data from the SHIFTBUF register or write 1 to the flag. Any read of the SHIFTBUF register clears the corresponding shifter status flag when the shifter is configured in Match Store mode. The flag is cleared regardless of what is reading the register (DMA or interrupt) or the state of the DMA or interrupt enables. See the functional description for SHIFTSTAT[SSF] to know how the flag is set or cleared for each mode.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set when an attempt to store matched data into a full SHIFTBUF register occurs (buffer overrun), or when a mismatch occurs on a start or stop bit check. Write 1 to clear the flag.

67.3.1.4 Match Continuous mode

In Match Continuous mode (SHIFTCTL*n*[SMOD] = 101b), the shifter shifts data in and continuously checks for a match result whenever a shift event is signaled by the assigned timer. You can compare up to 16 bits of data using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when a match occurs. The flag clears automatically as soon as no match exists between the shifter data and Shifter Buffer (SHIFTBUF0 - SHIFTBUF7).

You cannot clear the flag by reading the SHIFTBUF register.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set when a match occurs. To clear the flag, write 1 or perform a read from the SHIFTBUF register.

67.3.1.5 State mode

State mode enables you to implement any state machine with up to eight states, eight outputs, and three selectable inputs per state. This feature allows basic control functions to be offloaded from the CPU, which can remain in a low-power mode.

In State mode (SHIFTCTL*n*[SMOD] = 110b), when the shifter is selected by the current state pointer (SHIFTSTATE[STATE]), use the SHIFTBUF register to drive the output and compute the next state values. The following figure provides a detailed view of the shifter microarchitecture when configured for State mode.

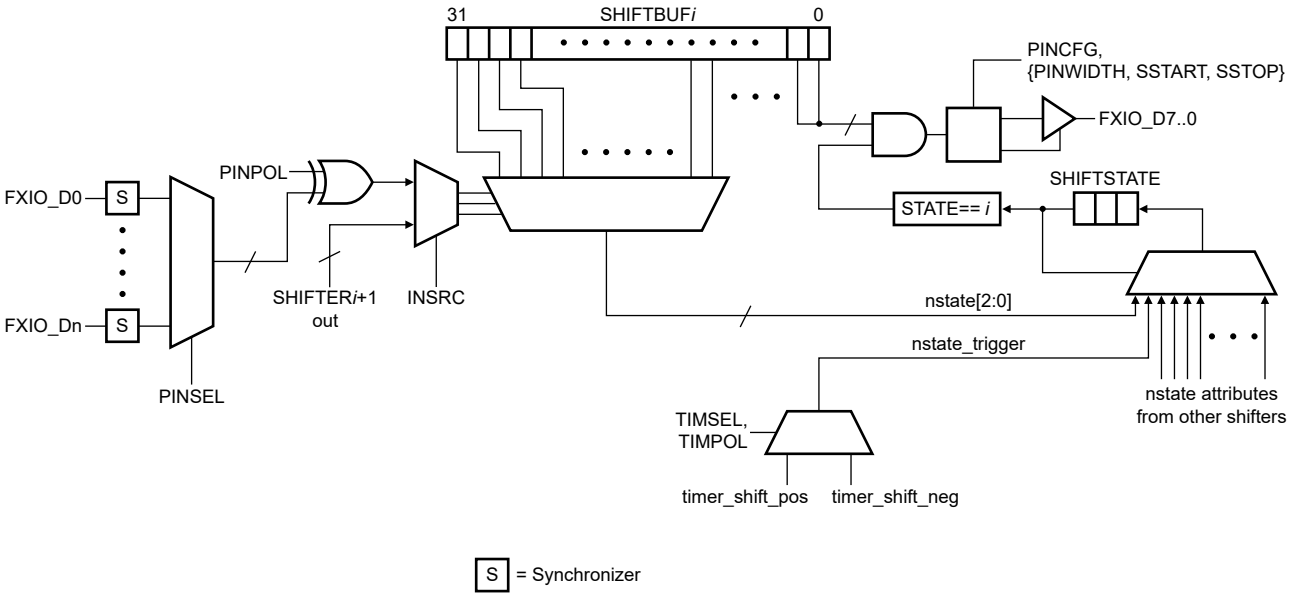

Figure 278. State microarchitecture

When the current state pointer selects a specific shifter (shifter *n*), output pins FXIO_D[7:0] are driven by SHIFTBUF*n*[31:24]; the configuration is defined by SHIFTCTL*n*[PINCFG]. Write 1 to Shifter Configuration (SHIFTCFG0 - SHIFTCFG7) {PWIDTH[3:0],SSTOP[1:0],SSTART[1:0]} to disable the output drive on pins FXIO_D[7:0] for state machine applications that require less than eight output pins.

Use the three input pins selected by SHIFTCTL*n*[PINSEL] and SHIFTBUF*n*[23:0] to compute the next state value.

NOTE

Each state can use a different set of three input pins.

The following table shows how the next state value is computed when the current state pointer is pointing to shifter *n*.

Table 615. Next state computation for SHIFTSTATE[STATE] = *n*

FXIO_D[PINSEL + 2]	FXIO_D[PINSEL + 1]	FXIO_D[PINSEL]	Next state value
0	0	0	SHIFTBUF*n*[2:0]
0	0	1	SHIFTBUF*n*[5:3]
0	1	0	SHIFTBUF*n*[8:6]
0	1	1	SHIFTBUF*n*[11:9]

Table continues on the next page...

Table 615. Next state computation for SHIFTSTATE[STATE] = *n* (continued)

FXIO_D[PINSEL + 2]	FXIO_D[PINSEL + 1]	FXIO_D[PINSEL]	Next state value
...	...	...	...
1	1	1	SHIFTBUF*n*[23:21]

NOTE

You can configure other shifters and timers to drive the input pins of a given state, allowing you to create complex combinations of shifters and timers as needed. For example, the output of a shifter configured for Logic mode can be used to drive a state machine input.

The next state transition is triggered using the timer output selected by SHIFTCTL*n*[TIMSEL], with polarity controlled by SHIFTCTL*n*[TIMPOL].

NOTE

Each state can use a different timer to trigger each next state transition, allowing various internal or external trigger sources and clocking configurations to be used. See Timer section for more information.

The current state pointer defaults to shifter 0 at reset; however, you can write to select a different shifter for the initial state. If the current state pointer selects a shifter that is not configured for State mode, then outputs are not driven and the next state transition is never triggered.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set when the shifter is selected by the current state pointer. The flag is cleared when the current state pointer is updated to a different shifter.

67.3.1.6 Logic mode

Logic mode enables you to implement a small amount of programmable digital logic within a FLEXIO shifter.

In Logic mode (SHIFTCTL*n*[SMOD] = 111b), use Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) to implement a 5-input, 32-bit programmable logic lookup table. The following figure provides a detailed view of shifter microarchitecture when configured for Logic mode.

Use the SHIFTBUF register to configure the lookup table for the four pin inputs. You can also use SHIFTER*n* to configure a feedback or delayed pin source as the fifth input to the lookup table.

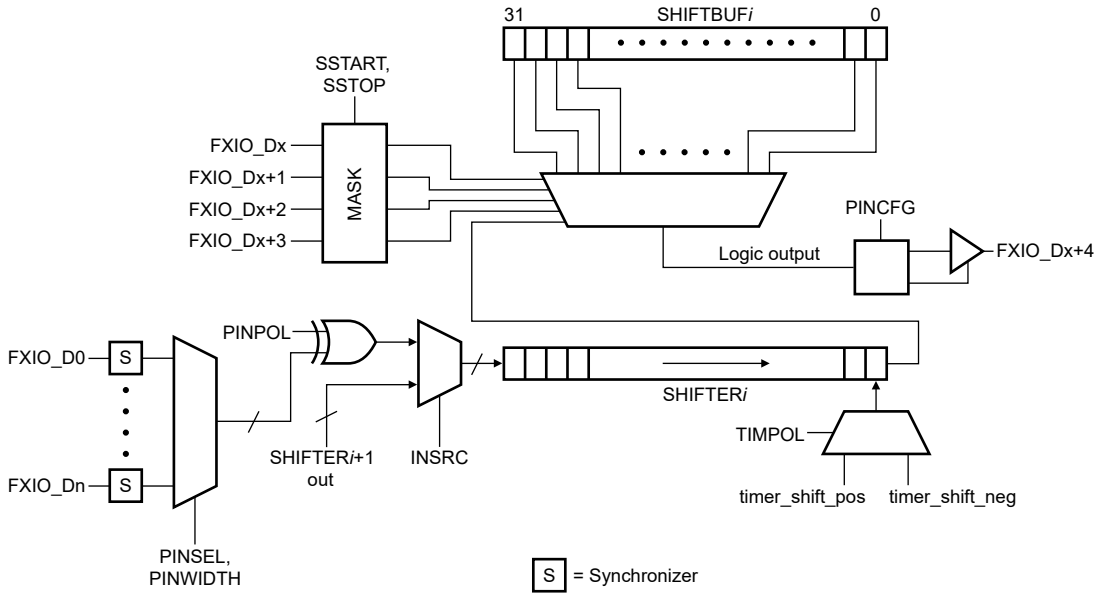

Figure 279. Logic microarchitecture

The lookup table is driven using four pin inputs (maskable using SHIFTCFG[SSTOP] and SHIFTCFG[SSTART]), plus one input from the internal shifter. It can be configured to drive an output pin using SHIFTCTL[PINCFG]. Pin inputs and outputs are fixed for each logic lookup table and are not selectable. The following table lists the logic output value selected by the lookup table for shifter *n*.

Table 616. Logic lookup table for shifter *n*

SHIFTER*n*[0]	FXIO_D[*x* + 3][1]	FXIO_D[*x* + 2]	FXIO_D[*x* + 1]	FXIO_D[*x*]	Logic output to FXIO_D[*x* + 4]
0	0	0	0	0	SHIFTBUF*n*[0]
0	0	0	0	1	SHIFTBUF*n*[1]
0	0	0	1	0	SHIFTBUF*n*[2]
0	0	0	1	1	SHIFTBUF*n*[3]
...	...	...	...	...	...
1	1	1	1	1	SHIFTBUF*n*[31]

1. for shifters *n* = 0...3, *x* = *n*

   for shifter *n* = 4...7, *x* = *n* + 4

To minimize output glitches, use SHIFTCFG*n*[SSTOP] and SHIFTCFG*n*[SSTART] to mask unused input pins. When these fields are 1, {SSTOP[1:0] and SSTART[1:0]} mask FXIO_D[*x* + 3]...FXIO_D[*x*] inputs respectively so that any transitions on these pins do not cause the logic output to glitch.

NOTE

You can configure other shifters and timers to drive the input pins of a given lookup table, allowing you to concatenate lookup tables or create complex combinations of shifters and timers as needed.

SHIFTCFG[PWIDTH] controls the number of delay stages introduced by the internal shifter input (SHIFTER*n*[0]). For example, when configured for a 1-bit shift (SHIFTCFG[PWIDTH] = 0), the internal shifter introduces a 32-shift clock delay before passing its

input (selected by SHIFTCTL[PINSEL]) to the lookup table. When configured for a 32-bit shift (SHIFTCFG[PWIDTH] = 16...31), the internal shifter introduces a 1-shift clock delay to its input.

The shifter status flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests are set whenever the output pin allocated to the logic lookup table has a value of 1 after being synchronized with the FLEXIO clock. The flag clears when the output pin has a value of 0. This also allows SHIFTSTAT[SSF] to be used as a trigger to a timer if needed.

The shifter error flag (SHIFTERR[SEF]) and any enabled interrupts are set when the output pin allocated to the logic lookup table is asserted. Clear the flag by writing 1 to it.

The Logic mode input pins, including pins driven by other shifters and timers, are synchronized with the FLEXIO functional clock before they are input to the programmable logic lookup table.

67.3.2 Timer operation

The FLEXIO 16-bit timers control the loading, shifting, and storing of the shift registers. The counters load the contents of the compare register and decrement down to zero on the FLEXIO clock. The counters can perform generic timer functions such as generating a clock, select output, or a PWM waveform. You can configure these timers to perform any of the following functions:

- Enable in response to a trigger, pin, or shifter condition.
- Decrement always or only on a trigger or pin edge.
- Reset in response to a trigger or pin condition.
- Disable on a trigger or pin condition or on a timer compare.

Timers can optionally include a start condition and a stop condition.

Although each timer operates independently, you can configure a timer to enable or disable at the same time as the previous timer (for example, timer 1 can enable or disable at the same time as timer 0) and a timer output can be used to trigger any other timer. The trigger used by each timer is configured independently as a timer output, shifter status flag, pin input, or an external trigger input. The trigger configuration is separate from pin configuration; you can perform it to configure input, output data, or output enable. See the chip-specific FLEXIO information for information on external trigger connections.

You must configure Timer Configuration (TIMCFG0 - TIMCFG7) before writing 1 to TIMCTL*n*[TIMOD].

67.3.2.1 Timer 8-bit Baud Counter mode

In 8-bit Baud Counter mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the baud rate of the shift clock and the upper 8 bits are used to configure the number of shift clock edges in the transfer. When the lower 8 bits decrement to zero, the timer output is toggled and the lower 8 bits reload from the compare register. The upper 8 bits decrement when the lower 8 bits become zero and decrement.

NOTE

A timer reset event in 8-bit Baud Counter mode only resets the lower 8-bit counter. The upper 8-bit counter is not affected and can decrement if the timer reset is configured to update the state of the timer output, which toggles as a result of the timer reset event.

A timer compare event occurs when the upper 8 bits equal zero and decrement. The timer status flag is set on a timer compare event.

67.3.2.2 Timer 8-bit High PWM mode

In 8-bit High PWM mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the timer output high period and the upper 8 bits are used to configure the timer output low period. The lower 8 bits decrement when the output is high. When the lower 8 bits become zero and decrement, the timer output is cleared and the lower 8 bits are reloaded from the compare register. The upper 8 bits decrement when the output is low. When the upper 8 bits become zero and decrement, the timer output is set and the upper 8 bits are reloaded from the compare register.

A timer compare event occurs when the upper 8 bits become zero and decrement. The timer status flag is set on a timer compare event.

67.3.2.3 Timer 16-bit Counter mode

In 16-bit Counter mode, you can use the 16-bit counter to configure either the baud rate of the shift clock (for example, TIMDEC[1:0] ≠ 10 or 11) or the number of shift clock edges in the transfer (for example, TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer compare event.

67.3.2.4 Timer 16-bit Counter Disable mode

In 16-bit Counter Disable mode, the 16-bit counter can be used to configure either the baud rate of the shift clock (for example, TIMDEC[1:0] ≠ 10 or 11) or the number of shift clock edges in the transfer (for example, TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer disable event.

67.3.2.5 Timer 8-bit Word Counter mode

In 8-bit Word Counter mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the number of shift clock edges in each word and the upper 8 bits are used to configure the number of words in the transfer. When the lower 8 bits decrement to zero, the timer output is toggled and the lower 8 bits reload from the compare register. The upper 8 bits only decrement when the lower 8 bits become zero and decrement.

A timer compare event occurs when the lower 8 bits become zero and decrement. The timer status flag is set when the upper 8 bits become zero and decrement.

67.3.2.6 Timer 8-bit Low PWM mode

In 8-bit Low PWM mode, the 16-bit counter is divided into two 8-bit counters. The lower 8 bits are used to configure the timer output low period and the upper 8 bits are used to configure the timer output high period. The lower 8 bits decrement when the output is low. When the lower 8 bits become zero and decrement, the timer output is set and the lower 8 bits are reloaded from the compare register. The upper 8 bits decrement when the output is high. When the upper 8 bits become zero and decrement, the timer output is cleared and the upper 8 bits are reloaded from the compare register.

A timer compare event occurs when the upper 8 bits become zero and decrement. The timer status flag is set on a timer compare event.

67.3.2.7 Timer enable and start functions

The following events occur when you configure TIMCTL*n*[TIMOD] for the desired mode and the condition configured by the timer enable (TIMCFG*n*[TIMENA]) is detected. When TIMCTL*n*[ONETIM] is 1, the timer status flag must be clear to generate a timer enable event; otherwise, the timer enable event is blocked. You can use this to enforce software intervention after each timer iteration:

- The timer counter loads the current value of the compare register and starts decrementing, as configured by TIMCFG*n*[TIMDEC].
- The timer output may update to its initial state depending on the configuration of TIMCFG*n*[TIMOUT]. Shifters that are controlled by this timer do not see this as a rising edge on the timer shift clock.
- Transmit shifters controlled by this timer either output their start bit value or load the shift register from the shift buffer and output the first bit, as configured by SHIFTCFG*n*[SSTART].

If the timer start bit is enabled, the timer counter reloads with the compare register on the first rising edge of the shift clock after the timer starts decrementing. If there is no falling edge on the shift clock before the first rising edge (for example, when TIMCFG*n*[TIMOUT] = 1), a shifter that is configured to shift on the falling edge and load on the first shift does not load correctly.

67.3.2.8 Timer decrement and reset functions

The timer generates the timer output and timer shift clock depending on the fields, TIMCTL*n*[TIMOD] and TIMCFG*n*[TIMDEC]. The shifter clock is either equal to the timer output (when TIMCFG*n*[TIMDEC] ≠ 10 or 11) or equal to the decrement clock (when TIMCFG*n*[TIMDEC] = 10 or 11). If you configure TIMCFG*n*[TIMDEC] to decrement from a pin or trigger, the timer decrements on both rising and falling edges.

If a timer is configured to decrement on the FLEXIO functional clock divided by 16 or 256 (when TIMCFG*n*[TIMDEC] = 100 or 101), then a common prescaler that is shared by all timers is used to generate the two divide ratios. This prescaler is reset when all timers are either idle or configured not to use the prescaler (TIMCFG*n*[TIMDEC] ≠ 100 or 101).

If you configure the timer to reset as determined by TIMCFG*n*[TIMRST], then the timer counter loads the current value of the compare register again. You can configure the timer output and timer shift clock to update on timer reset, as configured by TIMCFG*n*[TIMOUT]. If the time output toggles as a result of the timer reset, this can result in a timer shift clock edge. In 8-bit Baud Counter mode, this also decrements the upper 8 bits of the counter.

In general, when the timer counter decrements to zero, a timer compare event is triggered. The timer compare event causes:

- The timer counter to load the contents of the timer compare register.
- The timer output to toggle.
- Any configured transmit shift registers to load.
- Any configured receive shift registers to store.

Depending on the timer mode, the timer status flag may also be set.

67.3.2.9 Timer disable and stop functions

When the timer is configured to add a stop bit on each compare, the following additional events occur:

- Transmit shifters controlled by this timer output their stop bit value (if configured by SHIFTCFG*n*[SSTOP]).
- Receive shifters controlled by this timer store the contents of the shift register in their shift buffer, as configured by SHIFTCFG*n*[SSTOP].
- The timer counter reloads the current value of the compare register on the first rising edge of the shifter clock after the compare.

If you configure the timer to insert a stop bit on each compare, you must configure the transmit shifters to load on the first shift.

When the condition configured by timer disable (TIMCFG*n*[TIMDIS]) is detected, the following events occur:

- Timer counter reloads the current value of the compare register and starts decrementing as configured by TIMCFG*n*[TIMDEC].
- Timer output clears. Shifters that are controlled by this timer do not see this as a falling edge on the timer shift clock, but can generate a shift event if the timer shift clock otherwise generates one.
- Transmit shifters controlled by this timer output their stop bit value (if configured by SHIFTCFG*n*[SSTOP]).
- Receive shifters controlled by this timer store the contents of the shift register in their shift buffer, as configured by SHIFTCFG*n*[SSTOP].

If the timer stop bit is enabled, the timer counter continues decrementing until the next rising edge of the shift clock is detected, at which point it finishes decrementing. Although the timer output is forced low during the stop bit, the timer shift clock can toggle during the stop bit. The timer output does not generate shift events during the stop bit.

A timer enable condition can be detected in the same cycle as a timer disable condition (if timer stop bit is disabled), or on the first rising edge of the shift clock after the disable condition (if stop bit is enabled). When TIMCTL*n*[ONETIM] is 1, the timer status flag must be clear before the next timer enable condition is detected. When the timer is in the stop state condition, receive shift registers with stop bit enabled store the contents of the shift register into the shift buffer and verify the state of the input data on the configured shift edge. If there is no configured edge between the timer disable and the next rising edge of the shift clock, then the final store and verify do not occur.

67.3.3 Pin operation

The pin configuration for each timer and shifter can be set to use any FLEXIO pin with either polarity. You can configure each timer and shifter as an input, output data, output enable, or bidirectional output. A pin configured for output enable can be used as an open drain (with inverted polarity because the output enable assertion causes logic zero to be output on the pin) or to control the enable on the bidirectional output. You can configure any timer or shifter to control the output enable for a pin where the bidirectional output data is driven by another timer or shifter.

When more than one shifter or timer is configured to use the same pin for output data, then the output data to the pin is combined using an OR function. This also applies if more than one timer or shifter is configured to use the same pin for output enable.

67.3.3.1 Parallel interface

You can configure shifters to use multiple FLEXIO pins simultaneously by using SHIFTCFG*n*[PWIDTH], which is used to configure the following settings of a shifter:

1. Number of bits shifted per shift clock.
2. Number of pins driven by the shifter per shift clock (only on shifters supporting parallel transmit—that is, SHIFTER0 and SHIFTER4.)
3. Number of pins sampled by the shifter per shift clock (only on shifters supporting parallel receive—that is, SHIFTER3 and SHIFTER7.)

When configured for parallel shift, either 4, 8, 16, or 32 bits can be shifted on every shift clock. If an adjacent shifter is selected as the input source (SHIFTCFG*n*[INSRC] = 1), the least significant 4, 8, 16, or 32 bits from the adjacent shifter are sampled on each shift clock.

For shifters supporting parallel receive (SHIFTER3, SHIFTER7), you can configure the shifter to sample multiple pins (INSRC = 0), with PWIDTH and PINSEL selecting the pins as FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL].

NOTE

If PWIDTH is less than the number of bits being shifted on each shift clock, then the most significant bits are masked with 0. For example, if PINSEL = 7 and PWIDTH = 6, then SHIFTER[31:24] samples {0,0,FXIO_D[12:7]} on each shift clock.

For shifters supporting parallel transmit (SHIFTER0, SHIFTER4), you can configure the shifter to drive multiple pins using SHIFTCTL*n*[PINCFG], with PWIDTH and PINSEL selecting the pins as follows: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL].

NOTE

If PWIDTH is less than the number of bits being shifted on each shift clock, then the most significant pins are not driven. For example, if PINSEL = 7 and PWIDTH = 6, then SHIFTER[5:0] drives only FXIO_D[12:7] on each shift clock.

67.3.3.2 Pin synchronization

When you configure a pin as an input (this includes a timer trigger configured as a pin input), the input signal is first synchronized with the FLEXIO clock before a timer or shifter could use the signal. This introduces a small latency of 0.5–1.5 FLEXIO clock cycles when using an external pin input to generate an output or control a shifter. This sets the maximum setup time at 1.5 FLEXIO clock cycles.

If an input is used by more than one timer or shifter, then the synchronization occurs once to ensure any edge is seen on the same cycle by all timers and shifters using that input.

NOTE

FLEXIO pins are also connected internally. Configuring a FLEXIO shifter or timer to output data on an unused pin makes an internal connection that allows other shifters and timers to use this pin as an input. This allows a shifter output to trigger a timer or a timer output to be shifted into a shifter. This path is also synchronized with the FLEXIO clock and therefore incurs a one-cycle latency.

When using a pin input as a timer trigger, timer clock, or shifter data input, the following synchronization delays occur:

- 0.5–1.5 FLEXIO clock cycles for an external pin
- One FLEXIO clock cycle for an internally driven pin

See Application information for timing considerations such as output valid time and input setup time for specific applications (SPI controller, SPI target, I2C controller, I2S controller, and I2S target).

67.3.3.3 Pin override

You can change the state of any FLEXIO pin at any time. Pin Output Enable (PINOUTE) configures any pin as an output and drives that pin with the value in Pin Output Data (PINOUTD).

Alias registers for PINOUTE and data registers also exist. Writing a logic 1 to an alias register updates the corresponding register fields in both PINOUTE and PINOUTD as follows:

- Pin Output Disable (PINOUTDIS) clears Pin Output Enable (PINOUTE) and Pin Output Data (PINOUTD).
- Pin Output Clear (PINOUTCLR) sets Pin Output Enable (PINOUTE) and clears Pin Output Data (PINOUTD).
- Pin Output Set (PINOUTSET) sets Pin Output Enable (PINOUTE) and Pin Output Data (PINOUTD).
- Pin Output Toggle (PINOUTTOG) sets Pin Output Enable (PINOUTE) and toggles Pin Output Data (PINOUTD).

67.3.3.4 Pin interrupt

You can read the state of any FLEXIO pin at any time and also configure any pin to set a status flag when either a rising or falling edge is detected on that pin. Additionally, you can configure the pin status flag to generate an interrupt.

67.3.4 Low-power modes

FLEXIO remains functional during low-power modes, if CTRL[DOZEN] is 0 and the FLEXIO functional clock remains enabled.

The exception to this is in Deep Sleep mode. In this case, CTRL[DOZEN] is ignored and FLEXIO waits for all timers to complete any pending operation before acknowledging Deep Sleep mode entry.

67.3.5 Debug mode

FLEXIO remains functional in Debug mode, provided the value of CTRL[DBGE] is 1.

67.3.6 Clocking

Table 617. FLEXIO clocks

Clock	Description
Functional clock	Is asynchronous to the bus clock and can remain enabled in low-power modes. You must enable the FLEXIO functional clock before accessing any of the FLEXIO registers. Provided the FLEXIO functional clock is at least equal to the bus clock, you can configure CTRL[FASTACC] to support fast register accesses.
Bus clock	Is used only for bus accesses to the control and configuration registers.

67.3.7 Reset

Table 618. FLEXIO reset types

Reset	Description
Chip reset	Resets the FLEXIO logic and registers to their default states on chip reset.
Software reset	Resets, using CTRL[SWRST], all logic and registers to their default states, except for the Control register.

67.3.8 Interrupts and DMA requests

The following table shows the status flags that generate the FLEXIO interrupt and DMA requests.

Table 619. FLEXIO interrupts and DMA requests

Flag	Description	Interrupt	DMA request	Low-power wake-up
SHIFTSTAT[SSF]	Shifter status flag	Y	Y	Y
SHIFTERR[SEF]	Shifter error flag	Y	N	Y
TIMSTAT[TSF]	Timer status flag	Y	Y	Y
PINSTAT[PSF]	Pin status flag	Y	N	Y
TRGSTAT[ETSF]	External trigger status flag	Y	N	Y

67.3.9 Peripheral triggers

The connection between FLEXIO peripheral triggers and other peripherals is device-specific.

67.3.9.1 Output triggers

Each FLEXIO timer generates an output trigger equal to the timer output. The output trigger is not affected by the timer pin polarity configuration.

67.3.9.2 Input trigger

FLEXIO supports multiple external trigger inputs that can be used to trigger one or more FLEXIO timers. If a rising edge is detected on an external trigger when FLEXIO is enabled, then the external trigger status flag is set. The external triggers are synchronized to the FLEXIO functional clock and must assert for at least two cycles of the FLEXIO functional clock to be sampled correctly.

67.4 External signals

Table 620. External signals

Signal	Description	Direction
FXIO_D*n* (*n* = 0...15)	Bidirectional FLEXIO shifter and timer pin	Input or output

67.5 Initialization

Perform the following procedure to initialize FLEXIO registers:

1. Enable FLEXIO by writing 1 to CTRL[FLEXEN].
2. Configure shift registers for the given application. It is recommended to write to Shifter Configuration (SHIFTCFG0 - SHIFTCFG7) before writing to the corresponding register, Shifter Control (SHIFTCTL0 - SHIFTCTL7).

3. Configure timer registers for the given application. It is recommended to write to Timer Compare (TIMCMP0 - TIMCMP7) and Timer Configuration (TIMCFG0 - TIMCFG7) before writing to the corresponding register, Timer Control (TIMCTL0 - TIMCTL7).
4. Enable interrupts and/or DMA requests, as appropriate, for the given application.
5. Write transmit data to initiate a transfer (depending on the given application).

67.6 Application information

This section provides examples for a variety of FLEXIO module applications. See FLEXIO register descriptions for more information.

67.6.1 UART transmit

UART transmit can be supported using one timer, one shifter, and one pin (two pins, if supporting CTS). The start and stop bit insertion is handled automatically, and multiple transfers are supported using the DMA controller. The timer status flag is used to indicate when the stop bit of each word is transmitted.

Break and idle characters require software intervention. Before transmitting a break or idle character, you must modify SHIFTCFG*n*[SSTART] and SHIFTCFG*n*[SSTOP] to transmit the required state, and the data to transmit must equal FFh or 00h. Supporting a second stop bit requires the stop bit to be inserted into the data stream using software (and increasing the number of bits to transmit). When performing byte writes to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) (or Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) for transmitting MSB first), the rest of the register remains unaltered. This allows an address mark bit or additional stop bit to remain undisturbed.

NOTE

FLEXIO does not support automatic insertion of parity bits.

Table 621. UART transmit configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTL*n*	0003_0002h	Configure transmit using timer 0 on the positive edge of clock with output data on pin 0. You can configure the PINPOL field to invert output data, or support open-drain by writing 1h to the PINPOL and PINCFG fields.
TIMCMP*n*	0000_0F01h	Configure 8-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0000_2222h	Configure start bit, stop bit, enable on trigger asserted and disable on compare. You can support CTS by configuring the TIMENA field as 3h.
TIMCTL*n*	01C0_0001h	Configure the dual 8-bit counter using the shifter 0 status flag as an inverted internal trigger source. To support CTS, configure the PINSEL (for pin 1) and PINPOL fields as 1h.

Table continues on the next page...

Table 621. UART transmit configuration (continued)

Register	Value	Configuration
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer. Use the shifter status flag to indicate when data can be written using an interrupt or a DMA request. Write to SHIFTBUFBBS[7:0] instead to support MSB first transfer.

The following table shows an alternative configuration that supports slower baud rates. This configuration requires two timers.

Table 622. UART transmit configuration for slow baud rate

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTL*n*	0003_0002h	Configure transmit using timer 0 on the positive edge of clock with output data on pin 0. Invert output data by writing 1 to the PINPOL field. Support open-drain by configuring the PINPOL and PINCFG fields as 1h.
TIMCMP*n*	0000_000Fh	Configure for 8-bit transfer, and configure TIMCMP[15:0] as (number of bits × 2) - 1.
TIMCFG*n*	0030_2622h	Configure start bit, stop bit, enable on trigger rising edge, decrement on trigger and disable on compare.
TIMCTL*n*	0740_0003h	Configure the 16-bit counter using the timer 1 output as an internal trigger source.
TIMCMP(*n* + 1)	0000_0001h	Configure baud rate of divide by 4 of the FLEXIO clock, and configure TIMCMP[15:0] as (baud rate divider ÷ 2) - 1.
TIMCFG(*n* + 1)	0000_1200h	Configure enable on trigger asserted and disable on timer 0 disable. You can configure the TIMEN field as 3h to support CTS.
TIMCTL(*n* + 1)	01C0_0003h	Configure the 16-bit counter using the shifter 0 status flag as an inverted internal trigger source. You can support CTS by configuring the PINSEL (for pin 1) and PINPOL fields as 1h.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUF[7:0] to initiate an 8-bit transfer. Use the shifter status flag to

Table continues on the next page...

Table 622. UART transmit configuration for slow baud rate (continued)

Register	Value	Configuration
		indicate when data can be written using an interrupt or a DMA request. Write to SHIFTBUFBBS[7:0] instead to support MSB first transfer.

67.6.2 UART receive

UART receive can be supported using one timer, one shifter, and one pin (two timers and two pins, if supporting RTS). The start and stop bit verification is handled automatically and multiple transfers are supported using the DMA controller. The timer status flag is used to indicate when the stop bit of each word is received.

FLEXIO does not support triple voting of the received data, which is sampled only once in the middle of each bit. You can use a timer to implement a glitch filter on the incoming data and a different timer to detect an idle line of programmable length. Break characters cause the error flag to set, and the shifter buffer register returns 00h.

NOTE

FLEXIO does not support automatic verification of parity bits.

Table 623. UART receiver configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTL*n*	0080_0001h	Configure receive using timer 0 on the negative edge of clock with input data on pin 0. You can invert input data by writing 1 to the PINPOL field.
TIMCMP*n*	0000_0F01h	Configure 8-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0204_2422h	Configure start bit, stop bit, enable on pin positive edge and disable on compare. Enable resynchronization to received data with TIMOUT = 2h and TIMRST = 4h.
TIMCTL*n*	0000_0081h	Configure the dual 8-bit counter using the inverted pin 0 input.
SHIFTBUF*n*	Data to receive	You can read received data from SHIFTBUFBYS[7:0]. Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from SHIFTBUFBIS[7:0] instead to support MSB first transfer.

The UART receiver with RTS configuration uses a second timer to generate the RTS output. RTS asserts when the start bit is detected and negates when the data is read from the shifter buffer register. If no start bit is detected when the RTS is asserted, the received data is ignored.

Table 624. UART receiver with RTS configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Configure start bit of 0 and stop bit of 1.
SHIFTCTL*n*	0080_0001h	Configure receive using timer 0 on the negative edge of clock with input data on pin 0. Invert input data by writing 1 to the PINPOL field.
TIMCMP*n*	0000_0F01h	Configure 8-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0204_2522h	Configure start bit, stop bit, enable on pin positive edge with trigger asserted and disable on compare. Enable resynchronization to received data with TIMOUT = 2h and TIMRST = 4h.
TIMCTL*n*	02C0_0081h	Configure dual 8-bit counter using the inverted pin 0 input. Trigger is internal using the inverted pin 1 input.
TIMCMP(*n* + 1)	0000_FFFFh	Never compare.
TIMCFG(*n* + 1)	0030_6100h	Enable on timer *n* enable and disable on the trigger falling edge. Decrement on trigger to ensure no compare.
TIMCTL(*n* + 1)	0143_0003h	Configure 16-bit counter and output on pin 1. Trigger is internal using the shifter 0 flag.
SHIFTBUF*n*	Data to receive	You can read received data using SHIFTBUFBYS[7:0]. Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from SHIFTBUFBIS[7:0] instead to support MSB first transfer.

67.6.3 SPI controller

SPI Controller mode can be supported using two timers, two shifters, and four pins. Using the DMA controller, either CPHA = 0 or CPHA = 1 and transfers can be supported. For CPHA = 1, the chip select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The stop bit is used to guarantee a minimum of one clock cycle between the target chip select negating and before the next transfer. To initiate each transfer, either the core or DMA writes to the transmit buffer.

NOTE

Because of synchronization delays, the setup time for the serial input data is 1.5 FLEXIO clock cycles. This means the maximum baud rate is divide by 4 of the FLEXIO clock frequency.

Table 625. SPI controller (CPHA = 0) configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0000h	Start and stop bit disabled.
SHIFTCTL*n*	0083_0002h	Configure transmit using timer 0 on the negative edge of clock with output data on pin 0.
SHIFTCFG(*n* + 1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n* + 1)	0000_0101h	Configure receive using timer 0 on the positive edge of clock with input data on pin 1.
TIMCMP*n*	0000_3F01h	Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0100_2222h	Configure start bit, stop bit, enable on trigger high and disable on compare; initial clock state is logic 0.
TIMCTL*n*	01C3_0201h	Configure dual 8-bit counter using the pin 2 output (shift clock), with shifter 0 flag as the inverted trigger. Write 1 to the PINPOL field to invert the output shift clock.
TIMCMP(*n* + 1)	0000_FFFFh	Never compare.
TIMCFG(*n* + 1)	0000_1100h	Enable when timer 0 is enabled and disable when timer 0 is disabled.
TIMCTL(*n* + 1)	0003_0383h	Configure 16-bit counter (never compare) using the inverted pin 3 output as target select.
SHIFTBUF*n*	Data to transmit	You can write transmit data to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.

Table 626. SPI controller (CPHA = 1) configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0021h	Start bit loads data on first shift.
SHIFTCTL*n*	0003_0002h	Configure transmit using timer 0 on the positive edge of clock with output data on pin 0.
SHIFTCFG(*n* + 1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n* + 1)	0080_0101h	Configure receive using timer 0 on the negative edge of clock with input data on pin 1.
TIMCMP*n*	0000_3F01h	Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits x 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0100_2222h	Configure start bit, stop bit, enable on trigger high and disable on compare; initial clock state is logic 0.
TIMCTL*n*	01C3_0201h	Configure dual 8-bit counter using pin 2 output (shift clock), with the shifter 0 flag as the inverted trigger. Write 1 to the PINPOL field to invert the output shift clock, and set the TIMDIS field as 3 to keep target select asserted for as long as there is data in the transmit buffer.
TIMCMP(*n* + 1)	0000_FFFFh	Never compare.
TIMCFG(*n* + 1)	0000_1100h	Enable when timer 0 is enabled and disable when timer 0 is disabled.
TIMCTL(*n* + 1)	0003_0383h	Configure 16-bit counter (never compare) using inverted pin 3 output (as target select).
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUF. Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.

67.6.4 SPI target

SPI Target mode can be supported using one timer, two shifters, and four pins. Either CPHA = 0 or CPHA = 1 can be supported and transfers can be supported using the DMA controller. For CPHA = 1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

You must write the transmit data to the transmit buffer register before the external target select asserts; otherwise, the shifter error flag is set.

NOTE

Because of synchronization delays, the output valid time for the serial output data is 2.5 FLEXIO clock cycles. This means the maximum baud rate is divide by 6 of the FLEXIO clock frequency.

Table 627. SPI target (CPHA = 0) configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0000h	Start and stop bit disabled.
SHIFTCTL*n*	0083_0002h	Configure transmit using timer 0 on the falling edge of shift clock with output data on pin 0.
SHIFTCFG(*n* + 1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n* + 1)	0000_0101h	Configure receive using timer 0 on the rising edge of shift clock with input data on pin 1.
TIMCMP*n*	0000_003Fh	Configure 32-bit transfer. Set TIMCMP[15:0] as (number of bits × 2) - 1.
TIMCFG*n*	0120_0600h	Configure enable on trigger rising edge. Initial clock state is logic 0 and decrements on pin input.
TIMCTL*n*	06C0_0203h	Configure 16-bit counter using pin 2 input (shift clock), with pin 3 input (target select) as the inverted trigger.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.

Table 628. SPI target (CPHA = 1) configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0001h	Shifter configured to load on first shift and stop bit disabled.
SHIFTCTL*n*	0003_0002h	Configure transmit using timer 0 on rising edge of shift clock with output data on pin 0.
SHIFTCFG(*n* + 1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n* + 1)	0080_0101h	Configure receive using timer 0 on falling edge of shift clock with input data on pin 1.
TIMCMP*n*	0000_003Fh	Configure 32-bit transfer. Set TIMCMP[15:0] as (number of bits × 2) - 1).
TIMCFG*n*	0120_6602h	Configure start bit, enable on trigger rising edge, disable on trigger falling edge. Initial clock state is logic 0 and decrements on pin input.
TIMCTL*n*	06C0_0203h	Configure 16-bit counter using pin 2 input (shift clock), with pin 3 input (target select) as the inverted trigger.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7) instead to support MSB first transfer.

67.6.5 I2C controller

I2C Controller mode can be supported using two timers, two shifters, and two pins. One timer is used to generate the SCL output and another one is used to control the shifters. The two shifters that are used to transmit and receive for every word, when receiving the transmitter, must transmit FFh to 3-state the output. FLEXIO inserts a stop bit after every word to generate and verify the ACK or NACK. FLEXIO waits for the first write to the transmit data buffer before enabling SCL generation. Data transfers can be supported using the DMA controller and the shifter error flag sets on transmit underrun or receive overflow.

The first timer generates the bit clock for the entire packet (start to repeated start or stop condition), so you must program the compare register with the total number of clock edges in the packet (minus one). The timer supports clock stretching using the reset counter when pin is equal to output. However, this increases both the clock high and clock low periods by at least one FLEXIO

clock cycle each. The second timer uses the SCL input pin to control the transmit and receive shift registers. This enforces an SDA data hold time by an extra two FLEXIO clock cycles.

Both the transmit and receive shifters must be serviced for each word in the transfer. The transmit shifter must transmit FFh when receiving, and the receive shifter returns the data present on the SDA pin. The transmit shifter loads one additional word on the last falling edge of the SCL pin. When generating a stop condition or a repeated start condition, this word must be 00h and FFh, respectively. During the last word of a controller-receiver transfer, you must set the transmit SHIFTCFG*n*[SSTOP] field to generate a NACK.

The receive shift register asserts an error interrupt if a NACK is detected, but you are responsible for generating the stop or repeated start condition. If a NACK is detected during controller-transmit, the interrupt routine must immediately write 00h (when generating a stop condition) or FFh (when generating a repeated start condition) to the transmit shifter register. You must wait for the next rising edge on SCL before disabling both timers. The transmit shifter must be disabled after the setup delay for a repeated start or stop condition.

NOTE

Because of synchronization delays, the data valid time for the transmit output is two FLEXIO clock cycles. This means the maximum baud rate is divide by 6 of the FLEXIO clock frequency.

To guarantee SDA hold time, the I2C controller data valid is delayed by two cycles because the clock output is passed through a synchronizer before clocking the transmit or receive shifter. Because the SCL output is synchronous with FLEXIO clock, the synchronization delay is one cycle, and then an additional cycle is involved to generate the output.

Table 629. I2C controller configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0032h	Start bit enabled (logic 0) and stop bit enabled (logic 1).
SHIFTCTL*n*	0101_0082h	Configure transmit using timer 1 on the rising edge of clock with inverted output enable (open-drain output) on pin 0.
SHIFTCFG(*n* + 1)	0000_0020h	Start bit disabled and stop bit enabled (logic 0) for ACK or NACK detection.
SHIFTCTL(*n* + 1)	0180_0001h	Configure receive using timer 1 on the falling edge of clock with input data on pin 0.
TIMCMP*n*	0000_2501h	Configure 2 word transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of words × 18) + 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0102_2222h	Configure start bit, stop bit, enable on trigger high, disable on compare, reset if output equals pin. Initial clock state is logic 0 and is not affected by reset.
TIMCTL*n*	01C1_0101h	Configure dual 8-bit counter using pin 1 output enable (SCL open-drain), with the shifter 0 flag as the inverted trigger.
TIMCMP(*n* + 1)	0000_000Fh	Configure 8-bit transfer. Set TIMCMP[15:0] as (number of bits x 2) - 1.

Table continues on the next page...

Table 629. I2C controller configuration (continued)

Register	Value	Configuration
TIMCFG(*n* + 1)	0020_1112h	Enable when timer 0 is enabled; disable when timer 0 is disabled. Enable start bit and stop bit at the end of each word and decrement on pin input.
TIMCTL(*n* + 1)	01C0_0183h	Configure 16-bit counter using inverted pin 1 input (SCL).
SHIFTBUF*n*	Data to transmit	Transmit data can be written to SHIFTBUFBBS[7:0]. Use the shifter status flag to indicate when data can be written using interrupt or DMA request.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from SHIFTBUFBIS[7:0]. Use the shifter status flag to indicate when data can be read using interrupt or DMA request.

67.6.6 I2S controller

I2S Controller mode can be supported using two timers, two shifters, and four pins. One timer is used to generate the bit clock and control the shifters and another timer is used to generate the frame sync. FLEXIO waits for the first write to the transmit data buffer before enabling bit clock and frame sync generation. Data transfers are supported using the DMA controller and the shifter error flag sets on transmit underrun or receive overflow.

The bit clock frequency is an even integer divide of the FLEXIO clock frequency. The initial frame sync assertion occurs at the same time as the first bit clock edge. The timer uses the start bit to ensure that the frame sync is generated one clock cycle before the first output data.

NOTE

Because of synchronization delays, the setup time for the receiver input is 1.5 FLEXIO clock cycles. This means that the maximum baud rate is divide by 4 of the FLEXIO clock frequency.

Table 630. I2S controller configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0001h	Load transmit data on first shift and stop bit disabled.
SHIFTCTL*n*	0003_0002h	Configure transmit using timer 0 on the rising edge of clock with output data on pin 0.
SHIFTCFG(*n* + 1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n* + 1)	0080_0101h	Configure receive using timer 0 on the falling edge of clock with input data on pin 1.
TIMCMP*n*	0000_3F01h	Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of bits × 2)

Table continues on the next page...

Table 630. I2S controller configuration (continued)

Register	Value	Configuration
		- 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG*n*	0000_0202h	Configure start bit, enable on trigger high and never disable. Initial clock state is logic 1.
TIMCTL*n*	01C3_0281h	Configure dual 8-bit counter using inverted pin 2 output (bit clock), with shifter 0 flag as the inverted trigger. Write 0 to the PINPOL field to invert the polarity of the output shift clock.
TIMCMP(*n* + 1)	0000_007Fh	Configure 32-bit transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:0] as (number of bits × baud rate divider) ÷ 1.
TIMCFG(*n* + 1)	0000_0100h	Enable when timer 0 is enabled and never disable.
TIMCTL(*n* + 1)	0003_0383h	Configure 16-bit counter using inverted pin 3 output (as frame sync). Write 0 to the PINPOL field to invert the polarity of the output frame sync.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7). Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) instead to support LSB first transfer.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) instead to support LSB first transfer.

67.6.7 I2S target

I2S Target mode can be supported using three timers, two shifters, and four pins. For single transmit and single receive, other combinations of transmit and receive are possible.

The transmit data must be written to the transmit buffer register before the external frame sync asserts, otherwise the shifter error flag is set.

NOTE

Because of synchronization delays, the output valid time for the serial output data is 2.5 FLEXIO clock cycles. This means the maximum baud rate is divide by 6 of the FLEXIO clock frequency.

The output valid time of I2S target is maximum 2.5 cycles because there is a maximum 1.5 cycle delay on the clock synchronization, plus one cycle to output the data.

Timer 2 detects the falling edge of frame sync (start of new frame) and asserts output until the rising edge of bit clock (when the frame sync is normally sampled). Timer 0 detects the rising edge of bit clock with timer 2 output asserted and asserts output for length of frame. Timer 1 detects the falling edge of bit clock with timer 0 output asserted and controls shift registers for 32-bit transfers.

Table 631. I2S target configuration

Register	Value	Configuration
SHIFTCFG*n*	0000_0000h	Start and stop bit disabled.
SHIFTCTL*n*	0103_0002h	Configure transmit using timer 1 on the rising edge of shift clock with output data on pin 0.
SHIFTCFG(*n* + 1)	0000_0000h	Start and stop bit disabled.
SHIFTCTL(*n* + 1)	0180_0101h	Configure receive using timer 1 on the falling edge of shift clock with input data on pin 1.
TIMCMP*n*	0000_007Fh	Configure two 32-bit transfers per frame. Set TIMCMP[15:0] as (number of bits × 4) - 1.
TIMCFG*n*	0020_2500h	Configure enable on pin rising edge (inverted bit clock) with trigger high (timer 2) and disable on compare. Initial clock state is logic 1 and decrements on pin input (bit clock).
TIMCTL*n*	0B40_0203h	Configure 16-bit counter using pin 2 input (bit clock), with timer 2 output as the trigger.
TIMCMP(*n* + 1)	0000_003Fh	Configure 32-bit transfers. Set TIMCMP[15:0] as (number of bits × 2) - 1.
TIMCFG(*n* + 1)	0020_2500h	Configure enable on pin (bit clock) rising edge with trigger (timer 0) high and disable on compare. Initial clock state is logic 1 and decrement on pin input (bit clock).
TIMCTL(*n* + 1)	0340_0283h	Configure 16-bit counter using inverted pin 2 input (bit clock), with timer 0 output as the trigger.
TIMCMP(*n* + 2)	0000_0000h	Compare on zero (first edge).
TIMCFG(*n* + 2)	0020_6400h	Configure enable on inverted pin (frame sync) rising edge and disable on trigger falling edge (bit clock). Initial clock state is logic 1 and decrement on inverted pin input (frame sync).

Table continues on the next page...

Table 631. I2S target configuration (continued)

Register	Value	Configuration
TIMCTL(*n* + 2)	04C0_0383h	Configure 16-bit counter using inverted pin 3 input (frame sync), with pin 2 inverted input (bit clock) as the trigger.
SHIFTBUF*n*	Data to transmit	Transmit data can be written to Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7). Use the shifter status flag to indicate when data can be written using interrupt or DMA request. Write to the SHIFTBUF register instead to support LSB first transfer.
SHIFTBUF(*n* + 1)	Data to receive	Received data can be read from Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7). Use the shifter status flag to indicate when data can be read using interrupt or DMA request. Read from the SHIFTBUF register instead to support LSB first transfer.

67.6.8 SENT receiver

The SENT receiver can be supported by using one timer and one pin. The timer is configured as Input-Capture mode, and captures the counter value at the falling edge of the pin input. After the counter value is captured, the counter is automatically restarted from counter value 0. Therefore, the captured value always indicates the period between the previous falling edge and current falling edge. You can configure the CPU interrupt or DMA trigger at each capture of the counter. The CPU software performs the entire SENT frame decoding with the latest tick width adjustment.

Table 632. SENT receiver configuration

Register	Value	Configuration
TIMCMP*n*	—	Stores counter value at the falling edge of the pin.
TIMCFG*n*	0000_6000h	Timer is always enabled. It is disabled on trigger falling edge, decrement counter on FLEXIO clock.
TIMCTL*n*	0040_0007h	Single 16-bit input capture mode. The PINSEL field selects the timer pin input and output. Timer pin output disabled, internal trigger selected, select pin 0 as trigger.

67.6.9 Camera interface

Camera interface can be supported using one timer, one or more shifters, and multiple pins. Multiple transfers can be supported using the DMA controller.

The example configuration shown in the following table describes the FLEXIO configuration for interfacing with an 8-bit CMOS sensor with PCLK, VSYNC, HREF, and D[7:0] outputs. The example uses a 128-bit buffer to capture 16 pixels of image data before an interrupt or DMA transfer. You can use a bigger or smaller buffer depending on system DMA performance and FLEXIO resource usage by other applications.

NOTE

You can use additional timers to track the number of pixels per row and number of rows per frame, or HREF or VSYNC can be assigned as GPIO interrupts for software tracking.

Table 633. Camera interface configuration for 8-bit CMOS sensor

Register	Value	Configuration
SHIFTCFG*n*...*n*+2[1]	0007_0100h	Configure 8-bit parallel shift in from adjacent shifter.
SHIFTCFG*n*+3	0007_0000h	Configure 8-bit parallel shift in from pins FXIO_D[7:0] (D[7:0]).
SHIFTCTL*n*...*n*+3	0080_0001h	Configure receive using timer 0 on the negative edge of clock.
TIMCMP*n*	0000_001Fh	Configure 16 pixel (8 bits/pixel × 16 pixels = 128 bits) transfer. Set TIMCMP[15:0] as (number of pixels × 2) - 1.
TIMCFG*n*	0120_6600h	Configure enable on trigger (HREF) rising edge and disable on trigger falling edge. Initial shift clock state is logic 0 and decrement on PCLK input.
TIMCTL*n*	12C0_0803h	Configure 16-bit counter using FXIO_D[8] input (PCLK), with FXIO_D[9] input (HREF) as the inverted trigger.
SHIFTBUF*n*...*n*+3	Data to receive	Received data can be read from SHIFTBUF*n*...*n*+3. Use the shifter status flag to indicate when data can be read using interrupt or DMA request.

1. *n* = 0 or 4

67.6.10 Motorola 68K and Intel 8080 bus interface

Motorola 68K and Intel 8080 bus are two parallel interfaces commonly used by smart and asynchronous LCD controllers. With GPIO, FLEXIO can drive these interfaces using one timer and one shifter. Additional shifters can be used to support large transfers via the DMA controller.

Example configurations are provided for 1-beat and 16-beat transfers. Other lengths are also supported.

The following table provides an example of how to drive a 16-bit 68K or 8080 bus. For an 8080 bus, two GPIOs are used to drive the nCS and RS pins. For a 68K bus, an additional GPIO is required to drive the RDWR pin.

Table 634. Motorola 68K and Intel 8080 write configuration

Register	Value	Configuration
SHIFTCFG0...7	000F_0100h	Configure 16-bit parallel shift in from adjacent shifter.
SHIFTCTL0	0003_0002h	Configure transmit using timer 0 on the positive edge of clock with data output to FXIO_D[15:0].

Table continues on the next page...

Table 634. Motorola 68K and Intel 8080 write configuration (continued)

Register	Value	Configuration
SHIFTCTL1...7	0000_0002h	Configure transmit using timer 0 on the positive edge of clock.
TIMCMP0	0000_0101h (1 beat) 0000_1F01h (16 beats)	Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] as (number of beats × 2) - 1, and set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG0	0000_2200h	Configure enable on trigger high and disable on compare. Timer output high on enable.
TIMCTL0	01C3_1001h (Motorola 68K, 1 beat) 1DC3_1001h (Motorola 68K, 16 beats) 01C3_1081h (Intel 8080, 1 beat) 1DC3_1081h (Intel 8080, 16 beats)	Configure dual 8-bit counter using FXIO_D[16] output (EN pin for 68K, nWR pin for 8080), with shifter 0 (1-beat) or shifter 7 (16 beats) flag as the inverted trigger.
SHIFTBUF0...7	Data to transmit	Transmit data can be written to SHIFTBUF0 (1 beat) or SHIFTBUF0...7 (16-beats) to initiate a transfer; use the shifter status flag to indicate when data can be written using interrupt or DMA request.

Table 635. Motorola 68K and Intel 8080 read configuration

Register	Value	Configuration
SHIFTCFG0...6	000F_0100h	Configure 16-bit parallel shift in from the adjacent shifter.
SHIFTCFG7	000F_0000h	Configure 16-bit parallel shift in from pin.
SHIFTCTL0...7	0080_0001h	Configure receive using timer 0 on the negative edge of clock with data input from FXIO_D[15:0].
TIMCMP0	0000_0101h (1 beat) 0000_1F01h (16 beats)	Configure 1 or 16-beat transfer with baud rate of divide by 4 of the FLEXIO clock. Set TIMCMP[15:8] = (number of beats × 2) - 1, and set TIMCMP[7:0] = (baud rate divider ÷ 2) - 1.
TIMCFG0	0000_2220h	Configure stop_bit. Enable on trigger high and disable on compare. Timer output high on enable.
TIMCTL0	1DC3_1001h (Motorola 68K, 1 beat) 01C3_1001h (Motorola 68K, 16 beats)	Configure dual 8-bit counter using either FXIO_D[16] output (EN pin for 68K) or FXIO_D[17] output (nRD pin for 8080),

Table continues on the next page...

Table 635. Motorola 68K and Intel 8080 read configuration (continued)

Register	Value	Configuration
	1DC3_1181h (Intel 8080, 1 beat) 01C3_1181h (Intel 8080, 16 beats)	with shifter 7 flag (1-beat) or shifter 0 flag (16 beats) as the inverted trigger.
SHIFTBUF0...7	Data received	Received data can be read from SHIFTBUF0 (1 beat) or SHIFTBUF0...7 (16 beats). Use the shifter status flag to indicate when data can be read using interrupt or DMA request.

In general, any operation to a 68K or 8080 bus target begins with a register write cycle followed by one or more data read or write cycles. To accomplish this, perform the following procedure:

1. Configure FLEXIO with 1-beat write configuration.
2. Configure GPIO to assert the nCS and RS pins (and deassert the RDWR pin for 68K).
3. Write register index data to SHIFTBUF0[15:0].
4. Configure GPIO to deassert the RS pin (and assert the RDWR pin for 68K data read).
5. Configure FLEXIO with the desired read or write configuration (1 or 16 beats).
6. Use the shifter status flag to trigger interrupt or DMA driven data transfers to and from Shifter Buffer (SHIFTBUF0 - SHIFTBUF7).
7. Configure GPIO to deassert the nCS pin.

67.6.11 Low-power state machine

Table 636 shows an example of a hypothetical state machine to illustrate the flexibility allowed in Shifter State mode.

In this example, FLEXIO waits for the FXIO_D[2] pin to assert and then drives a complementary square wave output at a frequency of FLEXIO_CLK/131072 on the FXIO_D[1:0] pins while the comparator output is asserted. This assumes that the comparator is connected to external trigger 15. See the chip-specific FLEXIO information for actual FLEXIO trigger mappings. Throughout this operation, the CPU can be kept in a stop or VLPS mode by writing 0 to CTRL[DOZEN] and ensuring that FLEXIO_CLK is enabled. Figure 280 shows the states and transitions implemented by this example.

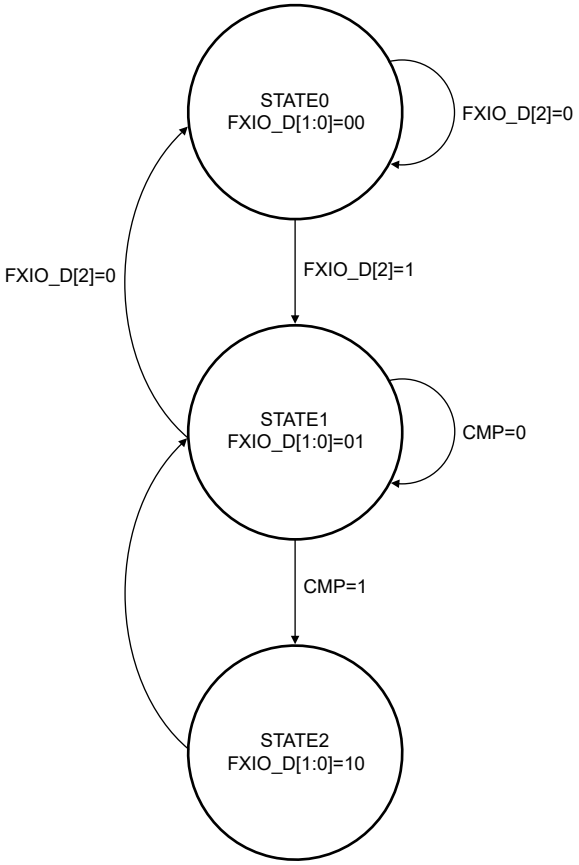

Figure 280. State diagram

Table 636. State machine configuration

Register	Value	Configuration
SHIFTCFG0...2	0000_0003h	Enable FXIO_D[1:0] as outputs.
SHIFTCTL0	0080_0206h	Configure for State mode using FXIO_D[4:2] as inputs to select next state and timer 0 output low to trigger next state.
SHIFTBUF0	0020_8208h	State0: Drive FXIO_D[1:0] = 00; transition to state0 if FXIO_D[2] = 0, state1 if FXIO_D[2] = 1.
SHIFTCTL1	0000_0206h	Configure for State mode using FXIO_D[4:2] as inputs to select next state and timer 0 output high to trigger next state.
SHIFTBUF1	0140_8408h	State1: Drive FXIO_D[1:0]=01; transition to state0 if FXIO_D[2]=0, state1 if CMP = 0, state2 if CMP = 1 (FXIO_D[3]=1).

Table continues on the next page...

Table 636. State machine configuration (continued)

Register	Value	Configuration
SHIFTCTL2	0080_0206h	Configure for State mode using FXIO_D[4:2] as inputs to select next state and timer 0 output low to trigger next state.
SHIFTBUF2	0224_9249h	State2: Drive FXIO_D[1:0] = 10, transition to state1 with timer 0 output low.
TIMCMP0	0000_FFFFh	Configure baud rate of divide by 131072 of the FLEXIO clock. Set TIMCMP[7:0] as (baud rate divider ÷ 2) - 1.
TIMCFG0	0000_0000h	Configure timer always enabled.
TIMCTL0	0000_0003h	Configure single 16-bit counter.
TIMCFG1	0010_7600h	Configure timer enabled on trigger rising edge, disabled on trigger falling edge, decrement on trigger edge.
TIMCTL1	0F03_0303h	Configure timer output enabled on FXIO_D[3], external trigger 15 (comparator output) selected.

67.6.12 Keypad interface

The keypad interface can support a 3 × 4 keypad matrix using three timers and three shifters, although a larger matrix can be supported using additional shifters. The configuration is designed for four columns configured as active low open-drain pins and three rows configured as input pins with pull-up resistors enabled.

One shifter is configured in Logic mode to assert its output when any of the row inputs are low, indicating a key is pressed. Use a timer to filter the shifter output to ensure that the key is pressed for a minimum amount of time before performing the column scan.

A different shifter is configured for parallel transmit. Use this shifter to scan each column when a keypress is detected. When not scanning, the shifter output is configured to assert all active low open-drain column outputs to detect any keypress. Use a dedicated timer to control the transmit shifter.

The last shifter is configured for parallel receive. Use this shifter to capture the result of the column scanning so that you can decode which key (or keys) was pressed. This configuration captures the state of both row and column pins for each scan, although the row state can also be deduced by the shift order. Use a dedicated timer to control the receive shifter, which shifts at half the frequency of the transmit shifter.

When the result of the key scan is available in the receive shifter register, FLEXIO continues to monitor the row inputs and can trigger multiple scans from a single keypress. To support debouncing, you can decide how many consecutive scans must be considered as a single keypress.

NOTE

Because the pins used in Logic mode are fixed per shifter and the shifters that support parallel shifts are limited, this configuration is restricted to what pins and shifters it can use. Increasing the matrix beyond four-row inputs requires multiple shifters in Logic mode. Increasing beyond four-column outputs requires concatenating transmit shifters to create a larger shift register.

Table 637. Keypad interface configuration

Register	Value	Configuration
SHIFTCFG0	0003_0032h	Start bit enabled (logic 0) and stop bit enabled (logic 1), configured for 4-bit shift.
SHIFTCTL0	0101_0402h	Configure transmit using timer 1 on the rising edge of clock generating open-drain output on pins[7:4] (column outputs).
SHIFTBUF0	0804_0201h	Static data containing the column scan pattern; each column is scanned one-hot with dead time in between.
SHIFTCFG1	0000_0020h	In Logic mode, mask input 3.
SHIFTCTL1	0000_0007h	Configure Logic mode.
SHIFTBUF1	07FF_07FFh	Static data configuring Logic mode LUT. Output asserts if pins [3:1] are logic 0.
SHIFTCFG3	0007_0000h	Configured for 8-bit shift.
SHIFTCTL3	0280_0001h	Configure receive using timer 2 on falling edge of clock with input data on pins [7:0] (both rows and columns; pin 0 is don't care).
TIMCMP0	0000_00ffh	Configure prescanning glitch filter to 256 FLEXIO clock cycles. For different filter cycles, configure TIMCMP[15:0] as (filter cycles) - 1.
TIMCFG0	0103_6600h	Configure enable on trigger rising edge and disable on trigger falling edge. Initial clock state is logic 0 and is not affected by reset.
TIMCTL0	0540_0003h	Configure 16-bit counter using the shifter 1 flag (logic state) as trigger.
TIMCMP1	0000_0F3Fh	Configure eight shifts (twice for each column) at column scan rate of divide by 128. For a different scan frequency, define TIMCMP[7:0] as (scan divider ÷ 2) - 1.
TIMCFG1	0020_2622h	Enable on trigger rising edge, disable on compare. Start and stop bits are enabled.
TIMCTL1	0340_0001h	Configure dual 8-bit counter using timer 0 output as the trigger.
TIMCMP2	0000_0801h	Configure four shifts at half the frequency of the timer 1 trigger.

Table continues on the next page...

Table 637. Keypad interface configuration (continued)

Register	Value	Configuration
TIMCFG2	0110_2100h	Enable on timer 1 enable, disable on compare, decrement on trigger input with output initially negated, and not affected by reset.
TIMCTL2	0740_0001h	Configure dual 8-bit counter using timer 1 output as the trigger.
SHIFTBUF3	Keypad scan result	Keypad scan result can be read from SHIFTBUF3. Each byte is the result of one scan with both row and column pin state from the scan (pin 0 is not used). Use the shifter status flag to indicate when data can be written using interrupt or DMA request.

67.7 Memory map and registers

67.7.1 FLEXIO register descriptions

NOTE

Invalid register accesses, which include reading a write-only register, writing to a read-only register, or accessing an invalid address, result in a bus error.

67.7.1.1 FLEXIO memory map

FLEXIO base address: 4041_6000h

Offset	Register	Width (In bits)	Access	Reset value

67.7.1.2 Version ID (VERID)

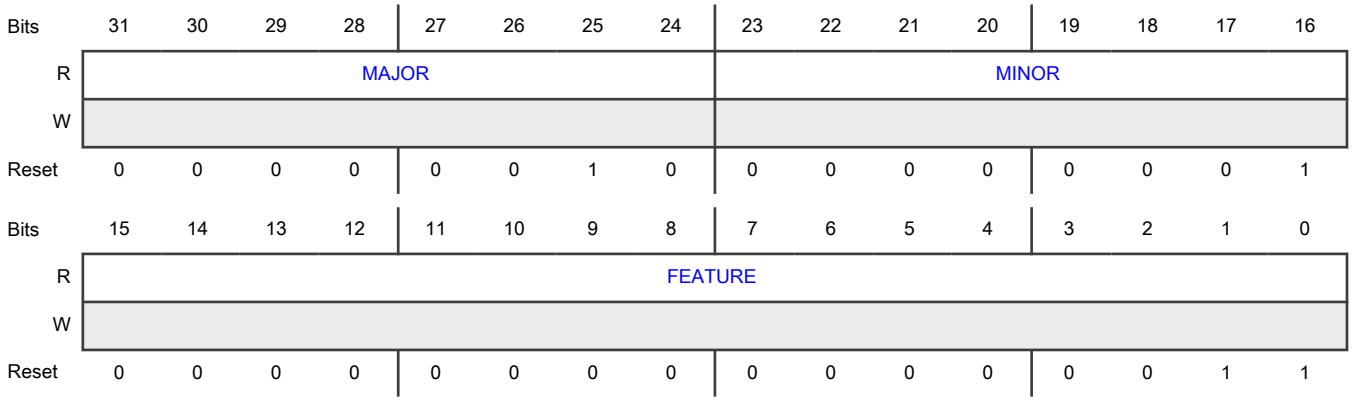
Offset

Register	Offset
VERID	0h

Function

Indicates the version of FLEXIO.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number Indicates the major version number of the module specification.
23-16 MINOR	Minor Version Number Indicates the minor version number of the module specification.
15-0 FEATURE	Feature Specification Number Indicates the feature set number. 0000_0000_0000_0000b - Standard features implemented

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0000_0000_0000_0001b - State, logic, and parallel modes supported 0000_0000_0000_0010b - Pin control registers supported 0000_0000_0000_0011b - State, logic, and parallel modes, plus pin control registers supported

67.7.1.3 Parameter (PARAM)

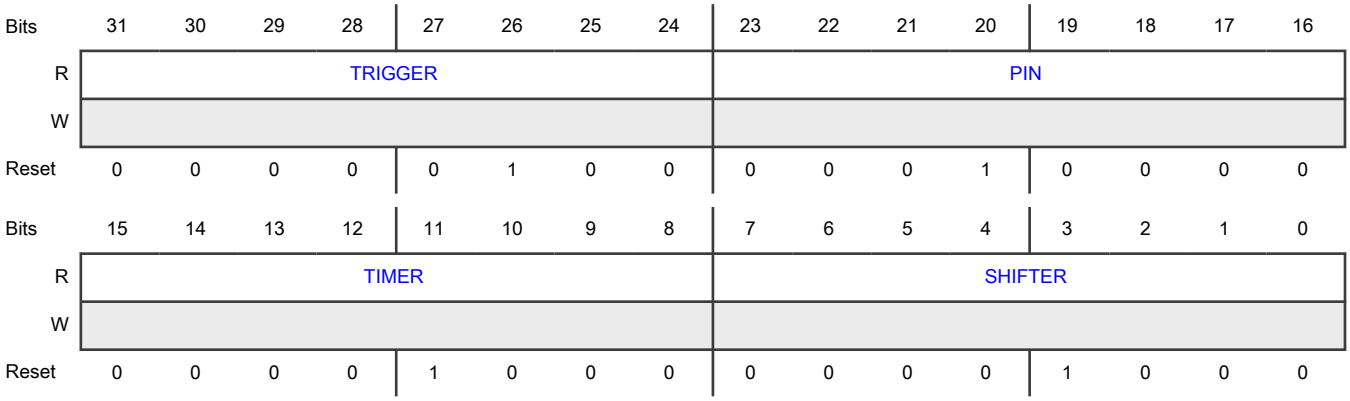
Offset

Register	Offset
PARAM	4h

Function

Contains the number of shifters, timers, pins, and triggers.

Diagram



Fields

Field	Function
31-24 TRIGGER	Trigger Number Indicates the number of external triggers implemented.
23-16 PIN	Pin Number Indicates the number of pins implemented.
15-8 TIMER	Timer Number Indicates the number of timers implemented.
7-0 SHIFTER	Shifter Number Indicates the number of shifters implemented.

67.7.1.4 FLEXIO Control (CTRL)

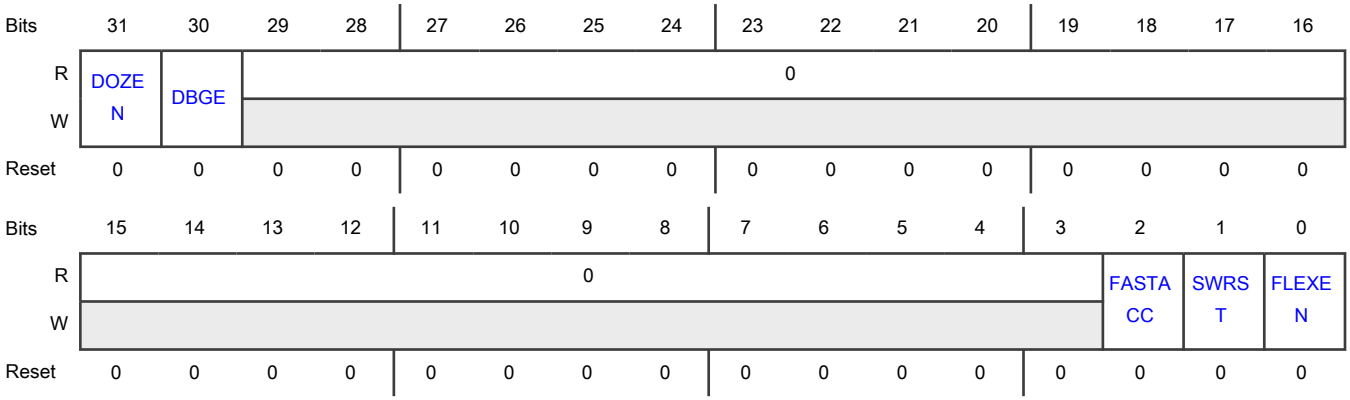
Offset

Register	Offset
CTRL	8h

Function

Controls various aspects of the FLEXIO operation.

Diagram



Fields

Field	Function
31 DOZEN	Doze Enable Disables FLEXIO operation in Doze modes. 0b - Enable 1b - Disable
30 DBGE	Debug Enable Enables the FLEXIO operation in Debug mode. 0b - Disable 1b - Enable
29-3 —	Reserved
2 FASTACC	Fast Access Configures fast or normal register accesses to FLEXIO registers, but requires the FLEXIO functional clock to be at least equal to the frequency of the bus clock.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Normal 1b - Fast
1 SWRST	Software Reset Specifies whether software reset is enabled. The software reset does not affect this register but it affects all other logic in FLEXIO. All other register accesses are ignored until this field is cleared. The field remains 1 until software clears it and the reset has cleared in the FLEXIO clock domain. If you write 1 to this field, all FLEXIO registers except the Control register are reset. 0b - Disabled 1b - Enabled
0 FLEXEN	FLEXIO Enable Enables FLEXIO. 0b - Disable 1b - Enable

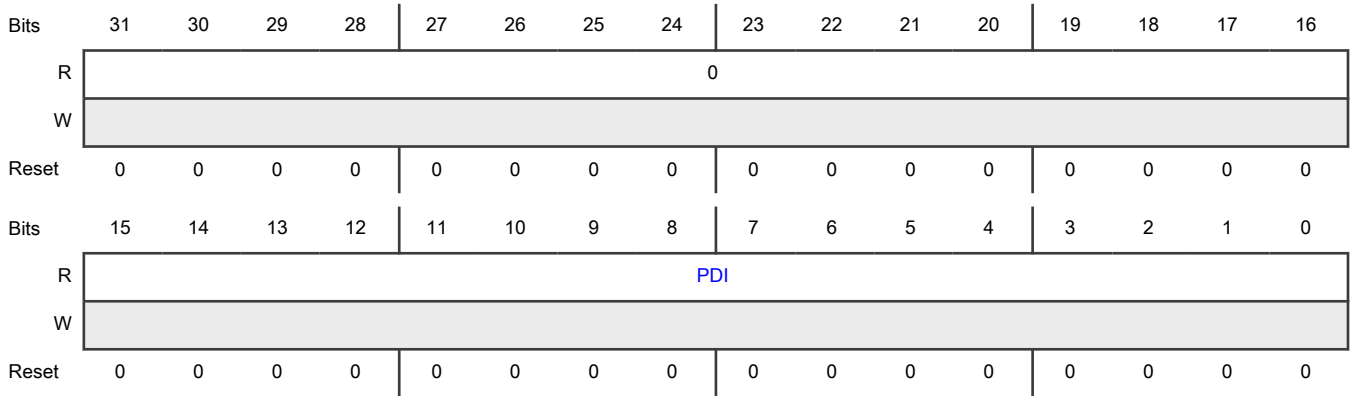
67.7.1.5 Pin State (PIN)

Offset

Register	Offset
PIN	Ch

Function
Indicates the status of the pin data input.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 PDI	Pin Data Input Indicates the input data on each of the FLEXIO pins.

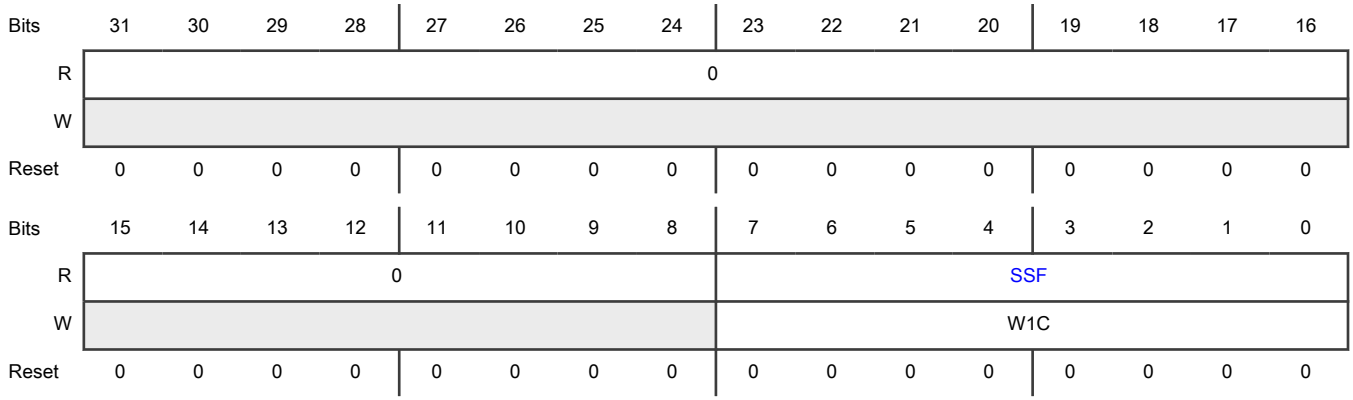
67.7.1.6 Shifter Status (SHIFTSTAT)

Offset

Register	Offset
SHIFTSTAT	10h

Function
Contains shifter status flags.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SSF	Shifter Status Flag Indicates the shifter status. This flag is updated in one of the following cases:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If SHIFTCTL*n*[SMOD] = 001b (Receive mode), the status flag is set when SHIFTBUF is loaded with data from the shifter (SHIFTBUF is full). The status flag is cleared when you read Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). • If SHIFTCTL*n*[SMOD] = 010b (Transmit mode), the status flag is set when SHIFTBUF data is transferred to the shifter (SHIFTBUF is empty) or when SHIFTCTL*n*[SMOD] is initially configured as 010b (Transmit mode). The status flag is cleared when you write to the SHIFTBUF register. • If SHIFTCTL*n*[SMOD] = 100b (Match Store mode), the status flag is set when a match occurs between SHIFTBUF and the shifter. The status flag is cleared when you read the SHIFTBUF register. • If SHIFTCTL*n*[SMOD] = 101b (Match Continuous mode), the status flag returns the current match result between SHIFTBUF and the shifter. You cannot clear the status flag by reading the SHIFTBUF register. • If SHIFTCTL*n*[SMOD] = 110b (State mode), the status flag for a shifter sets when it is selected by the current state pointer. • If SHIFTCTL*n*[SMOD] = 111b (Logic mode), the status flag returns the current value of the programmable logic block output. You can clear this status flag by writing a logic one to the flag for all modes except Match Continuous mode, State mode, and Logic mode. **NOTE** This field behaves differently for register reads and writes. When reading 0000_0000b - Clear 0000_0001b - Set When writing 0000_0000b - No effect 0000_0001b - Clear the flag

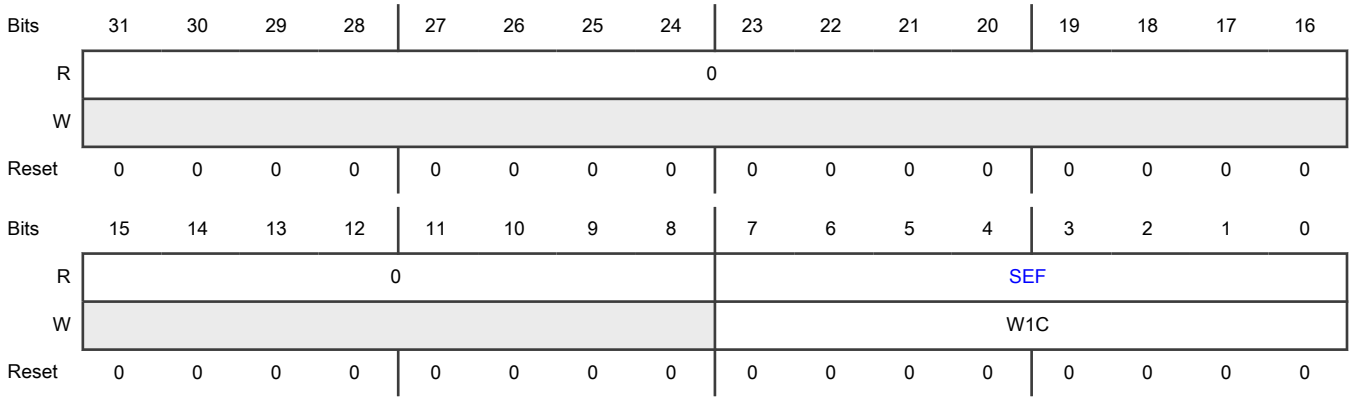
67.7.1.7 Shifter Error (SHIFTERR)

Offset

Register	Offset
SHIFTERR	14h

Function
Reports shifter errors.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SEF	Shifter Error Flag Indicates shifter error flag status. This flag is set when one of the following events occurs: • If SHIFTCTL*n*[SMOD] = 001b (Receive mode), it indicates that either the shifter is ready to store new data into SHIFTBUF before the previous data is read from SHIFTBUF (SHIFTBUF overrun), or the received start or stop bit does not match the expected value. • If SHIFTCTL*n*[SMOD] = 010b (Transmit mode), it indicates that the shifter is ready to load new data from SHIFTBUF before new data is written into SHIFTBUF (SHIFTBUF underrun). • If SHIFTCTL*n*[SMOD] = 100b (Match Store mode), it indicates the occurrence of a match event before the previous match data is read from SHIFTBUF (SHIFTBUF overrun). • If SHIFTCTL*n*[SMOD] = 101b (Match Continuous mode), the error flag is set when a match occurs between SHIFTBUF and the shifter. • If SHIFTCTL*n*[SMOD] = 111b (Logic mode), the error flag is set when the output of the programmable logic block is asserted. For SHIFTCTL*n*[SMOD] = 101b (Match Continuous mode), the flag can also be cleared when you read Shifter Buffer (SHIFTBUF0 - SHIFTBUF7). **NOTE** This field behaves differently for register reads and writes. When reading 0000_0000b - Clear 0000_0001b - Set When writing 0000_0000b - No effect 0000_0001b - Clear the flag

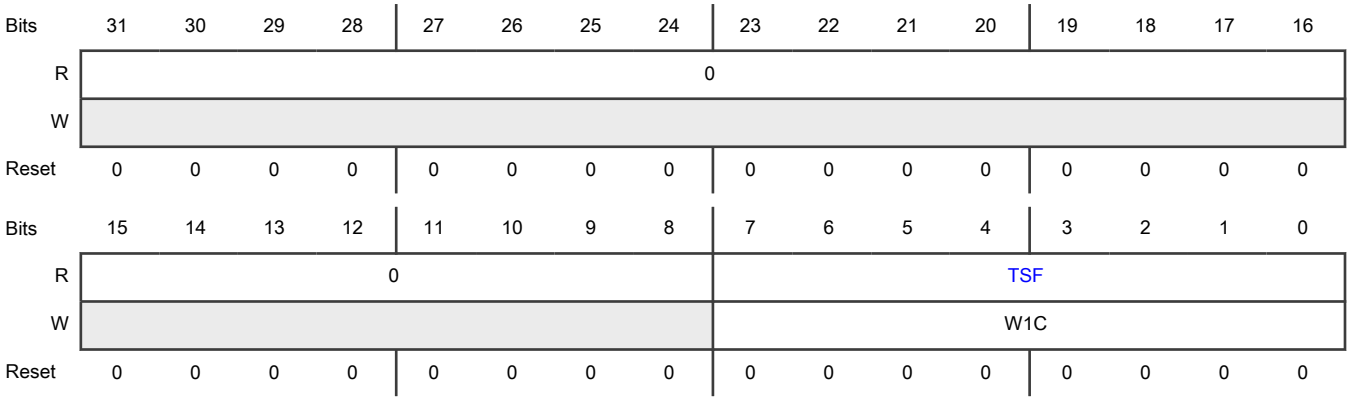
67.7.1.8 Timer Status Flag (TIMSTAT)

Offset

Register	Offset
TIMSTAT	18h

Function
Reports timer status.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 TSF	Timer Status Flag Indicates timer status. This flag is set depending on Timer mode: • In 8-bit baud counter mode, this flag is set when the upper 8-bit counter equals zero and decrements. • In 8-bit high PWM mode, this flag is set when the upper 8-bit counter equals zero and decrements. • In 16-bit counter mode, this flag is set when the 16-bit counter equals zero and decrements. • In 16-bit counter disable mode, TSF is set when a timer disable event is detected. • In 8-bit word counter mode, TSF is set when the upper 8-bit counter equals zero and decrements. • In 8-bit low PWM mode, TSF is set when the upper 8-bit counter equals zero and decrements. • In 16-bit input capture mode, TSF is set when a timer disable event is detected and the flag is clear. In this mode, you must read Timer Control (TIMCTL0 - TIMCTL7) only when TSF is set. **NOTE** This field behaves differently for register reads and writes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When reading 0000_0000b - Clear 0000_0001b - Set When writing 0000_0000b - No effect 0000_0001b - Clear the flag

67.7.1.9 Shifter Status Interrupt Enable (SHIFTSIEN)

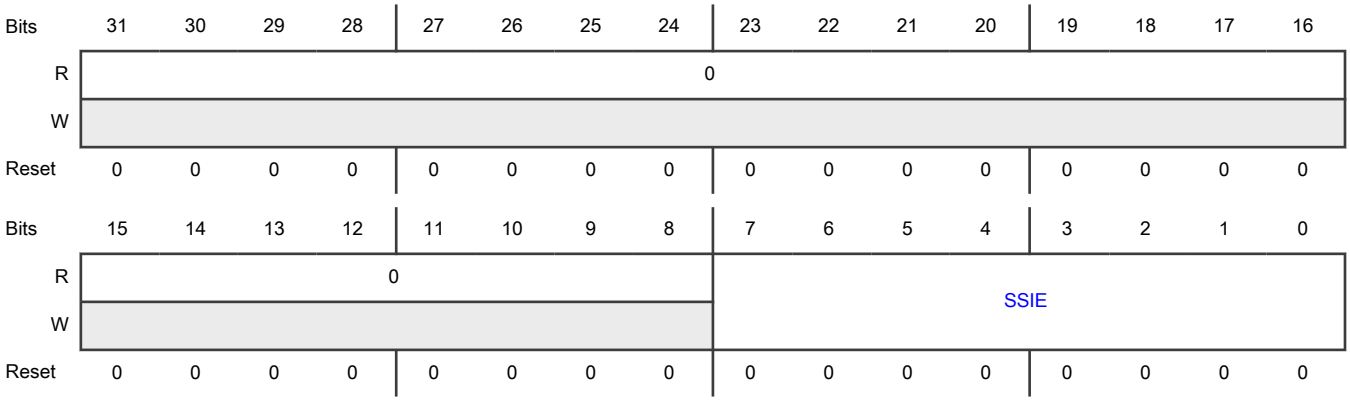
Offset

Register	Offset
SHIFTSIEN	20h

Function

Enables shifter status interrupts.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SSIE	Shifter Status Interrupt Enable Enables interrupt generation when the corresponding SHIFTSTAT[SSF] flag is set. If you write 0 to this field, SHIFTSTAT[SSF] is disabled; and if you write 1 to this field, SHIFTSTAT[SSF] is enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable

67.7.1.10 Shifter Error Interrupt Enable (SHIFTEIEN)

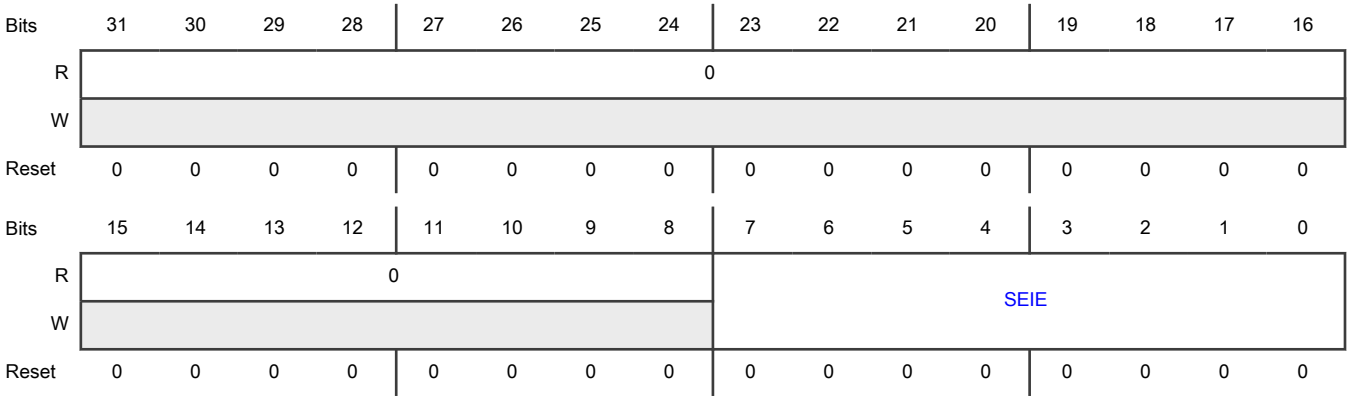
Offset

Register	Offset
SHIFTEIEN	24h

Function

Enables shifter error interrupts.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SEIE	Shifter Error Interrupt Enable Enables interrupt generation when the corresponding SHIFTERR[SEF] flag is set. If you write 0 to this field, SHIFTERR[SEF] is disabled; and if you write 1 to this field, SHIFTERR[SEF] is enabled. 0b - Disable 1b - Enable

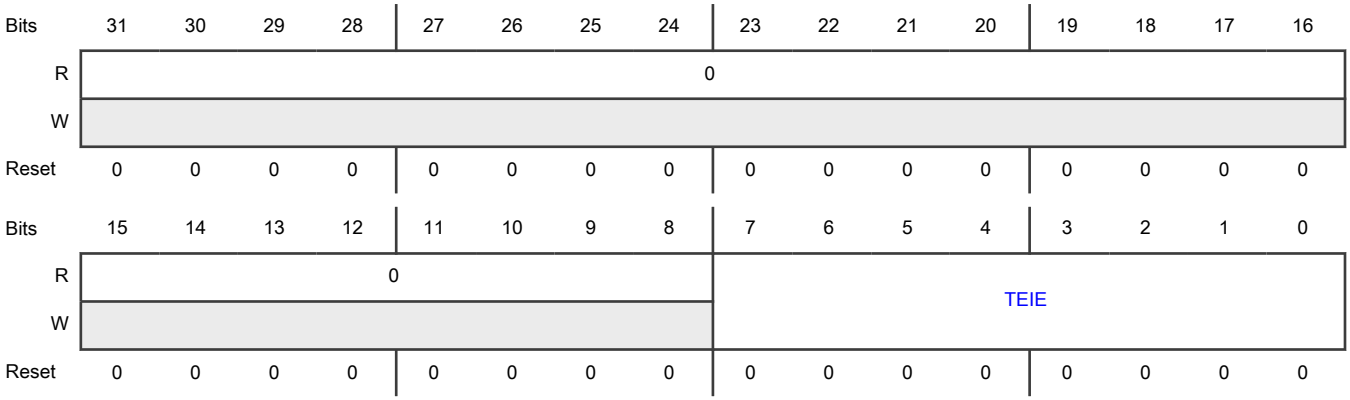
67.7.1.11 Timer Interrupt Enable (TIMIEN)

Offset

Register	Offset
TIMIEN	28h

Function
Enables timer status interrupts.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 TEIE	Timer Status Interrupt Enable Enables interrupt generation when the corresponding TIMSTAT[TSF] flag is set. If you write 0 to this field, TIMSTAT[TSF] is disabled; and if you write 1 to this field, TIMSTAT[TSF] is enabled. 0b - Disable 1b - Enable

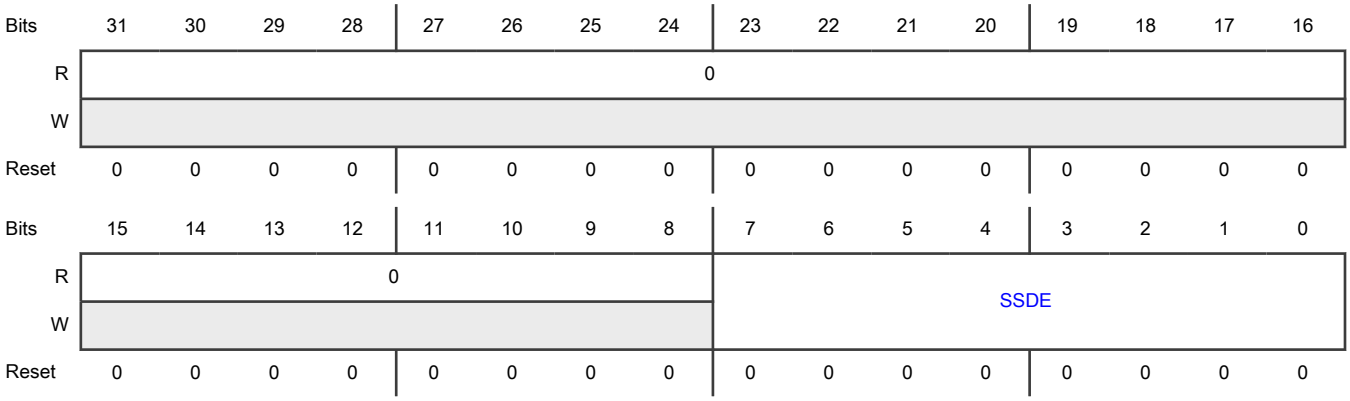
67.7.1.12 Shifter Status DMA Enable (SHIFTSDEN)

Offset

Register	Offset
SHIFTSDEN	30h

Function
Enables shifter DMA requests.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 SSDE	Shifter Status DMA Enable Enables DMA request generation when the corresponding SHIFTSTAT[SSF] flag is set. If you write 0 to this field, SHIFTSTAT[SSF] is disabled; and if you write 1 to this field, SHIFTSTAT[SSF] is enabled. 0b - Disable 1b - Enable

67.7.1.13 Timer Status DMA Enable (TIMERSDEN)

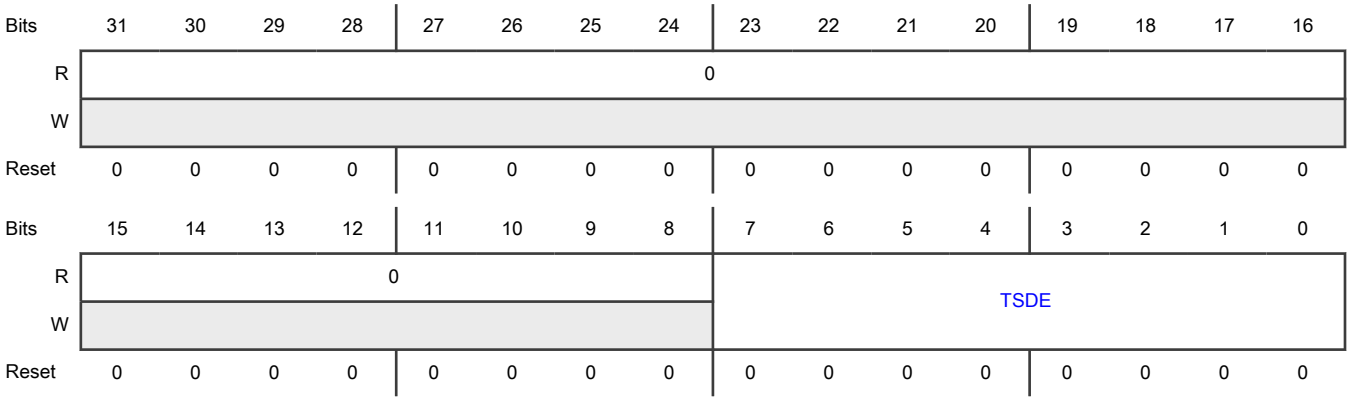
Offset

Register	Offset
TIMERSDEN	38h

Function

Enables DMA requests when the timer status flag is set.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 TSDE	Timer Status DMA Enable Enables DMA request generation when the corresponding TIMSTAT[TSF] flag is set. When the timer status DMA request is enabled, reading or writing to a timer compare register clears the corresponding timer status register. The DMA must therefore read or write to the timer compare register as part of the DMA transfer; otherwise, the DMA request remains asserted. 0b - Disable 1b - Enable

67.7.1.14 Shifter State (SHIFTSTATE)

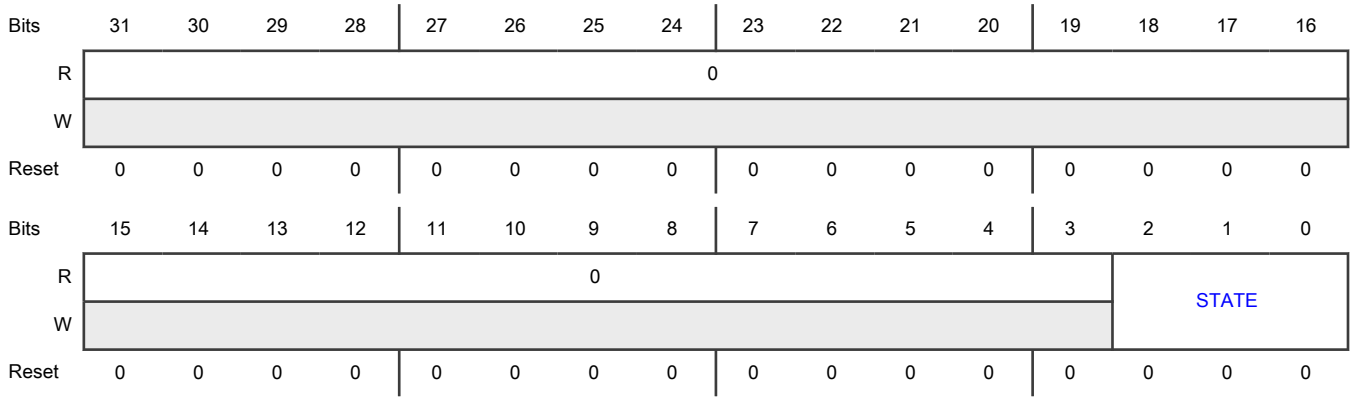
Offset

Register	Offset
SHIFTSTATE	40h

Function

Contains a pointer to track the current shifter.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 STATE	Current State Pointer Maintains a pointer to track the current shifter (configured for State mode) enabled to drive outputs and compute the next state. Reading this register when the state pointer is updating can result in the return of an incorrect state. The value that you write to this field overrides the current state.

67.7.1.15 Trigger Status (TRGSTAT)

Offset

Register	Offset
TRGSTAT	48h

Function

Contains external trigger status flags.

Diagram

Fields

Field	Function
31-16 —	Reserved
15-0 PSF	Pin Status Flag Indicates whether the pin status flag is set when a rising edge or falling edge (if configured) is detected on the corresponding pin, as configured by the pin. **NOTE** This field behaves differently for register reads and writes. When reading 0000_0000_0000_0000b - Clear 0000_0000_0000_0001b - Set When writing 0000_0000_0000_0000b - No effect 0000_0000_0000_0001b - Clear the flag

67.7.1.18 Pin Interrupt Enable (PINIEN)

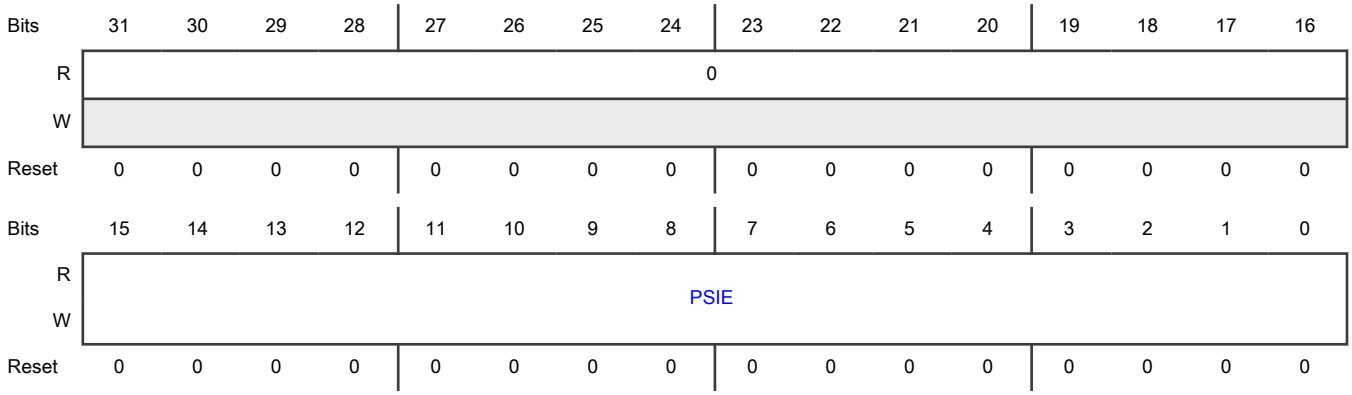
Offset

Register	Offset
PINIEN	54h

Function

Enables pin status interrupts.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 PSIE	Pin Status Interrupt Enable Enables interrupt generation when the corresponding PINSTAT[PSF] flag is set. If you write 0 to this field, PINSTAT[PSF] is disabled, and if you write 1 to this field, PINSTAT[PSF] is enabled. 0b - Disable 1b - Enable

67.7.1.19 Pin Rising Edge Enable (PINREN)

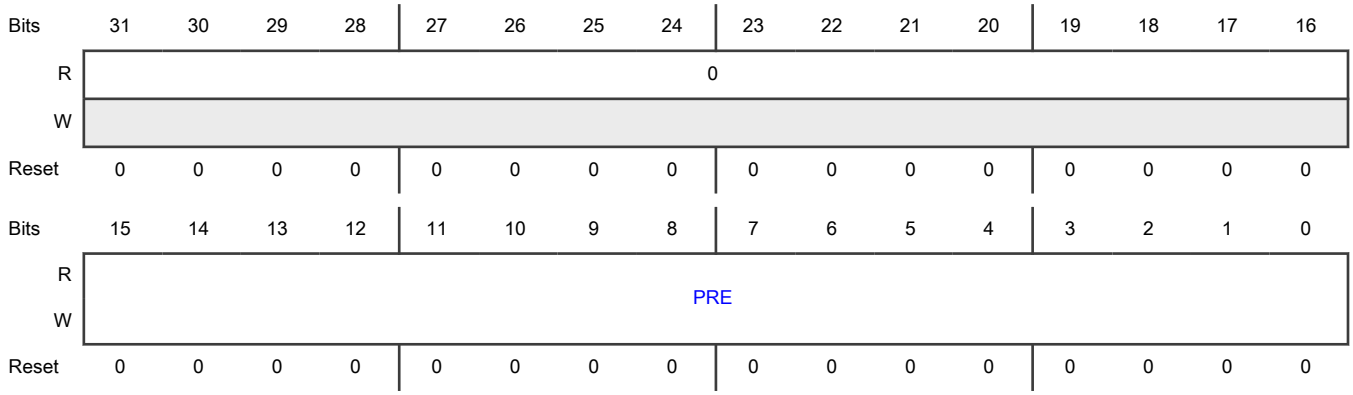
Offset

Register	Offset
PINREN	58h

Function

Enables the pin status flag on a rising edge.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 PRE	Pin Rising Edge Specifies whether the pin status flag is set whenever a rising edge is detected on the pin. 0b - Not set 1b - Set

67.7.1.20 Pin Falling Edge Enable (PINFEN)

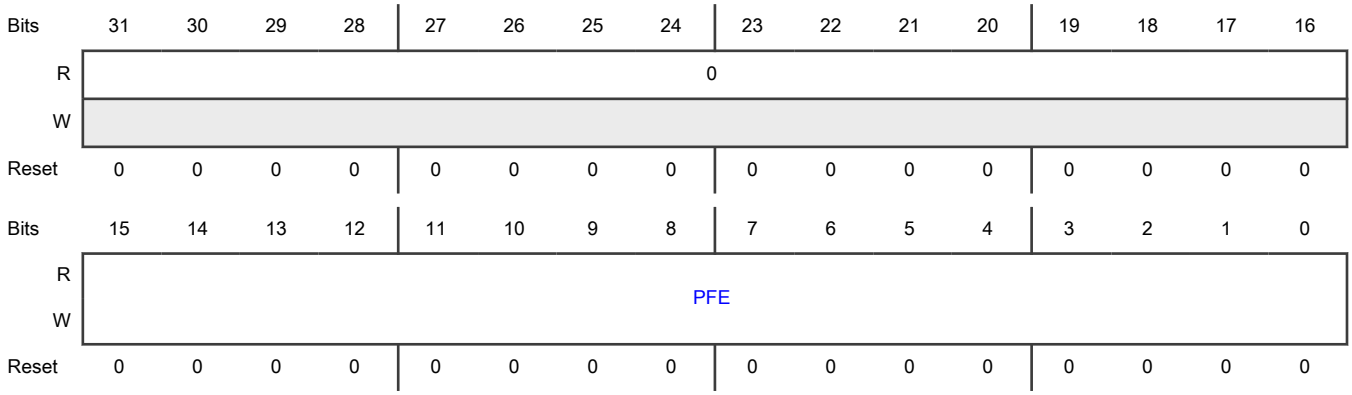
Offset

Register	Offset
PINFEN	5Ch

Function

Enables the pin status flag on a falling edge.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 PFE	Pin Falling Edge Specifies whether the pin status flag is set whenever a falling edge is detected on the pin. 0b - Not set 1b - Set

67.7.1.21 Pin Output Data (PINOUTD)

Offset

Register	Offset
PINOUTD	60h

Function

Contains data output when direct pin output is enabled.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	OUTD															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 —	Reserved
15-0 OUTD	Output Data Configures the value driven on the corresponding pin when direct pin output is enabled. 0b - Logic zero 1b - Logic one

67.7.1.22 Pin Output Enable (PINOUTE)

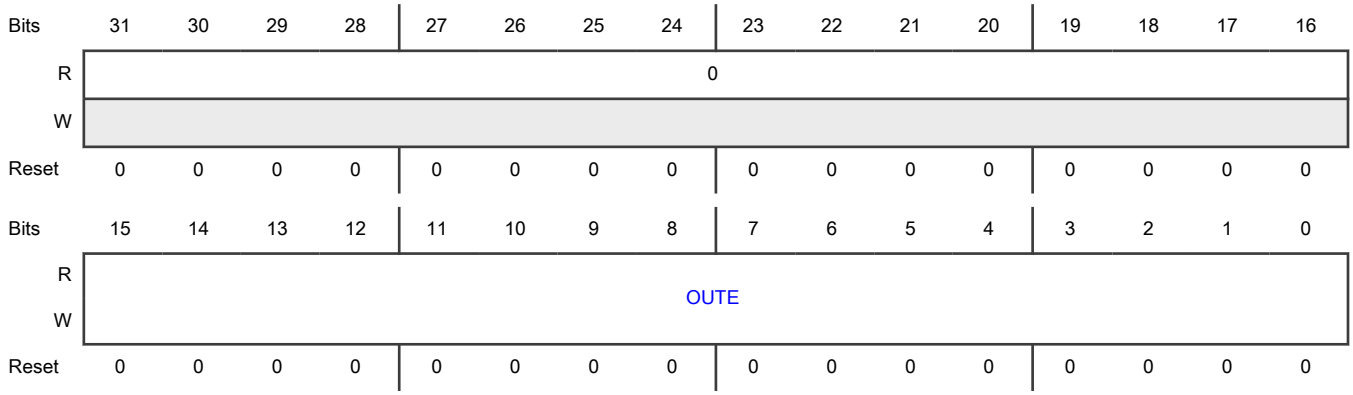
Offset

Register	Offset
PINOUTE	64h

Function

Enables pin output.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 OUTE	Output Enable Enables direct output on the corresponding pin. If this field is 0, the pin is controlled by timer/shifter configuration, and if this field is 1, pin is an output and driven with the value of Pin Output Data (PINOUTD). 0b - Controlled by timer/shifter configuration 1b - Output; driven with value of PINOUTD

67.7.1.23 Pin Output Disable (PINOUTDIS)

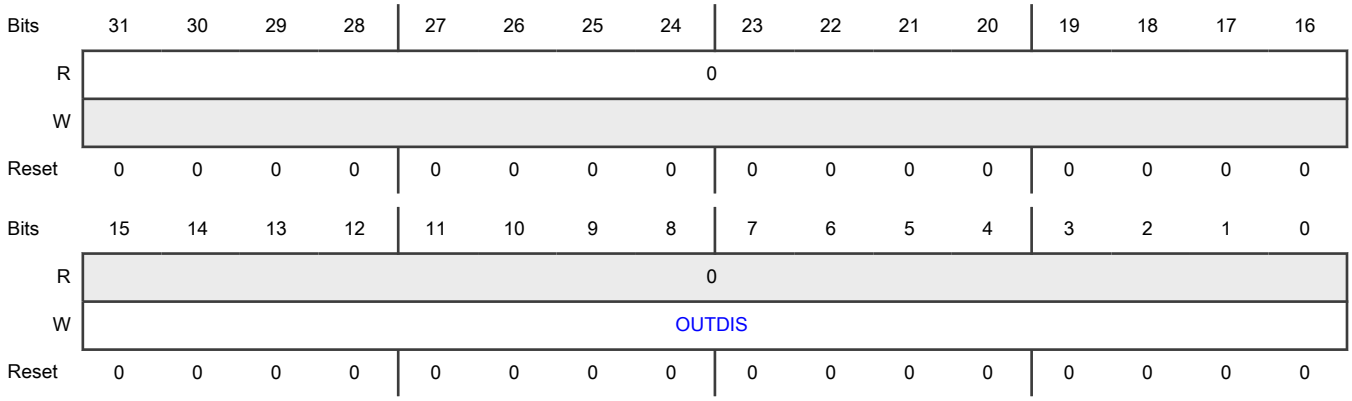
Offset

Register	Offset
PINOUTDIS	68h

Function

Disables pin output.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 OUTDIS	Output Disable Configures the corresponding pins to disable direct output. If this field is 1, the corresponding fields in Pin Output Data (PINOUTD) and Pin Output Enable (PINOUTE) become 0. 0b - No effect 1b - Corresponding fields become 0

67.7.1.24 Pin Output Clear (PINOUTCLR)

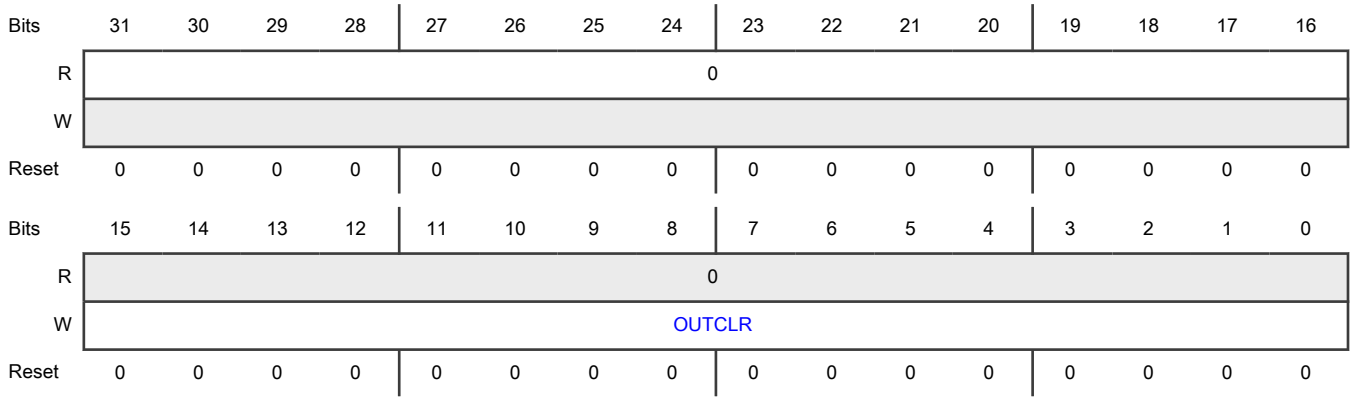
Offset

Register	Offset
PINOUTCLR	6Ch

Function

Clears pin output.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 OUTCLR	Output Clear Configures the corresponding pins to output zero. If this field is 1, the corresponding field in Pin Output Data (PINOUTD) becomes 0 and the one in Pin Output Enable (PINOUTE) becomes 1. 0b - No effect 1b - Corresponding field in PINOUTD becomes 0; corresponding field in PINOUTE becomes 1

67.7.1.25 Pin Output Set (PINOUTSET)

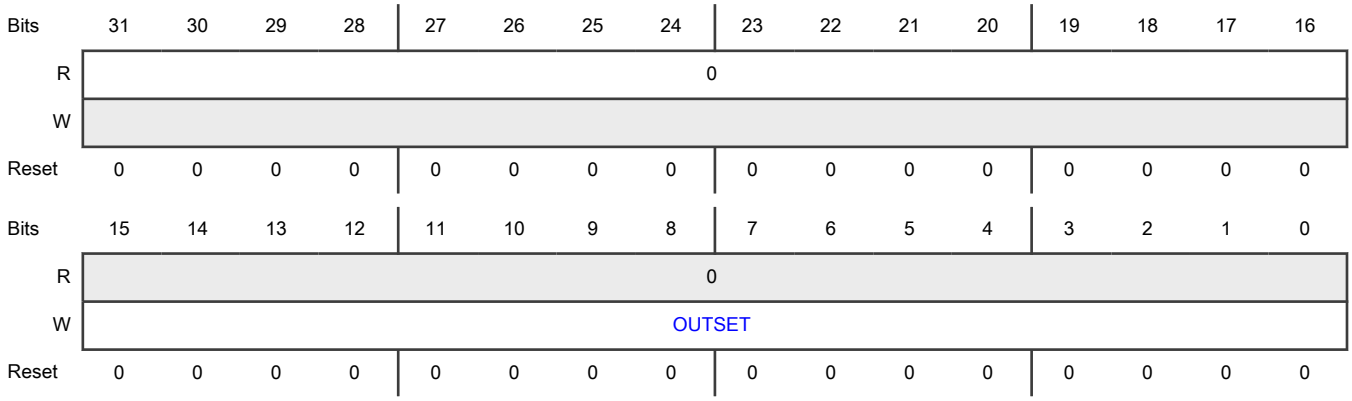
Offset

Register	Offset
PINOUTSET	70h

Function

Sets pin output.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 OUTSET	Output Set Configures the corresponding pins to output logic one. If this field is 1, the corresponding fields in Pin Output Data (PINOUTD) and Pin Output Enable (PINOUTE) become 1. 0b - No effect 1b - Corresponding fields become 1

67.7.1.26 Pin Output Toggle (PINOUTTOG)

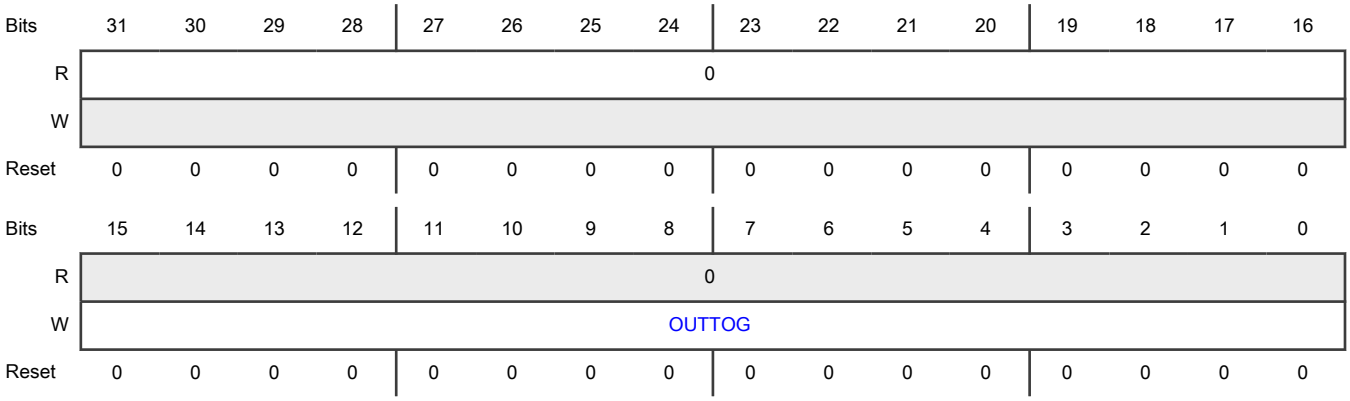
Offset

Register	Offset
PINOUTTOG	74h

Function

Toggles pin output.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 OUTTOG	Output Toggle Configures the corresponding pins to toggle. If this field is 1, the corresponding field in Pin Output Data (PINOUTD) is inverted and the one in Pin Output Enable (PINOUTE) becomes 1. 0b - No effect 1b - Corresponding field in PINOUTD is inverted; corresponding field in PINOUTE becomes 1

67.7.1.27 Shifter Control (SHIFTCTL0 - SHIFTCTL7)

Offset

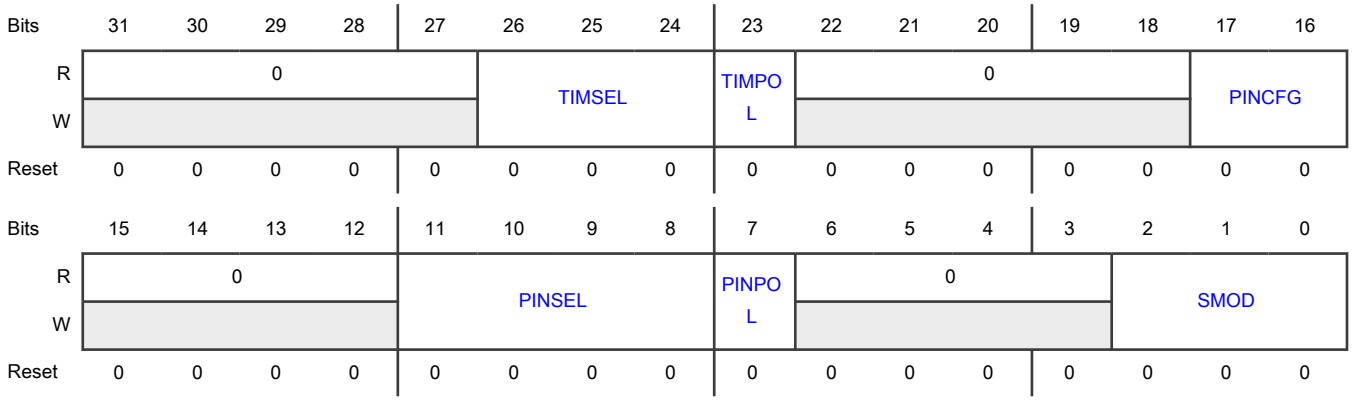
For n = 0 to 7:

Register	Offset
SHIFTCTLn	80h + (n × 4h)

Function

Provides shifter controls.

Diagram



Fields

Field	Function
31-27 —	Reserved
26-24 TIMSEL	Timer Select Selects which timer is used for controlling the logic or shift register and generating the shift clock. TIMSEL = i selects TIMERi.
23 TIMPOL	Timer Polarity Determines whether the shift occurs on the positive edge or negative edge of the shift clock. 0b - Positive edge 1b - Negative edge
22-18 —	Reserved
17-16 PINCFG	Shifter Pin Configuration Specifies shifter pin configuration. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register. **NOTE** When initially configuring PINCFG as 11b, FLEXIO may briefly drive the pin low. To avoid this, you can configure PINCFG as 10b along with the rest of the Control register and then perform a subsequent write to set PINCFG as 11b. Likewise, when changing the value of PINCFG from 11b to 00b, you must perform an initial write to set PINCFG as 10b and then perform a subsequent write to update the rest of the Control register with the value of PINCFG as 00b. 00b - Shifter pin output disabled 01b - Shifter pin open-drain or bidirectional output enable

Table continues on the next page...

	10b - Shifter pin bidirectional output data 11b - Shifter pin output
15-12 —	Reserved
11-8 PINSEL	Shifter Pin Select Selects the pin that is used by the shifter input or output. PINSEL = i selects the FXIO_Di pin. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register.
7 PINPOL	Shifter Pin Polarity Specifies the shifter pin polarity. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to this register. 0b - Active high 1b - Active low
6-3 —	Reserved
2-0 SMOD	Shifter Mode Configures the mode of the shifter. 000b - Disable 001b - Receive mode; capture the current shifter content into SHIFTBUF on expiration of the timer 010b - Transmit mode; load SHIFTBUF contents into the shifter on expiration of the timer 011b - Reserved 100b - Match Store mode; shifter data is compared to SHIFTBUF content on expiration of the timer 101b - Match Continuous mode; shifter data is continuously compared to SHIFTBUF contents 110b - State mode; SHIFTBUF contents store programmable state attributes 111b - Logic mode; SHIFTBUF contents implement programmable logic lookup table

67.7.1.28 Shifter Configuration (SHIFTCFG0 - SHIFTCFG7)

Offset

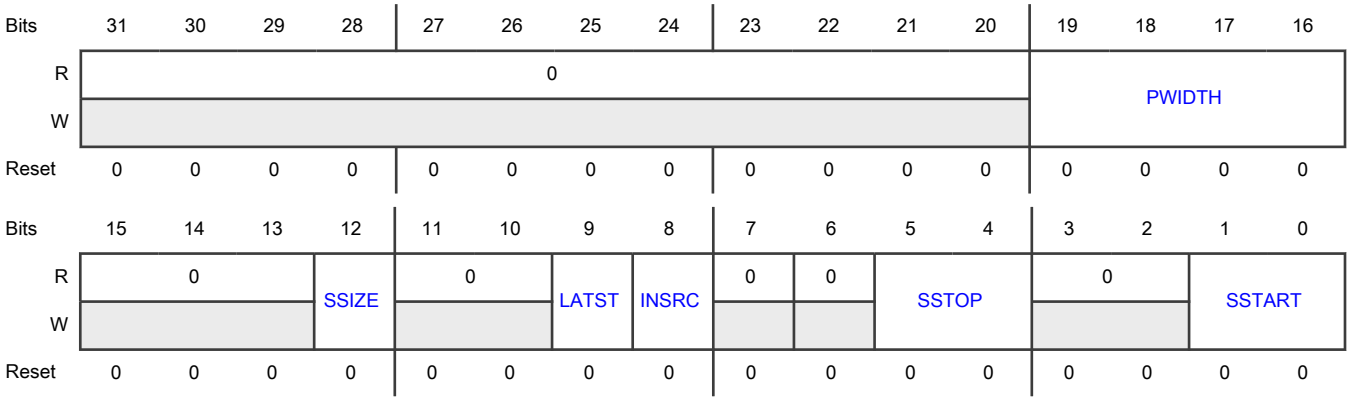
For n = 0 to 7:

Register	Offset
SHIFTCFGn	100h + (n × 4h)

Function

Provides fields for shifter configuration.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-16 PWIDTH	Parallel Width Configures the number of bits to be shifted on each shift clock for all shifters: • 1-bit shift for PWIDTH = 0 • 2-bit shift for PWIDTH = 1 • 4-bit shift for PWIDTH = 2...3 • 8-bit shift for PWIDTH = 4...7 • 16-bit shift for PWIDTH = 8...15 For shifters that support parallel transmit (SHIFTER0, SHIFTER4, ...) or parallel receive (SHIFTER3, SHIFTER7, ...), this field, together with PINSEL, also selects the pins to be driven or sampled on each shift clock: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL]. Shifters that do not support parallel transmit or parallel receive only support parallel shift when SHIFTCFG*n*[INSRC] = 1. If SHIFTCTL*n*[SMOD] = 110b (State mode), use this field to disable state outputs (see State mode).
15-13 —	Reserved
12 SSIZE	Shifter Size Configures the size of the Shift registers. A 24-bit Shift register shifts data only into bits [23:0] and does not update bits [31:24] during shift operations.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When the Shift register is configured for a 24-bit shift, configuring PWIDTH as 8..15 performs a 12-bit shift and PWIDTH as 16..31 performs a 24-bit shift. 0b - 32-bit 1b - 24-bit
11-10 —	Reserved
9 LATST	Late Store Configures what happens when a receive or match Shift register is configured to both shift and store on the same cycle. 0b - Store the pre-shift register state 1b - Store the post-shift register state
8 INSRC	Input Source Selects the input source for the shifter. Configuring this field as 1 is not supported for the last shifter. 0b - Pin 1b - Shifter n+1 output
7 —	Reserved
6 —	Reserved
5-4 SSTOP	Shifter Stop Allows automatic stop bit insertion, if the selected timer has also enabled a stop bit, when SHIFTCTL*n*[SMOD] is 10b (Transmit mode). If SHIFTCTL*n*[SMOD] is 1b or 100b (Receive mode or Match Store mode), this field allows automatic stop bit checking if the selected timer has also enabled a stop bit. If SHIFTCTL*n*[SMOD] is 110b (State mode), this field disables state outputs (see State mode). If SHIFTCTL*n*[SMOD] is 111b (Logic mode), this field masks logic pin inputs (see Logic mode). 00b - Stop bit disabled for Transmitter, Receiver, and Match Store modes 01b - Stop bit disabled for Transmitter, Receiver, and Match Store modes; when timer is in stop condition, Receiver and Match Store modes store receive data on the configured shift edge 10b - Transmitter mode outputs stop bit value 0 in Match Store mode; if stop bit is not 0, Receiver and Match Store modes set error flag (when timer is in stop condition, these modes also store receive data on the configured shift edge)

Table continues on the next page...

Table continued from the previous page...

Field	Function
	11b - Transmitter mode outputs stop bit value 1 in Match Store mode; if stop bit is not 1, Receiver and Match Store modes set error flag (when timer is in stop condition, these modes also store receive data on the configured shift edge)
3-2 ——	Reserved
1-0 SSTART	Shifter Start Allows automatic start bit insertion, if the selected timer has also enabled a start bit, when SHIFTCTL*n*[SMOD] is 10b (Transmit mode). If SHIFTCTL*n*[SMOD] = 1b (Receive mode) or 100b (Match Store mode), this field allows automatic start bit checking if the selected timer has also enabled a start bit. If SHIFTCTL*n*[SMOD] is 110b (State mode), this field disables state outputs (see State mode). If SHIFTCTL*n*[SMOD] = 111b (Logic mode), this field masks logic pin inputs (see Logic mode). 00b - Start bit disabled for Transmitter, Receiver, and Match Store modes; Transmitter mode loads data on enable 01b - Start bit disabled for Transmitter, Receiver, and Match Store modes; Transmitter mode loads data on first shift 10b - Transmitter mode outputs start bit value 0 before loading data on first shift; if start bit is not 0, Receiver and Match Store modes set error flag 11b - Transmitter mode outputs start bit value 1 before loading data on first shift; if start bit is not 1, Receiver and Match Store modes set error flag

67.7.1.29 Shifter Buffer (SHIFTBUF0 - SHIFTBUF7)

Offset

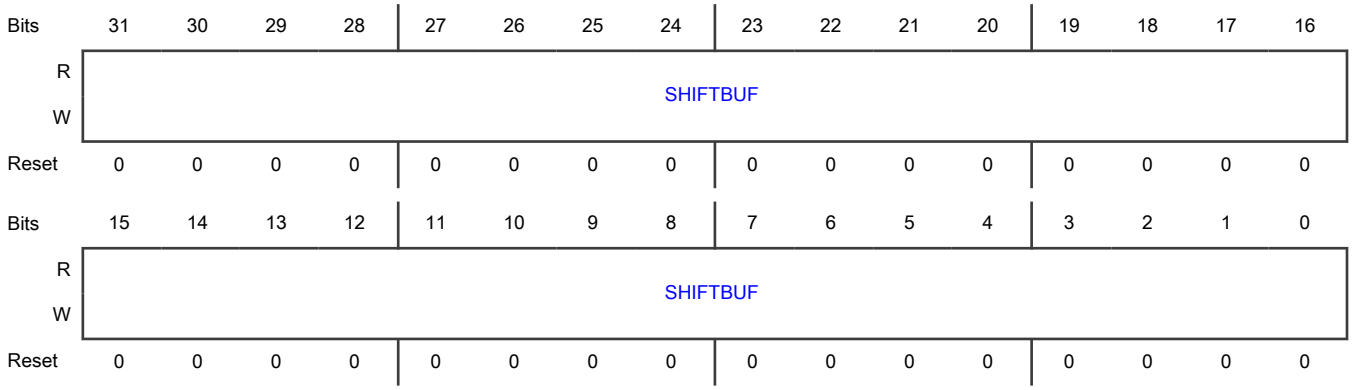
For n = 0 to 7:

Register	Offset
SHIFTBUFn	200h + (n × 4h)

Function

Contains shift buffer data.

Diagram



Fields

Field	Function
31-0 SHIFTBUF	Shift Buffer Contains the data to be matched with the shifter contents and is used for various other functions, depending on the setting of SHIFTCTL*n*[SMOD]: • If SHIFTCTL0[SMOD] is 1b (Receive mode), shifter data is transferred into SHIFTBUF at the expiration of the timer. You must read this register only when the corresponding SHIFTSTAT[SSF] flag is set, indicating that new shifter data is available. • If SHIFTCTL0[SMOD] is 10b (Transmit mode), SHIFTBUF data is transferred into the shifter before the timer begins. • If SHIFTCTL0[SMOD] is 100b (Match Store mode), SHIFTBUF[31:16] contains the data to be matched with the shifter contents and SHIFTBUF[15:0] can be used to mask the match result (1 = mask, 0 = no mask). The match is checked when the timer expires. Shifter data [31:16] is written to SHIFTBUF[31:16] whenever a match event occurs. You must read this register only when the corresponding shifter status flag is set, indicating that new shifter data is available. • If SHIFTCTL0[SMOD] is 101b (Match Continuous mode), SHIFTBUF[31:16] contains the data to be matched with the shifter contents, and SHIFTBUF[15:0] can be used to mask the match result (1 = mask, 0 = no mask). • If SHIFTCTL0[SMOD] is 111b (Logic mode), SHIFTBUF[31:0] implements a 5-input, 32-bit programmable logic lookup table (see Logic mode). • If SHIFTCTL0[SMOD] is 110b (State mode), use SHIFTBUF[31:24] to drive the output value when this shifter is selected by the current state pointer and use SHIFTBUF[23:0] to configure the value of the next state transition (see State mode).

67.7.1.30 Shifter Buffer Bit Swapped (SHIFTBUFBIS0 - SHIFTBUFBIS7)

Offset

For n = 0 to 7:

Register	Offset
SHIFTBUFBISn	280h + (n × 4h)

Function

Contains Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) content, but it is bit-swapped.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	SHIFTBUFBIS

R W	SHIFTBUFBIS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 SHIFTBUFBIS	Shift Buffer Acts as an alias to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), but reads or writes to this register are bit-swapped. Reads return SHIFTBUF[0:31].

67.7.1.31 Shifter Buffer Byte Swapped (SHIFTBUFBYS0 - SHIFTBUFBYS7)

Offset

For n = 0 to 7:

Register	Offset
SHIFTBUFBYSn	300h + (n × 4h)

Function

Contains Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) content, but it is byte-swapped.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	SHIFTBUFBYS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R W	SHIFTBUFBYS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 SHIFTBUFBYS	Shift Buffer Acts as an alias to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), but reads or writes to this register are byte-swapped. Reads return {SHIFTBUF[7:0], SHIFTBUF[15:8], SHIFTBUF[23:16], SHIFTBUF[31:24]}.

67.7.1.32 Shifter Buffer Bit Byte Swapped (SHIFTBUFBBS0 - SHIFTBUFBBS7)

Offset

For n = 0 to 7:

Register	Offset
SHIFTBUFBBSn	380h + (n × 4h)

Function

Contains the register data for Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), but it is bit-swapped within each byte.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	SHIFTBUFBBS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R W	SHIFTBUFBBS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 SHIFTBUFBBS	Shift Buffer Acts as an alias to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), except that reads or writes to this register are bit-swapped within each byte. Reads return {SHIFTBUF[24:31], SHIFTBUF[16:23], SHIFTBUF[8:15], SHIFTBUF[0:7]}.

67.7.1.33 Timer Control (TIMCTL0 - TIMCTL7)

Offset

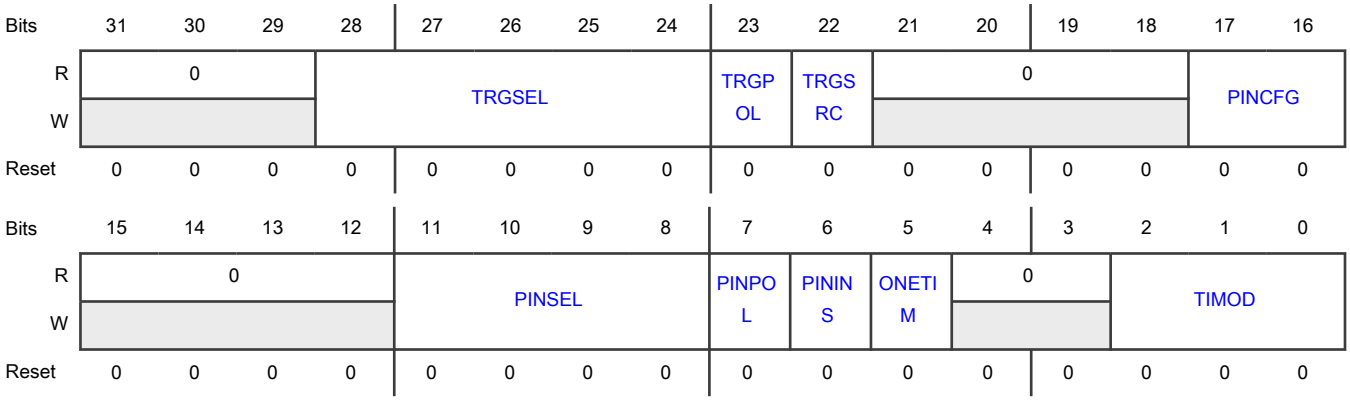
For n = 0 to 7:

Register	Offset
TIMCTLn	400h + (n × 4h)

Function

Controls various settings for timer *n*.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-24 TRGSEL	Trigger Select Selects the trigger. The valid values for TRGSEL depend on the configuration of Parameter (PARAM): • If TRGSRC = 1, the valid values for *n* depend on the settings of PARAM[PIN], PARAM[TIMER], and PARAM[SHIFTER]. • If TRGSRC = 0, the valid values for *n* depend on PARAM[TRIGGER]. See the chip-specific FLEXIO information for external trigger selection. **NOTE** For a pin, *n* = 0 to 15, for a shifter, *n* = 0 to 7, and for a timer, *n* = 0 to 7. If TRGSRC = 0, configure the trigger selection as *n* = external trigger *n* input. If TRGSRC = 1, you can configure the internal trigger to select an input pin as 2×*n* = pin *n* input. If TRGSRC = 1, you can configure the internal trigger to select a shifter or timer signal as: • 4×*n* + 1 = shifter *n* status flag • 4×*n* + 3 = timer *n* trigger output Following are the values for expanded internal trigger selection (TRGSRC = 1):

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• 0000 = Pin 0 • 0001 = Shifter 0 flag • 0010 = Pin 1 • 0011 = Timer 0 trigger • 0100 = Pin 2 • 0101 = Shifter 1 flag • 0110 = Pin 3 • 0111 = Timer 1 trigger • ... • This continues up to pin 15, shifter 7, and timer 7.
23 TRGPOL	Trigger Polarity Specifies whether the trigger is active high or active low. 0b - Active high 1b - Active low
22 TRGSRC	Trigger Source Specifies whether the selected trigger source is external or internal. 0b - External 1b - Internal
21-18 —	Reserved
17-16 PINCFG	Timer Pin Configuration Configures the direction of the timer pin. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register. **NOTE** When you initially configure PINCFG as 11b, FLEXIO may briefly drive the pin low. To avoid this, configure PINCFG as 10b along with the rest of the Control register and then perform a subsequent write to set the value of PINCFG as 11b. Likewise, when changing the value of PINCFG from 11b to 00b, you must perform an initial write to set PINCFG as 10b, and then perform a subsequent write to update the rest of the Control register with PINCFG as 00b. 00b - Timer pin output disabled 01b - Timer pin open-drain or bidirectional output enable 10b - Timer pin bidirectional output data 11b - Timer pin output

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-12 —	Reserved
11-8 PINSEL	Timer Pin Select Selects the pin that is used by the timer input or output. PINSEL = i selects the FXIO_Di pin. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register.
7 PINPOL	Timer Pin Polarity Specifies the timer pin polarity. For pins configured as an output (PINCFG = 11b), this field takes effect when you write to the register. 0b - Active high 1b - Active low
6 PININS	Timer Pin Input Select Specifies what selects the timer pin input. If this field is 1, the timer input pin is different from the timer output pin. PINSEL must select an even-numbered pin when this field is 1, which means that the output pin is even-numbered and input pin is odd-numbered. 0b - PINSEL selects timer pin input and output 1b - PINSEL + 1 selects the timer pin input; timer pin output remains selected by PINSEL
5 ONETIM	Timer One Time Operation Configures the timer to perform a single enable or disable iteration. Clear the timer status flag for the timer to be enabled again. 0b - Generate the timer enable event as normal 1b - Block the timer enable event unless the timer status flag is clear
4-3 —	Reserved
2-0 TIMOD	Timer Mode Specifies the timer mode: • In 8-bit baud counter mode, the lower 8 bits of the counter and compare register are used to configure the baud rate of the timer shift clock. The upper 8 bits are used to configure the shifter bit count. • In 8-bit PWM high mode, the lower 8 bits of the counter and compare register are used to configure the high period of the timer shift clock. The upper 8 bits are used to configure the low period of the timer shift clock. The shifter bit count is configured using another timer or external signal. • In 16-bit counter mode, the full 16 bits of the counter and compare register are used to configure either the baud rate of the shift clock or the shifter bit count. • In 16-bit counter disable mode, the full 16 bits of the counter and compare register are used to configure either the baud rate of the shift clock or the shifter bit count.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• In 8-bit word counter mode, the lower 8 bits of the counter and compare register are used to configure the shifter bit count. The upper 8 bits are used to configure the shifter word count. • In 8-bit PWM low mode, the lower 8 bits of the counter and compare register are used to configure the low period of the timer shift clock. The upper 8 bits are used to configure the high period of the timer shift clock. Use another timer or external signal to configure the shifter bit count. • In 16-bit input capture mode, the inverted value of the 16-bit counter is latched into the compare register when a timer counter disable condition is detected (as configured by TIMCFG*n*[TIMDIS]). This also sets the timer status flag. The timer counter is immediately restarted from FFFFh. 000b - Timer disabled 001b - Dual 8-bit counters baud mode 010b - Dual 8-bit counters PWM high mode 011b - Single 16-bit counter mode 100b - Single 16-bit counter disable mode 101b - Dual 8-bit counters word mode 110b - Dual 8-bit counters PWM low mode 111b - Single 16-bit input capture mode

67.7.1.34 Timer Configuration (TIMCFG0 - TIMCFG7)

Offset

For n = 0 to 7:

Register	Offset
TIMCFGn	480h + (n × 4h)

Function

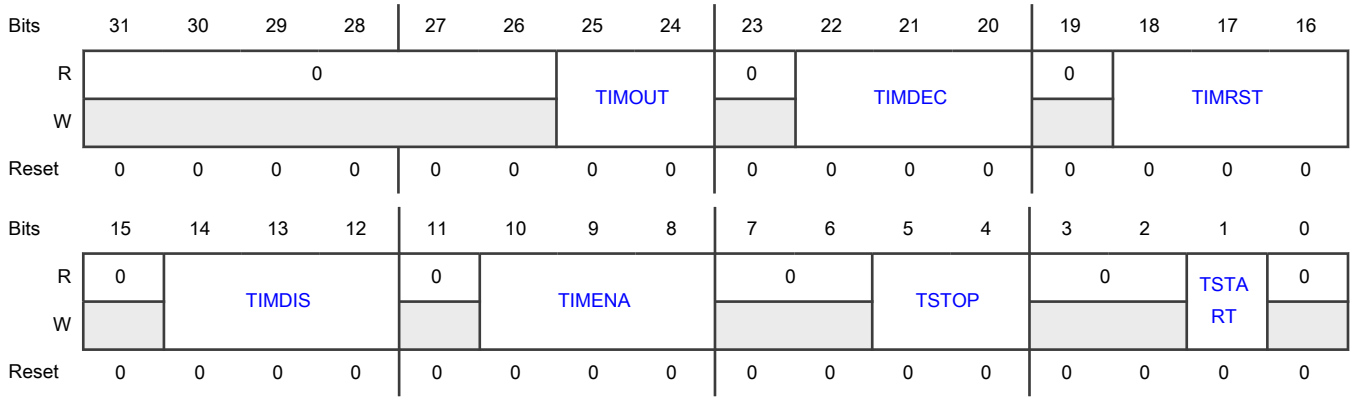
Controls various aspects of timer configuration.

The options to enable or disable the timer using the timer *n* - 1 enable or disable are reserved when *n* is evenly divisible by 4 (timer 0, for example).

NOTE

The pin and trigger level and edges specified in this register refer to the signal state after being modified by the settings of TIMCTL*n*[PINPOL] and TIMCTL*n*[TRGPOL]. For example, "trigger low" means that a trigger is actually at logic level 1 if TIMCTL*n*[TRGPOL] is 1 (active low).

Diagram



Fields

Field	Function
31-26 —	Reserved
25-24 TIMOUT	Timer Output Configures the initial state of the timer output and whether it is affected by the timer reset. 00b - Logic one when enabled; not affected by timer reset 01b - Logic zero when enabled; not affected by timer reset 10b - Logic one when enabled and on timer reset 11b - Logic zero when enabled and on timer reset
23 —	Reserved
22-20 TIMDEC	Timer Decrement Configures the source of the timer decrement and that of the shift clock. 000b - Decrement counter on FLEXIO clock; shift clock equals timer output 001b - Decrement counter on trigger input (both edges); shift clock equals timer output 010b - Decrement counter on pin input (both edges); shift clock equals pin input 011b - Decrement counter on trigger input (both edges); shift clock equals trigger input 100b - Decrement counter on FLEXIO clock divided by 16; shift clock equals timer output 101b - Decrement counter on FLEXIO clock divided by 256; shift clock equals timer output 110b - Decrement counter on pin input (rising edge); shift clock equals pin input 111b - Decrement counter on trigger input (rising edge); shift clock equals trigger input
19 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
18-16 TIMRST	Timer Reset Configures the condition that causes the timer counter (and optionally the timer output) to be reset. In 8-bit counter mode, the timer reset only resets the lower 8 bits that configure the baud rate. In all other modes, the timer reset resets full 16 bits of the counter. 000b - Never reset timer 001b - Timer reset on timer output high. 010b - Timer reset on timer pin equal to timer output 011b - Timer reset on timer trigger equal to timer output 100b - Timer reset on timer pin rising edge 101b - Reserved 110b - Timer reset on trigger rising edge 111b - Timer reset on trigger rising or falling edge
15 —	Reserved
14-12 TIMDIS	Timer Disable Configures the condition that causes the timer to be disabled and stop decrementing. 000b - Timer never disabled 001b - Timer disabled on timer n-1 disable 010b - Timer disabled on timer compare (upper 8 bits match and decrement) 011b - Timer disabled on timer compare (upper 8 bits match and decrement) and trigger low 100b - Timer disabled on pin rising or falling edge 101b - Timer disabled on pin rising or falling edge provided trigger is high 110b - Timer disabled on trigger falling edge 111b - Reserved
11 —	Reserved
10-8 TIMENA	Timer Enable Configures the condition that causes the timer to be enabled and start decrementing. 000b - Timer always enabled 001b - Timer enabled on timer n-1 enable 010b - Timer enabled on trigger high 011b - Timer enabled on trigger high and pin high

Table continues on the next page...

Table continued from the previous page...

Field	Function
	100b - Timer enabled on pin rising edge 101b - Timer enabled on pin rising edge and trigger high 110b - Timer enabled on trigger rising edge 111b - Timer enabled on trigger rising or falling edge
7-6 —	Reserved
5-4 TSTOP	Timer Stop Specifies whether the stop bit is enabled. The stop bit can be added on a timer compare (between each word) or on a timer disable. When stop bit is enabled, configured shifters output the contents of the stop bit when the timer is disabled. When stop bit is enabled on timer disable, the timer remains disabled until the next rising edge of the shift clock. If configured for both timer compare and timer disable, only one stop bit is inserted on timer disable. 00b - Disabled 01b - Enabled on timer compare 10b - Enabled on timer disable 11b - Enabled on timer compare and timer disable
3-2 —	Reserved
1 TSTART	Timer Start Specifies whether the start bit is enabled. If it is enabled, configured shifters output the contents of the start bit when the timer is enabled. The timer counter reloads from the compare register on the first rising edge of the shift clock. 0b - Disabled 1b - Enabled
0 —	Reserved

67.7.1.35 Timer Compare (TIMCMP0 - TIMCMP7)

Offset

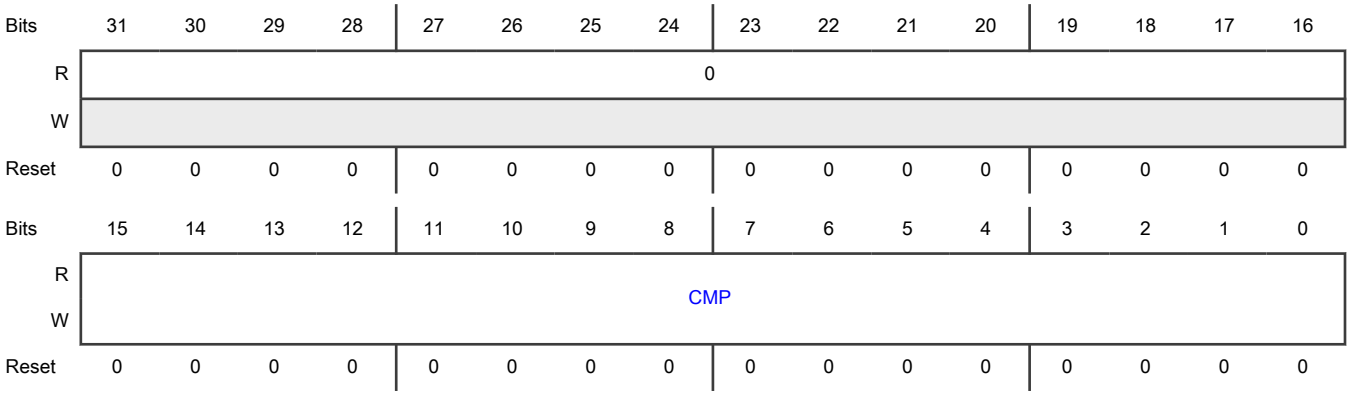
For n = 0 to 7:

Register	Offset
TIMCMPn	500h + (n × 4h)

Function

Contains the timer compare value.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 CMP	Timer Compare Value Loads into the timer counter when the timer is first enabled, when the timer is reset, and when the timer decrements down to zero. In 8-bit baud counter mode, the lower 8 bits configure the baud rate divider as (CMP[7:0] + 1) × 2. The upper 8 bits configure the number of bits in each word as (CMP[15:8] + 1) ÷ 2. In 8-bit PWM high mode, the lower 8 bits configure the high period of the output to (CMP[7:0] + 1) and the upper 8 bits configure the low period of the output to (CMP[15:8] + 1). In 16-bit counter mode, the compare value can be used to generate the baud rate divider (if shift clock source is timer output) as (CMP[15:0] + 1) × 2. When the shift clock source is a pin or trigger input, the compare register is used to set the number of bits in each word as (CMP[15:0] + 1) ÷ 2. In 16-bit counter disable mode, the compare value can be used to generate the baud rate divider (if shift clock source is timer output) as (CMP[15:0] + 1) × 2. When the shift clock source is a pin or trigger input, the compare register is used to set the number of bits in each word as (CMP[15:0] + 1) ÷ 2. In 8-bit word counter mode, the lower 8 bits configure the number of bits in each word as (CMP[7:0] + 1) ÷ 2. The upper 8 bits configure the number of words to transfer equal to (CMP[15:8] + 1) ÷ 2. In 8-bit PWM low mode, the lower 8 bits configure the low period of the output to (CMP[7:0] + 1) and the upper 8 bits configure the high period of the output to (CMP[15:8] + 1). In 16-bit input capture mode, the compare register is updated with the inverse of the timer counter value whenever the timer status flag is set. You must read this register only when the timer status flag is set.

67.7.1.36 Shifter Buffer Nibble Byte Swapped (SHIFTBUFNBS0 - SHIFTBUFNBS7)

Offset

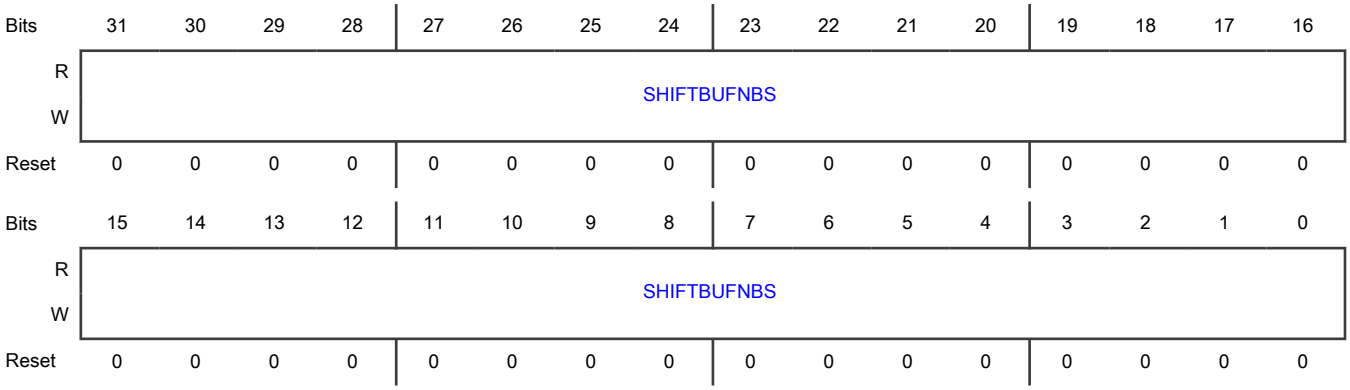
For n = 0 to 7:

Register	Offset
SHIFTBUFNBSn	680h + (n × 4h)

Function

Contains Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) content, but it is nibble-swapped within each byte.

Diagram



Fields

Field	Function
31-0 SHIFTBUFNBS	Shift Buffer Acts as an alias to Shifter Buffer (SHIFTBUF0 - SHIFTBUF7), but reads or writes to this register are nibble-swapped within each byte. Reads return {SHIFTBUF[27:24], SHIFTBUF[31:28], SHIFTBUF[19:16], SHIFTBUF[23:20], SHIFTBUF[11:8], SHIFTBUF[15:12], SHIFTBUF[3:0], SHIFTBUF[7:4]}.

67.7.1.37 Shifter Buffer Halfword Swapped (SHIFTBUFHWS0 - SHIFTBUFHWS7)

Offset

For n = 0 to 7:

Register	Offset
SHIFTBUFHWSn	700h + (n × 4h)

Function

Contains Shifter Buffer (SHIFTBUF0 - SHIFTBUF7) content, but it is halfword-swapped.

68.1.1 Module instances

This device has 21 instances of LP_FLEXCOMM module, numbered LP_FLEXCOMM0 through LP_FLEXCOMM20:

- LP_FLEXCOMM14 and LP_FLEXCOMM16 support only LPSPI functions.
- LP_FLEXCOMM15 supports only LPI2C functions.
- The rest 18 LP_FLEXCOMM instances support LPUART, LPSPI, and LPI2C functions.

NOTE

Not all LP_FLEXCOMM instance pins are available for each package. You need to configure the module functions according to the package pin availability listed in External signals and pin multiplexing.

Both CPU0 and CPU1 can operate LP_FLEXCOMM14 and LP_FLEXCOMM16. You need to use CPU0 to configure LP_FLEXCOMM14 and LP_FLEXCOMM16 ports by IOPCTL0 registers before either CPU to operate them.

68.1.2 LP_FLEXCOMM configuration

LP_FLEXCOMM supports 8 words FIFO, which is shared between the different configurations.

When configured for LPSPI, LP_FLEXCOMM supports 8x32 bits FIFOs. When configured for LPI2C and LPUART, two 8x16 bits FIFOs are supported, one for each module. In any one of the instances, except for LP_FLEXCOMM14 to LP_FLEXCOMM16, UART and I2C can be used simultaneously with limited functionality. All LP_FLEXCOMM instances, except for LP_FLEXCOMM14 to LP_FLEXCOMM16, support modbus and DMA End of Packet (EOP). There is one interrupt for each instance, see System interrupts. The DMA requests and the trigger inputs are shared.

All the LPI2C instances do not support HS mode when using as controllers.

68.1.3 Register access

For this chip, the LP_FLEXCOMM interface supports only 32-bit register accesses, ignore all the information about supports 8-bit, aligned 16-bit access.

68.1.4 Output trigger

For this chip, all the LP_FLEXCOMM modules have no output triggers, ignore all the information about output triggers in this chapter.

68.1.5 PINT configuration

When an LP_FLEXCOMM is used as LPUART, and its LP_FLEXCOMMx_TRIG[TRIGIN] in INPUTMUX is configured as 1100b to select PINT Boolean pattern-match output as input trigger, the related PMCFG[CFGy] in PINT must not be configured as 111b (Event).

68.2 LP_FLEXCOMM

68.2.1 Overview

Each LP_FLEXCOMM interface provides one peripheral communications function from a choice of several, chosen by software. This chapter describes the overall LP_FLEXCOMM interface and how to choose the communications function. See the corresponding communications module chapter for details on each function provided.

68.2.1.1 Block diagram

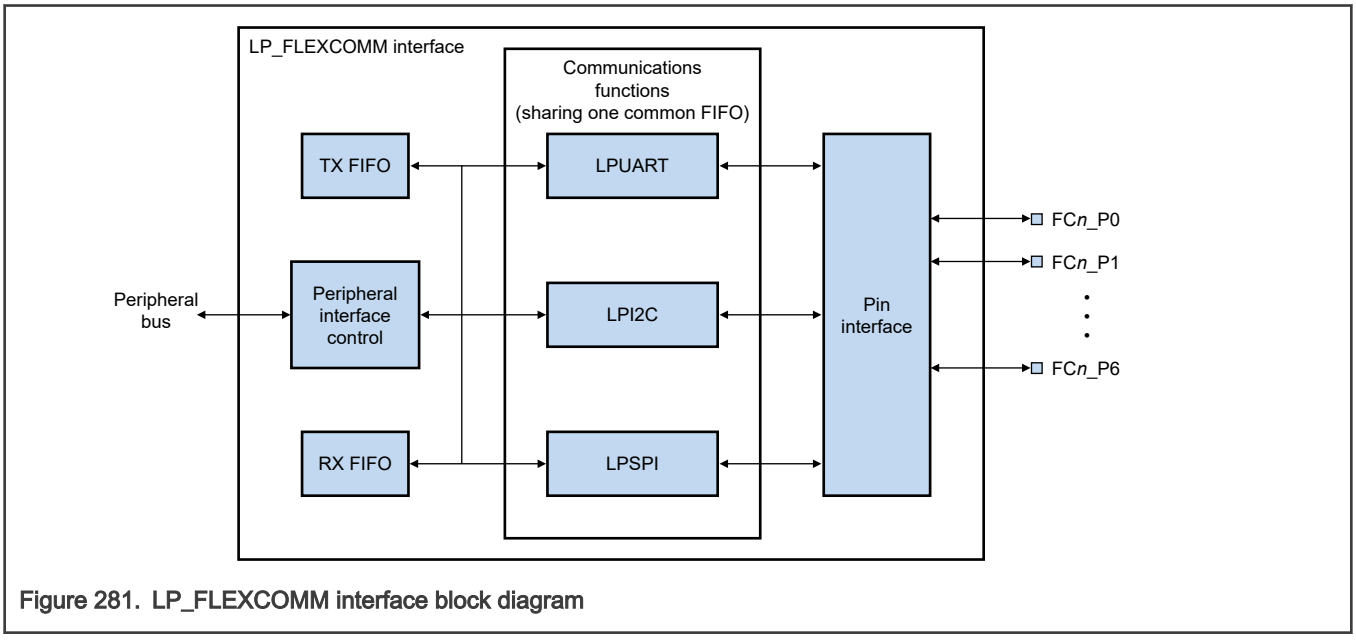

Figure 281. LP_FLEXCOMM interface block diagram

68.2.1.2 Features

Each LP_FLEXCOMM interface provides a choice of peripheral communications functions. You must choose one of them before you can configure and use the function.

- LPUART with asynchronous transmit and receive
- LPSPI controller or subordinate, with up to four peripheral chip selects
- LPI2C with separate controller and subordinate functions

LPUART and LPI2C can be selected at the same time with reduced interface.

A FIFO of 8 words is shared between the different interfaces. The LPI2C subordinate does not support a FIFO.

68.2.2 Functional description

The following sections describe the functional details of LP_FLEXCOMM.

68.2.2.1 Modes

This section describes the modes present in LP_FLEXCOMM.

68.2.2.1.1 Operating modes

Some communication options might not be available on a particular LP_FLEXCOMM interface. Reading PSELID shows which communication functions are available. You can select a specific supported function by writing the appropriate value to PSELID[PERSEL].

68.2.2.1.2 Low-power modes

The LP_FLEXCOMM interface follows the low-power mode operation of the selected communications module.

68.2.2.1.3 Debug mode

When the LP_FLEXCOMM interface is configured as LPSPI or LPI2C, you can configure it not to initiate a new transaction when the CPU is halted.

68.2.2.2 Clocking

The LP_FLEXCOMM interface requires a bus interface clock for the register interface of the selected communications module. It also requires a functional clock which generates the clocking for the peripheral communications interface. The clocks for unselected functions are internally gated.

68.2.2.3 Reset

The LP_FLEXCOMM interface receives a single reset that returns the entire module to its reset state. Out of reset, no peripheral communications function is selected, and the lock bit is clear.

68.2.2.4 Interrupts

The LP_FLEXCOMM interface generates a single interrupt from the configured peripheral communications function(s). When the LP_FLEXCOMM interface is configured for both LPUART and LPI2C functions, you can read the source of the interrupt from ISTAT.

68.2.2.5 DMA

The LP_FLEXCOMM interface generates two DMA requests:

- Transmit DMA Request
- Receive DMA Request (with End Of Packet support)

When the LP_FLEXCOMM interface is configured for both LPUART and LPI2C functions, you must enable DMA requests for only one of them.

68.2.2.6 Triggers

The LP_FLEXCOMM interface receives a single input trigger that is routed to all internal modules. When configured for both LPUART and LPI2C functions, you must enable the input trigger for only one of them.

The LP_FLEXCOMM interface generates 4 output triggers:

Output	LPSPI	LPUART	LPI2C	LPUART+LPI2C
Trigger 0	Frame	TX Word	Controller EOP	Controller EOP
Trigger 1	Word	RX Word	Subordinate EOP	Subordinate EOP
Trigger 2	—	RX Idle	Controller Busy	RX Idle
Trigger 3	—	TX Data	Bus Busy	TX Data

68.2.3 External signals

This table describes the LP_FLEXCOMM interface module signals. Pin usage for a specific communications function is described in the corresponding chapter of each communications module.

Signal	LPSPI	LPUART	LPI2C	LPUART+LPI2C
FC_P0	SDO/DATA[0]	RXD	SDA	SDA
FC_P1	SCK	TXD	SCL	SCL
FC_P2	SDI/DATA[1]	RTS_b	SCLS	TXD
FC_P3	PCS[0]	CTS_b	SDAS	RXD
FC_P4	PCS[3]/DATA[3]	—	HREQ_b	CTS_b
FC_P5	PCS[2]/DATA[2]	—	—	RTS_b
FC_P6	PCS[1]/HREQ	—	—	HREQ_b

68.2.4 Initialization

To initialize a LP_FLEXCOMM interface:

1. Enable the bus interface clock for the LP_FLEXCOMM interface.
2. Select a clock source for the functional clock of the selected communications module.
3. Select the function by writing the appropriate value to PSELID[PERSEL].
4. See the specific communications module chapter to complete the configuration.

68.2.5 Application information

LP_FLEXCOMM interface applications mirror those of the selected communications module.

68.2.6 Memory Map and register definition

This section includes the LP_FLEXCOMM interface module memory map and detailed descriptions of all registers.

The LP_FLEXCOMM interface supports 8-bit, aligned 16-bit, and aligned 32-bit register accesses, unless otherwise noted in the register description of the selected peripheral function.

68.3 Low-Power Inter-Integrated Circuit (LPI2C)

68.3.1 Overview

LPI2C supports an efficient interface to an I2C bus as a controller and target:

- Implements logic support for Standard, Fast, Fast+, Ultra Fast, and High-Speed (HS) modes of operation
- Uses little CPU overhead, with DMA offloading of FIFO register accesses
- Continues operating in Stop modes if an appropriate clock is available

LPI2C also complies with the System Management Bus (SMBus) Specification, version 3. The SMBus is a single-ended simple two-wire bus, which is typically used for low-bandwidth communications.

The Inter-Integrated Circuit (I^2C) serial bus is multi-controller, multi-target, packet-switched, and single-ended, and is often used to attach microcontroller ICs to lower-speed peripheral ICs.

NOTE

Terminology in this chapter has been updated to align with I^2C-bus specification, Rev. 7.0, as shown in Table 640.

Table 640. Updated terms

Updated term	Deprecated term
Controller	Master
Target	Slave

68.3.1.1 Block diagram

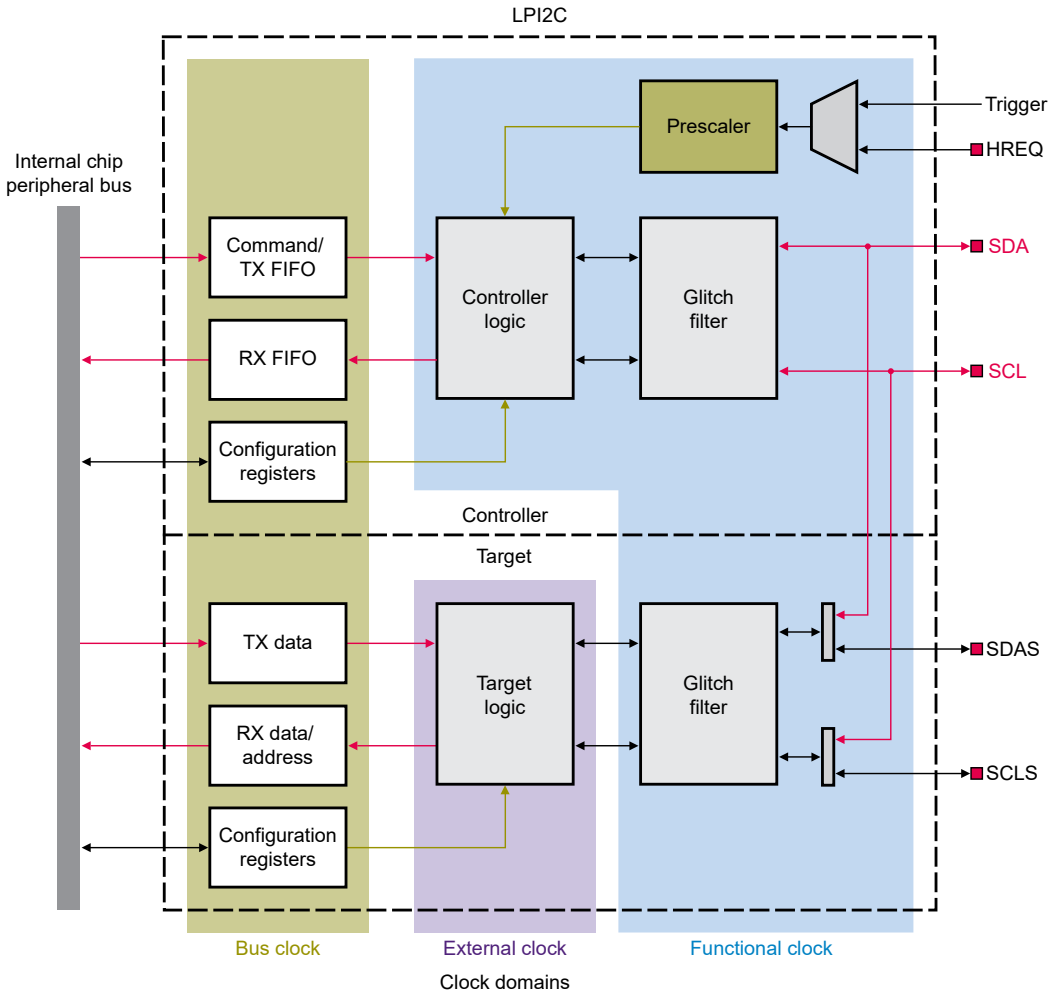

Figure 282. Block diagram

68.3.1.2 Features

LPI2C supports:

- Standard, Fast, Fast+ and Ultra Fast modes

- HS mode in target mode and controller mode
- Multicontroller, including synchronization and arbitration, means that any number of controller nodes can be present. Also, controller and target roles can be changed between messages (after a Stop signal is sent).
- Clock stretching. Used on the SCL line, as an I2C flow control mechanism.
- Arbitration for when the system has more than one controller. When used on the SDA line, ensures that there is only one I2C transmitter at a time.
- General call, seven-bit addressing, and ten-bit addressing
- Software reset, Start byte, and device ID (also require software support)

The LPI2C controller supports:

- Command and transmit FIFO of 8 words (8-bit transmit data + 3-bit command)
- Receive FIFO of 8 words (8-bit receive data).
- Command FIFO waiting for an I2C idle bus before initiating a transfer
- Initiation of repeated Start and Stop conditions and one or more controller-receiver transfers by command FIFO
- Stop condition generation from command FIFO, or automatic generation of Stop condition when the transmit FIFO is empty
- Host request input to control the start time of an I2C bus transfer
- Interrupt generation on data match and unwanted data rejection, via flexible receive data match
- Flags and optional interrupt signals at repeated Start condition, Stop condition, loss of arbitration, unexpected NACK, and command word errors
- Configurable bus idle timeout and pin-stuck-low timeout

The LPI2C target supports:

- Separate I2C target registers to minimize software overhead because of controller or target switching
- 7-bit or 10-bit addressing, address range, SMBus alert, and general call address.
- Transmit data register that supports interrupt or DMA requests
- Receive data register that supports interrupt or DMA requests
- Software-controllable ACK or NACK, with optional clock stretching on ACK or NACK field
- Configurable clock stretching, to avoid transmit-FIFO-underrun and receive-FIFO-overrun errors
- Flags and optional interrupt at end of packet, Stop condition, or bit error detection

68.3.2 Functional description

68.3.2.1 Controller mode

The LPI2C controller logic operates independently from the target logic to perform all controller-mode transfers on the I2C bus.

68.3.2.1.1 Transmit and Command FIFO commands

The transmit FIFO stores command data to initiate various I2C operations. The following operations can be initiated through commands in the transmit FIFO:

- Start or repeated Start condition with address byte, expecting ACK or NACK.
- Transmit data. This operation is the default for zero-extended-byte writes to the transmit FIFO.
- Receive 1-256 bytes of data. You can configure this operation to discard received data and not to store it in the receive FIFO.

- Stop condition. You can configure this operation to send a Stop condition when the transmit FIFO is empty.

Multiple transmit and receive commands can be inserted between the Start and Stop conditions. To comply with the I2C specification, transmit and receive commands must not be interleaved. The receive data command and the receive data and discard commands can be interleaved. This interleaving ensures that only the desired received data is stored in the receive FIFO (or compared with the data match logic).

The LPI2C controller automatically transmits a NACK on the last byte of a receive data command. It transmits the NACK unless the next command in the FIFO is also a receive data command. If the transmit FIFO is empty when a receive data command completes, a NACK is also automatically transmitted.

The LPI2C controller supports 10-bit addressing via a (repeated) Start condition, followed by a transmit data byte containing the second address byte, followed by any number of data bytes with the controller transmit data.

A Start or repeated Start condition expecting a NACK (for example, HS mode controller code) must be followed by a Stop or (repeated) Start condition.

68.3.2.1.2 Controller operations

When LPI2C is enabled, it monitors the I2C bus to detect when the I2C is idle (MSR[BBF]). If either SCL or SDA are low, the I2C bus is no longer considered idle. The bus becomes idle if a Stop condition is detected or if a bus idle timeout is detected (as configured by MCFGR2[BUSIDLE]). After the bus is idle, if the transmit FIFO is not empty and the host request is asserted or disabled, the LPI2C controller initiates a transfer on the bus. This transfer involves the following steps:

1. Wait the bus idle time equal to (MCCR0[CLKLO] + 1) multiplied by the prescaler (MCFGR1[PRESCALE]).
2. Transmit a Start condition and address byte using the timing configuration in Controller Clock Configuration 0 (MCCR0). If an HS mode transfer is configured, the timing configuration from Controller Clock Configuration 1 (MCCR1) is used instead.
3. Perform controller transmit or controller receive transfers, as configured by the transmit FIFO.
4. Transmit NACK on the last byte of a controller receive transfer. This action is performed unless the next command in the transmit FIFO is also a receive data command and the transmit FIFO is not empty.
5. Transmit a repeated Start or Stop condition as configured by the transmit FIFO or MCFGR1[AUTOSTOP]. A repeated Start can change which timing configuration register is used.

When MCFGR0[RELAX] is 1, the LPI2C controller does not wait for the I2C bus to be idle before starting a transfer. It also relaxes some restrictions on the order of FIFO commands. For example, it allows a Stop command when it is idle to generate a Start condition, followed by one SCL clock pulse, and then a Stop condition.

When the LPI2C controller is disabled, LPI2C continues emptying the transmit FIFO until a Stop condition is transmitted. (The controller could be disabled due to MCR[MEN] being 0, or automatically due to mode entry.) However, LPI2C no longer stalls the I2C bus by waiting for the transmit or receive FIFO. After the transmit FIFO is empty, LPI2C generates a Stop condition automatically.

The LPI2C controller can stall the I2C bus under certain conditions. This stalling results in SCL pulled low continuously on the first bit of a byte, until these conditions change:

- The LPI2C controller is enabled and busy, the transmit FIFO is empty, and MCFGR1[AUTOSTOP] is 0. The LPI2C controller continues to stall the bus until the transmit FIFO is loaded with more data.
- The LPI2C controller is enabled and receiving data, receive data is not being discarded (due to command or receive data match), and the receive FIFO is full. The LPI2C controller continues to stall the I2C bus until the receive FIFO is emptied.

The LPI2C controller aborts the existing transfer when MCFGR0[ABORT] becomes 1. This action causes the LPI2C controller to complete the existing word and then transmit a Stop condition. If the receive FIFO is full when the receive operation is aborted, the last received data is discarded. A new transfer does not start while MCFGR0[ABORT] is 1.

68.3.2.1.3 Receive FIFO and data matching

The receive FIFO stores receive data during controller-receiver transfers. You can configure the LPI2C controller to discard received data instead of storing it in the receive FIFO. This option is configured via the command word in the transmit FIFO.

Received data supports a receive data match function that can match received data against one of two bytes, or against a masked data byte. You can configure the data match function to compare only the first one or two data words received since the last (repeated) Start condition. Received data that is already discarded due to the command word cannot cause a data match. It delays the match on the first data word received until after the discarded data is received.

You can configure the receiver match function to discard all received data until a data match is detected, using MCFGR0[RDMO]. Following a data match, write 0 to MCFGR0[RDMO] before writing 0 to MSR[DMF] to allow all subsequent data to be received.

68.3.2.1.4 Timing parameters

The LPI2C controller can configure the following timing parameters. Parameters are configured separately for HS mode (Controller Clock Configuration 1 (MCCR1)) and other modes (Controller Clock Configuration 0 (MCCR0)). This separation allows the HS mode controller code to be sent using regular timing parameters. Then it allows a switch to HS mode timing (following a repeated Start) until the next STOP condition.

Configure the LPI2C controller timing parameters, measured in LPI2C functional clock cycles, as shown in Table 641. You must configure these parameters to meet the I2C timing specification for the required mode.

Table 641. Timing parameters

I2C specification timing parameter	I2C specification timing symbol	LPI2C timing parameter (in LPI2C functional clock cycles)
SCL clock period	tSCL	(CLKHI + CLKLO + 2 + SCL_LATENCY) × (2 ^ PRESCALE)
Hold time (repeated) Start condition	tHD:STA	(SETHOLD +1) × (2 ^ PRESCALE)
Low period of the SCL clock	tLOW	(CLKLO + 1) × (2 ^ PRESCALE)
High period of the SCL clock	tHIGH	(CLKHI + 1 + SCL_LATENCY) × (2 ^ PRESCALE)
Setup time for a repeated Start condition or Stop condition	tSU:STA, tSU:STO	(SETHOLD + 1 + SCL_LATENCY) × (2 ^ PRESCALE)
Data hold time	tHD:DAT	(DATAVD + 1) × (2 ^ PRESCALE)
Data setup time	tSU:DAT	(SDA_LATENCY + 1) × (2 ^ PRESCALE)
Bus free time between a Stop and Start condition	tBUF	(CLKLO + 1 + SDA_LATENCY) × (2 ^ PRESCALE)
Data valid time, data valid acknowledge time	tVD:DAT, tVD:ACK	(DATAVD + 1) × (2 ^ PRESCALE)

Table 642 defines the latency parameters. These parameters assume that the risetime is less than one LPI2C functional clock cycle. The risetime depends on a number of factors, including the I/O propagation delay, the I2C bus loading, and the external pullup resistor sizing. A larger risetime increases the number of cycles that the signal takes to propagate through the synchronizer (and glitch filter), which increases the latency.

Table 642. Synchronization latency

Timing parameter	Timing definition
SCL_LATENCY	ROUNDDOWN ((2 + FILTSCL + SCL_RISETIME) ÷ (2 ^ PRESCALE))
SDA_LATENCY	ROUNDDOWN ((2 + FILTSDA + SDA_RISETIME) ÷ (2 ^ PRESCALE))

The following timing restrictions must be enforced to avoid unexpected Start or Stop conditions on the I2C bus. These restrictions also avoid unexpected Start or Stop conditions detected by the LPI2C controller. The timing restrictions can be summarized as "SDA cannot change when SCL is high outside a transmitted (repeated) Start or Stop condition."

Table 643. LPI2C timing parameter restrictions

Timing parameter	Minimum	Maximum	Comment
CLKLO	03h	—	CLKLO x (2 ^ PRESCALE) > SCL_LATENCY
CLKHI	01h	—	Configure CLKHI to meet the duty cycle requirements in the I2C specification
SETHOLD	02h	—	SETHOLD × (2 ^ PRESCALE) > SDA_LATENCY
DATAVD	01h	CLKLO – SDA_LATENCY – 1	Configure DATAVD to meet the data hold requirement in the I2C specification
FILTSCL	00h	[CLKLO × (2 ^ PRESCALE)] – 3	FILTSCL and FILTSDA are the only parameters not multiplied by (2 ^ PRESCALE)
FILTSDA	FILTSCL	[CLKLO × (2 ^ PRESCALE)] – 3	Configuring FILTSDA greater than FILTSCL can delay the SDA input to compensate for board level skew
BUSIDLE	(CLKLO + SETHOLD + 2) × 2	—	Must also be greater than (CLKHI + 1)

See the UM10204, *I2C-bus specification and user manual*.

See Application information for example LPI2C timing configurations.

68.3.2.1.5 Error conditions

The LPI2C controller monitors errors while it is active. The following conditions generate an error flag and block a new Start condition from being sent, until the flag is cleared by software:

- A Start or Stop condition is detected and is not generated by the LPI2C controller (MSR[ALF] becomes 1).
- Transmitting data on SDA and different values are received (MSR[ALF] becomes 1). LPI2C controller stops driving SDA immediately, but continues to drive SCL for the remainder of the byte.
- NACK is detected when transmitting data, and MCFGR1[IGNACK] is 0 (MSR[NDF] becomes 1).
- NACK is detected and is expecting ACK for the address byte, and MCFGR1[IGNACK] is 0 (MSR[NDF] becomes 1).
- ACK is detected and is expecting NACK for the address byte, and MCFGR1[IGNACK] is 0 (MSR[NDF] becomes 1).
- Transmit FIFO is requesting to transmit or receive data without a Start condition (MSR[FEF] becomes 1). This restriction is ignored when MCFGR0[RELAX] is 1.
- SCL (or SDA if MCFGR1[TIMECFG] is 1) is low for (MCFGR2[TIMELOW] × 256) prescaler cycles without a pin transition (MSR[PLTF] becomes 1).

You must respond to MSR[PLTF] to terminate the existing command. You can terminate the command cleanly by writing 0 to MCR[MEN], or you can terminate it abruptly by writing 1 to MCR[RST].

You can use MCFGR0[RELAX] to attempt to recover a target with SDA stuck low. If MCFGR0[RELAX] is 1, the LPI2C controller does not wait for the I2C bus to be idle before starting a transfer. Initiating a Start command with address FFh, then the Stop condition, should generate sufficient SCL clock edges to cause the target to release SDA.

You can use MCFGR2[BUSIDLE] to force the I2C bus to be considered idle when SCL and SDA remain high for (BUSIDLE + 1) prescaler cycles. The bus is considered idle when the LPI2C controller is first enabled. When BUSIDLE is configured greater than zero, then SCL or SDA must be high for (BUSIDLE + 1) prescaler cycles before the I2C bus is considered idle.

68.3.2.1.6 DMA support

For efficient DMA transfers to the transmit and command FIFO, two alias regions support incrementing 8-bit, 16-bit, or 32-bit write accesses to that FIFO.

- Controller Transmit Command Burst (MTCBR0 - MTCBR127) is a 512-byte region that supports pushing CMD and DATA into the transmit FIFO.
- Transmit Data Burst (MTDBR0 - MTDBR252) is a 1024-byte region that supports pushing zero extended DATA into the transmit FIFO.

The two regions are contiguous. A DMA transfer can start in the MTCBR region to initialize the transfer including START condition with address. The same transfer can complete in the MTDBR region with the data to transmit without changing the transfer size.

The transmit FIFO prevents writes that overflow the FIFO, but this prevention does not signal an error. Do not perform 32-bit writes to the MTDBR unless there are four empty slots in the transmit FIFO. Do not perform 16-bit writes to the MTDBR unless there are two empty slots in the transmit FIFO.

68.3.2.1.7 Pin configuration

Configuration	Description
Open-drain support	The LPI2C controller defaults to open-drain configuration of the SDA and SCL pins. Support for true open drain depends on the specific device, and requires the pins where LPI2C pins are muxed to support true open drain.
HS mode support	Support for HS mode depends on the specific device. This mode requires the SCL pin to support the current source pullup required in the I2C specification.
Ultra-Fast mode support	The LPI2C controller supports the output-only push-pull function required for I2C Ultra-Fast mode using the SDA and SCL pins. Support for Ultra-Fast mode also requires MCFGR1[IGNACK] to be 1.
Push-pull two-wire support	A push-pull two-wire configuration is available to the LPI2C controller. If LPI2C is the only controller and all I2C pins on the bus are at the same voltage, this configuration may support a partial HS mode. A partial HS mode, not a full HS mode, because this configuration actively drives high rather than enabling a current service pull-up. This configuration sets the SCL pin as push-pull for every clock except the first clock pulse, to allow HS-mode-compatible targets to perform clock stretching. In this mode, the SDA pin is tristated for controller-receive data bits and controller-transmit ACK/NACK bits, and is configured as push-pull at other times. To avoid the risk of contention when SDA is push-pull, configure the pin for open-drain operation, as part of the device-specific configuration.
Push-pull four-wire support	The push-pull four-wire configuration separates the SCL input data and output data into separate pins. It also separates the SDA input data and output data into separate pins. The SCL/SDA pins are used for input data; the SCLS/SDAS pins are used for output data, with configurable polarity. This configuration simplifies external connections when connecting the LPI2C to the I2C bus through external level shifters or discrete components. When using this four-wire configuration, the LPI2C controller logic and LPI2C target logic cannot connect to separate I2C buses.

68.3.2.2 Target mode

To perform all target mode transfers on the I2C bus, the LPI2C target logic operates independently from the LPI2C controller logic.

68.3.2.2.1 Address matching

You can configure the LPI2C target:

- To match one of two addresses, using either 7-bit or 10-bit addressing modes for each address.
- To match a range of addresses in either 7-bit or 10-bit addressing modes.
- To match the general call address and generate appropriate flags.
- To match the SMBus alert address and generate appropriate flags.
- To detect the HS mode controller code address, and to disable the digital filters and output valid delay time until the next Stop condition is detected.

After a valid address is matched, the LPI2C target automatically performs target-transmit or target-receive transfers until:

- A NACK is detected (unless SCFGR1[IGNACK] becomes 1).
- A bit error is detected (the LPI2C target is driving SDA, but a different value is sampled).
- A (repeated) Start or Stop condition is detected.

When SCFGR1[RXALL] is 1, the LPI2C target receives all addresses and data on the I2C bus. Unless the address is matched, it never drives the SDA pin. Configure the LPI2C target to match only on 7-bit address mode when this feature is enabled. Software can support 10-bit address mode. This option is intended for debugging the contents of an I2C transfer between another controller and target. Likewise, SCFGR1[SDCFG] and SCFGR1[RSCFG] configure the Stop or repeated Start flags to assert on all Stop or repeated Start conditions, even when there is no address match.

68.3.2.2.2 Transmit and receive data

Target Transmit Data (STDR) and Target Receive Data (SRDR) are double-buffered and only update during a target-transmit and target-receive transfer, respectively.

You can configure the target address that was received to be read from SRDR (for example, when using DMA to transfer data) or from Target Address Status (SASR).

You can configure STDR to request data only after a target-transmit transfer is detected. You can also configure it to request new data whenever STDR is empty.

Write to STDR only when SSR[TDF] is set.

Read SRDR only when SSR[RDF] is set, or when SSR[AVF] is set and SCFGR1[RXCFG] = 1.

Read SASR only when SSR[AVF] is set.

68.3.2.2.3 Read request

The LPI2C target generates a read request when the I2C bus is idle and you write 1 to SCFGR0[RDREQ]. This occurrence causes the LPI2C target to pull the SDA pin low until either the first SCL falling edge or SCFGR0[RDREQ] becomes 0. Following the next Stop condition or a software timeout, you can proceed as follows:

- If the LPI2C target is accessed at the correct address, the read request is acknowledged, and you must write 0 to SCFGR0[RDREQ].
- If SCFGR0[RDACK] is 1, the read request is acknowledged by a Start followed by one SCL pulse followed by a STOP condition. You must write 0 to SCFGR0[RDREQ].
- If neither of the first two cases occurred, the read request is not acknowledged. You must write 0 and then 1 to SCFGR0[RDREQ] after an appropriate delay, provided the I2C bus is idle.
- If a software timeout occurs, the read request is not acknowledged, and you should write 0 to SCFGR0[RDREQ]. Another request can be generated after an appropriate delay.

Writing to SCFGR0[RDREQ] when the I2C bus is busy results in a logic 0 being written. Write 1 to SCFGR0[RDREQ], then confirm that the register is written to correctly. If the register does not update correctly, the I2C bus is no longer idle and the read request must be attempted later.

68.3.2.2.4 Clock stretching

The LPI2C target supports many configurable options for clock stretching. You can configure these conditions to perform clock stretching:

- SSR[AVF] is set during the ninth clock pulse of the address byte.
- SSR[TDF] is set during the ninth clock pulse of a target-transmit transfer.
- SSR[RDF] is set during the ninth clock pulse of a target-receive transfer.
- SSR[TAF] is set during the eighth clock pulse of an address byte or a target-receive transfer. In HS mode, this option is disabled.
- Clock stretching can be extended for a number of cycles equal to the value of SCFGR2[CLKHOLD] cycles. This stretching allows additional setup time to sample the SDA pin externally. In HS mode, this option is disabled.

When clock stretching is enabled, clock stretching extends for one peripheral bus clock cycle after SDA updates, unless extended by the SCFGR2[CLKHOLD] configuration.

68.3.2.2.5 Timing parameters

The LPI2C target can configure the following timing parameters:

- SDA data valid time from SCL negation to SDA update
- SCL hold time when clock stretching is enabled to increase setup time when sampling SDA externally
- SCL glitch filter time
- SDA glitch filter time

These parameters are disabled when SCR[FILTEN] is 0, when SCR[FILTDZ] is 1 in Doze mode, and when LPI2C target detects HS mode. When disabled, the LPI2C target is clocked directly from the I2C bus. In this case, the target may not satisfy all timing requirements of the I2C specification (such as SDA minimum hold time in Standard/Fast mode).

The LPI2C target places the following restrictions on the timing parameters:

- You must configure SCFGR2[FILTSDA] to be greater than or equal to SCFGR2[FILTSCL] (unless compensating for board level skew between SDA and SCL).
- You must configure SCFGR2[DATAVD] to be less than the minimum SCL low period.

68.3.2.2.6 Error conditions

The LPI2C target can flag the following error conditions:

- SSR[BEF] is set when the LPI2C target is driving SDA but it samples a different value than what is expected.
- SSR[FEF] is set due to a transmit data underrun or a receive data overrun. To eliminate the possibility of underrun and overrun, enable clock stretching. When SCFGR1[RXNACK] is 1, the LPI2C target generates a NACK on a receive data overrun.
- SSR[FEF] is also set due to an address overrun, but only when SCFGR1[RXCFG] is 1. To eliminate the possibility of overrun, enable clock stretching. When SCFGR1[RXNACK] is 1, the LPI2C target generates a NACK on an address overrun regardless of the value of SCFGR1[RXCFG].

The LPI2C target does not implement a timeout due to SCL or SDA being stuck low. If this detection is required, use the LPI2C controller logic so you can reset the LPI2C target when this condition is detected.

68.3.2.3 Low-power modes

LPI2C remains functional during low-power modes, if MCR[DOZEN] = 0 and LPI2C uses an external or internal clock source that remains enabled. LPI2C can generate an interrupt or DMA request to cause a wake-up from low-power modes.

You can configure LPI2C to be disabled in low-power modes when MCR[DOZEN] = 1. In this case, LPI2C waits for the current transfer to complete any pending operation.

NOTE

See the chip-specific information for low-power modes available on your chip.

68.3.2.4 Debug mode

Table 644. Debug mode

Mode	LPI2C operation
Debug	If MCR[DBGEN] = 1, can continue operating in Debug mode.

68.3.2.5 Peripheral triggers

The connection of the LPI2C peripheral triggers to other peripherals depends upon the specific device being used.

Table 645. LPI2C triggers

Trigger	Description
Controller output trigger	Generates an output trigger that can be connected to other peripherals on the device. The controller output trigger asserts on either a repeated Start or a Stop condition. The trigger remains asserted for one cycle of the LPI2C functional clock divided by MCFGR1[PRESCALE].
Target output trigger	Generates an output trigger that can be connected to other peripherals on the device. The target output trigger asserts on either a repeated Start or a Stop condition that occurs after a target address match. The target output trigger remains asserted until the next target SCL pin negation.
Input trigger	To control the start of a LPI2C bus transfer, the LPI2C input trigger can be selected instead of the HREQ input. The input trigger is synchronized. To be detected, the input trigger must assert for at least two cycles of the LPI2C functional clock divided by the value of MCFGR1[PRESCALE]. When LPI2C is busy, the HREQ input (and therefore the input trigger) is ignored.

68.3.2.6 Clocking

Table 646. LPI2C clocks

Clock	Description
LPI2C functional clock	The LPI2C functional clock is asynchronous to the bus clock. It can remain enabled in low-power modes to support I2C bus transfers by the LPI2C controller. The functional clock is also used by the LPI2C target to support digital filter and data hold time configurations. The LPI2C controller divides the functional clock by a prescaler (MCFGR1[PRESCALE]) and the resulting frequency must be at least eight times faster than the I2C bus bandwidth.
External clock	The LPI2C target logic is clocked directly from the external pins. These pins are SCL and SDA, or SCLS and SDAS if the controller and target are implemented on separate pins). This clocking allows the LPI2C target to remain operational, even when the LPI2C functional clock is disabled. **NOTE** If the LPI2C functional clock is disabled, the LPI2C target digital filter must be disabled. This condition can affect compliance with some timing parameters of the I2C specification, such as data hold time.

Table continues on the next page...

Table 646. LPI2C clocks (continued)

Clock	Description
Bus clock	The bus clock is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPI2C controller and target registers.

For chip-specific clocking information, see the Clocking chapter.

68.3.2.7 Reset

Table 647. LPI2C resets

Reset	Description
Chip reset	The logic and registers for the LPI2C controller and target are reset to their default states after a chip reset.
Software reset	The LPI2C controller implements a software reset field in its control register. MCR[RST] resets all controller logic and registers to their default states, except for Controller Control (MCR) itself. The LPI2C target implements a software reset field in its control register. SCR[RST] resets all target logic and registers to their default states, except for Target Control (SCR) itself.
FIFO reset	The LPI2C controller implements write-only control fields that reset the transmit FIFO (MCR[RTF]) and receive FIFO (MCR[RRF]). After a FIFO is reset, that FIFO is empty. The LPI2C target implements write-only control fields that reset the transmit data register (SCR[RTF]) and receive data register (SCR[RRF]). After a data register is reset, that data register is empty.

68.3.2.8 Interrupts and DMA requests

Depending on the configuration, interrupts and DMA requests can be combined:

- LPI2C controller and target interrupts
- LPI2C controller and target transmit DMA requests
- LPI2C controller and target receive DMA requests

68.3.2.8.1 Controller mode

Table 648 lists the Controller mode sources that can generate LPI2C controller interrupts and LPI2C controller transmit and receive DMA requests.

Table 648. Controller interrupts and DMA requests

Status flag	Description	Can generate		
		Interrupt?	DMA request?	Low-power wake-up?
Transmit Data Flag (MSR[TDF])	Data can be written to transmit FIFO, as configured by MFCR[TXWATER].	Y	TX	Y
Receive Data Flag (MSR[RDF])	Data can be read from the receive FIFO, as configured by MFCR[RXWATER].	Y	RX	Y

Table continues on the next page...

Table 648. Controller interrupts and DMA requests (continued)

Status flag	Description	Can generate		
		Interrupt?	DMA request?	Low-power wake-up?
End Packet Flag (MSR[EPF])	Controller has transmitted a repeated Start or Stop condition.	Y	N	Y
Stop Detect Flag (MSR[SDF])	Controller has transmitted a Stop condition (and the LPI2C controller is idle, if MCFGR1[STOPCFG] = 1) .	Y	N	Y
NACK Detect Flag (MSR[NDF])	During an address byte, the controller expects an ACK but detects a NACK. During an address byte, the controller expects a NACK but detects an ACK. During a controller-transmitter data byte, the controller detects a NACK.	Y	N	Y
Arbitration Lost Flag (MSR[ALF])	The controller lost arbitration due to a Start or Stop condition detected at the wrong time, or the controller was transmitting data but received data different from the data that was transmitted.	Y	N	Y
FIFO Error Flag (MSR[FEF])	The controller expects a Start condition in the command FIFO, but the next entry in the command FIFO is not a Start condition.	Y	N	Y
Pin Low Timeout Flag (MSR[PLTF])	Pin low timeout is enabled and SCL (or SDA, if configured) is low for longer than the configured timeout.	Y	N	Y
Data Match Flag (MSR[DMF])	The received data matches the configured data match, but the received data is not discarded due to a command FIFO entry.	Y	N	Y
Start Detect Flag (MSR[STF])	A Start condition is detected on the I2C bus (and the LPI2C controller is idle, if MCFGR1[STARTCFG] = 1).	Y	N	Y
Controller Busy Flag (MSR[MBF])	LPI2C controller is busy transmitting or receiving data.	N	N	N
Bus Busy Flag (MSR[BBF])	LPI2C controller is enabled and activity is detected on the I2C bus, but no Stop condition is detected and no bus idle timeout (if enabled) occurred.	N	N	N

68.3.2.8.2 Target mode

Table 649 lists the target mode sources that can generate LPI2C target interrupts and LPI2C target transmit and receive DMA requests.

Table 649. Target interrupts and DMA requests

Status flag	Description	Can generate		
		Interrupt?	DMA request?	Low-power wake-up?
Transmit Data Flag (SSR[TDF])	Data can be written to Target Transmit Data (STDR).	Y	TX	Y
Receive Data Flag (SSR[RDF])	Data can be read from Target Receive Data (SRDR).	Y	RX	Y
Address Valid Flag (SSR[AVF])	Address can be read from Target Address Status (SASR).	Y	RX	Y
Transmit ACK Flag (SSR[TAF])	ACK or NACK can be written to Target Transmit ACK (STAR).	Y	N	Y
Repeated Start Flag (SSR[RSF])	Target has detected an address match followed by a repeated Start condition.	Y	RX	Y
Stop Detect Flag (SSR[SDF])	Target has detected an address match followed by a Stop condition.	Y	RX	Y
Bit Error Flag (SSR[BEF])	Target was transmitting data, but received data is different from what was transmitted.	Y	N	Y
FIFO Error Flag (SSR[FEF])	This flag is set by: • Transmit data underrun • Receive data overrun • Address status overrun when SCFGR1[RXCFG] = 1 This flag can only be set when clock stretching is disabled.	Y	N	Y
Address Match 0 Flag (SSR[AM0F])	Target detected an address match SAMR[ADDR0].	Y	N	N
Address Match 1 Flag (SSR[AM1F])	Target detected an address match with SAMR[ADDR1] or using an address range.	Y	N	N
General Call Flag (SSR[GCF])	Target detected an address match with the general call address.	Y	N	N
SMBus Alert Response Flag (SSR[SARF])	Target detected an address match with the SMBus alert address.	Y	N	N
Target Busy Flag (SSR[SBF])	LPI2C target is busy receiving an address byte or is transmitting or receiving data.	N	N	N
Bus Busy Flag (SSR[BBF])	LPI2C target is enabled and a Start condition is detected on I2C bus, but no Stop condition detected.	N	N	N

68.3.2.8.3 End-of-packet DMA transfer

End-of-packet functionality serves serial interfaces where the transfer size may not be known in advance and the data is pushed by an external device. Examples include UART receive, I2C Target mode, and SPI Target mode. End-of-packet processing

is intended to ensure that data does not become stranded in either the receive FIFO or DMA receive buffer. Support for end-of-packet processing must be implemented in both the serial interfaces and DMA controller.

The condition that signals the end of packet differs for each serial interface but is processed by the serial peripheral and DMA in the same way. For example:

- UART end of packet is signaled by an idle line condition.
- I2C end of packet is signaled by Stop or repeated Start condition.
- SPI end of packet is signaled by PCS negation.

When the serial peripheral is configured to signal an end-of-packet condition to the DMA and the serial interface detects an end-of-packet condition, it asserts the DMA request for the receive FIFO regardless of the watermark configuration. For larger watermark configurations, this behavior ensures that the last few words of the transfer are first flushed from the receive FIFO.

The DMA then reads the contents of the receive FIFO, depending on the first word in the FIFO:

- If the receive FIFO is empty, the serial interface signals an end-of-packet condition to the DMA controller.
- If the receive FIFO is not empty, but the first word in the FIFO starts a new packet, data is not pulled from the receive FIFO. Also, the serial interface signals an end-of-packet condition to the DMA controller.
- If the receive FIFO is not empty, and the first word in the FIFO does not start a new packet, the DMA transfers data as normal.

Because the DMA may transfer multiple words per request, the end-of-packet condition persists until the DMA minor loop finishes and no additional data is pulled from the FIFO. The status flag that triggered the end-of-packet condition is cleared when the minor loop completes after the end of packet is signaled to the DMA controller.

When the DMA detects the end-of-packet condition, it writes all received words up to the end of packet into system memory. It also saves the destination address for the word after the last valid data. The DMA then terminates the channel as if the major loop completed, including final offsets and optional interrupts, channel linking, and scatter-gather. The final destination address can be saved to system memory or is available in the destination address register.

Because the DMA terminates the major loop, the receive FIFO is not serviced until the DMA is reconfigured. You can perform this reconfiguration through software or hardware (for example, channel linking or scatter-gather). Minimize this delay to avoid receiver FIFO overrun. Automatic DMA end-of-packet processing is not recommended when there are only a few words transferred between end-of-packet conditions. In this case, the DMA spends more time processing the end of packet than transferring the data. For example, to avoid an excessive number of idle conditions, increase the UART idle line length as needed.

68.3.3 External signals

Table 650. External signals

Signal	Name	Two-wire scheme	Four-wire scheme	Direction
SCL	LPI2C clock line	SCL	In Four-Wire mode, this pin is the SCL input pin.	Input or output
SDA	LPI2C data line	SDA	In Four-Wire mode, this pin is the SDA input pin.	Input or output
SCLS	Secondary I2C clock line	Not used	In Four-Wire mode, this pin is the SCLS output pin. If LPI2C controller/target are configured to use separate pins, then this pin is the LPI2C target SCL pin.	Input or output
SDAS	Secondary I2C data line	Not used	In Four-Wire mode, this pin is the SDAS output pin. If LPI2C controller/target are	Input

Table continues on the next page...

Table 650. External signals (continued)

Signal	Name	Two-wire scheme	Four-wire scheme	Direction
			configured to use separate pins, then this pin is the LPI2C target SDA pin.	or output
HREQ	Host request	When configured for controller (input), if host request is asserted and the I2C bus is idle, it initiates a transfer. When configured for target (output), it asserts while valid data is present in Target Transmit Data (STDR). HREQ is an additional pin separate from the two-wire or four-wire scheme.		Input or output

Figure 283 shows the two-signal connection.

Figure 284 shows a possible four-signal connection.

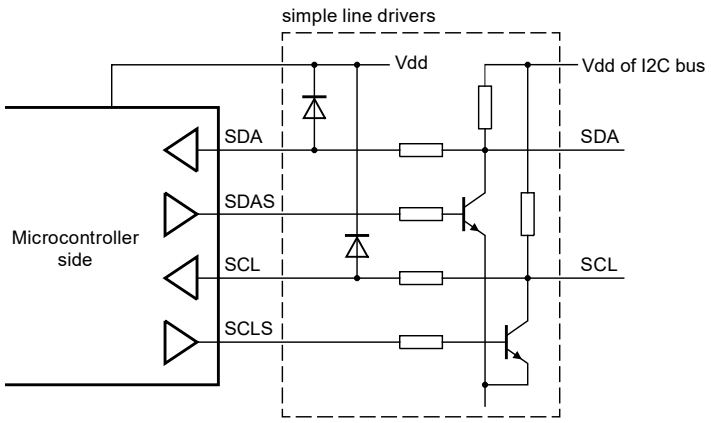

Figure 284. I²C four-wire serial bus

68.3.4 Initialization

To initialize the LPI2C controller:

1. Configure Controller Configuration 0 (MCFGR0)–Controller Configuration 3 (MCFGR3) as required by the application.

2. Configure Controller Clock Configuration 0 (MCCR0) and Controller Clock Configuration 1 (MCCR1) to satisfy the timing requirements of the I2C mode supported by the application.
3. Enable controller interrupts and DMA requests as required by the application.
4. Enable the LPI2C controller by writing 1 to MCR[MEN].

To initialize the LPI2C target:

1. Configure Target Address Match (SAMR) with the I2C address of the target location on the I2C bus.
2. Configure Target Configuration 0 (SCFGR0) and Target Configuration 1 (SCFGR1) as required by the application.
3. Configure Target Configuration 2 (SCFGR2) to satisfy the timing requirements of the I2C mode supported by the application.
4. Enable target interrupts and DMA requests as required by the application.
5. Enable the LPI2C target by writing 1 to SCR[SEN].

68.3.5 Application information

Configure the I2C timing parameters to meet the requirements of the I2C specification. This configuration depends on the supported mode and LPI2C functional clock frequency. When switching between two modes using different clock configuration registers (for example, Fast mode and HS mode), MCFGR1[PRESCALE] must remain constant between the modes.

Table 651. Example timing configurations

I2C mode	Clock frequency	Baud rate	PRESCALE	FILTSCL / FILTSDA	SETHOLD	CLKLO	CLKHI	DATAVD
Standard	8 MHz	100 kbit/s	0h	0h/0h	24h	28h	24h	02h
Standard	48 MHz	100 kbit/s	2h	1h/1h	37h	3Fh	37h	03h
Standard	60 MHz	100 kbit/s	2h	1h/1h	45h	50h	44h	04h
Fast	8 MHz	400 kbit/s	0h	0h/0h	04h	0Bh	05h	02h
Fast+	8 MHz	1 Mbit/s	0h	0h/0h	02h	03h	01h	01h
Fast	48 MHz	400 kbit/s	0h	1h/1h	1Dh	3Eh	35h	0Fh
Fast	48 MHz	400 kbit/s	2h	1h/1h	07h	11h	0Bh	03h
Fast+	48 MHz	1 Mbit/s	2h	1h/1h	03h	06h	04h	04h
HS	48 MHz	3.2 Mbit/s	0h	0h/0h	07h	08h	03h	01h
Fast	60 MHz	400 kbit/s	1h	2h/2h	11h	28h	1Fh	08h
Fast+	60 MHz	1 Mbit/s	1h	2h/2h	07h	0Fh	0Bh	01h
HS	60 MHz	3.33 Mbit/s	1h	0h/0h	04h	04h	02h	01h

68.3.6 Memory map and registers

68.3.6.1 LPI2C register descriptions

Writing to a read-only register or reading from a write-only register can cause bus errors. This module does not check whether programmed values in the registers are correct; you must ensure that valid programmed values are written to the registers.

68.3.6.1.1 LPI2C memory map

LPI2C0 base address: 4011_0800h

LPI2C1 base address: 4011_1800h

68.3.6.1.4 Controller Control (MCR)

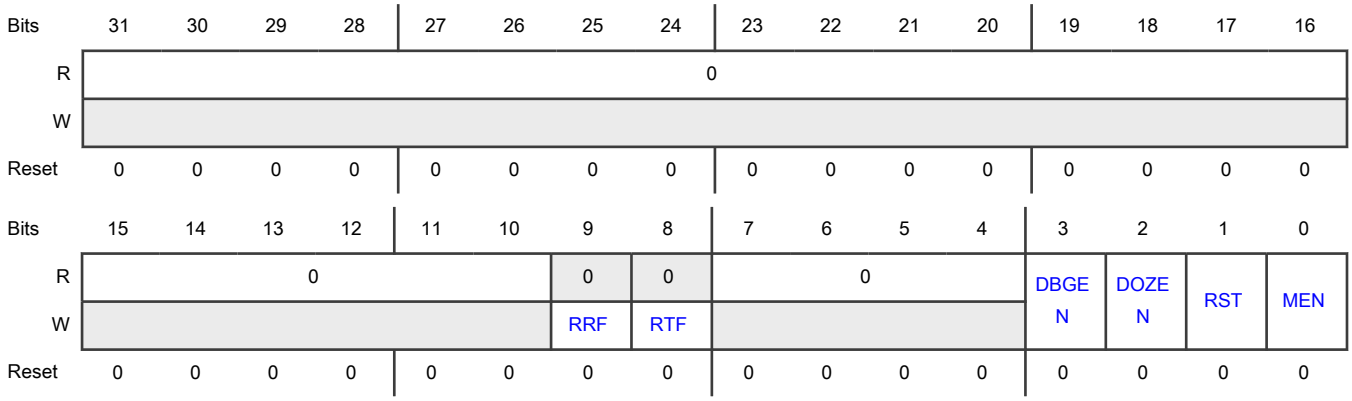
Offset

Register	Offset
MCR	10h

Function

Contains resets, debug enable, and other controller control settings.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 RRF	Reset Receive FIFO Resets the receive FIFO in Controller Receive Data (MRDR). 0b - No effect 1b - Reset receive FIFO
8 RTF	Reset Transmit FIFO Resets the transmit FIFO in Controller Transmit Data (MTDR). 0b - No effect 1b - Reset transmit FIFO
7-4 —	Reserved
3 DBGEN	Debug Enable Enables the controller in Debug mode. 0b - Disable 1b - Enable
2 DOZEN	Doze Mode Enable Enables the controller in Doze mode. 0b - Enable 1b - Disable
1	Software Reset

Table continues on the next page...

Table continued from the previous page...

Field	Function
RST	Resets all internal controller logic and registers except Controller Control (MCR). This field remains 1 (enabled) until you write 0 to it. The reset takes effect immediately and remains asserted until negated by software. There is no minimum delay required before clearing the software reset. 0b - No effect 1b - Reset
0 MEN	Controller Enable Enables the controller logic. 0b - Disable 1b - Enable

68.3.6.1.5 Controller Status (MSR)

Offset

Register	Offset
MSR	14h

Function

Contains status flags for transmit and receive data, for start and stop conditions, and for bus and controller busy or idle status.

Diagram

Fields

Field	Function
31-26 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
25 BBF	Bus Busy Flag Specifies whether the I2C bus is busy. 0b - Idle 1b - Busy
24 MBF	Controller Busy Flag Specifies whether the I2C controller is busy. 0b - Idle 1b - Busy
23-16 —	Reserved
15 STF	Start Flag Specifies whether a Start condition is detected on the bus when the bus is idle. When MCFGR1[STARTCFG] is 0, this field becomes 1 only if the LPI2C controller is also idle. When MCFGR1[STARTCFG] is 1, STF becomes 1 for any Start condition when the I2C bus is idle. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Start condition not detected 1b - Start condition detected When writing 0b - No effect 1b - Clear the flag
14 DMF	Data Match Flag Indicates whether the received data matches MDMR[MATCH0] or MDMR[MATCH1] (as configured by MCFGR1[MATCFG]). Received data discarded due to MTDR[CMD] does not cause this flag to set. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Matching data not received 1b - Matching data received When writing 0b - No effect 1b - Clear the flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
13 PLTF	Pin Low Timeout Flag Indicates whether pin low timeout has occurred. Sets when the SCL or SDA input is low for more than the number of PINLOW cycles defined by MCFGR3[PINLOW], even when the LPI2C controller is idle. You must resolve the pin low condition via software. PLTF cannot be cleared as long as the pin low timeout continues. Before LPI2C can initiate a Start condition, you must clear this flag. See MCFGR1[TIMECFG] for the SCL and/or SDA timeout settings. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Pin low timeout did not occur 1b - Pin low timeout occurred When writing 0b - No effect 1b - Clear the flag
12 FEF	FIFO Error Flag Detects the LPI2C controller's attempt to send or receive data without first generating a (repeated) Start condition. This error can occur when the transmit FIFO underflows when MCFGR1[AUTOSTOP] = 1. When this flag is set, the LPI2C controller sends a Stop condition (if busy). The controller does not initiate a new Start condition until the flag is cleared. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No FIFO error 1b - FIFO error When writing 0b - No effect 1b - Clear the flag
11 ALF	Arbitration Lost Flag Indicates whether arbitration is lost. Either of these conditions sets this flag: • The LPI2C controller transmits a logic 1 and detects a logic 0 on the I2C bus. • The LPI2C controller detects a Start or Stop condition when the LPI2C controller is transmitting data. When ALF is set, the LPI2C controller releases the I2C bus (goes idle), and the LPI2C controller does not initiate a new Start condition until the ALF is cleared.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - Controller did not lose arbitration 1b - Controller lost arbitration When writing 0b - No effect 1b - Clear the flag
10 NDF	NACK Detect Flag Indicates whether an unexpected NACK has been detected. This flag is set when the LPI2C controller detects a NACK it was not expecting when transmitting an address or data. When set, the controller does not initiate a new Start condition until this flag is cleared. If a NACK is expected for a given address (as configured by the command word), this flag is set if a NACK is not generated. When this flag is set, the LPI2C controller automatically transmits a Stop condition if MCFGR1[AUTOSTOP] = 1, or if the transmit FIFO is not empty. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No unexpected NACK detected 1b - Unexpected NACK detected When writing 0b - No effect 1b - Clear the flag
9 SDF	Stop Detect Flag Indicates whether the LPI2C controller has generated a Stop condition. When MCFGR1[STOPCFG] = 0, this flag is set for any Stop condition. When MCFGR1[STOPCFG] = 1, this flag is set only when the LPI2C controller is also idle (transmit FIFO is empty). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No Stop condition generated 1b - Stop condition generated When writing 0b - No effect

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Clear the flag
8 EPF	End Packet Flag Indicates whether the LPI2C controller has generated a repeated Start condition or a Stop condition. When the controller first generates a Start condition, this flag is not set. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No Stop or repeated Start generated 1b - Stop or repeated Start generated When writing 0b - No effect 1b - Clear the flag
7-2 —	Reserved
1 RDF	Receive Data Flag Indicates whether the receive data is ready. This flag is set when the number of words in the receive FIFO is greater than MFCR[RXWATER]. 0b - Receive data not ready 1b - Receive data ready
0 TDF	Transmit Data Flag Indicates whether transmit data is requested. This flag is set when the number of words in the transmit FIFO is equal or less than MFCR[TXWATER]. 0b - Transmit data not requested 1b - Transmit data requested

68.3.6.1.6 Controller Interrupt Enable (MIER)

Offset

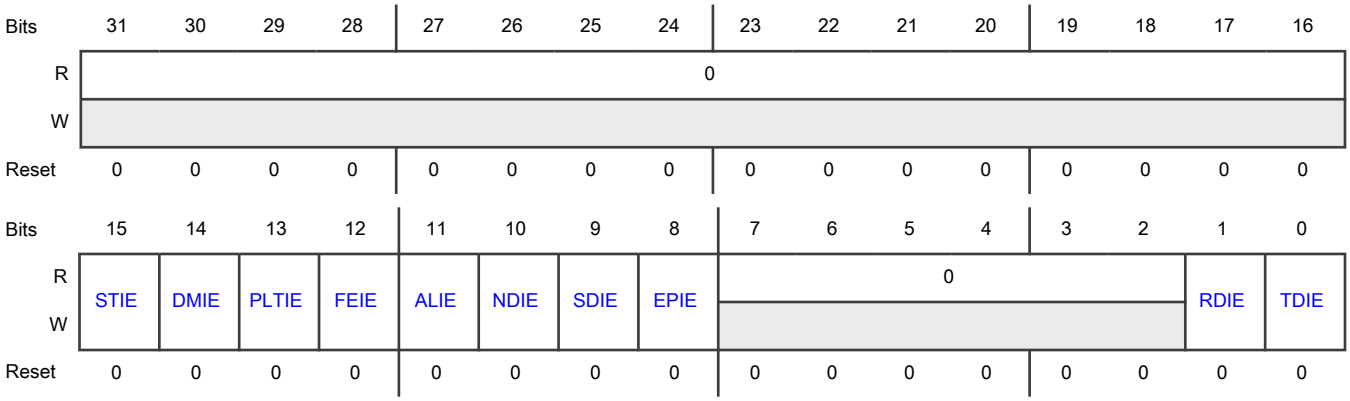
Register	Offset
MIER	18h

Function
Contains enables for:

- Transmit and receive data interrupts

- Start, Stop, and NACK detection interrupts
- DMA interrupts

Diagram



Fields

Field	Function
31-16 —	Reserved
15 STIE	Start Interrupt Enable Enables interrupt for Start condition. 0b - Disable 1b - Enable
14 DMIE	Data Match Interrupt Enable Enables interrupt for data match. 0b - Disable 1b - Enable
13 PLTIE	Pin Low Timeout Interrupt Enable Enables interrupt for pin-low timeout. 0b - Disable 1b - Enable
12 FEIE	FIFO Error Interrupt Enable Enables interrupt for FIFO error. 0b - Disable 1b - Enable
11	Arbitration Lost Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
ALIE	Enables interrupt for arbitration lost. 0b - Disable 1b - Enable
10 NDIE	NACK Detect Interrupt Enable Enables interrupt for NACK detection. 0b - Disable 1b - Enable
9 SDIE	Stop Detect Interrupt Enable Enables interrupt for Stop detection. 0b - Disable 1b - Enable
8 EPIE	End Packet Interrupt Enable Enables interrupt for end packet. 0b - Disable 1b - Enable
7-2 —	Reserved
1 RDIE	Receive Data Interrupt Enable Enables interrupt for receive data. 0b - Disable 1b - Enable
0 TDIE	Transmit Data Interrupt Enable Enables interrupt for transmit data. 0b - Disable 1b - Enable

68.3.6.1.7 Controller DMA Enable (MDER)

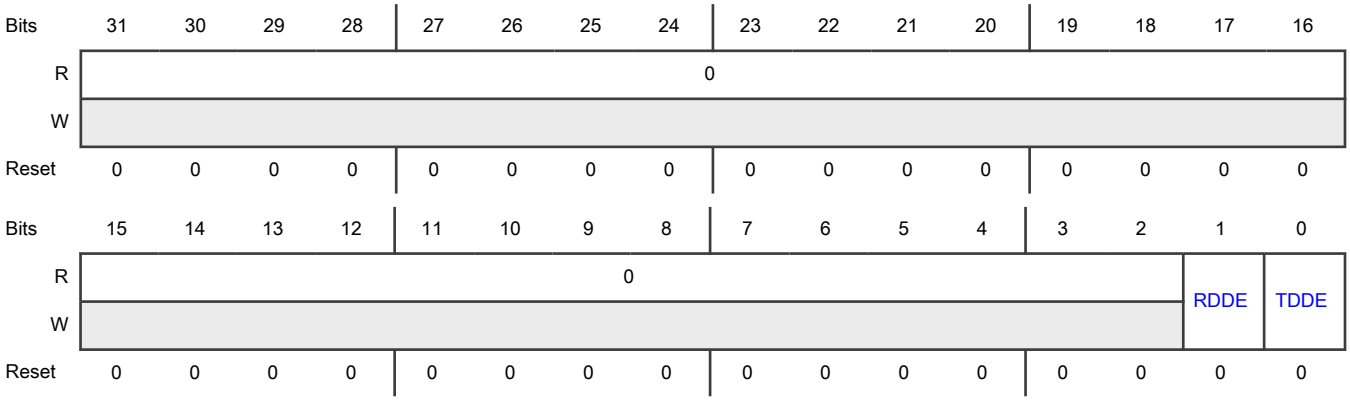
Offset

Register	Offset
MDER	1Ch

Function

Contains DMA transmit, request, and receive enables.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 RDDE	Receive Data DMA Enable Enables DMA receive data. 0b - Disable 1b - Enable
0 TDDE	Transmit Data DMA Enable Enables DMA transmit data. 0b - Disable 1b - Enable

68.3.6.1.8 Controller Configuration 0 (MCFGR0)

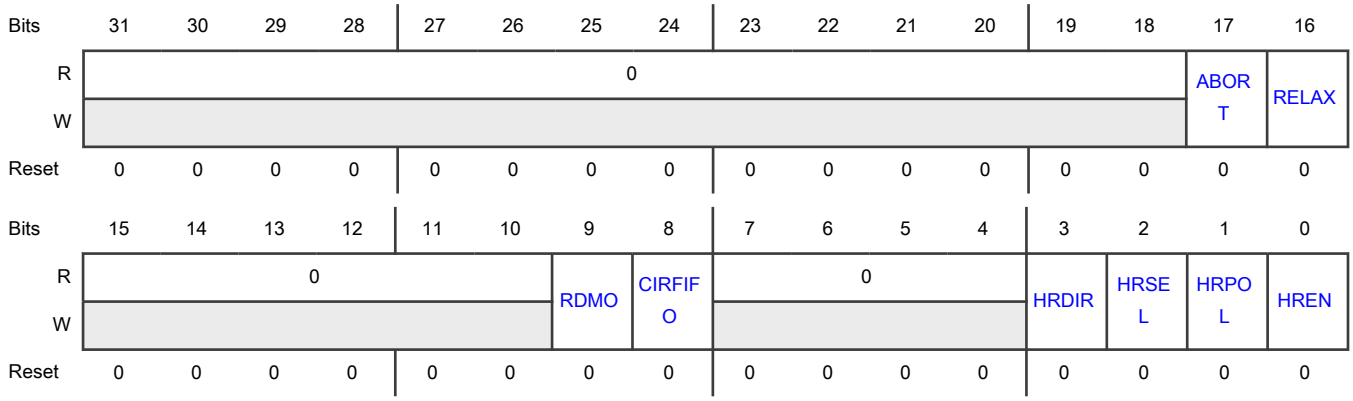
Offset

Register	Offset
MCFGR0	20h

Function

Contains host settings and other receive and transfer settings.

Diagram



Fields

Field	Function
31-18 —	Reserved
17 ABORT	Abort Transfer Determines whether the LPI2C controller completes the existing byte and then sends a Stop condition. A new transfer does not start while this field is 1. 0b - Normal transfer 1b - Abort existing transfer and do not start a new one
16 RELAX	Relaxed Mode Specifies the type of transfer. If this field is 1, the LPI2C controller relaxes several transfer restrictions. Transfers start when the bus is busy and FIFO commands are not checked for errors. You can use this mode to attempt recovery of a stuck I2C target by toggling the SCL pin. 0b - Normal transfer 1b - Relaxed transfer
15-10 —	Reserved
9 RDMO	Receive Data Match Only Determines whether all received data that does not set MSR[DMF] is discarded. After MSR[DMF] is set, the RDMO configuration is ignored. When disabling RDMO, write 0 to this field before writing 0 to MSR[DMF] to ensure that no receive data is lost. 0b - Received data is stored in the receive FIFO 1b - Received data is discarded unless MSR[DMF] is set
8 CIRFIFO	Circular FIFO Enable Enables the transmit FIFO read pointer to be saved to a temporary register. The transmit FIFO empties as normal. After the LPI2C controller is idle and the transmit FIFO is empty, the read pointer value is

Table continues on the next page...

Table continued from the previous page...

Field	Function
	restored from the temporary register. This setting causes the contents of the transmit FIFO to be cycled through repeatedly. If MCFGR1[AUTOSTOP] is 1, then a Stop condition is sent whenever the transmit FIFO is empty and the read pointer is restored. 0b - Disable 1b - Enable
7-4 —	Reserved
3 HRDIR	Host Request Direction Configures the direction of the HREQ pin. When this field is 1, the LPI2C target drives the HREQ output pin and the pin becomes 1 when there is data in the target transmit data register. For proper operation when this field is 1, write 1 to SCFGR1[TXCFG]. 0b - HREQ pin is input (for LPI2C controller) 1b - HREQ pin is output (for LPI2C target)
2 HRSEL	Host Request Select Selects the source of the host request input. When host request is enabled, this field must not change. 0b - Host request input is pin HREQ 1b - Host request input is input trigger
1 HRPOL	Host Request Polarity Configures the polarity of the host request input. When host request is enabled, this field must not change. HRPOL sets the polarity for both the HREQ pin and the input trigger. • When HRPOL=0, the polarity is configured for active low, so host request is asserted if the HREQ pin or input trigger are logic 0. • When HRPOL=1, the polarity is configured for active high, so host request is asserted if the HREQ pin or input trigger are logic 1. 0b - Active low 1b - Active high
0 HREN	Host Request Enable Enables host request. When enabled, the LPI2C controller only initiates a Start condition if the host request input is asserted and the bus is idle. A repeated Start condition is not affected by the host request. 0b - Disable 1b - Enable

68.3.6.1.9 Controller Configuration 1 (MCFGR1)

Offset

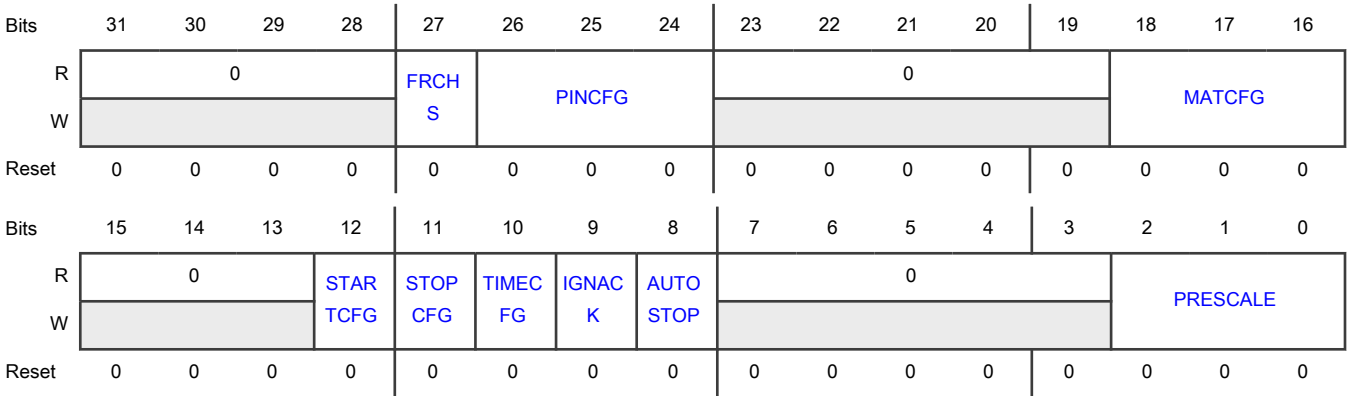
Register	Offset
MCFGR1	24h

Function

Contains controls for pin configuration, clock prescaler, and various other control settings.

Write to this register only when the I2C controller is disabled.

Diagram



Fields

Field	Function
31-28 —	Reserved
27 FRCHS	Force HS Mode Forces the LPI2C pin state into HS mode. Writing 1 to this field does not impact the digital filter configuration or digital timing parameters. 0b - No effect 1b - LPI2C pin state forced into HS mode
26-24 PINCFG	Pin Configuration Configures the pin mode for LPI2C. 000b - Two-pin open drain mode. SCL/SDA pins: Bidirectional open drain for controller and target. SCLS/SDAS pins: Not used. 001b - Two-pin output only mode (Ultra-Fast mode). SCL/SDA pins: Output-only (Ultra-Fast mode) open drain for controller and target. SCLS/SDAS pins: Not used.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	010b - Two-pin push-pull mode. SCL/SDA pins: Bidirectional push-pull for controller and target. SCLS/SDAS pins: Not used. 011b - Four-pin push-pull mode. SCL/SDA pins: Input only for controller and target. SCLS/SDAS pins: Output-only push-pull for controller and target. 100b - Two-pin open-drain mode with separate LPI2C target. SCL/SDA pins: Bidirectional open drain for controller. SCLS/SDAS pins: Bidirectional open drain for target. 101b - Two-pin output only mode (Ultra-Fast mode) with separate LPI2C target. SCL/SDA pins: Output-only (Ultra-Fast mode) open drain for controller. SCLS/SDAS pins: Output-only open drain for target. 110b - Two-pin push-pull mode with separate LPI2C target. SCL/SDA pins: Bidirectional push-pull for controller. SCLS/SDAS pins: Bidirectional push-pull for target. 111b - Four-pin push-pull mode (inverted outputs). SCL/SDA pins: Input only for controller and target. SCLS/SDAS pins: Inverted output-only push-pull for controller and target.
23-19 —	Reserved
18-16 MATCFG	Match Configuration Configures the condition that sets MSR[DMF]. See Controller Data Match (MDMR). 000b - Match is disabled 001b - Reserved 010b - Match is enabled: first data word equals MDMR[MATCH0] OR MDMR[MATCH1] 011b - Match is enabled: any data word equals MDMR[MATCH0] OR MDMR[MATCH1] 100b - Match is enabled: (first data word equals MDMR[MATCH0]) AND (second data word equals MDMR[MATCH1) 101b - Match is enabled: (any data word equals MDMR[MATCH0]) AND (next data word equals MDMR[MATCH1) 110b - Match is enabled: (first data word AND MDMR[MATCH1]) equals (MDMR[MATCH0] AND MDMR[MATCH1]) 111b - Match is enabled: (any data word AND MDMR[MATCH1]) equals (MDMR[MATCH0] AND MDMR[MATCH1])
15-13 —	Reserved
12 STARTCFG	Start Configuration Configures the conditions that set MSR[STF] when a Start condition occurs. When this field is 0, MSR[STF] is set on a Start condition when both the I2C bus and LPI2C are idle. In other words, any nonrepeated Start condition is initiated by any controller on the bus except the LPI2C controller.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field is 1, MSR[STF] is set on a Start condition when the I2C bus is idle. In other words, any nonrepeated Start condition is initiated by any controller on the bus including the LPI2C controller. 0b - Sets when both I2C bus and LPI2C controller are idle 1b - Sets when I2C bus is idle
11 STOPCFG	Stop Configuration Configures the conditions that set MSR[SDF]. When this field is 0, any Stop condition generated by the LPI2C controller sets SDF. When this field is 1, the last Stop condition before the LPI2C controller is idle sets SDF. In this case, the transmit FIFO is empty at the time of the Stop condition. 0b - Any Stop condition 1b - Last Stop condition
10 TIMECFG	Timeout Configuration Configures which signals must be low for longer than the configured timeout to set MSR[PLTF]. When this field is 0, MSR[PLTF] is set when SCL is low for longer than the configured timeout. 0b - SCL 1b - SCL or SDA
9 IGNACK	Ignore NACK Determines whether the LPI2C controller ignores a received NACK and treats it as an ACK. In this case, MSR[NDF] is never set. This field must be 1 in Ultra-Fast mode. 0b - No effect 1b - Treat a received NACK as an ACK
8 AUTOSTOP	Automatic Stop Generation Determines whether a Stop condition is generated when the LPI2C controller is busy and the transmit FIFO is empty. A Stop condition can also be generated using a transmit FIFO command. When this field is 1, a Stop condition is automatically generated when the transmit FIFO is empty and the LPI2C controller is busy. 0b - No effect 1b - Stop automatically generated
7-3 —	Reserved
2-0 PRESCALE	Prescaler Configures the clock prescaler used for all LPI2C controller logic except the digital glitch filters. 000b - Divide by 1

Table continues on the next page...

Table continued from the previous page...

Field	Function
	001b - Divide by 2 010b - Divide by 4 011b - Divide by 8 100b - Divide by 16 101b - Divide by 32 110b - Divide by 64 111b - Divide by 128

68.3.6.1.10 Controller Configuration 2 (MCFGR2)

Offset

Register	Offset
MCFGR2	28h

Function

Contains the configuration for the bus idle timeout and glitch filters for SDA and SCL.

Write to this register only when the I2C controller is disabled.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-28 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
27-24 FILTSDA	Glitch Filter SDA Configures the I2C controller digital glitch filters for the SDA input. The latency through the glitch filter is equal to the number of cycles defined by this field. The value of this field must be less than the minimum SCL low or high period. Glitches equal to or less than the number of cycles defined by this field are filtered out and ignored. Writing 0 to this field disables the glitch filter. MCFGR1[PRESCALE] does not affect the glitch filter cycle count. It is automatically bypassed in HS mode.
23-20 —	Reserved
19-16 FILTSCL	Glitch Filter SCL Configures the I2C controller digital glitch filters for SCL input. The latency through the glitch filter is equal to the number of cycles defined by this field. The value of this field must be less than the minimum SCL low or high period. Glitches equal to or less than the number of cycles defined by this field are filtered out and ignored. These cycles are based on the functional clock. Writing 0 to this field disables the glitch filter. MCFGR1[PRESCALE] does not affect the glitch filter cycle count. It is automatically bypassed in HS mode.
15-12 —	Reserved
11-0 BUSIDLE	Bus Idle Timeout Configures the bus idle timeout period, in clock cycles. If both SCL and SDA are high for longer than the number of cycles defined by this field, the I2C bus is assumed to be idle and the controller can generate a Start condition. Writing 0 to this field disables the bus idle timeout.

68.3.6.1.11 Controller Configuration 3 (MCFGR3)

Offset

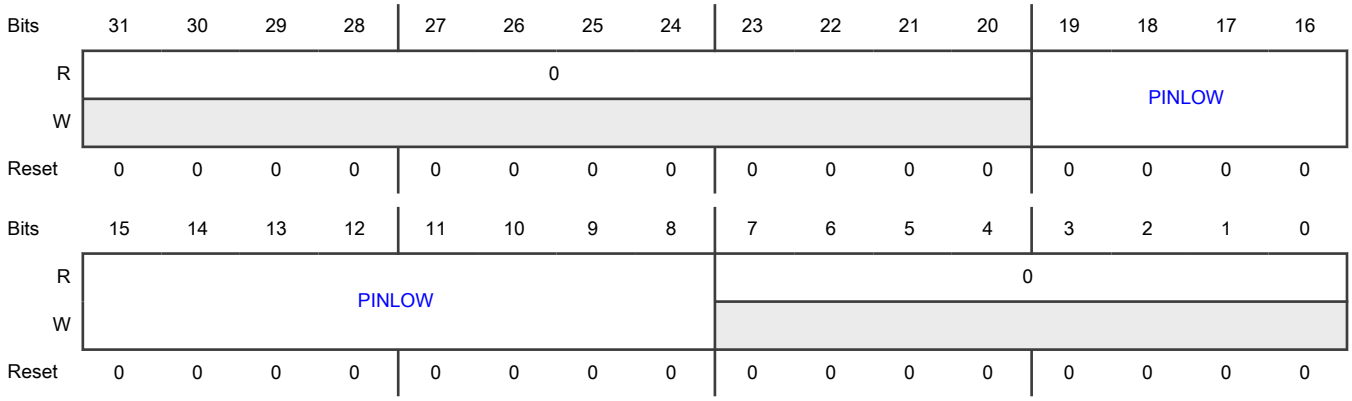
Register	Offset
MCFGR3	2Ch

Function

Configures the threshold value for the pin low timeout flag.

Write to this register only when the I2C controller is disabled.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-8 PINLOW	Pin Low Timeout Configures the threshold value, in clock cycles, that sets MSR[PLTF]. If SCL or SDA (selected by MCFGR1[TIMECFG]) is low for longer than (PINLOW × 256) cycles, MSR[PLTF] is set. When this field is 0, the pin low timeout feature is disabled.
7-0 —	Reserved

68.3.6.1.12 Controller Data Match (MDMR)

Offset

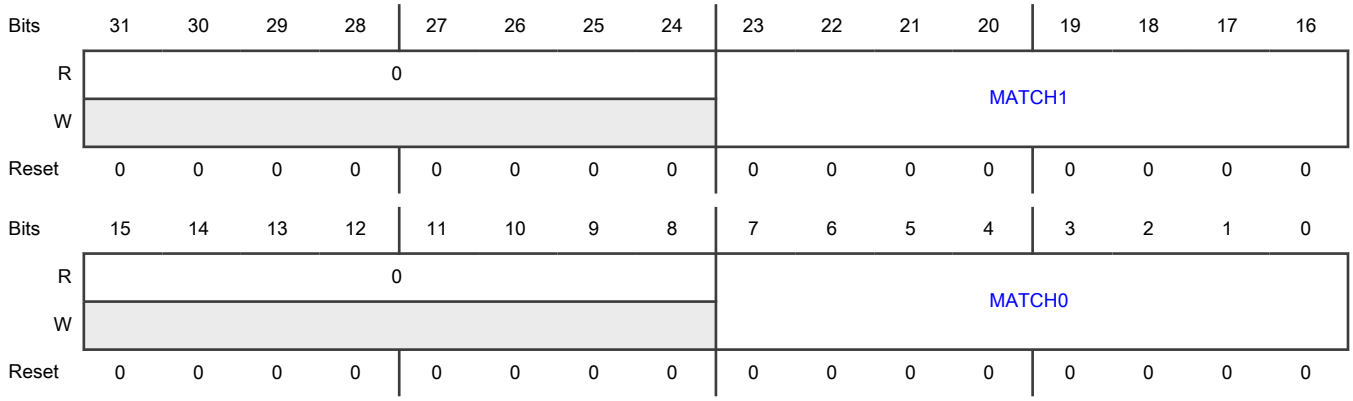
Register	Offset
MDMR	40h

Function

Contains data match values.

Write to this register only when the I2C controller is disabled or idle.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 MATCH1	Match 1 Value Specifies match 1 value that is compared to the received data when receive data match is enabled.
15-8 —	Reserved
7-0 MATCH0	Match 0 Value Specifies match 0 value that is compared to the received data when receive data match is enabled.

68.3.6.1.13 Controller Clock Configuration 0 (MCCR0)

Offset

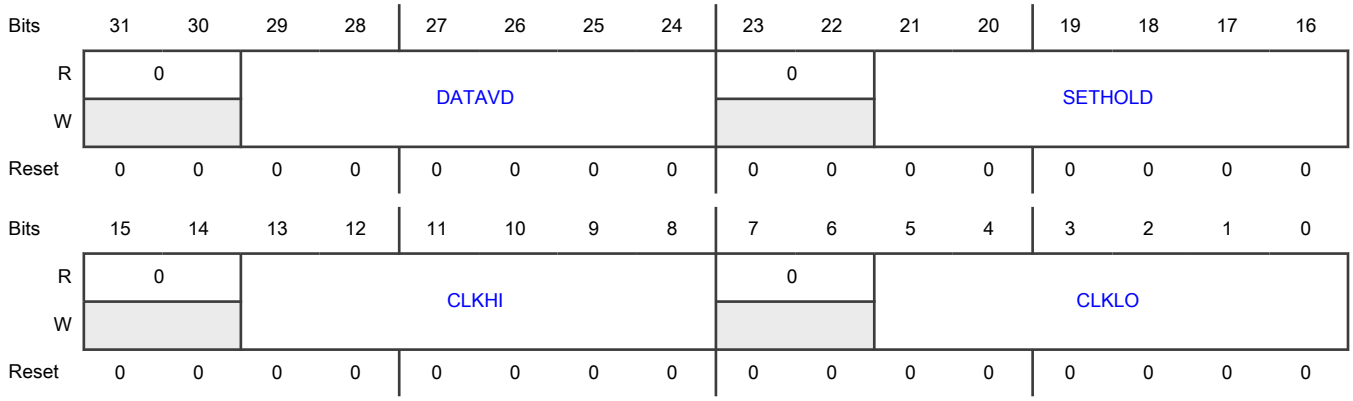
Register	Offset
MCCR0	48h

Function

Configures various clock controls.

You cannot make changes to this register when the I2C controller is enabled and is used for standard, fast, fast-mode plus, and ultra-fast transfers.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-24 DATAVD	Data Valid Delay Specifies the minimum number of cycles (minus one) used as the data hold time for SDA. This value must be less than the minimum SCL low period.
23-22 —	Reserved
21-16 SETHOLD	Setup Hold Delay Specifies the minimum number of cycles (minus one) used by the controller for these conditions: • Hold time for a Start • Setup and hold time for a repeated Start • Setup time for a Stop The setup time is extended by the time it takes to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.
15-14 —	Reserved
13-8 CLKHI	Clock High Period Specifies the minimum number of cycles (minus one) that the controller drives the SCL clock high. The SCL high time is extended by the time needed to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.
7-6 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
5-0 CLKLO	Clock Low Period Specifies the minimum number of cycles (minus one) that the controller drives the SCL clock low. This value is also used for the minimum bus free time between a Stop and a Start condition. This period is extended by the time needed to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.

68.3.6.1.14 Controller Clock Configuration 1 (MCCR1)

Offset

Register	Offset
MCCR1	50h

Function

Configures various clock controls.

You cannot makes changes to this register when the I2C controller is enabled and is used for HS mode transfers. The separate clock configuration for HS mode allows arbitration to take place in Fast mode (with timing configured by Controller Clock Configuration 0 (MCCR0)), before switching to HS mode (with timing configured by MCCR1).

Fields

Field	Function
31-30 —	Reserved
29-24 DATAVD	Data Valid Delay

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Specifies the minimum number of cycles (minus one) used as the data hold time for SDA. This value must be less than the minimum SCL low period.
23-22 —	Reserved
21-16 SETHOLD	Setup Hold Delay Specifies the minimum number of cycles (minus one) used by the controller for these conditions: • Hold time for a Start condition • Setup and hold time for a repeated Start condition • Setup time for a Stop condition The setup time is extended by the time needed to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.
15-14 —	Reserved
13-8 CLKHI	Clock High Period Specifies the minimum number of cycles (minus one) that the controller drives the SCL clock high. The SCL high time is extended by the time needed to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.
7-6 —	Reserved
5-0 CLKLO	Clock Low Period Specifies the minimum number of cycles (minus one) that the controller drives the SCL clock low. This value is also used for the minimum bus free time between a Stop and a Start condition. This period is extended by the time needed to detect a rising edge on the external SCL pin. Ignoring any additional board delay due to external loading, this time is equal to (2 + FILTSCL) ÷ 2^PRESCALE cycles.

68.3.6.1.15 Controller FIFO Control (MFCR)

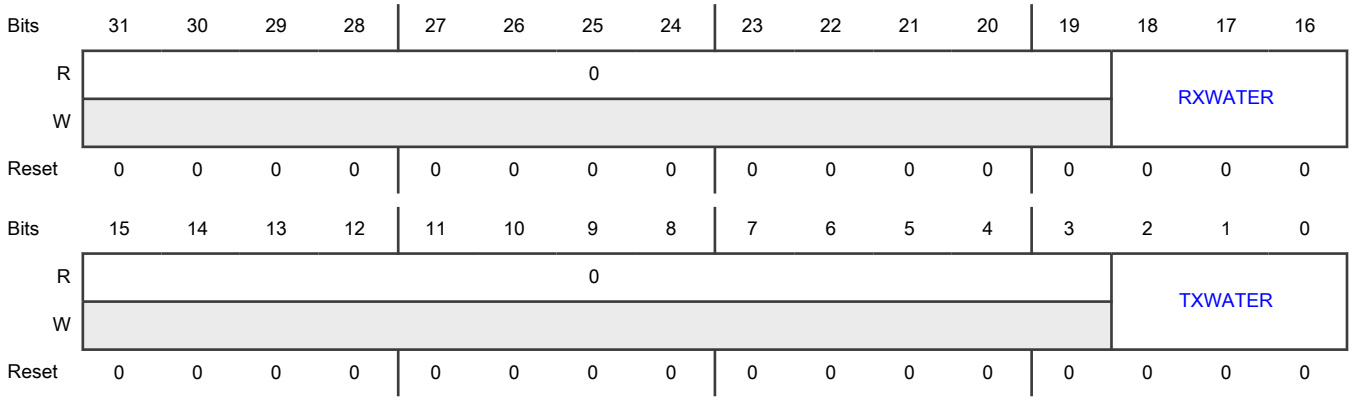
Offset

Register	Offset
MFCR	58h

Function

Controls the receive and transmit FIFO watermark values.

Diagram



Fields

Field	Function
31-19 —	Reserved
18-16 RXWATER	Receive FIFO Watermark Determines the watermark for setting SSR[RDF]. That flag is set when the number of words in the receive FIFO is greater than the value of this field. Writing a value equal to or greater than the FIFO size truncates the value.
15-3 —	Reserved
2-0 TXWATER	Transmit FIFO Watermark Determines the watermark for setting SSR[TDF]. That flag is set when the number of words in the transmit FIFO is equal or less than the value of this field. Writing a value equal to or greater than the FIFO size truncates the value.

68.3.6.1.16 Controller FIFO Status (MFSR)

Offset

Register	Offset
MFSR	5Ch

Function

Specifies the number of words in the transmit and receive FIFOs.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-20 —	Reserved
19-16 RXCOUNT	Receive FIFO Count Specifies the number of words in the receive FIFO.
15-4 —	Reserved
3-0 TXCOUNT	Transmit FIFO Count Specifies the number of words in the transmit FIFO.

68.3.6.1.17 Controller Transmit Data (MTDR)

Offset

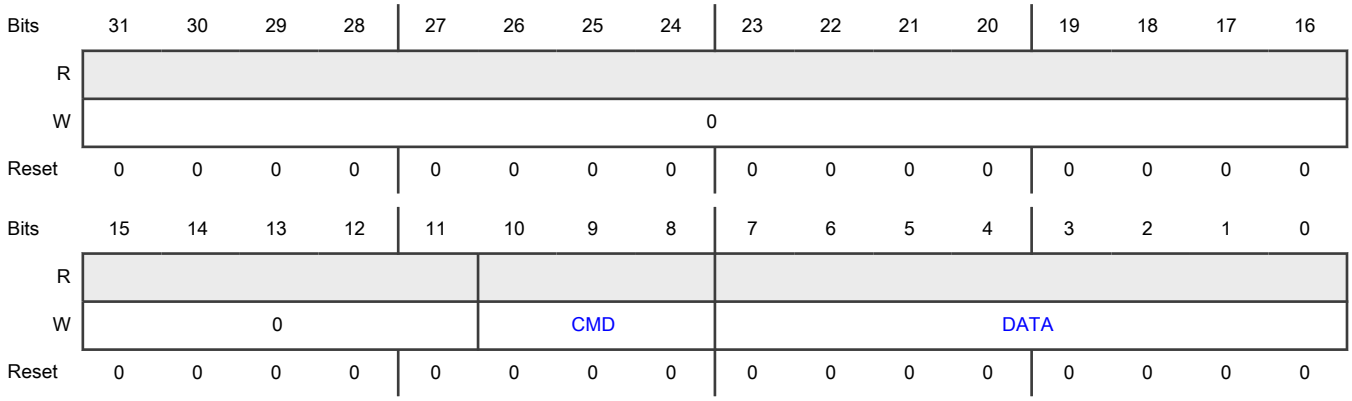
Register	Offset
MTDR	60h

Function

Configures transmit data:

- An 8-bit write to MTDR[CMD] is ignored and does not increment the FIFO write pointer.
- An 8-bit write to MTDR[DATA] zero-extends the value of MTDR[CMD] and increments the FIFO write pointer.
- A 16-bit or 32-bit write operation writes to both MTDR[CMD] and MTDR[DATA] and increments the FIFO write pointer.

Diagram



Fields

Field	Function
31-11 —	Reserved
10-8 CMD	Command Data Selects command transmitted by controller. 000b - Transmit the value in DATA[7:0] 001b - Receive (DATA[7:0] + 1) bytes. DATA[7:0] is used as a byte counter. Receive that many bytes and check each for a data match (if configured) before storing the received data in the receive FIFO. 010b - Generate Stop condition on I2C bus 011b - Receive and discard (DATA[7:0] + 1) bytes. DATA[7:0] is used as a byte counter. Receive that many bytes but do not check for a data match or store those bytes in the receive FIFO. 100b - Generate (repeated) Start on the I2C bus and transmit the address in DATA[7:0] 101b - Generate (repeated) Start on the I2C bus and transmit the address in DATA[7:0] (this transfer expects a NACK to be returned) 110b - Generate (repeated) Start on the I2C bus and transmit the address in DATA[7:0] using HS mode 111b - Generate (repeated) Start on the I2C bus and transmit the address in DATA[7:0] using HS mode (this transfer expects a NACK to be returned)
7-0 DATA	Transmit Data Contains data used by the commands listed in MTDR[CMD]. Performing an 8-bit write to this field zero-extends the value of MTDR[CMD].

68.3.6.1.18 Controller Receive Data (MRDR)

Offset

Register	Offset
MRDR	70h

Function

Contains the status of the receive FIFO and the data received by the I2C controller that has not been discarded.

Diagram

Fields

Field	Function
31-26 —	Reserved
25 BBF	Bus Busy Flag Indicates whether an I2C bus is idle or busy. 0b - Idle 1b - Busy
24 SBF	Target Busy Flag Indicates whether an I2C target is idle or busy. 0b - Idle 1b - Busy
23-16 —	Reserved
15 SARF	SMBus Alert Response Flag Indicates whether an SMBus alert response has been detected. You can clear this flag by reading Target Address Status (SASR). This flag cannot generate an asynchronous wakeup. 0b - Disabled or not detected 1b - Enabled and detected
14 GCF	General Call Flag Indicates whether a target has detected the general call address. You can clear this flag by reading Target Address Status (SASR). This flag cannot generate an asynchronous wakeup. 0b - General call address disabled or not detected 1b - General call address detected
13 AM1F	Address Match 1 Flag Indicates whether the received address matches the value in ADDR1, or it falls within the ADDR0 to ADDR1 range as configured by SCFGR1[ADDRCFG]. This flag is cleared by reading Target Address Status (SASR). This flag cannot generate an asynchronous wakeup. 0b - Matching address not received 1b - Matching address received
12	Address Match 0 Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
AM0F	Indicates whether the received address matches the ADDR0 field, as configured by SCFGR1[ADDRCFG]. This flag is cleared by reading Target Address Status (SASR). This flag cannot generate an asynchronous wakeup. 0b - ADDR0 matching address not received 1b - ADDR0 matching address received
11 FEF	FIFO Error Flag Indicates whether there is a FIFO error. This flag can only be set when clock stretching is disabled. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No FIFO error 1b - FIFO error When writing 0b - No effect 1b - Clear the flag
10 BEF	Bit Error Flag Indicates whether the LPI2C target has transmitted a logic 1 and detects a logic 0 on the I2C bus. The target ignores the rest of the transfer until the next (repeated) Start condition. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No bit error occurred 1b - Bit error occurred When writing 0b - No effect 1b - Clear the flag
9 SDF	Stop Detect Flag Indicates whether the LPI2C target detects a Stop condition, and if the LPI2C target matched the last address byte. When SCFGR1[SDCFG] = 1, this flag is set on any Stop condition. **NOTE** This field behaves differently for register reads and writes. When reading

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No Stop detected 1b - Stop detected When writing 0b - No effect 1b - Clear the flag
8 RSF	Repeated Start Flag Indicates whether the LPI2C target detects a repeated Start condition and if the LPI2C target matched the last address byte. When SCFGR1[RSCFG] = 1, this flag is set on any repeated Start condition. This flag is not set when the target first detects a Start condition. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No repeated Start detected 1b - Repeated Start detected When writing 0b - No effect 1b - Clear the flag
7-4 —	Reserved
3 TAF	Transmit ACK Flag Indicates whether a transmit ACK or NACK is required. You can clear this flag by writing to Target Transmit ACK (STAR). 0b - Not required 1b - Required
2 AVF	Address Valid Flag Indicates whether the contents of Target Address Status (SASR) are valid. You can clear this flag by reading SASR. When SCFGR1[RXCFG] = 1, this flag is also cleared by reading Target Receive Data (SRDR). 0b - Not valid 1b - Valid
1 RDF	Receive Data Flag Indicates whether receive data is ready. You can clear this flag by reading Target Receive Data (SRDR). When SCFGR1[RXCFG] = 1, this flag is not cleared when reading Target Receive Data (SRDR) if SSR[AVF] = 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not ready 1b - Ready
0 TDF	Transmit Data Flag Indicates whether transmit data has been requested. This flag is cleared by writing to Target Transmit Data (STDR). When SCFGR1[TXCFG] = 0, if a NACK, repeated Start, or Stop condition is detected, this flag is also cleared. 0b - Transmit data not requested 1b - Transmit data is requested

68.3.6.1.22 Target Interrupt Enable (SIER)

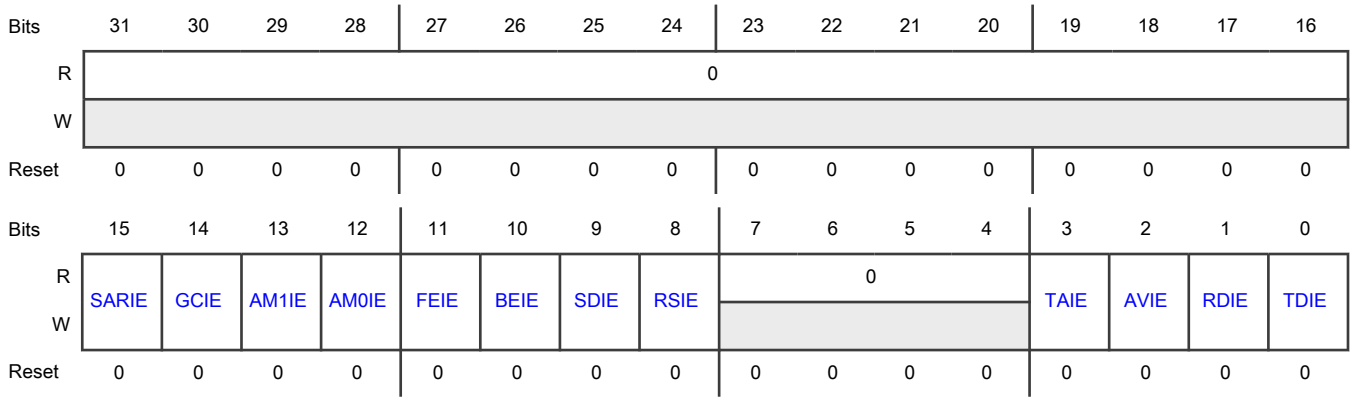
Diagram



Fields

Field	Function
31-2 —	Reserved
1 RDACK	Read Acknowledge Flag Indicates whether a Start then Stop sequence with one SCL pulse between them acknowledged the read request while SCFGR0[RDREQ] = 1. You can clear this flag by writing 0 to SCFGR0[RDREQ]. 0b - Read Request not acknowledged 1b - Read Request acknowledged
0 RDREQ	Read Request Enables read request. When the I2C bus is idle, writing 1 to this field causes the LPI2C target to drive SDA low, triggering a Start condition. The LPI2C target releases SDA on the next falling edge of SCL or when you write 0 to this field. To initiate a second read request (for example, following I2C bus activity that did not acknowledge the request), write 0 then 1 to this field. When the I2C bus is busy, writing to this register always writes 0 to this field. 0b - Disable 1b - Enable

68.3.6.1.25 Target Configuration 1 (SCFGR1)

Offset

Register	Offset
SCFGR1	124h

Function

Configures various aspects of the target.

Write to this register only when the I2C target is disabled.

NOTE

Each module instance supports a different number of registers.

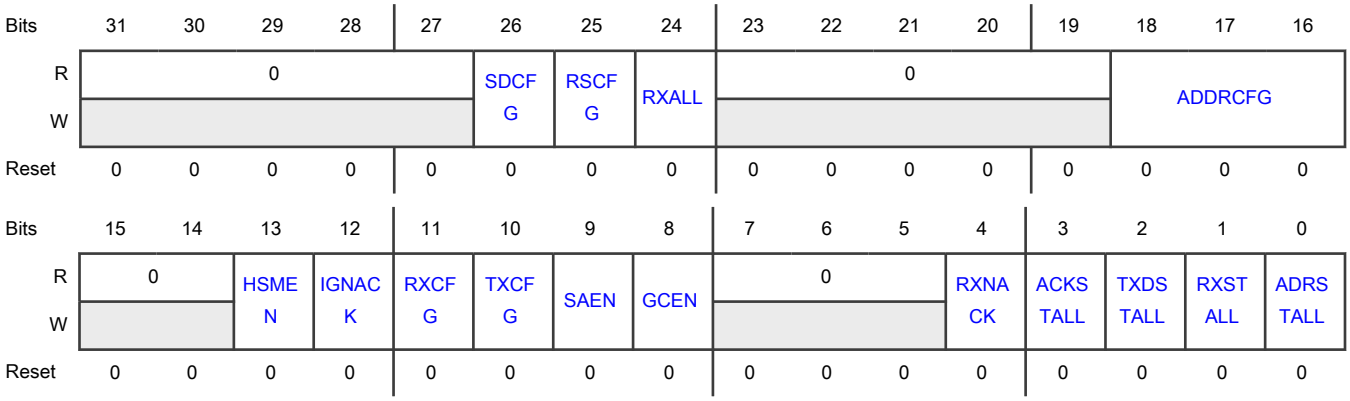
Diagram



Fields

Field	Function
31-27 —	Reserved
26 SDCFG	Stop Detect Configuration Configures the conditions that set SSR[SDF]. 0b - Any Stop condition following an address match 1b - Any Stop condition
25 RSCFG	Repeated Start Configuration Configures the conditions that set SSR[RSF]. 0b - Any repeated Start condition following an address match 1b - Any repeated Start condition
24 RXALL	Receive All Enables receive-all functionality. When enabled, the LPI2C target stores all addresses on the I2C bus in Target Address Status (SASR) and all data on the I2C bus in Target Receive Data (SRDR). However, the LPI2C target does not drive SDA (for ACK or target-transmit transfer) unless there is an address match. The LPI2C target can drive SCL if clock stretching is enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field is 1, the LPI2C target only supports 7-bit addressing modes (you must configure SCFGR1[ADDRCFG] for 7-bit address match). Software can support 10-bit addresses, however. The first byte of a 10-bit address is saved to Target Address Match (SAMR). The second byte is saved as the first data byte in Target Receive Data (SRDR). Use this field to aid debugging of the I2C bus by saving all data on the bus without altering the state of the bus. When this field is 1, it is recommended to also write 1 to SCFGR1[RSCFG] and SCFGR1[SDCFG] so you can track the full state of the I2C bus. 0b - Disable 1b - Enable
23-19 —	Reserved
18-16 ADDRCFG	Address Configuration Configures the condition that causes an address to match. 000b - Address match 0 (7-bit) 001b - Address match 0 (10-bit) 010b - Address match 0 (7-bit) or address match 1 (7-bit) 011b - Address match 0 (10-bit) or address match 1 (10-bit) 100b - Address match 0 (7-bit) or address match 1 (10-bit) 101b - Address match 0 (10-bit) or address match 1 (7-bit) 110b - From address match 0 (7-bit) to address match 1 (7-bit) 111b - From address match 0 (10-bit) to address match 1 (10-bit)
15-14 —	Reserved
13 HSMEN	HS Mode Enable Enables detection of the HS mode controller code of target address 0000_1XX, but does not cause an address match on this code. When this field is 1 and any HS mode controller code is detected, SCR[FILTEN] and SCFGR1[ACKSTALL] are ignored until the next Stop condition is detected. 0b - Disable 1b - Enable
12 IGNACK	Ignore NACK Determines whether the target ends transfer when a NACK condition is detected. When this field is 1, the LPI2C target continues transfers after a NACK is detected. This field is required to be 1 in Ultra-Fast mode. 0b - End transfer on NACK 1b - Do not end transfer on NACK

Table continues on the next page...

Table continued from the previous page...

Field	Function
11 RXCFG	Receive Data Configuration Configures which data is returned and which flags are cleared when reading Target Receive Data (SRDR). When this field is 0, reading SRDR returns received data and clears SSR[RDF]. When this field is 1, reading SRDR: • Returns the value of Target Address Status (SASR) and clears SSR[AVF] when SSR[AVF] is set. • Returns received data and clears SSR[RDF] when SSR[AVF] is not set. 0b - Return received data, clear SSR[RDF] 1b - Return SASR and clear SSR[AVF] when SSR[AVF] is set, return received data and clear SSR[RDF] when SSR[AFV] is not set
10 TXCFG	Transmit Flag Configuration Determines which conditions set SSR[TDF]. This field always becomes 1 before a NACK is detected at the end of a target-transmit transfer. This change can cause an extra word to be written to the transmit data FIFO. When this field is 0, Target Transmit Data (STDR) is automatically emptied when a target-transmit transfer is detected. SSR[TDF] is set when a target-transmit transfer is detected, and SSR[TDF] is cleared at the end of the target-transmit transfer. When this field is 1, SSR[TDF] is set when STDR is empty, and SSR[TDF] is cleared when STDR is full. This setting allows STDR to be filled before a target-transmit transfer is detected. However, it can cause STDR to be written before a NACK is detected on the last byte of a target-transmit transfer. 0b - SSR[TDF] is set only during a target-transmit transfer when STDR is empty 1b - SSR[TDF] is set whenever STDR is empty
9 SAEN	SMBus Alert Enable Enables a match on an SMBus alert. 0b - Disable 1b - Enable
8 GCEN	General Call Enable Enables a general call address. 0b - Disable 1b - Enable
7-5 —	Reserved
4 RXNACK	Receive NACK Determines whether to override the setting of STAR[TXNACK] when the LPI2C receives a matching address during an overrun.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When this field is 1, the LPI2C target responds with a NACK under the following conditions: • SSR[AVF] would be set due to matching an address, but that flag is already 1 (address overrun). • SSR[RDF] would be set due to receiving data, but that flag is already 1 (receive data overrun). 0b - ACK or NACK always determined by STAR[TXNACK] 1b - NACK always generated on address overrun or receive data overrun, otherwise ACK or NACK is determined by STAR[TXNACK]
3 ACKSTALL	ACK SCL Stall Enables SCL clock stretching during target-transmit address bytes and target-receiver address and data bytes, so you can write to Target Transmit ACK (STAR) before the ACK or NACK is transmitted. Clock stretching occurs when transmitting the ninth bit, and is therefore not compatible with HS mode. If this field is 1: • You do not need to write 1 to SCFGR1[RXSTALL] or SCFGR1[ADRSTALL]. • When there is an address match on the first byte of a 10-bit address, SSR[AVF] is set, allowing you to read the received address before writing to Target Transmit ACK (STAR). 0b - Disable 1b - Enable
2 TXDSTALL	Transmit Data SCL Stall Enables SCL clock stretching when SSR[TDF] = 1 during a target-transmit transfer. Clock stretching occurs following the ninth bit, and is therefore compatible with HS mode. 0b - Disable 1b - Enable
1 RXSTALL	RX SCL Stall Enables SCL clock stretching when SSR[RDF] = 1 during a target-receive transfer. Clock stretching occurs following the ninth bit, and is therefore compatible with HS mode. 0b - Disable 1b - Enable
0 ADRSTALL	Address SCL Stall Enables SCL clock stretching when SSR[AVF] = 1. Clock stretching only occurs following the ninth bit, and is therefore compatible with HS mode. 0b - Disable 1b - Enable

68.3.6.1.26 Target Configuration 2 (SCFGR2)

Offset

Register	Offset
SCFGR2	128h

Function

Configures data valid delay, clock hold time, and glitch filters for SDA and SCL.

Write to this register only when the I2C target is disabled.

NOTE

Each module instance supports a different number of registers.

Fields

Field	Function
31-28 —	Reserved
27-24 FILTSDA	Glitch Filter SDA Configures the I2C target digital glitch filters for SDA input. Writing 0 to this field disables the glitch filter. Glitches equal to or less than the number of cycles defined by this field are filtered out and ignored. The latency through the glitch filter is equal to the number of cycles defined by this field + 3. The latency must be configured to be less than the minimum SCL low or high period. MCFGR1[PRESCALE] does not affect the glitch filter cycle count, and the glitch filter cycle count is disabled in HS mode.
23-20 —	Reserved
19-16 FILTSCL	Glitch Filter SCL Configures the I2C target digital glitch filters for SCL input. Writing 0 to this field disables the glitch filter. Glitches equal to or less than the number of cycles defined by this field are filtered out and ignored.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The latency through the glitch filter is equal to the number of cycles defined by this field + 3. The latency must be configured to be less than the minimum SCL low or high period. MCFGR1[PRESCALE] does not affect the glitch filter cycle count, and the glitch filter cycle count is disabled in HS mode.
15-14 —	Reserved
13-8 DATAVD	Data Valid Delay Configures the SDA data valid delay time for the I2C target, which is equal to FILTSCL + DATAVD + 3 cycles. The data valid delay must be configured to be less than the minimum SCL low period. MCFGR1[PRESCALE] does not affect the I2C target data valid delay time, and the I2C target data valid delay time is disabled in HS mode.
7-4 —	Reserved
3-0 CLKHOLD	Clock Hold Time Configures the minimum clock hold time for the I2C target, when clock stretching is enabled. The minimum hold time is equal to the number of cycles defined by this field + 3. MCFGR1[PRESCALE] does not affect the I2C target clock hold time, and the I2C target clock hold time is disabled in HS mode.

68.3.6.1.27 Target Address Match (SAMR)

Offset

Register	Offset
SAMR	140h

Function

Contains address values for received target match comparison.

Write to this register only when the I2C target is disabled.

NOTE

Each module instance supports a different number of registers.

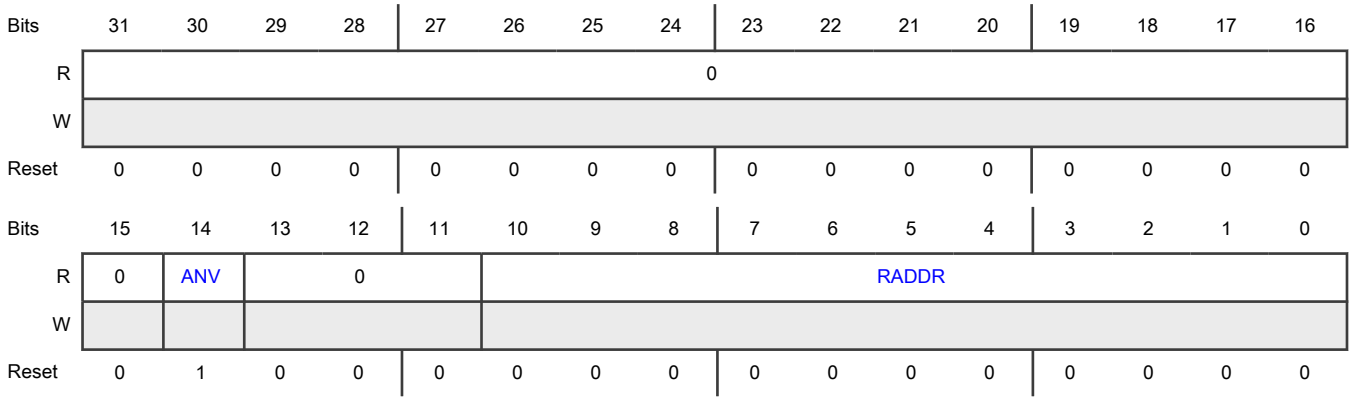
LPI2C20	SASR	—

Diagram



Fields

Field	Function
31-15 —	Reserved
14 ANV	Address Not Valid Indicates whether SASR[RADDR] is valid. 0b - Valid 1b - Not valid
13-11 —	Reserved
10-0 RADDR	Received Address Contains the received address. Updates whenever SSR[AM0F] or SSR[AM1F] is set. Reading Target Address Status (SASR) clears SSR[AM0F] and SSR[AM1F]. In 7-bit mode, the address byte is stored in RADDR[7:0]. In 10-bit mode, the first address byte is {11110, RADDR[10:9], RADDR[0]} and the second address byte is RADDR[8:1]. The Read-or-Write bit is therefore always stored in RADDR[0]. When SCFGR1[ACKSTALL] = 1, if the first address byte matches in 10-bit mode, the first address byte is stored in RADDR[7:0] so you can read this field before writing the Transmit ACK. If the second address byte matches, this field is then updated with the full 10-bit address.

68.3.6.1.29 Target Transmit ACK (STAR)

Offset

Register	Offset
STAR	154h

Function

Configures choice of ACK or NACK on each received word.

You can write to this register only when SCFGR1[ACKSTALL] = 1.

SCFGR1[ACKSTALL] enables clock stretching during the ACK-or-NACK bit slot. During this time, you can write to this register.

The logic ensures that the clock stretching continues for at least one bus clock cycle after this register is updated.

This clock stretching time can be extended via SCFGR2[CLKHOLD].

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported

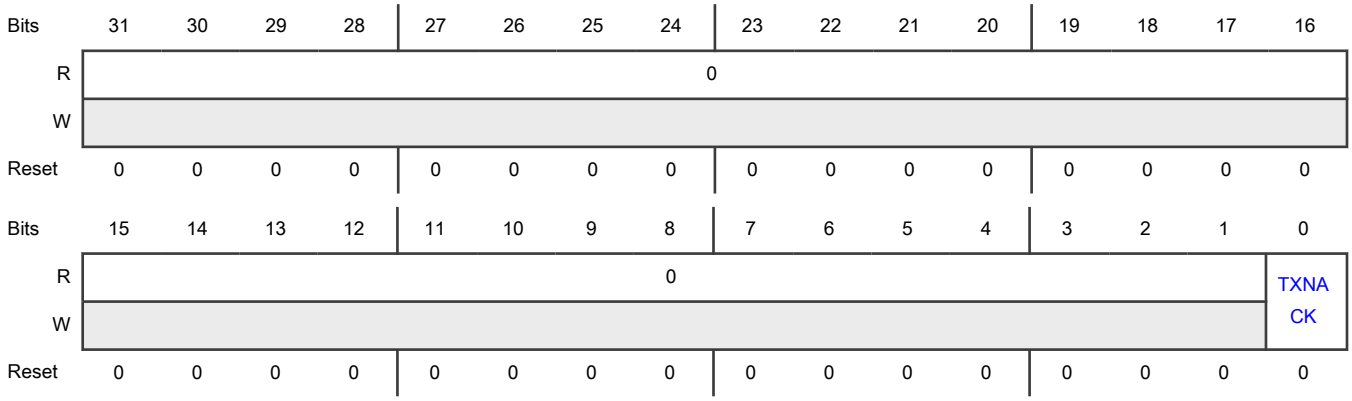
LPI2C19	STAR	—
LPI2C20	STAR	—

Diagram



Fields

Field	Function
31-1 —	Reserved
0 TXNACK	Transmit NACK Selects whether transmit ACK (logic 0) or NACK (logic 1) is returned on the bus by the I2C target after receiving each word. • When SCFGR1[ACKSTALL] = 1, a transmit NACK signal must be written once for each matching address byte and each received word. SCFGR1[ACKSTALL] must be 1, because that setting stalls the data transfer until software reads the received word (and determines whether to respond with an ACK or NACK). • To configure the default (ACK or NACK), you can write to this field when LPI2C target is disabled or idle. 0b - Transmit ACK 1b - Transmit NACK

68.3.6.1.30 Target Transmit Data (STDR)

Offset

Register	Offset
STDR	160h

Function

Contains the I2C target data to transmit.

Clock stretching (enabled or disabled) affects when the transmit data is transferred. SCFGR1[TXDSTALL] enables clock stretching during the first data bit of a target-transmit transfer.

If clock stretching is enabled (SCFGR1[TXDSTALL] = 1), the transmit data transfer is stalled until this register is updated. Clock stretching is extended by at least 1 bus clock cycle after this register is updated. Clock stretching can be delayed further by using SCFGR2[CLKHOLD].

If clock stretching is disabled (SCFGR1[TXDSTALL] = 0), the transmit data must be written before the start of the target-transmit transfer, otherwise SSR[FEF] is set.

NOTE

Each module instance supports a different number of registers.

7-0 DATA	Receive Data Contains data received by the LPI2C target. When both SCFGR1[RXCFG] and SSR[AVF] are 1, bits [7:0] of SASR[RADDR] are returned.

68.3.6.1.33 Controller Transmit Command Burst (MTCBR0 - MTCBR127)

Offset

For n = 0 to 127:

Register	Offset
MTCBRn	200h + (n × 4h)

Function

Contains transmit Command and Data fields to support burst transfers.

Is an alias of the Controller Transmit Data Register designed to support incrementing burst transfers to the transmit FIFO by a DMA controller using aligned 8-bit, 16-bit, or 32-bit writes. The size of the Controller Transmit Data Burst Register is 512-bytes.

- An aligned 32-bit write in this region pushes one entry into the transmit FIFO.
- An aligned 16-bit write in this region to MTCBRn[15:0] pushes one entry into the transmit FIFO.
- An 8-bit write in this region to MTCBRn[7:0] updates DATA[7:0], but does not push the data into the transmit FIFO.
- An 8-bit write in this region to MTCBRn[15:8] pushes the data written to CMD[2:0] plus the previously written DATA[7:0] into the transmit FIFO.
- An 8-bit or 16-bit write in this region to MTXBRn[31:16] is ignored.

68.3.6.1.34 Transmit Data Burst (MTDBR0 - MTDBR252)

Offset

For n = 0 to 252:

Register	Offset
MTDBRn	400h + (n × 4h)

Function

Contains transmit Data fields to support burst transfers.

Is an alias of the Transmit Data Register designed to support incrementing burst transfers to the transmit FIFO by a DMA controller using 8-bit, 16-bit, or 32-bit writes. The CMD field is always zero-extended for transmit data. The size of the Transmit Data Burst Register is 1012 bytes.

- An aligned 32-bit write in this region pushes four zero-extended DATA entries into the transmit FIFO (DATA0 byte first). Note that the register access is extended by 3 wait states.
- An aligned 16-bit write in this region to either half of a 32-bit word pushes two zero-extended DATA entries into the transmit FIFO (DATA0 or DATA2 first). Note that the register access is extended by 1 wait state.
- An 8-bit write in this region pushes one zero-extended DATA entry into the transmit FIFO.

68.4 Low Power Serial Peripheral Interface (LPSPI)

68.4.1 Overview

LPSPI provides an efficient interface (either as a controller or peripheral) to an SPI bus, which is a synchronous serial communication interface used in embedded systems. It is typically used to perform short distance communications between microcontrollers and peripheral devices, on printed circuit boards. Typical applications include interfacing with secure digital cards and LCD displays.

NOTE

The terminology in this chapter has been updated to align with NXP's inclusive language standards, as shown in the table below.

Table 652. Updated terms

Updated term	Deprecated term
Controller	Master
Peripheral	Slave

68.4.1.1 Block diagram

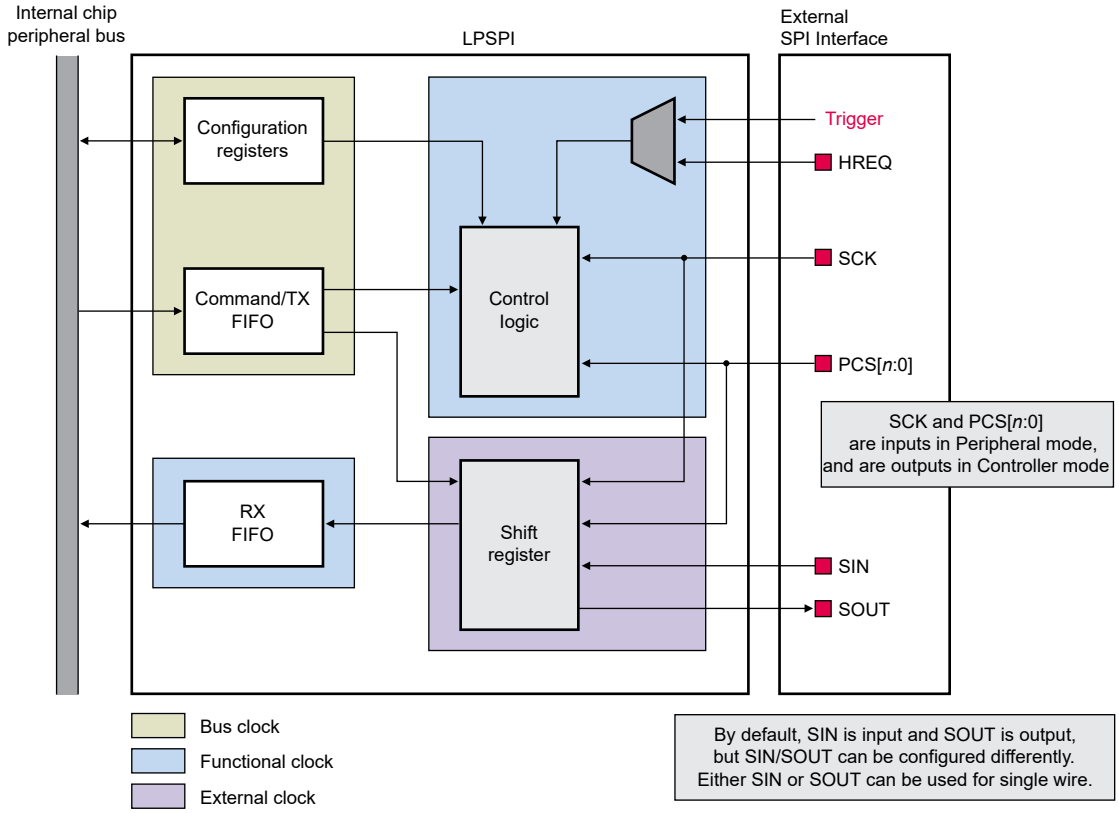

Figure 285. Block diagram

68.4.1.2 Features

- Minimal CPU overhead, with DMA transmit and receive requests supporting FIFO register accesses
- Operation continues in Stop mode, if configured to do so and an appropriate clock is available
- Support available for 32-bit word size
- Configurable clock polarity and phase
- Support available for 4 peripheral chip selects in Controller mode
- Support available for Peripheral mode
- 8-word transmit and command FIFO
- 8-word receive FIFO
- Flexible timing parameters in Controller mode, including SCK frequency and duty cycle, and delays between PCS and SCK edges
- Continuous transfer option to keep PCS asserted across multiple frames
- Full-duplex transfers that support 1-bit transmit and receive on each clock edge
- Half-duplex transfers that support:
  - 1-bit transmit or receive on each clock edge
  - 2-bit transmit or receive on each clock edge
  - 4-bit transmit or receive on each clock edge

- Option to use host request to control the start of an SPI bus transfer
- Receive data match logic that discards nonmatching data and interrupt on data match

68.4.2 Functional description

68.4.2.1 Controller mode

68.4.2.1.1 Transmit and command FIFO commands

The transmit and command FIFO is a combined FIFO that includes both transmit data words and command words. You store:

- Transmit data words in the transmit and command FIFO, by writing to Transmit Data (TDR).
- Command words in the transmit and command FIFO, by writing to Transmit Command (TCR).

When a command word is at the top of the transmit and command FIFO, the actions that can occur depend on whether LPSPI is busy or between frames (see TCR[CONT] and TCR[CONTC]). See Table 653 for conditions and possible corresponding actions when a command word is at the top of the transmit and command FIFO.

Table 653. Possible actions when a command word is at the top of the transmit and command FIFO

Condition	Action
LPSPI is enabled and idle.	The command word is pulled from the FIFO, and this command word controls all subsequent transfers.
LPSPI is busy and TCR[CONTC] is 0.	The SPI frame completes at the end of the existing word, ignoring TCR[FRAMESZ]. The command word is then pulled from the FIFO and that command word controls all subsequent transfers (or until the next update to the command word). Note that a command word with TCR[CONTC] = 0 always terminates the existing transfer regardless of the previous TCR[CONT] value.
LPSPI is busy; the existing TCR[CONT] value is 1 and the new TCR[CONTC] value is 1.	The command word must be updated at the frame boundary. The command word is pulled from the FIFO during the last SCK pulse of the existing frame (based on the value of FRAMESZ), and the frame continues using the new command value for the rest of the frame (or until the next update to the command word). When TCR[CONTC] = 1, only the lower 24 bits of the command word are updated. If the command word is updated at a word boundary, then the transfer halts (stops) after that word. TCR[CONTC] is ignored when not at a frame boundary, so the frame ends prematurely.

TCR[CONT] = 1 keeps PCS asserted at end of frame, allowing the transfer to continue.

TCR[CONTC] = 1 specifies that this command word must not terminate the existing frame, and the transfer can continue using the new command word.

TCR[CONTC] = 1 is restricted in the sense that the new command must load on a frame boundary, and the only way for a transfer to continue from a frame boundary is when the previous command has TCR[CONT] = 1.

You can read the current state of the existing command word from Transmit Command (TCR). It requires at least three LPSPI functional clock cycles for Transmit Command (TCR) to update after you write to it (assuming an empty FIFO), and LPSPI must be enabled (CR[MEN] = 1).

Writing to Transmit Command (TCR) does not initiate an SPI bus transfer, unless TCR[TXMSK] = 1. When TCR[TXMSK] = 1, a new command word is not loaded until the end of the existing frame (based on the value of TCR[FRAMESZ]); at the end of the transfer, TCR[TXMSK] transitions to 0.

In Controller mode, the LPSPI command word in Transmit Command (TCR) controls SPI attributes based on the selections in register fields. See Table 654 for TCR fields and associated functionality related to data transfer.

Table 654. Command word in Controller mode

Transmit Command (TCR)		Description	Can this field be modified during a data transfer?
Field	Name		
CPOL	Clock polarity	Specifies the polarity of the SCK pin. Any change of CPOL value causes a transition on the SCK pin.	N
CPHA	Clock phase	Specifies the clock phase of the transfer.	N
PRESCALE	Prescaler value	Specifies a prescaler used to divide the LPSPI functional clock, to generate the timing parameters of the SPI bus transfer. Changing PRESCALE in conjunction with PCS enables LPSPI to connect to different peripheral devices at different frequencies.	N
PCS	Peripheral chip select	Specifies which PCS pin asserts for the transfer; the polarity of PCS is static and specified by CFGR1[PCSPOL]. If CFGR1[PCSCFG] = 1, do not select PCS[3:2].	N
LSBF	LSB first	Specifies whether LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.	Y
BYSW	Byte swap	Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing with devices that organize data as big-endian.	Y
CONT	Continuous transfer	Configures LPSPI for a continuous transfer that keeps PCS asserted between frames (as specified by FRAMESZ). You must write a new command word to cause PCS to negate. Also, this field supports changing the command word at frame size boundaries.	Y
CONTC	Continuing command	Indicates that this is a new command word for the existing continuous transfer. When CONTC = 1, the command word must only be written to the transmit and command FIFO on a frame boundary.	Y
RXMSK	Receive data mask	Masks the receive data and does not store the masked receive data in the receive FIFO or perform receive data matching. This option is useful for half-duplex transfers or to specify which fields are compared during receive data matching.	Y
TXMSK	Transmit data mask	Masks the transmit data; masked transmit data is not pulled from the transmit FIFO, and the output data pin is 3-stated (unless otherwise configured by CFGR1[OUTCFG]). This option is useful for half-duplex transfers.	Y
WIDTH	Transfer width	Specifies the number of bits shifted on each SCK pulse: • 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats. • 2-bit and 4-bit half-duplex transfers are useful for interfacing with QuadSPI memory devices, and either TXMSK or RXMSK must also be 1.	Y
FRAMESZ	Frame size	Configures the frame size in number of bits equal to (FRAMESZ + 1):	Y

Table continues on the next page...

Table 654. Command word in Controller mode (continued)

Transmit Command (TCR)		Description	Can this field be modified during a data transfer?
Field	Name		
		• The minimum frame size is 8 bits. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contains the remaining bits. For example, a 72-bit transfer consists of three words: the first and second words are 32 bits, and the third word is 8 bits.	

68.4.2.1.1.1 SPI bus transfers

LPSPI initiates an SPI bus transfer when all these conditions are true:

- Data is written to the transmit FIFO.
- The HREQ pin is asserted (or the HREQ function is disabled).
- LPSPI is enabled.

To perform the SPI bus transfer, LPSPI uses the attributes configured in Transmit Command (TCR) and the timing parameters defined in Clock Configuration (CCR).

The SPI bus transfer ends after the number of bits indicated by the value of FRAMESZ have been transferred (provided CONT = 0), or at the end of a word when a new transmit command word is at the top of the transmit and command FIFO. When LPSPI is disabled, the SPI bus transfers end after the transmit FIFO is empty and LPSPI is idle.

The HREQ input is only checked when PCS is negated.

68.4.2.1.1.2 Circular FIFO

The transmit and command FIFO supports a circular FIFO feature. This feature enables the LPSPI controller to (periodically) repeat a short data transfer that fits within the transmit and command FIFO, without requiring additional FIFO accesses. When the circular FIFO is enabled (CFGR0[CIRFIFO] = 1), the current state of the FIFO read pointer is saved and the status flags are not updated. After the FIFO is empty and LPSPI is idle, the FIFO read pointer is restored with the saved version, so the contents of the transmit and command FIFO are not permanently pulled from the FIFO when Circular FIFO mode is enabled.

68.4.2.1.2 Receive FIFO and data match

The receive FIFO stores received data during SPI bus transfers. When TCR[RXMSK] = 1, the received data is discarded instead of being stored in the receive FIFO:

- Received data is written to the receive FIFO when the last bit of the word is sampled.
- If the transmit FIFO is empty during a multiple-word or continuous transfer, then the receive data is written to the receive FIFO before the transfer stalls (assuming CFGR1[NOSTALL] = 0) while waiting for new transmit data or for a command word to be written.

LPSPI provides a receive data match function that can match received data against one of the two words in DMR0 and DMR1, or against a masked data word. You can also configure the received data match function to compare only the first one or two received data words since the start of the frame:

- Received data that is already discarded because of TCR[RXMSK] cannot cause the data match flag to set, and delays the receive data match on the first received data word, until all discarded data is received.

- You can configure the receive data match function to discard all received data until a data match is detected, using CFGR0[RDMO].
- After a receive data match, to allow all subsequent data to be received, write 0 to CFGR0[RDMO], and then write 0 to SR[DMF].

68.4.2.1.3 Timing parameters

The timing parameters that are used for all SPI bus transfers are relative to the LPSPI functional clock divided by the selection specified in TCR[PRESCALE]. Although you can only change Clock Configuration (CCR) when LPSPI is disabled (CR[MEN] = 0), to support interfacing with different peripheral devices at different frequencies, you can change the TCR[PRESCALE] selection between SPI bus transfers by using Transmit Command (TCR).

NOTE

The minimum value shown in Table 655 is the minimum counter value, but the values of Clock Configuration (CCR) must also satisfy the data sheet specs based on the LPSPI functional clock frequency and prescaler value.

Table 655. Timing parameters

Clock Configuration (CCR) Clock Configuration 1 (CCR1)		Description	Minimum value	Maximum value
Field	Name			
SCKSET	SCK setup phase	Configures the SCK setup phase to (SCKSET + 1) cycles. The setup phase is the SCK high period when either CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. Otherwise, it is the SCK low period. The SCK period is defined as (SCKSET + SCKHLD + 2) and the duty cycle is the difference between SCKSET and SCKHLD.	0 (1 cycle)	255 (256 cycles)
SCKHLD	SCK hold phase	Configures the SCK hold phase to (SCKHLD + 1) cycles. The hold phase is the SCK low period when either CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. Otherwise, it is the SCK high period. The SCK period is defined as (SCKSET + SCKHLD + 2) and the duty cycle is the difference between SCKSET and SCKHLD.	0 (1 cycle)	255 (256 cycles)
PCSPCS	PCS-to-PCS delay	Configures the minimum delay between PCS negation and the next PCS assertion to (PCSPCS + PCSPCS + 2) cycles. When the command word is updated between transfers, there is a minimum of (PCSPCS + 1) cycles between the command word update and any change on PCS pins.	0 (2 cycles)	255 (512 cycles)
SCKSCK	SCK-to-SCK delay	Configures the delay during a continuous transfer between the last SCK edge of a frame and the first SCK edge of the continuing frame to (SCKSCK + 1) cycles. This is useful when the external peripheral requires a large delay between different words of an SPI bus transfer.	0 (1 cycle)	255 (256 cycles)

Table continues on the next page...

Table 655. Timing parameters (continued)

Clock Configuration (CCR) Clock Configuration 1 (CCR1)		Description	Minimum value	Maximum value
Field	Name			
PCSSCK	PCS-to-SCK delay	Configures the minimum delay between PCS assertion and the first SCK edge to (PCSSCK + 1) cycles.	0 (1 cycle)	255 (256 cycles)
SCKPCS	SCK-to-PCS delay	Configures the minimum delay between the last SCK edge and the PCS negation to (SCKPCS + 1) cycles.	0 (1 cycle)	255 (256 cycles)

Figure 286 shows the timing settings controlled by:

- TCR[CPHA]
- TCR[CPOL]
- CCR[SCKPCS]
- CCR[PCSSCK]
- CCR1[SCKSET]
- CCR1[SCKHLD]

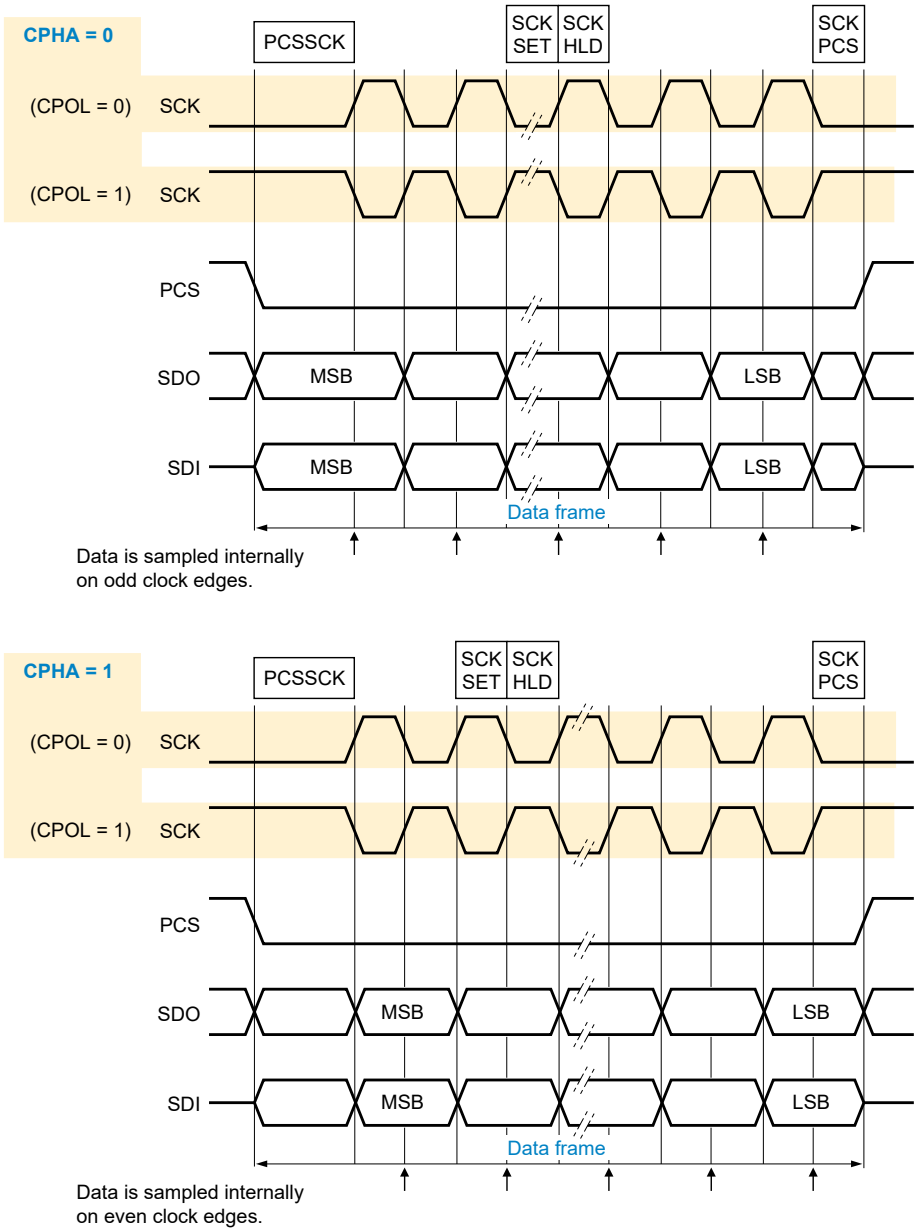

Figure 286. Clock phase (TCR[CPHA]) timing diagram example

To configure for a baud rate of 10 MHz with 50/50 duty cycle and with a functional clock frequency of 100 MHz, use the following settings:

- CCR1[SCKSET] = 0x4 (5 cycles)
- CCR1[SCKHLD] = 0x4 (5 cycles)
- CCR1[PCSPCS] = 0x8 (10 cycles)
- CCR1[SCKSCK] = 0x4 (5 cycles)
- CRR[PCSSCK] = 0x4 (5 cycles)
- CRR[SCKPCS] = 0x4 (5 cycles)
- TCR[PRESCALE] = 0x0 (divide by 1)

68.4.2.1.4 Pin configuration

Following are the pin configuration settings for half-duplex transfers:

- To swap directions or to support half-duplex transfers on the same pin, you can configure the SIN and SOUT pins using CFGR1[PINCFG].
- To specify whether an output data pin (SOUT, for example) 3-states when PCS is negated, or if the output data pin retains the last value, use CFGR1[OUTCFG].
- When configuring half-duplex transfers, you must configure the output data pins to 3-state when PCS is negated (CFGR1[OUTCFG] = 1).
- When performing half-duplex 2-bit transfers, you can write any value to CFGR1[PCSCFG].
- When performing half-duplex 4-bit transfers, you must write 1h to CFGR1[PCSCFG].

68.4.2.1.5 Clock loopback

Configure the LPSPI controller to use one of the following clocks to sample the input data:

- The SCK output clock
- A delayed version of the SCK output clock

The delayed version of the SCK is chosen by the SCK pin output delay, plus the SCK pin input delay, and is selected by writing 1 to CFGR1[SAMPLE]. Enabling the loopback version of the SCK pin can improve the setup time of the input data from the peripheral.

See the chip data sheet for the specific input setup time in Controller Loopback mode.

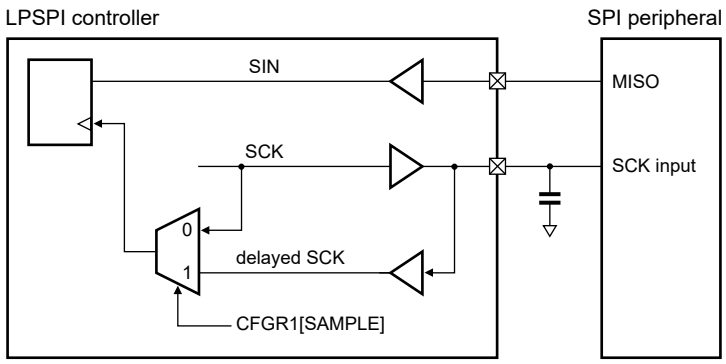

Figure 287. Clock loopback

68.4.2.2 Peripheral mode

LPSPI Peripheral mode:

- Uses the same shift register and logic that Controller mode uses.
- Does not use Clock Configuration (CCR).
- Requires Transmit Command (TCR) to remain static (unchanged) during SPI bus transfers.

68.4.2.2.1 Transmit and command FIFO commands

You must initialize Transmit Command (TCR) before enabling LPSPI in Peripheral mode, although this register is not updated until after LPSPI is enabled. After LPSPI is enabled, you must make changes to this register only when LPSPI is idle. In Peripheral mode, the LPSPI command word in this register controls SPI attributes. Before the PCS input asserts, the transmit FIFO must be filled with transmit data, or the transmit error flag sets.

Table 656. Command word in Peripheral mode

Transmit Command (TCR)		Description
Field	Name	
CPOL	Clock polarity	Specifies the polarity of the external SCK input.
CPHA	Clock phase	Specifies the clock phase of transfer.
PRESCALE	Prescaler value	Specifies the LPSPI functional clock prescaler.
PCS	Peripheral chip select	Specifies which PCS is used. The polarity of PCS is static and configured by CFGR1[PCSPOL]. If CFGR1[PCSCFG] is not equal to zero, then do not select the PCS[3:2] pins.
LSBF	LSB first	Specifies whether LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted or received first.
BYSW	Byte swap	Enables byte swap on each 32-bit word when transmitting and receiving data. Byte swapping can be useful when interfacing with devices that organize data as big-endian.
CONT	Continuous transfer	When continuous transfer is selected in Peripheral mode, after the number of bits indicated by FRAMESZ are transferred, LPSPI passes through and transmits the received data until the next PCS negation. Whatever is shifted in on the receive data is shifted out as transmit data considering that there is a 32-bit shift register.
CONTC	Continuing command	When the continuing command is enabled in Peripheral mode, after the number of bits indicated by FRAMESZ are transferred, RXMSK is considered equal to 1 and TXMSK is considered equal to 0 until the next PCS negation. CONTC can be used to change the direction of a transfer after the number of bits indicated by FRAMESZ.
RXMSK	Receive data mask	Masks the receive data; LPSPI does not store masked receive data in the receive FIFO or perform receive data matching. This option is useful for half-duplex transfers or to specify which fields are compared during receive data matching.
TXMSK	Transmit data mask	Masks the transmit data so that the masked transmit data is not pulled from transmit FIFO, and the output data pin is 3-stated (unless otherwise specified in CFGR1[OUTCFG]). This option is useful for half-duplex transfers.
WIDTH	Transfer width	Specifies the number of bits shifted on each SCK pulse: • 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats. • 2-bit and 4-bit half-duplex transfers are useful for interfacing with QuadSPI memory devices, and at least either TCR[TXMSK] or TCR[RXMSK] must be 1.
FRAMESZ	Frame size	Specifies the frame size in number of bits equal to (FRAMESZ + 1): • The minimum frame size is 8 bits. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contain the remainder bits. For example, a 72-bit transfer consists of three words: the first and second words are 32 bits, and the third word is 8 bits.

68.4.2.2.2 Receive FIFO and data match

The receive FIFO stores receive data during SPI bus transfers. When TCR[RXMSK] = 1, the received data is discarded instead of storing the received data in the receive FIFO.

Receive data supports a receive data match function that can match received data against one of the two words in DMR0 and DMR1 or against a masked data word. You can also configure the data match function to compare only the first one or two received data words since the start of the frame.

- Received data that is already discarded because TCR[RXMSK] = 1 cannot cause the data match to set, and delays the match on the first received data word, until all discarded data is received.
- By using CFGR0[RDMO], you can also configure the receiver match function to discard all received data until a data match is detected.
- After a receive data match, to allow all subsequent data to be received, first write 0 to CFGR0[RDMO], then clear SR[DMF].

68.4.2.2.3 Partial received word

When the PCS pin deasserts and the receive shift register shifts in a partial word, you can configure the receive shift register to either discard the partial word or to store it in the receive FIFO. You must specify this using CFGR1[PARTIAL].

A partial word is defined as less than TCR[FRAMESZ] bits (when TCR[FRAMESZ] is equal or less than 32 bits, or it is the last word in a multi-word frame) or less than 32 bits (when TCR[FRAMESZ] is greater than 32 bits and not the last word in a multi-word frame).

A single-bit frame is not supported. A partial received word of 1 bit is supported, but a partial received frame of 1 bit is not supported.

68.4.2.2.4 Clocked interface

LPSPI supports interfacing with external controllers that provide only clock and data pins (PCS is not required). This interface requires:

- Writing 1 to TCR[CPHA] (data is changed on the leading edge of SCK and captured on the following edge).
- Configuring the PCS input to be always asserted (CFGR1[PCSPOL*n*] = 1). For example, to configure PCS[0] to be always asserted, write 1 to PCSPOL[0], and do not configure PCS[0] in the pin muxing. The chip-level drives PCS to a certain value (ideally 1); you could use CFGR1[PCSPOL*n*] to invert that value.
- Writing 1 to CFGR1[AUTOPCS] to enable automatic PCS generation. When CFGR1[AUTOPCS] = 1, a minimum of four LPSPI functional clock cycles (divided by the selection specified in TCR[PRESCALE]) is required between the last SCK edge of one word and the first SCK edge of the next word.

68.4.2.3 Low-power modes

LPSPI remains functional during low-power modes, if CR[DOZEN] = 0 and LPSPI uses an external or internal clock source that remains enabled. LPSPI can generate an interrupt or DMA request to cause a wake-up from low-power modes.

68.4.2.4 Debug mode

Table 657. Debug mode

Chip mode	LPSPI operation
Debug (the core is in Debug or Halted mode)	Can continue operating in Debug mode, if CR[DBGEN] = 1

68.4.2.5 Clocking

Table 658. LPSPI clocks

Type of clock	Description
Functional	• Asynchronous to the bus clock. • If the LPSPI functional clock remains enabled in low-power modes, then LPSPI can perform SPI bus transfers and low-power wakeups in both Controller and Peripheral modes. • LPSPI divides the functional clock by a prescaler; the resulting frequency must be at least two times faster than the SPI external clock frequency (SCK).
External	• The LPSPI shift register is clocked directly by the SCK clock. • How the SCK clock is generated or supplied depends on the mode (Controller or Peripheral): — In Controller mode, the SCK clock is generated internally. — In Peripheral mode, the SCK clock is supplied externally.
Bus	The bus clock is only used for bus accesses to the LPSPI control and configuration registers. The bus clock frequency must be high enough to support the data bandwidth requirements of the LPSPI registers, including the FIFOs.

See the chip-specific LPSPI information for more.

68.4.2.6 Reset

Table 659. LPSPI resets

Type of reset	Description
Chip	Resets the LPSPI logic and registers to their default states.
Software	• Resets the LPSPI logic and registers to their default states, except for the Control register. • The LPSPI software reset is controlled using CR[RST].
FIFO	• Resets the transmit and command FIFO and the receive FIFO. • CR[RTF] and CR[RRF] are write-only. • After being reset, FIFO is empty.

68.4.2.7 Interrupts and DMA requests

The following table lists sources (status flags) that can generate LPSPI interrupts and LPSPI transmit and receive DMA requests.

Table 660. Interrupts and DMA requests

Status (SR)		Description	Can generate		
Status flag	Name		Interrupt?	DMA request?	Low-power wake-up?
TDF	Transmit data flag	Indicates that data can be written to transmit FIFO, as configured by the transmit FIFO watermark, FCR[TXWATER].	Y	TX	Y

Table continues on the next page...

Table 660. Interrupts and DMA requests (continued)

Status (SR)		Description	Can generate		
Status flag	Name		Interrupt?	DMA request?	Low-power wake-up?
RDF	Receive data flag	Indicates that data can be read from the receive FIFO, as configured by the receive FIFO watermark, FCR[RXWATER].	Y	RX	Y
WCF	Word complete flag	Indicates that the word is complete and the last bit of the word has been sampled.	Y	N	Y
FCF	Frame complete flag	Indicates that the frame is complete and PCS is deasserted.	Y	RX	Y
TCF	Transfer complete flag	Indicates that transfer is complete, PCS is deasserted, and the transmit and command FIFO is empty.	Y	N	Y
TEF	Transmit error flag	Indicates a transmit and command FIFO underrun. In Controller mode, when CFGR1[NOSTALL] = 0 (transfers stall when transmit FIFO is empty), TEF cannot be set.	Y	N	Y
REF	Receive error flag	Indicates a receive FIFO overflow. In Controller mode, when CFGR1[NOSTALL] = 0 (transfers stall when receive FIFO is full), REF cannot be set.	Y	N	Y
DMF	Data match flag	Indicates that the received data matches the configured data match value.	Y	N	Y
MBF	Module busy flag	Indicates that LPSPI is busy performing an SPI bus transfer.	N	N	N

68.4.2.7.1 End-of-packet DMA transfer

The end-of-packet functionality is designed for serial interfaces where you may not be aware of the size of the transfer in advance and the data is pushed by an external device. Examples include UART receive, I2C Peripheral mode, and SPI Peripheral mode. The end-of-packet processing is intended to ensure that data is not stranded in either the receive FIFO or the DMA receive buffer. Support for end-of-packet processing must be implemented in both the serial interfaces and the DMA controller.

The condition that signals the end of packet is different for each serial interface but the serial peripheral and DMA process it in the same way. For example, UART end of packet is signaled by an idle line condition, I2C end of packet by a stop and/or repeated start condition, and SPI end of packet by PCS negation.

If you configure the serial peripheral to signal the end-of-packet condition to the DMA and the serial interface detects an end-of-packet condition, it asserts the DMA request for the receive FIFO irrespective of the watermark configuration. For larger watermark configurations, this ensures that the last few words of the transfer are first flushed from the receive FIFO.

The DMA then reads the contents of the receive FIFO, depending on the first word in the FIFO:

- If the receive FIFO is empty, the serial interface signals an end-of-packet condition to the DMA controller.
- If the receive FIFO is not empty, but the first word in the FIFO is the start of a new packet, then data is not pulled from the receive FIFO and the serial interface signals an end-of-packet condition to the DMA controller.
- If the receive FIFO is not empty, and the first word in the FIFO is not the start of a new packet, the DMA transfers the receive data as normal.

Because the DMA may be transferring multiple words on each request, the end-of-packet condition persists until the DMA minor loop is complete and no additional data is pulled from the receive FIFO. The status flag that triggered the end-of-packet condition is cleared when the minor loop completes following end of packet being signaled to the DMA controller.

When the DMA detects the end-of-packet condition, it writes all received words up to the end of the packet into the system memory and saves the destination address for the word after the last valid data. The DMA then terminates the channel as if the major loop is complete, including final offsets and optional interrupts, channel linking and scatter/gather. The final destination address can optionally be saved in the system memory or is available in the destination address register.

After the DMA terminates the major loop, no servicing of the receive FIFO occurs until either software or hardware reconfigures the DMA (for example, channel linking or scatter/gather). This delay must be minimized to avoid receiver FIFO overrun. NXP does not recommend automatic DMA end-of-packet processing when there are only a few words transferred between end-of-packet conditions. That is because the DMA spends more time processing the end of packet than transferring the data. For example, the UART idle line length must be increased as needed to avoid an excessive number of idle conditions.

68.4.2.7.2 DMA support registers

To support efficient DMA transfers to the transmit and control FIFO, an alias register supports 32-bit write access to the Transmit Command (TCR) and an alias region supports incrementing 32-bit write accesses to the Transmit Data (TDR).

- Transmit Command Burst (TCBR) is a 32-bit alias register for writing to TCR.
- Transmit Data Burst (TDBR0 - TDBR127) is a 512-byte alias region that supports writing to the TDR.

The burst alias locations are contiguous. A DMA transfer can start by writing to the TCBR register to initialize the transfer and then increment into the TDBR region without changing the DMA transfer size. The alias registers can also be used by the DMA to perform burst transfers when accessing the transmit FIFO.

The transmit FIFO prevents writes that overflow the FIFO, but this prevention does not signal an error. Do not perform writes to the TDBR unless there is sufficient room in the transmit FIFO.

Receive Data Burst (RDBR0 - RDBR127) is a 512-byte alias region that supports reading the Receive Data. This can be used by the DMA to perform burst transfers when accessing the receive FIFO.

68.4.2.8 Peripheral triggers

The connection of the LPSPI peripheral triggers with other peripherals depends on the device that is used.

Table 661. Peripheral triggers

Type of trigger	Description	Additional information
Frame output	The frame output trigger: • Asserts at the end of each frame (when PCS deasserts). • Remains asserted for one cycle of the LPSPI functional clock divided by the configuration defined in TCR[PRESCALE].	LPSPI generates two output triggers that can be connected to other peripherals on the chip.
Word output	The word output trigger: • Asserts at the end of each received word. • Remains asserted for one cycle of the LPSPI functional clock divided by the configuration defined in TCR[PRESCALE].	
Input	To control the start of an LPSPI bus transfer, the LPSPI input trigger can be selected instead of the HREQ input:	

Table continues on the next page...

Table 661. Peripheral triggers (continued)

Type of trigger	Description	Additional information
	• The LPSPI input trigger is synchronized, and must assert for at least two cycles of the LPSPI functional clock divided by the configuration defined in TCR[PRESCALE] so that the input trigger can be detected. • When LPSPI is busy, the HREQ input (and therefore the LPSPI input trigger) is ignored. • When LPSPI is busy, both the HREQ and LPSPI input triggers are ignored. They are used to start a new transfer when LPSPI is idle.	

68.4.3 External signals

Table 662. External signals

Signal	Name	Description	I/O
SCK	Serial clock	• Input in Peripheral mode • Output in Controller mode	I/O
PCS[0]	Peripheral chip select	• Input in Peripheral mode • Output in Controller mode	I/O
PCS[1]/HREQ	Peripheral chip select or host request	Host request pin is selected when CFGR0[HREN] = 1 and CFGR0[HRSEL] = 0: • Input in either Peripheral mode or when used as controller host request • Output in either Controller mode or when used as peripheral host request	I/O
PCS[2]/DATA[2]	Peripheral chip select or data pin 2 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Peripheral mode • Output in Controller mode When CFGR1[PCSCFG] = 1: • Input in half-duplex parallel data receive transfers • Output in half-duplex parallel data transmit transfers	I/O
PCS[3]/DATA[3]	Peripheral chip select or data pin 3 during parallel data transfers	When CFGR1[PCSCFG] = 0: • Input in Peripheral mode • Output in Controller mode When CFGR1[PCSCFG] = 1: • Input in half-duplex parallel data receive transfers	I/O

Table continues on the next page...

Table 662. External signals (continued)

Signal	Name	Description	I/O
		• Output in half-duplex parallel data transmit transfers	
SOUT/DATA[0]	Serial data output	Can be configured as serial data input signal (used as data pin 0 in half-duplex parallel data transfers)	I/O
SIN/DATA[1]	Serial data input	Can be configured as serial data output signal (used as data pin 1 in half-duplex parallel data transfers)	I/O

68.4.4 Initialization

This module does not require initialization.

68.4.5 Memory map and registers

NOTE

- Writing to a read-only register or reading a write-only register can cause bus errors.
- LPSPI does not check values programmed in registers for validity, so you must take care to write valid values only.

68.4.5.1 LPSPI register descriptions

68.4.5.1.1 LPSPI memory map

LPSPI0 base address: 4011_0000h

LPSPI1 base address: 4011_1000h

LPSPI2 base address: 4011_2000h

LPSPI3 base address: 4011_3000h

LPSPI4 base address: 4017_1000h

LPSPI5 base address: 4017_2000h

LPSPI6 base address: 4017_3000h

LPSPI7 base address: 4017_4000h

LPSPI8 base address: 4019_9000h

LPSPI9 base address: 4019_A000h

LPSPI10 base address: 4019_B000h

LPSPI11 base address: 4019_C000h

LPSPI12 base address: 4019_D000h

LPSPI13 base address: 4019_E000h

LPSPI14 base address: 4048_4000h

LPSPI16 base address: 4040_5000h

LPSPI17 base address: 4032_6000h

LPSPI18 base address: 4032_7000h

LPSPI19 base address: 4032_8000h

LPSPI20 base address: 4032_9000h

Offset	Register	Width (In bits)	Access	Reset value

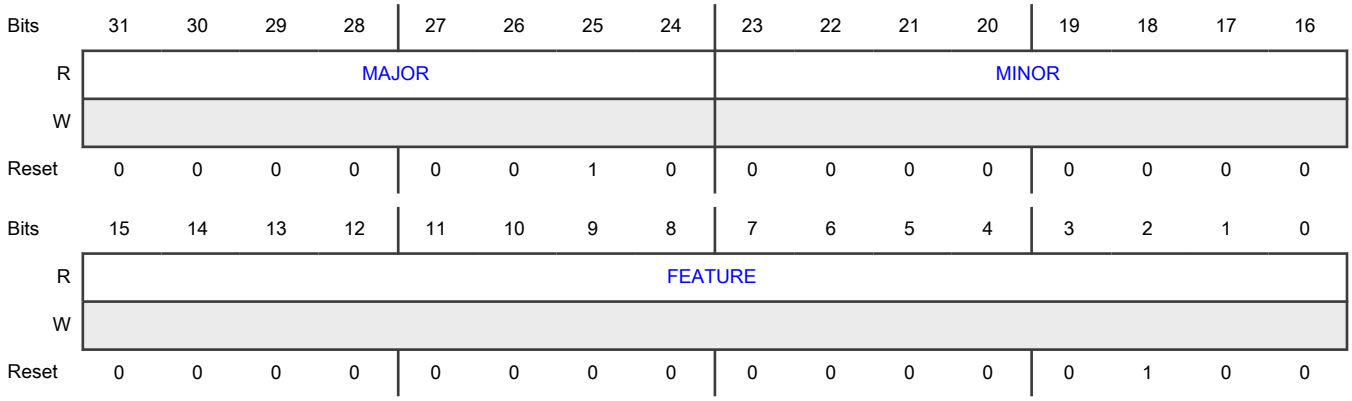
68.4.5.1.2 Version ID (VERID)

Offset

Register	Offset
VERID	0h

Function
Contains version numbers for the module design and feature set.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Version Number Indicates the major version number of the module specification.
23-16 MINOR	Minor Version Number Indicates the minor version number of the module specification.
15-0 FEATURE	Module Identification Number Indicates the feature set number 0000_0000_0000_0100b - Standard feature set supporting a 32-bit shift register. All other values are reserved.

68.4.5.1.3 Parameter (PARAM)

Offset

Register	Offset
PARAM	4h

Function

Contains:

- Number of PCS pins.
- Receive FIFO size.
- Transmit FIFO size.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0								PCSNUM							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RXFIFO								TXFIFO							
W																
Reset	0	0	0	0	0	0	1	1	0	0	0	0	0	0	1	1

Fields

Field	Function
31-24 —	Reserved
23-16 PCSNUM	PCS Number Indicates the number of PCS pins supported.
15-8 RXFIFO	Receive FIFO Size Indicates the maximum number of words in the receive FIFO. The maximum number of words is 2^{RXFIFO}.
7-0 TXFIFO	Transmit FIFO Size Indicates the maximum number of words in the transmit FIFO. The maximum number of words is 2^{TXFIFO}.

68.4.5.1.4 Control (CR)

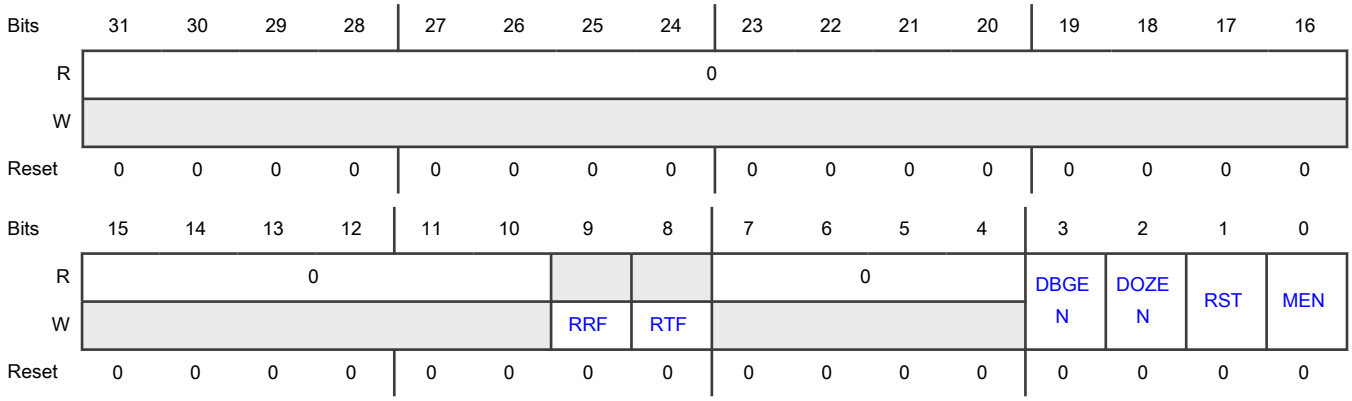
Offset

Register	Offset
CR	10h

Function

Contains fields that control the module operation.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 RRF	Reset Receive FIFO Deletes all entries in the receive FIFO. This field always reads 0. 0b - No effect 1b - Reset
8 RTF	Reset Transmit FIFO Deletes all entries in the transmit FIFO. This field always reads 0. 0b - No effect 1b - Reset
7-4 —	Reserved
3 DBGEN	Debug Enable Enables LPSPI when the CPU is in Debug mode. If this field is 0, LPSPI is disabled when the CPU is halted; the PCS pin is deasserted after the transmit FIFO is empty regardless of the state of Transmit Command (TCR). You must update this field only when LPSPI is disabled (MEN = 0). 0b - Disable 1b - Enable
2 DOZEN	Doze Mode Enable Enables LPSPI when the chip is in Doze mode. You must update this field only when LPSPI is disabled (MEN = 0).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Enable 1b - Disable
1 RST	Software Reset Resets all internal logic and registers, except Control (CR). The reset takes effect immediately and remains asserted until you write 0 to it. There is no minimum delay required before clearing the software reset by writing 0. 0b - Not reset 1b - Reset
0 MEN	Module Enable Enables the module. After writing 0, MEN remains set until LPSPI has completed the current transfer and is idle. 0b - Disable 1b - Enable

68.4.5.1.5 Status (SR)

Offset

Register	Offset
SR	14h

Function
Contains data flow status.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0		DMF	REF	TEF	TCF	FCF	WCF	0						RDF	TDF
W			W1C	W1C	W1C	W1C	W1C	W1C								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Fields

Field	Function
31-25 —	Reserved
24 MBF	Module Busy Flag Indicates, in Controller mode, whether there is data to transmit and LPSPI is able to transmit (for example, the HREQ pin is asserted). The HREQ pin deasserts after the PCS pin deasserts and the LPSPI controller has waited for half the time specified in CCR[DBT] with no new data to transmit. Peripheral mode sets this flag when LPSPI is enabled and PCS is asserted. 0b - LPSPI is idle 1b - LPSPI is busy
23-14 —	Reserved
13 DMF	Data Match Flag Indicates whether the received data matches DMR0[MATCH0] and/or DMR1[MATCH1] (as configured by CFGR1[MATCFG]). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No match 1b - Match When writing 0b - No effect 1b - Clear the flag
12 REF	Receive Error Flag Indicates a receive FIFO overflow error. When this flag is set: 1. End the transfer. 2. Empty the receive FIFO. 3. Clear this flag. 4. Restart the transfer from the beginning. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No overflow

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Overflow When writing 0b - No effect 1b - Clear the flag
11 TEF	Transmit Error Flag Indicates a transmit FIFO underrun error. When this flag is set: 1. End the transfer. 2. Clear this flag. 3. Restart the transfer from the beginning. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No underrun 1b - Underrun When writing 0b - No effect 1b - Clear the flag
10 TCF	Transfer Complete Flag Indicates, in Controller mode, whether all transfers are complete and LPSPI has returned to the Idle state and the transmit FIFO is empty. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not complete 1b - Complete When writing 0b - No effect 1b - Clear the flag
9 FCF	Frame Complete Flag Indicates whether a frame transfer is complete after PCS deasserts. **NOTE** This field behaves differently for register reads and writes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When reading 0b - Not complete 1b - Complete When writing 0b - No effect 1b - Clear the flag
8 WCF	Word Complete Flag Indicates whether the last bit of a received word is sampled. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not complete 1b - Complete When writing 0b - No effect 1b - Clear the flag
7-2 —	Reserved
1 RDF	Receive Data Flag Indicates whether the number of words in the receive FIFO is greater than the value in FCR[RXWATER]. 0b - Receive data not ready 1b - Receive data ready
0 TDF	Transmit Data Flag Indicates whether the number of words in the transmit FIFO is equal to or less than the value in FCR[TXWATER]. 0b - Transmit data not requested 1b - Transmit data requested

68.4.5.1.6 Interrupt Enable (IER)

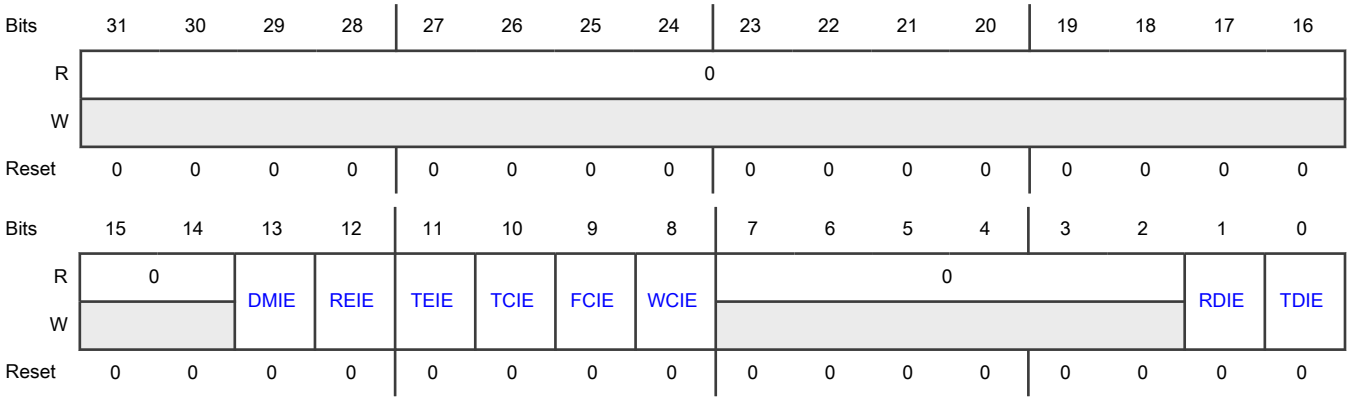
Offset

Register	Offset
IER	18h

Function

Enables interrupts based on data flow and errors.

Diagram



Fields

Field	Function
31-14 —	Reserved
13 DMIE	Data Match Interrupt Enable Enables the data match interrupt. 0b - Disable 1b - Enable
12 REIE	Receive Error Interrupt Enable Enables the receive error interrupt. 0b - Disable 1b - Enable
11 TEIE	Transmit Error Interrupt Enable Enables the transmit error interrupt. 0b - Disable 1b - Enable
10 TCIE	Transfer Complete Interrupt Enable Enables the transfer complete interrupt. 0b - Disable 1b - Enable
9	Frame Complete Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
FCIE	Enables the frame complete interrupt. 0b - Disable 1b - Enable
8 WCIE	Word Complete Interrupt Enable Enables the word complete interrupt. 0b - Disable 1b - Enable
7-2 —	Reserved
1 RDIE	Receive Data Interrupt Enable Enables the receive data interrupt. 0b - Disable 1b - Enable
0 TDIE	Transmit Data Interrupt Enable Enables the transmit data interrupt. 0b - Disable 1b - Enable

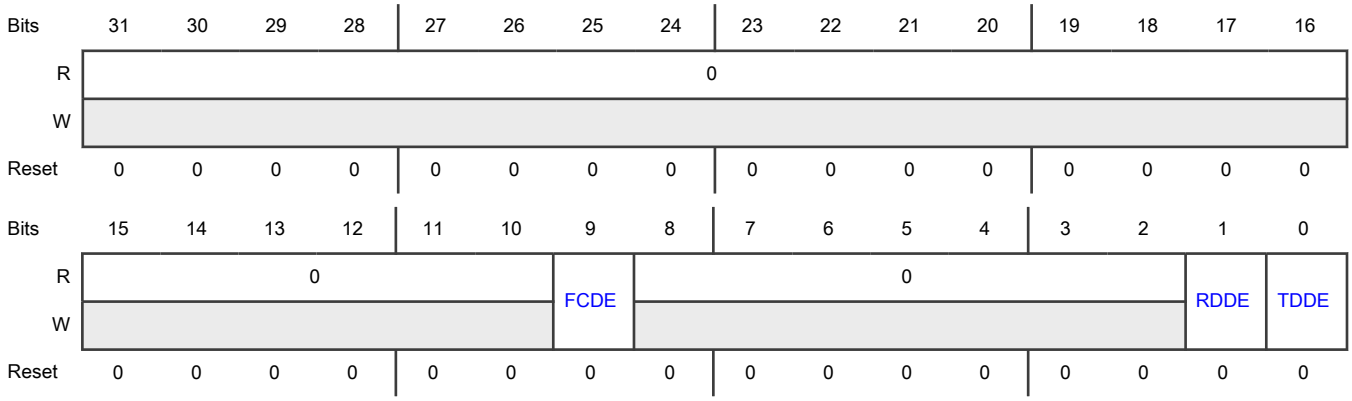
68.4.5.1.7 DMA Enable (DER)

Offset

Register	Offset
DER	1Ch

Function
Enables the DMA data flow.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 FCDE	Frame Complete DMA Enable Enables DMA end-of-packet processing. After the last word of a frame is read from the receive data FIFO, reading the receive data FIFO returns an end-of-packet signal with the receive data forced to FFFF_FFFFh. This continues until the DMA minor loop completes, and then SR[FCF] deasserts if the receive FIFO is empty or if LPSPI is busy (SR[MBF] = 1). **NOTE** This field is not supported in every instance. The following table includes only supported registers.

Instance	Field supported in	Field not supported in
LPSPI0	DER	—
LPSPI1	DER	—
LPSPI2	DER	—
LPSPI3	DER	—
LPSPI4	DER	—
LPSPI5	DER	—
LPSPI6	DER	—
LPSPI7	DER	—
LPSPI8	DER	—

68.4.5.1.8 Configuration 0 (CFGR0)

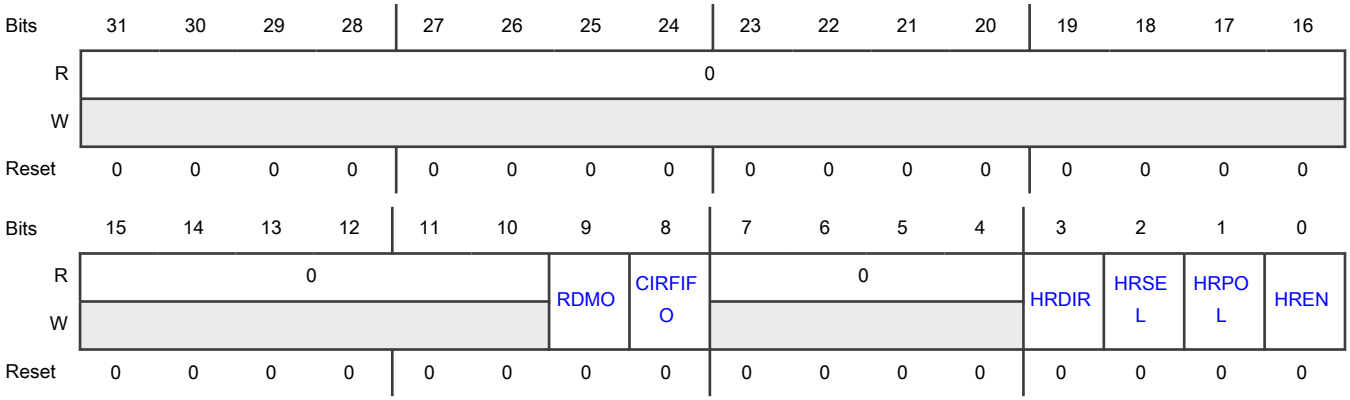
Offset

Register	Offset
CFGR0	20h

Function

Includes fields to configure LPSPI.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 RDMO	Receive Data Match Only Enables receive data match. When enabled, all received data that does not cause SR[DMF] to assert is discarded: • Write 1 to this field when LPSPI is idle and SR[DMF] = 0. • After SR[DMF] = 1, this field is ignored. • To ensure that no receive data is lost when disabling RDMO, write 0 to this field before clearing SR[DMF]. See CFGR1[MATCFG] for the received data matching options. When disabled, all received data is stored in the receive FIFO. 0b - Disable 1b - Enable
8 CIRFIFO	Circular FIFO Enable Enables circular FIFO.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When enabled, the transmit FIFO read pointer is saved to a temporary register. The transmit FIFO is emptied as in normal operation, but when LPSPI is idle and the transmit FIFO is empty, the read pointer value is restored from the temporary register. This restoring of the read pointer causes the contents of the transmit FIFO to be cycled through repeatedly. **NOTE** The read pointer is restored for as long as this field is 1. Writing additional words to the FIFO when this field is 1 adds them to the end of the FIFO, up to the size of the transmit FIFO. 0b - Disable 1b - Enable
7-4 —	Reserved
3 HRDIR	Host Request Direction Specifies the direction of the HREQ pin. You must configure the HREQ pin only as an output when LPSPI is in Peripheral mode. The HREQ pin direction must be an input for Controller mode. 0b - Input 1b - Output
2 HRSEL	Host Request Select Specifies the source of the host request input. When the host request function is enabled with the HREQ pin, the PCS[1] function is disabled. 0b - HREQ pin 1b - Input trigger
1 HRPOL	Host Request Polarity Specifies the polarity of the HREQ pin or input trigger. 0b - Active high 1b - Active low
0 HREN	Host Request Enable Enables LPSPI, in Controller mode, to start a new SPI bus transfer only if the host request input is asserted. When LPSPI is busy, the host request input is ignored. In Peripheral mode, causes the HREQ output pin to assert when data is available to be transmitted. 0b - Disable 1b - Enable

68.4.5.1.9 Configuration 1 (CFGR1)

Offset

Register	Offset
CFGR1	24h

Function

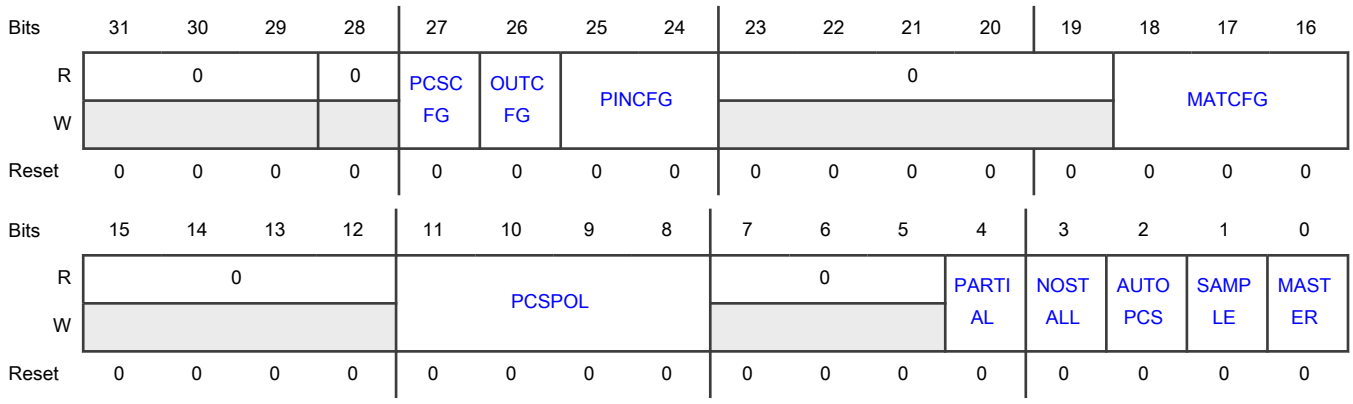
Includes fields to configure LPSPI. You must write to this register only when LPSPI is disabled.

In addition to pin and output configurations, this register contains match configuration details; the following table shows match conditions specified in MATCFG.

Table 663. Match conditions for CFGR1[MATCFG]

Condition	Description
Match first data word with compare word	Match if first data word equals MATCH0 logically ORed with MATCH1 first_data_word == (MATCH0 || MATCH1)
Match any data word with compare word	Match if any data word equals MATCH0 logically ORed with MATCH1 any_data_word == (MATCH0 || MATCH1)
Sequential match, first data word	Match if first data word equals MATCH0, and second data word equals MATCH1 (first_data_word == MATCH0) && (second_data_word == MATCH1)
Sequential match, any data word	Match if any data word equals MATCH0, and the next data word equals MATCH1 (any_data_word == MATCH0) && (next_data_word == MATCH1)
Match first data word (masked) with compare word (masked)	Match if first data word logically ANDed with MATCH1 equals MATCH0 logically ANDed with MATCH1 (first_data_word && MATCH1) == (MATCH0 && MATCH1)
Match any data word (masked) with compare word (masked)	Match if any data word logically ANDed with MATCH1 equals MATCH0 logically ANDed with MATCH1 (any_data_word && MATCH1) == (MATCH0 && MATCH1)

Diagram



Fields

Field	Function
31-29 —	Reserved
28 —	Reserved
27 PCSCFG	Peripheral Chip Select Configuration Specifies PCS pin configuration. When performing parallel transfers, you must configure this field to enable the desired transfer. 0b - PCS[3:2] configured for chip select function 1b - PCS[3:2] configured for half-duplex 4-bit transfers (PCS[3:2] = DATA[3:2])
26 OUTCFG	Output Configuration Specifies whether the output data is 3-stated between accesses (when PCS is deasserted). When performing half-duplex transfers, this field must be 1. 0b - Retain last value 1b - 3-stated
25-24 PINCFG	Pin Configuration Specifies the pins used for input and output data during serial transfers. **NOTE** When performing parallel transfers, this field must be 00b or 10b. 00b - SIN is used for input data; SOUT is used for output data 01b - SIN is used for both input and output data; only half-duplex serial transfers are supported 10b - SOUT is used for both input and output data; only half-duplex serial transfers are supported 11b - SOUT is used for input data; SIN is used for output data
23-19 —	Reserved
18-16 MATCFG	Match Configuration Specifies the condition that causes SR[DMF] to assert. See the match conditions listed in Table 1 for more information. **NOTE** When writing to this field, either the old value or new value must be in the disabled state (0). You cannot transition from a nonzero value to another nonzero value. 000b - Match is disabled 001b - Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
	010b - Match first data word with compare word 011b - Match any data word with compare word 100b - Sequential match, first data word 101b - Sequential match, any data word 110b - Match first data word (masked) with compare word (masked) 111b - Match any data word (masked) with compare word (masked)
15-12 —	Reserved
11-8 PCSPOL	Peripheral Chip Select Polarity Specifies the polarity of each PCS pin. Bit *n* in this field (the least-significant bit is bit 0) corresponds to PCS[*n*]. 0000b - Active low 0001b - Active high
7-5 —	Reserved
4 PARTIAL	Partial Enable Specifies whether LPSPI, when in Peripheral mode, stores a partial received word in the receive FIFO, or discards it, when PCS deasserts. See Partial received word for more information. 0b - Discard 1b - Store
3 NOSTALL	No Stall Disables a normal operating feature that causes LPSPI, when in Controller mode, to stall transfers when the transmit FIFO is empty or when the receive FIFO is full. This feature prevents transmit FIFO underruns and receive FIFO overruns. Writing 1 to this field disables this functionality. 0b - Disable 1b - Enable
2 AUTOPCS	Automatic PCS Enables automatic PCS generation. For correct operation in Peripheral mode, LPSPI requires the PCS signal to deassert between frames. Writing 1 to this field generates an internal PCS signal at the end of each transfer word when TCR[CPHA] = 1. When this field is 1, SCK must remain idle for at least four LPSPI functional clock cycles, divided by the prescaler (see TCR[PRESCALE]) selected between each word to ensure correct operation. This field is ignored in Controller mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
1 SAMPLE	Sample Point Specifies the SCK clock edge on which LPSPI, when in Controller mode, samples input data. Writing 1 to this field causes LPSPI to sample input data on a delayed loopback SCK clock edge, which improves the setup time when sampling data (see Clock loopback). In this configuration, the input data setup time in Controller mode is equal to the input data setup time in Peripheral mode. In Peripheral mode, this field is ignored. **NOTE** When SAMPLE = 1, both the input and output buffers must be enabled for the SCK pin. Buffers are configured at the chip level. 0b - SCK edge 1b - Delayed SCK edge
0 MASTER	Controller Mode Specifies the LPSPI operating mode, Controller or Peripheral. This field directly controls the direction of the SCK and PCS pins. 0b - Peripheral mode 1b - Controller mode

68.4.5.1.10 Data Match 0 (DMR0)

Offset

Register	Offset
DMR0	30h

Function

Specifies the match data to be used when data matching is enabled. See CFGR1[MATCFG] for the received data matching options.

NOTE

Do not change the value in this register when CFGR1[MATCFG] > 0.

Diagram

Field	Function
31-0 MATCH1	Match 1 Value Specifies the MATCH1 value to be compared against received data.

68.4.5.1.12 Clock Configuration (CCR)

Offset

Register	Offset
CCR	40h

Function

Contains clock configuration fields that are used only in Controller mode; you can only change them when LPSPI is disabled (CR[MEN] = 0).

Warning

Writing a 32-bit value to this register overwrites Clock Configuration 1 (CCR1); DBT and SCKDIV always read 0.

To avoid overwriting CCR1, do one of the following:

- Write to all four fields in Clock Configuration (CCR) simultaneously and only once in a 32-bit data.
- Modify the values of CCR[SCKPCS] and/or CCR[PCSSCK]; write only these two upper bytes in a 16-bit data or one of them in an 8-bit data.
- Modify CCR1[PCSPCS] and CCR1[SCKSCK] only or CCR1[SCKSET] and CCR1[SCKHLD] only, write respectively to CCR[DBT] or CCR[SCKDIV] in 8-bit data.

Diagram

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24	SCK-to-PCS Delay

Table continues on the next page...

Table continued from the previous page...

Field	Function
SCKPCS	Configures SCK-to-PCS delay. In Controller mode, this field helps you configure the delay from the last SCK edge to PCS negation: • The delay is equal to (SCKPCS + 1) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The minimum delay is one cycle. See Figure 286 for more information.
23-16 PCSSCK	PCS-to-SCK Delay Configures PCS-to-SCK delay. In Controller mode, this field helps you configure the delay from PCS assertion to the first SCK edge: • The delay is equal to (PCSSCK + 1) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The minimum delay is one cycle. See Figure 286 for more information.
15-8 DBT	Delay Between Transfers Configures the delay between transfers. Writing to this field updates the contents of CCR1[PCSPCS] and CCR1[SCKSCK].
7-0 SCKDIV	SCK Divider Updates the contents of CCR1[SCKSET] and CCR1[SCKHLD]. Baud rate = function clock ÷ (2^PRESCALE × (SCKSET + SCKHLD + 2))

68.4.5.1.13 Clock Configuration 1 (CCR1)

Offset

Register	Offset
CCR1	44h

Function

Contains clock configuration fields, which are used only in Controller mode. You can change them only when LPSPI is disabled (CR[MEN] = 0).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	SCKSCK								PCSPCS							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	SCKHLD								SCKSET							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-24 SCKSCK	SCK Inter-Frame Delay Configures SCK inter-frame delay in Controller mode: • This field helps you configure the delay from the last SCK pulse of a frame and the first SCK pulse of the following frame, in a continuous transfer. • The delay is equal to (SCKSCK + 1) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The minimum delay is one cycle. **NOTE** For backward compatibility, writing to CCR[DBT] updates this field with the value written.
23-16 PCSPCS	PCS to PCS Delay Configures PCS to PCS delay in Controller mode: • This field helps you configure the delay from the PCS negation to the next PCS assertion. • The delay is equal to (PCSPCS + PCSPCS + 2) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The minimum delay is two cycles. • Half of the delay (PCSPCS + 1) occurs before PCS assertion and the other half of the delay (PCSPCS + 1) occurs after PCS negation. If the command word is updated between two transfers, then the command word is updated halfway between the PCS negation of the last transfer and PCS assertion of the next transfer. • The command word specifies which PCS signal is used, the polarity and phase of the SCK signal, and the selected prescaler. **NOTE** For backward compatibility, writing to CCR[DBT] updates this field with (DBT÷2) rounded up.
15-8	SCK Hold

Table continues on the next page...

Table continued from the previous page...

Field	Function
SCKHLD	Configures the hold phase of the SCK pin in Controller mode: • The hold phase is the delay between the SCK edge that samples the receive data and the SCK edge that drives the transmit data. • It is the SCK low period when CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. It is the SCK high period when CPHA = 0, CPOL = 0 and CPHA = 1, CPOL = 1. • The SCK hold phase delay is equal to (SCKHLD + 1) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The minimum delay is one cycle. • The SCK period is equal to (SCKSET + SCKHLD + 2) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The SCK duty cycle is based on the difference between SCKSET and SCKHLD. You must configure both these fields to the same value for a 50/50 duty cycle. See Figure 286 for more information. **NOTE** For backward compatibility, writing to CCR[SCKDIV] updates this field with (SCKDIV ÷ 2) rounded down.
7-0 SCKSET	SCK Setup Configures the setup phase of the SCK pin in Controller mode: • The setup phase is the delay between the SCK edge that drives the transmit data and the SCK edge that samples the receive data. • It is the SCK high period when CPHA = 0 and CPOL = 1, or CPHA = 1 and CPOL = 0. It is the SCK low period when CPHA = 0 and CPOL = 0, or CPHA = 1 and CPOL = 1. • The SCK setup phase delay is equal to (SCKSET + 1) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The minimum delay is one cycle. • The SCK period is equal to (SCKSET + SCKHLD + 2) cycles of the LPSPI functional clock divided by the selected prescaler (see TCR[PRESCALE]). • The SCK duty cycle is based on the difference between SCKSET and SCKHLD. You must configure both these fields to the same value for a 50/50 duty cycle. See Figure 286 for more information. **NOTE** For backward compatibility, writing to CCR[SCKDIV] updates this field with (SCKDIV ÷ 2) rounded up.

68.4.5.1.16 Transmit Command (TCR)

Offset

Register	Offset
TCR	60h

Function

Pushes the data into the transmit FIFO, in the same order as written.

When you write to either this register or to Transmit Data (TDR), each write pushes data into the transmit FIFO. You must write to this register only using 32-bit writes, which are tagged and cause the command register to update; after that the entry reaches the top of the FIFO and LPSPI is enabled. This allows changes to the command word and the transmit data itself to be interleaved. That is, writes to the two registers can be interleaved (write command word, then data word, then command word, and so on). Changing the command word causes all subsequent SPI bus transfers to be performed using the new command word:

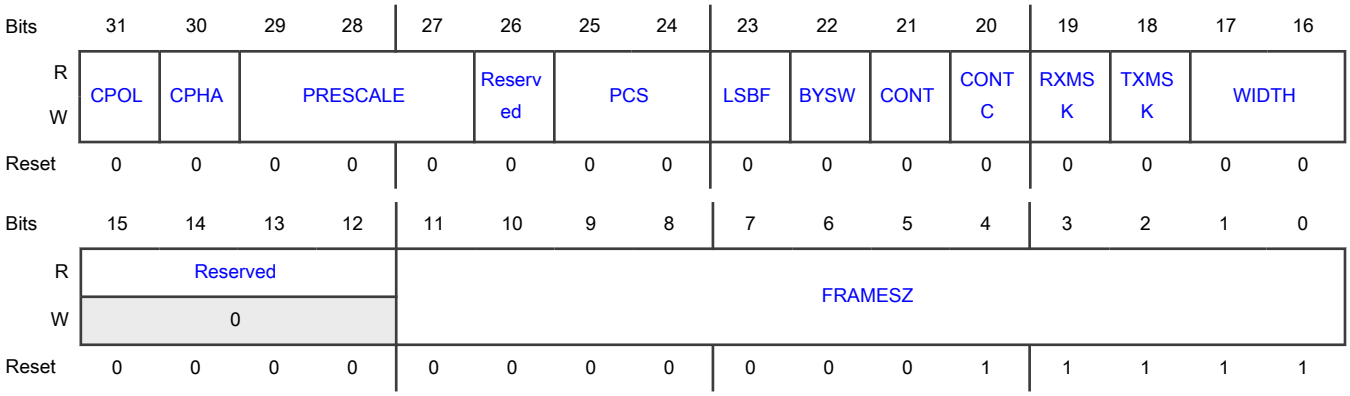
- In Controller mode, writing a new command word does not initiate a new transfer, unless TXMSK is 1. Transfers are initiated by transmit data in the transmit FIFO, or by a new command word (with TXMSK = 1). Hardware writes 0 to TXMSK when PCS deasserts.
- In Controller mode, if the command word is changed before an existing frame has completed, then the existing frame terminates and the command word updates. The command word can be changed during a continuous transfer, if CONTC of the new command word is 1 and the command word is written on a frame size boundary.
- In Peripheral mode, the command word must be changed only when LPSPI is idle and there is no SPI bus transfer.

Avoid resetting the transmit FIFO after writing to this register; wait for the command register to update from the FIFO first.

Avoid register reading problems: Reading this register returns the current state of the register. Reading this register at the same time that it is loaded from the transmit FIFO can return an incorrect register value. It is recommended to:

- Read this register when the transmit FIFO is empty.
- Read this register more than once and then compare the returned values.

Diagram



Fields

Field	Function
31 CPOL	Clock Polarity Specifies the value of SCK when it is idle. You can update this field only when PCS is deasserted. See Figure 286 for more information. 0b - Inactive low 1b - Inactive high
30 CPHA	Clock Phase Indicates whether data is captured or changed on the leading edge of SCK and captured or changed on the following edge of SCK. You can update this field only when PCS is deasserted. See Figure 286 for more information. 0b - Captured 1b - Changed
29-27 PRESCALE	Prescaler Value Specifies the division of the LPSPI functional clock. For all SPI bus transfers, this value is applied to Clock Configuration (CCR). You can update this field only when PCS is deasserted. 000b - Divide by 1 001b - Divide by 2 010b - Divide by 4 011b - Divide by 8 100b - Divide by 16 101b - Divide by 32 110b - Divide by 64 111b - Divide by 128
26 —	Reserved
25-24 PCS	Peripheral Chip Select Configures the peripheral chip select used for the transfer. This field is updated only when PCS is deasserted. **NOTE** This entire field is not fully supported in every LPSPI module instance. See the chip-specific LPSPI information. 00b - Transfer using PCS[0] 01b - Transfer using PCS[1] 10b - Transfer using PCS[2]

Table continues on the next page...

Table continued from the previous page...

Field	Function
	11b - Transfer using PCS[3]
23 LSBF	LSB First Indicates whether data is transferred with MSB first or LSB first. 0b - MSB first 1b - LSB first
22 BYSW	Byte Swap Swaps the contents of [31:24] with [7:0] and [23:16] with [15:8] for each transmit data word read from the FIFO and for each received data word stored to the FIFO (or compared with match registers). 0b - Disable byte swap 1b - Enable byte swap
21 CONT	Continuous Transfer Enables continuous transfer: • In Controller mode, this field keeps PCS asserted at the end of the frame size until a command word is received that starts a new frame. • In Peripheral mode, when this field is enabled, LPSPI only transmits the first FRAMESZ bits, after which LPSPI transmits received data (assuming a 32-bit shift register) until the next PCS negation. 0b - Disable 1b - Enable
20 CONTC	Continuing Command Enables the command word to be changed within a continuous transfer in Controller mode: • The initial command word must enable continuous transfer (CONT = 1). • The continuing command must have CONTC = 1. • The continuing command word must be loaded on a frame size boundary. For example, if the continuous transfer has a frame size of 64 bits, then a continuing command word must be loaded on a 64-bit boundary. In Peripheral mode, this field modifies the internal RXMSK and TXMSK configuration after the first FRAMESZ bits and until PCS negation: • Receive data is discarded after the first FRAMESZ bits. If CONT is also 1, this does not block the transmission of received data. • Transmit data is not masked after the first FRAMESZ bits. This allows the first FRAMESZ bits to be received and a response transmitted. 0b - Command word for start of new transfer 1b - Command word for continuing transfer
19	Receive Data Mask

Table continues on the next page...

Table continued from the previous page...

Field	Function
RXMSK	Masks receive data (receive data is not stored in the receive FIFO). 0b - Normal transfer 1b - Mask receive data
18 TXMSK	Transmit Data Mask Masks transmit data (no data is loaded from the transmit FIFO and the output pin is 3-stated). In Controller mode, TXMSK initiates a new transfer that cannot be aborted by another command word. TXMSK automatically transitions to 0 at the end of the transfer. 0b - Normal transfer 1b - Mask transmit data
17-16 WIDTH	Transfer Width Configures serial (1-bit) or parallel transfers. For half-duplex parallel transfers, either RXMSK or TXMSK must be 1. 00b - 1-bit transfer 01b - 2-bit transfer 10b - 4-bit transfer 11b - Reserved
15-12 —	Reserved
11-0 FRAMESZ	Frame Size Configures the frame size in number of bits equal to (FRAMESZ + 1): • The minimum frame size is 8 bits. • If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32 bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately. • If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO contains the remainder bits. For example, a 72-bit transfer consists of three words: the first and second words are 32 bits, and the third word is 8 bits.

68.4.5.1.17 Transmit Data (TDR)

Offset

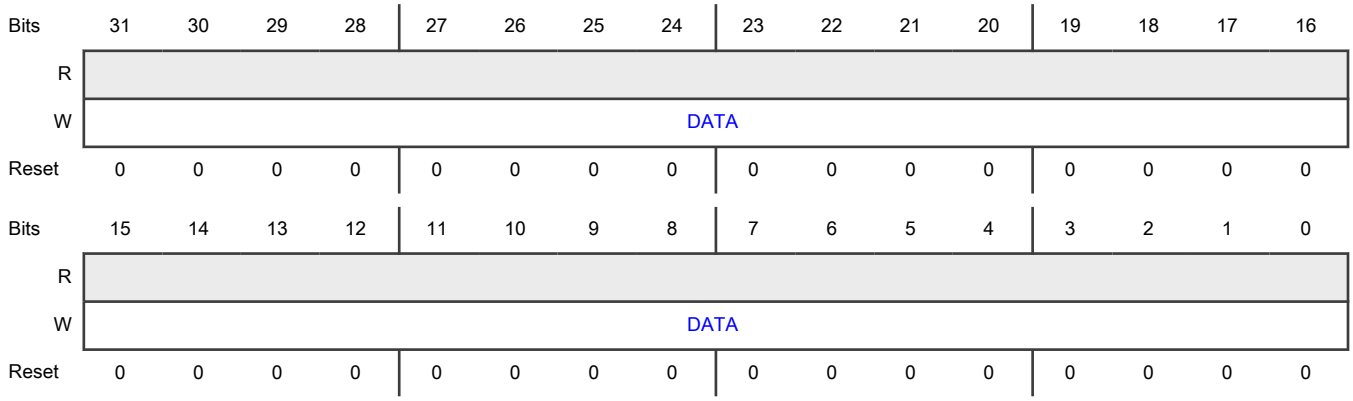
Register	Offset
TDR	64h

Function

Pushes the data into the transmit FIFO, in the same order that the data is written. You can write to this register using 32-, 16-, or 8-bit writes.

When you write to this register or to Transmit Command (TCR), each write pushes data into the FIFO with zero pushed in unwritten bytes.

Diagram



Fields

Field	Function
31-0 DATA	Transmit Data Indicates transmit data. Both 8-bit and 16-bit writes of transmit data zero-extend the data written and push the data into the transmit FIFO. To zero-extend 8-bit and 16-bit writes (to 32 bits) means that the higher order (most significant) empty parts of the 8-bit and 16-bit writes are filled with zeroes.

68.4.5.1.18 Receive Status (RSR)

Offset

Register	Offset
RSR	70h

68.5 Low Power Universal Asynchronous Receiver/Transmitter (LPUART)

68.5.1 Overview

LPUART provides asynchronous, serial communication capabilities with external devices. It supports the non-return-to-zero (NRZ) encoding format and infrared data association (IrDA)-compatible, low-speed serial infrared (SIR) protocol. LPUART can continue operating when the processor is in Low-Power mode, if an appropriate peripheral clock is available.

68.5.1.1 Block diagram

Figure 288 shows the transmitter portion of LPUART.

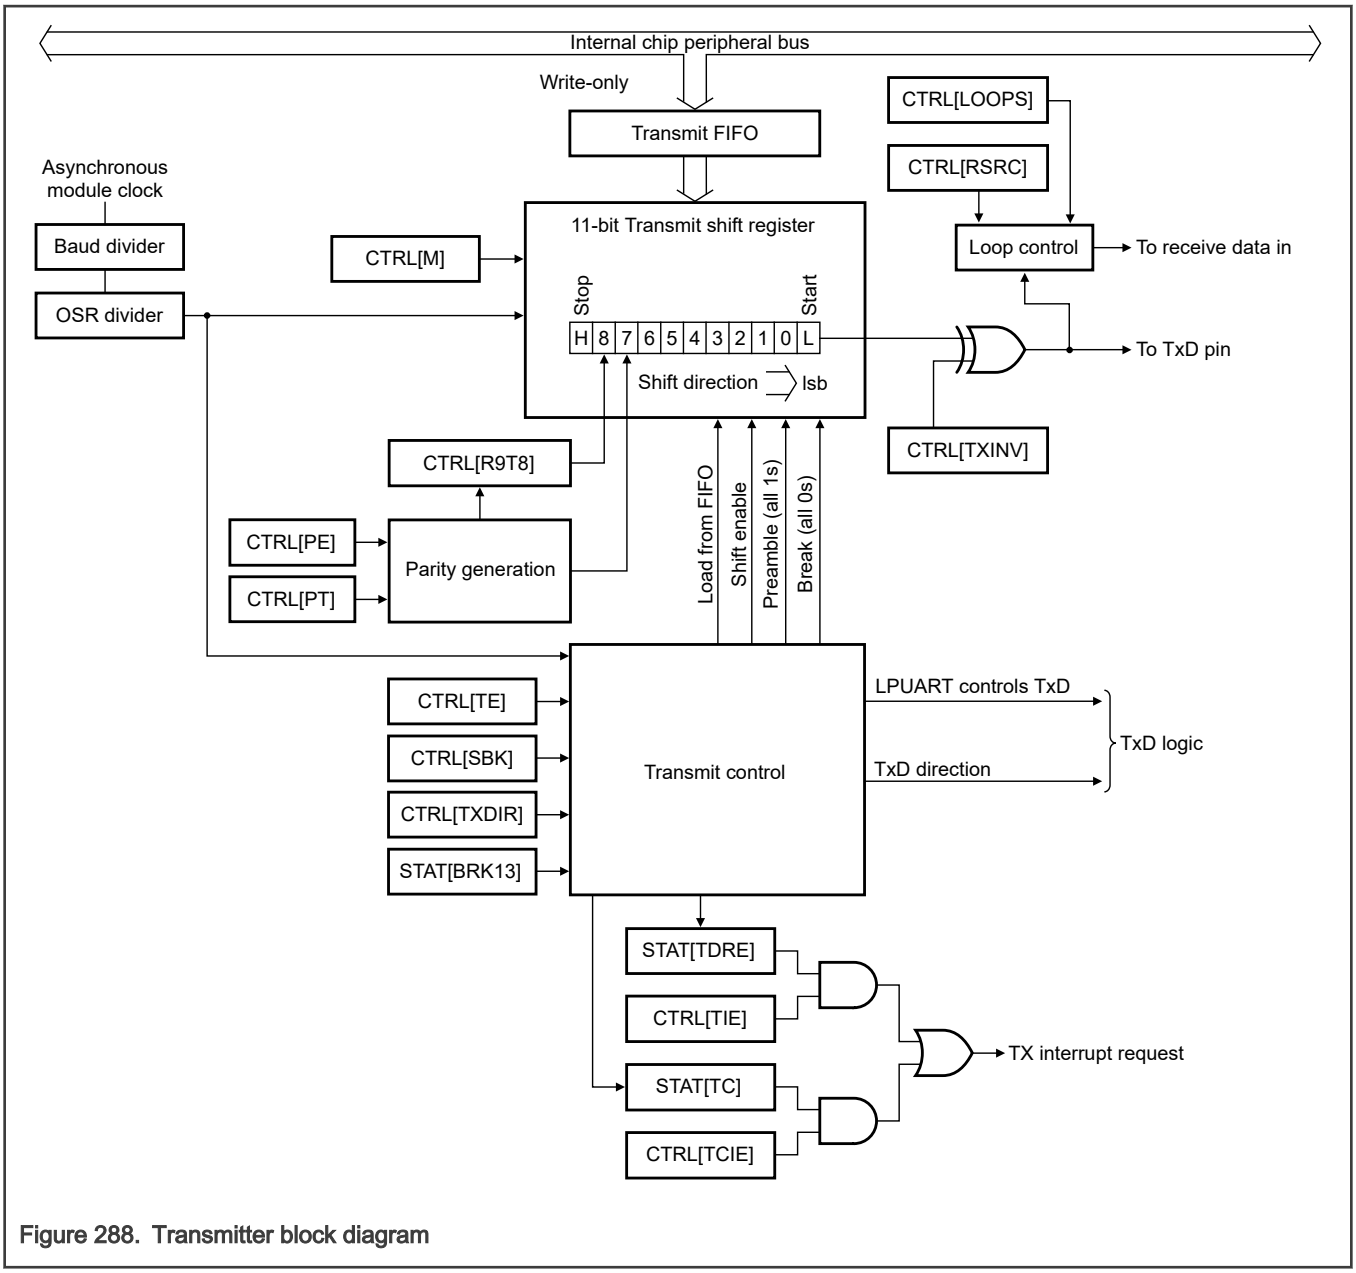

Figure 288. Transmitter block diagram

Figure 289 shows the receiver portion of LPUART.

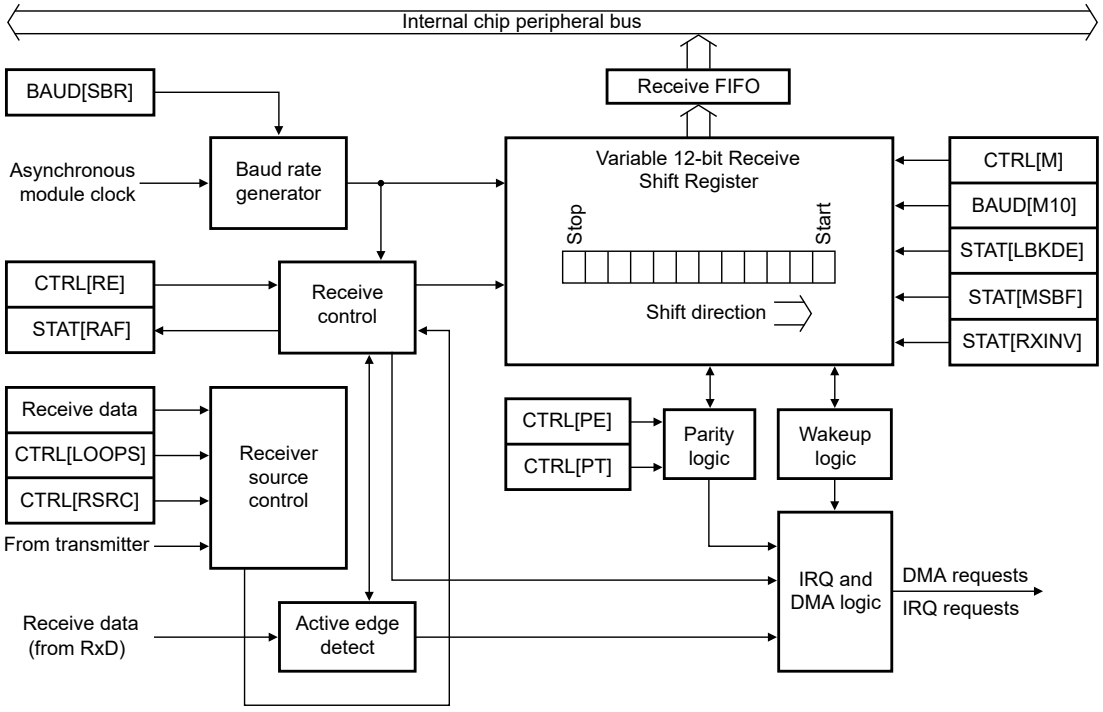

Figure 289. Receiver block diagram

68.5.1.2 Features

- Full-duplex, standard NRZ format
- Programmable baud rates (13-bit modulo divider) with a configurable oversampling ratio (OSR) from 4× to 32×
- Asynchronous operation of transmit and receive baud rates with respect to the bus clock:
  - Baud rate can be configured independently of the bus clock frequency.
  - Operation in Low-Power modes is supported.
- Interrupt, DMA, or polled operations:
  - Transmit data empty and transmission complete
  - Receive data full
  - Receive overrun, parity error, framing error, and noise error
  - Idle receiver detect
  - Active edge on receive pin
  - Break detect supporting LIN
  - Receive data match
- Hardware parity generation and checking
- Programmable 7-bit, 8-bit, 9-bit, or 10-bit character length
- Programmable 1-bit or 2-bit stop bits
- Support for three receiver wake-up methods:
  - Idle line wake-up

  - Address mark wake-up
  - Receive data match
- Automatic address matching to reduce ISR overhead:
  - Address mark matching
  - Idle line address matching
  - Address match start, address match end
- Optional 13-bit and 11-bit break character generation
- Configurable idle length detection supporting 1, 2, 4, 8, 16, 32, 64, or 128 idle characters
- Selectable transmitter output and receiver input polarity
- Hardware flow control support for request to send (RTS) and clear to send (CTS) signals
- Selectable IrDA 1.4 return-to-zero-inverted (RZI) format with a programmable pulse width
- Independent FIFO structure for transmit and receive functions:
  - Separate configurable watermarks for receive and transmit requests
  - Option for receiver to assert request after a configurable number of idle characters, if receive FIFO is not empty

68.5.2 Functional description

LPUART supports full-duplex, asynchronous, NRZ serial communication and comprises a baud rate generator, transmitter, and receiver block. The transmitter and receiver operate independently, although they use the same baud rate generator. The following sections describe all LPUART blocks.

68.5.2.1 Baud rate generation

A 13-bit modulus counter in the baud rate generator derives the baud rate for both the receiver and transmitter. The value, ranging from 1 to 8191, written to BAUD[SBR] determines the baud clock divisor for the asynchronous LPUART baud clock. The baud rate clock drives the receiver, while a bit clock, generated from the baud rate clock divided by the OSR, drives the transmitter. Depending on the OSR, the receiver has an acquisition rate of 4 to 32 samples per bit time. LPUART requires BAUD[SBR] and BAUD[OSR] to accurately match the baud rate requirement. There is a relationship between the required baud rate and the input clock frequency, SBR, and OSR. See the below figure for details.

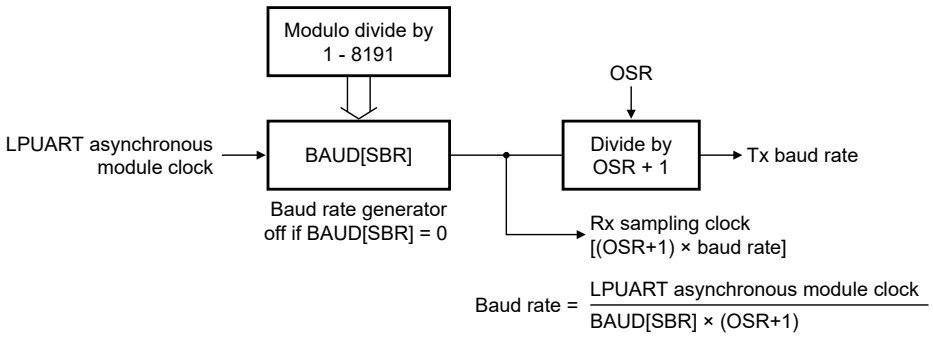

Figure 290. Baud rate generation

Baud rate generation is subject to these sources of error:

- Integer division of the asynchronous LPUART baud clock may not give the exact target frequency.
- Synchronization with the asynchronous LPUART baud clock can lead to a phase shift.

Baud rate generation is a free-running counter that continues whenever the transmitter or receiver is enabled. The transmitter bit clock continues whenever the transmitter is enabled; each transmitted character aligns to the next edge of the transmit bit clock.

In general, configuring OSR for a higher ratio and/or sampling on both edges of the clock slightly improves LPUART's tolerance to baud rate mismatch between the received data and LPUART configured baud rate. However, the three data samples in each bit (see Data sampling technique) are also closer together, which may impact noise sensitivity.

68.5.2.2 Baud rate tolerance

A transmitting device may operate at a baud rate below or above that of the receiver.

Accumulated bit time misalignment can cause one of the three stop bit data samples to fall outside the actual stop bit. A noise error will occur if the three samples are not all the same logical values. A framing error will occur if the receiver clock is misaligned in such a way that the majority of the three stop bit samples are a logic zero.

As the receiver samples an incoming frame, it may resynchronize the oversampling clock on any valid falling edge within the frame. Resynchronization within frames will correct a misalignment between transmitter bit times and receiver bit times.

In general, increasing the number of samples per bit will increase the baud rate tolerance and decreasing the number of samples per bit will reduce the baud rate tolerance. Note that since LPUART implements triple voting on consecutive receive data samples, increasing the number of samples per bit will move those samples closer together which would reduce the width of noise that can be filtered by the triple voting logic.

68.5.2.3 Calculating baud rate tolerance

Using the following definitions:

- SAM is the number of sample points per bit (valid range from 8 to 32; equal to (OSR + 1) × (BOTHEDGE + 1)).
- BIT is the number of bits in a character including start, data and stop bits (valid range from 9 to 13).

The ideal baud rate tolerance can be calculated as follows:

- Slow data rate tolerance = ((SAM ÷ 2) - 1) ÷ ((SAM × BIT) - (SAM ÷ 2) + 2)
- Fast data rate tolerance = ((SAM ÷ 2) - 2) ÷ (SAM × BIT)

As an example, if configured for 8-bit data, 1 stop bit (BIT = 10) and with OSR=0x7 and BOTHEDGE = 1 (SAM = 16):

- Slow data rate tolerance = (8 - 1) ÷ (160 - 8 + 2) = 7 ÷ 154 = 4.54%
- Fast data rate tolerance = (8 - 2) ÷ 160 = 6 ÷ 160 = 3.75%

If configured for 9-bit data with 1 stop bit (BIT = 11) with same oversampling configuration, then:

- Slow data rate tolerance = (8 - 1) ÷ (176 - 8 + 2) = 7 ÷ 170 = 4.12%
- Fast data rate tolerance = (8 - 2) ÷ 176 = 6 ÷ 176 = 3.41%

NOTE

Additional factors can contribute to a lower baud rate tolerance than the ideal. These include clock uncertainty or jitter on the LPUART functional clock source, differences in rise and fall times on the transmitter output and synchronization of the external receive pin to the local LPUART functional clock.

68.5.2.4 Transmitter functional description

This section describes the functioning of the LPUART transmitter, as shown in the transmitter portion of Block diagram, as well as specialized functions for sending break and idle characters.

The transmitter output (TXD) idle state defaults to logic high; the transmitter output is inverted when you write 1 to CTRL[TXINV], which becomes 0 following reset. You can enable the transmitter by writing 1 to CTRL[TE]. This queues a preamble character that is one full character frame of the Idle state. The transmitter then remains idle until data is available in the transmit FIFO and programs store data in the transmit FIFO by writing to Data (DATA).

The central element of the LPUART transmitter is the transmit shift register that is 9-bit to 13-bit long depending on the settings of CTRL[M], CTRL[M7], BAUD[M10], and BAUD[SBNS]. Going forward in this discussion, assume that CTRL[M], CTRL[M7], BAUD[M10], and BAUD[SBNS] are 0, selecting the normal 8-bit Data mode, in which the shift register holds a start bit, eight data bits, and a stop bit. When the transmit shift register is available for a new character, the value waiting in transmit FIFO is transferred to the transmit shift register, synchronized with the baud rate clock, and STAT[TDRE] becomes 1 to indicate that another character may be written to the transmit FIFO at Data (DATA).

If no new character is waiting in the transmit FIFO after a stop bit is shifted out of the TXD pin, the transmitter sets the transmit complete flag and enters an idle mode, with TXD high, waiting for more characters to transmit.

Writing 0 to CTRL[TE] does not immediately disable the transmitter. The current transmit activity in progress must first be completed (that could include a data character, idle character, or break character), although the transmitter does not start transmitting another character.

68.5.2.4.1 Break character length

CTRL[SBK] sends break characters, originally used to gain the attention of old teletype receivers. Break characters are a full character time of logic 0, 9-bit to 12-bit times, including the start and stop bits. You can enable a longer break of 13-bit times by writing 1 to STAT[BRK13]. Normally, a program waits for STAT[TDRE] to become 1 to indicate that the last character of a message has moved to the transmit shifter. Next, the program writes 1 and then writes 0 to CTRL[SBK]. This action queues a break character to be sent as soon as the shifter is available. If CTRL[SBK] remains 1 when the queued break moves into the shifter, synchronized with the baud rate clock, an additional break character is queued. When LPUART is the receiving module, it receives a break character as 0s in all data bits and a framing error (STAT[FE] = 1) is detected.

You can also transmit a break character by writing to Data (DATA) with DATA[FRETSC] = 1 and the data bits clear. This supports transmitting the break character as part of the normal data stream and also allows DMA to transmit a break character.

When idle line wake-up is used, a full character time of idle (logic 1) is needed between messages to wake up any sleeping receivers. Normally, a program waits for STAT[TDRE] to become 1 to indicate that the last character of a message has moved to the transmit shifter. Next, write 0 and then write 1 to CTRL[TE]. This action queues an idle character to be sent as soon as the shifter is available. As long as the character in the shifter does not finish while CTRL[TE] becomes 0, the LPUART transmitter does not release control of the TXD pin.

You can also write to Data (DATA) to transmit an idle character, with DATA[FRETSC] and DATA[R9T9] = 1 and the values of all the other fields = 0. This supports transmitting the idle character as part of the normal data stream and also allows DMA to transmit an idle character.

As shown in the following table, STAT[BRK13], CTRL[M], CTRL[M7], BAUD[M10], and BAUD[SBNS] affect the length of the break character.

Table 664. Break character length

STAT[BRK13]	CTRL[M]	BAUD[M10]	CTRL[M7]	BAUD[SBNS]	Break character length (in bit times)
0	0	0	0	0	10
0	0	0	0	1	11
0	0	0	1	0	9
0	0	0	1	1	10
0	1	0	—	0	11

0	—	1	—	0	12
0	—	1	—	1	13
1	0	0	0	0	13

Table continues on the next page...

Table 664. Break character length (continued)

STAT[BRK13]	CTRL[M]	BAUD[M10]	CTRL[M7]	BAUD[SBNS]	Break character length (in bit times)
1	0	0	0	1	13
1	0	0	1	0	12
1	0	0	1	1	12
1	1	0	—	0	14
1	1	0	—	1	14
1	—	1	—	0	15
1	—	1	—	1	15

68.5.2.4.2 Hardware flow control

The transmitter supports hardware flow control by gating the transmission with the value of CTS_B. If the CTS operation is enabled, the character is transmitted when CTS_B is asserted. If CTS_B is deasserted in the middle of a transmission with characters remaining in the transmitter FIFO, the character in the transmit shift register is complete. Any characters in the FIFO wait for CTS_B to assert again, and TXD remains in the mark state (idle state) until CTS_B is reasserted. The CTS_B pin must assert for longer than one bit period to guarantee that a new transmission is started when the transmitter is idle with CTS.

If the CTS operation is disabled, the transmitter ignores the state of CTS_B.

The transmitter's CTS_B signal can be enabled even if the same LPUART receiver's RTS_B signal is disabled.

68.5.2.4.3 Transceiver driver enable

The transmitter can use RTS_B as an enable signal for the driver of an external transceiver. See Transceiver driver enable using RTS_B for details. If the RTS operation is enabled, when a character is placed into an empty transmit shift register, RTS_B asserts 1-bit time before the start bit is transmitted. RTS_B remains asserted for the whole time that the transmit shift register has any characters. RTS_B deasserts 1-bit time after all characters in the transmit FIFO and shift register are completely sent, including the last stop bit. In other words, when RTS_B is used as a transceiver enable, RTS_B asserts 1-bit time before the transmitter starts transmitting and negates 1-bit time after the transmitter goes idle.

Transmitting a break character also asserts RTS_B, with the same assertion and deassertion timing as having a character in the transmit shift register.

The transmitter's RTS_B signal asserts only when the transmitter is enabled. However, the transmitter's RTS_B signal is unaffected by its CTS_B signal. RTS_B remains asserted until the transfer is complete, even if the transmitter is disabled mid-way through a data transfer.

68.5.2.4.4 Transceiver driver enable using RTS_B

RS-485 is a multiple drop communication protocol in which the LPUART transceiver's driver is three-stated unless LPUART is driving. The transmitter can use the RTS_B signal to enable the driver of a transceiver. The polarity of RTS_B can be matched to the polarity of the transceiver's driver enable signal.

The following figure shows the receiver enable signal asserted. This connection can also connect RTS_B to both DE and RE_B. The transceiver's receiver is disabled when driving. A pullup can pull RXD to a nonfloating value during this time. You can refine this option further by operating LPUART in Single-Wire mode, freeing the RXD pin for other uses.

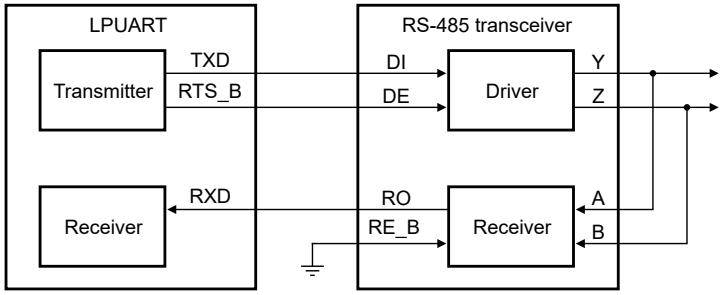

Figure 291. Transceiver driver enable using RTS_B

68.5.2.5 Receiver functional description

This section discusses the functioning of the LPUART receiver, as shown in the receiver portion of Block diagram. The section also discusses:

- The data sampling technique used to reconstruct receiver data.
- Different variations of the receiver wake-up function.

You can invert the receiver input by writing 1 to STAT[RXINV] and enable the receiver by writing 1 to CTRL[RE]. Character frames consist of a start bit of logic 0, along with N (7, 8, 9, 10) bits (MSB or LSB first), and one or two stop bits of logic 1. For information about 7-bit, 9-bit, or 10-bit Data mode, see Data modes. Going forward in this discussion, assume that LPUART is configured for a normal 8-bit Data mode.

After receiving the stop bit into the receive shifter, and provided the receive data register is not already full (STAT[RDRF] = 0), the data character is transferred to the receive FIFO, resulting in STAT[RDRF] becoming 1. However, if STAT[RDRF] is already 1, indicating that the receive data buffer is already full, STAT[OR] becomes 1 and the new data is lost.

Because the LPUART receiver is separate from the receive FIFO, the receive shift register can receive the next word when the receive FIFO is full, and it is only at the end of the character that the next data is written into the receive FIFO, potentially triggering the overrun flag if the FIFO is full.

When a program detects that the receive data register is full (STAT[RDRF] = 1), it gets the data from the FIFO by reading Data (DATA). See Interrupts for details about flag clearing.

68.5.2.5.1 Data sampling technique

The LPUART receiver supports a configurable oversampling rate of between 4× and 32× of the baud rate clock for sampling. The receiver starts by considering logic level samples at the oversampling rate times the baud rate to search for a falling edge on the RXD serial data input pin. A falling edge is defined as a logic 0 sample after three consecutive logic 1 samples. The oversampling baud rate clock divides the bit time into 4 to 32 segments from 1 to OSR (where OSR is the configured oversampling ratio). When a falling edge is located, three more samples are taken at (OSR ÷ 2), (OSR ÷ 2) + 1, and (OSR ÷ 2) + 2 to ensure that this is a real start bit and not merely noise. If at least two of these three samples are 0, the receiver assumes they are synchronized to a received character. If another falling edge is detected before the receiver is considered synchronized, the receiver restarts sampling from the first segment.

The receiver then samples each bit time, including the start and stop bits, at (OSR ÷ 2), (OSR ÷ 2) + 1, and (OSR ÷ 2) + 2, to determine the logic level for that bit. The logic level is interpreted to be that of the majority of the samples taken during the bit time. If any sample in any bit time, including the start and stop bits, in a character frame fails to agree with the logic level for that bit, noise flag (STAT[NF]) becomes 1 when the received character is transferred to the receive FIFO.

When the LPUART receiver is configured to sample on both edges of the baud rate clock (that is, when BAUD[BOTHEDGE] = 1), the number of segments in each received bit is effectively doubled (from 1 to OSR× 2). The start and data bits are then sampled at OSR, OSR + 1, and OSR + 2. You must enable sampling on both edges of the clock for oversampling rates of 4× to 7×. This sampling is optional for higher oversampling rates.

The synchronization feature of LPUART synchronizes the internal oversampling counter with a detected falling edge on the receive signal, and to adjust the data sampling window. The falling edge detection needs three consecutive 1s prior to the "1->0" (one to zero) transition. After the initial falling edge detection for the start bit, the circuit continuously monitors the next falling edge, and resets the counter after another falling edge is detected. This synchronization to the start bit is termed as resynchronization.

When BAUD[RESYNCDIS] is 0, you perform this falling edge detection and resynchronization not only for the start bit but also for the rest of the character reception after the start bit.

When BAUD[RESYNCDIS] is 1, you perform the falling edge detection and resynchronization only for the start bit. The use case for disabling the resynchronization is protocols that require this (for example, LIN 2.1 prohibits resynchronization within a byte).

The following table and figure explain LPUART resynchronization.

Table 665. LPUART resynchronization settings

Resynchronization	BAUD[RESYNCDIS] = 0	BAUD[RESYNCDIS] = 1
For the starting bit falling edge	Yes	Yes
For all falling edges after the start bit	Yes	No

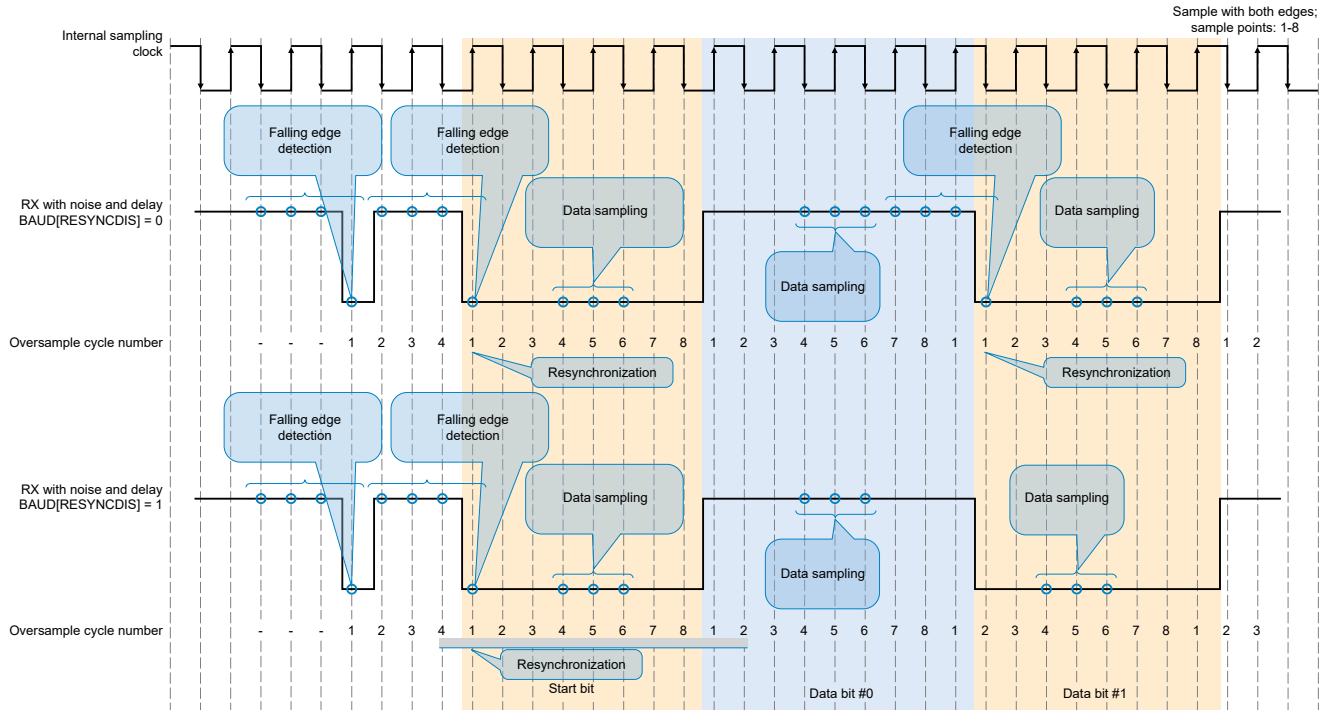

Figure 292. LPUART resynchronization diagram

68.5.2.5.2 Receiver wake-up operation

Receiver wake-up and receiver address matching are hardware mechanisms that allow an LPUART receiver to ignore the characters in a message intended for a different receiver.

During receiver wake-up, all receivers evaluate the first character(s) of each message, and as soon as they determine the message is intended for a different receiver, they write 1 to CTRL[RWU].

When CTRL[RWU] and STAT[RWUID] are 1, the status fields associated with the receiver, with the exception of STAT[IDLE], are inhibited from becoming 1, thus eliminating the software overhead for handling the unimportant message characters. At the end of a message, all receivers automatically force CTRL[RWU] to become 0. This results in all receivers waking up in time to look at the first character(s) of the next message.

During receiver address matching, the address matching is performed in hardware and the LPUART receiver ignores all characters that do not meet the address match requirements.

Table 666. Receiver wake-up options

CTRL[RWU]	BAUD[MAEN1] | BAUD[MAEN2]	BAUD[MATCFG]	CTRL[WAKE]: STAT[RWUID]	Receiver wake-up
0	0	X	X	Normal operation
1	0	00	00	Receiver wake-up on idle line; STAT[IDLE] = 0
1	0	00	01	Receiver wake-up on idle line; STAT[IDLE] = 1
1	0	00	10	Receiver wake-up on address mark
1	1	11	10	Receiver wake-up on data match
0	1	00	X0	Address mark address match; STAT[IDLE] = 0 for discarded characters
0	1	00	X1	Address mark address match; STAT[IDLE] = 1 for discarded characters
0	1	01	X0	Idle line address match
0	1	10	X0	Match on and match off; STAT[IDLE] = 0 for discarded characters
0	1	10	X1	Match on and match off; STAT[IDLE] = 1 for discarded characters

68.5.2.5.2.1 Idle line wake-up

When CTRL[WAKE] is 0, you can configure the receiver for an idle line wake-up. In this mode, CTRL[RWU] becomes 0 automatically when the receiver detects a full character time of the idle-line level.

When CTRL[RWU] is set the receiver ignores everything until an idle condition is detected. After the idle condition is detected the CTRL[RWU] is cleared by hardware and the receiver starts receiving data.

The STAT[RWUID] indicates that whether the STAT[IDLE] flag is set or not as a result of the idle condition detection which clears CTRL[RWU].

The STAT[RWUID] says that if the STAT[IDLE] flag is to be set as a result of the idle condition which clears CTRL[RWU].

CTRL[M], CTRL[M7], and BAUD[M10] select 7-bit to 10-bit Data mode and BAUD[SBNS] selects a 1-bit or 2-bit stop bit number that determines how many bit times of idle are needed to constitute a full character time, 9 to 13 bit times because of the start and stop bits.

When CTRL[RWU] is 1 and STAT[RWUID] is 0, the idle condition that wakes up the receiver does not lead to STAT[IDLE] becoming 1. The receiver wakes up and waits for the first data character of the next message that leads to STAT[RDRF] becoming 1 and generates an interrupt if enabled. When STAT[RWUID] is 1, any idle condition leads to STAT[IDLE] becoming 1 and generates an interrupt if enabled, regardless of whether CTRL[RWU] is 0 or 1.

These are the ways to detect an idle line:

- When CTRL[ILT] is 0, the idle bit counter starts after the start bit so that the stop bit and any logic 1s at the end of a character count to calculate the full character time of idle.
- When CTRL[ILT] is 1, the idle bit counter does not start until after the stop bit time so that the data in the last character of the previous message does not impact the idle detection.

68.5.2.5.2.2 Address mark wake-up

When CTRL[WAKE] is 1, you can configure the receiver for an address mark wake-up. In this mode, CTRL[RWU] becomes 0 automatically when the receiver detects a logic 1 in the most significant bit of the received character. When parity is enabled, the second most significant bit is used for address mark wake-up.

Address mark wake-up allows messages to contain idle characters, but requires one bit to be reserved for use in address frames. The logic 1 in the most significant bit (or second most significant bit when parity is enabled) of an address frame writes 0 to CTRL[RWU] and writes 1 to STAT[RDRF]. In this case, the character with the address mark bit is received even if the receiver is sleeping during most of this character time.

68.5.2.5.2.3 Data match wake-up

When CTRL[RWU] and CTRL[WAKE] are 1, and BAUD[MATCFG] equals 11, the receiver is configured for a data match wake-up. In this mode, CTRL[RWU] becomes 0 automatically when the receiver detects a character that matches MATCH[MA1] when BAUD[MAEN1] is 1, or that matches MATCH[MA2] when BAUD[MAEN2] is 1.

68.5.2.5.2.4 Address match operation

You can enable the address match operation when either BAUD[MAEN1] or BAUD[MAEN2] is 1 and BAUD[MATCFG] is 0. In this function, a character that the RXD pin receives with a logic 1 in the most significant bit (or the second most significant bit when parity is enabled) is considered an address and is compared to the associated MATCH[MA1] or MATCH[MA2]. The character is only transferred to the receive buffer, and STAT[RDRF] becomes 1 if the comparison matches. All subsequent characters received with a logic 0 in the most significant bit (or the second most significant bit when parity is enabled) are considered to be data associated with the address and are transferred to the receive FIFO. If no marked address match occurs, no transfer is made to the receive FIFO, and all the characters that follow, with logic 0 in the most significant bit (or second most significant bit when parity is enabled), are also discarded. If both BAUD[MAEN1] and BAUD[MAEN2] are 0, the receiver operates normally, and all the received data is transferred to the receive FIFO.

The address match operation functions in the same way for both MATCH[MA1] and MATCH[MA2]:

- If either BAUD[MAEN1] or BAUD[MAEN2] is 1, a marked address is compared only to the associated Match Address (MATCH) and data is transferred to the receive FIFO only on a match.
- If both BAUD[MAEN1] and BAUD[MAEN2] are 1, a marked address is compared to both MATCH[MA1] and MATCH[MA2] and data is transferred only on a match with either of these fields.

68.5.2.5.2.5 Idle match operation

You can enable the idle match operation when either BAUD[MAEN1] or BAUD[MAEN2] is 1 and BAUD[MATCFG] is 1. In this function, the first character that the RXD pin receives after an idle line condition is considered an address and is compared to the associated MATCH[MA1] or MATCH[MA2]. The character is transferred only to the receive buffer, and STAT[RDRF] becomes 1, if the comparison matches. All subsequent characters are considered to be data associated with the address and are transferred

to the receive FIFO until the next idle line condition is detected. If no address match occurs, no transfer is made to the receive FIFO, and all the frames that follow, until the next idle condition, are also discarded. If both BAUD[MAEN1] and BAUD[MAEN2] are 0, the receiver operates normally, and all the received data is transferred to the receive FIFO.

An idle match operation functions in the same way for both MATCH[MA1] and MATCH[MA2]:

- If either BAUD[MAEN1] or BAUD[MAEN2] is 1, the first character after an idle line is compared only to the associated Data (DATA) and data is transferred to the receive FIFO only on a match.
- If both BAUD[MAEN1] and BAUD[MAEN2] are 1, the first character after an idle line is compared to both MATCH[MA1] and MATCH[MA2] and data is transferred only on a match with either of these fields.

68.5.2.5.2.6 Match on, match off operation

The match on, match off operation is enabled when both BAUD[MAEN1] and BAUD[MAEN2] are 1 and BAUD[MATCFG] = 10. In this function, a character that the RXD pin receives matches MATCH[MA1] and is transferred to the receive buffer, and STAT[RDRF] becomes 1. All subsequent characters are considered to be data and are also transferred to the receive FIFO, until a character that matches MATCH[MA2] is received. The character that matches MATCH[MA2], along with all subsequent characters, is discarded; and this continues until another character that matches MATCH[MA1] is received. If both BAUD[MAEN1] and BAUD[MAEN2] are 0, the receiver operates normally, and all the received data is transferred to the receive FIFO.

NOTE

The match on, match off operation requires both BAUD[MAEN1] and BAUD[MAEN2] to be 1.

68.5.2.5.3 Hardware flow control

To support hardware flow control, you can program the receiver to automatically assert and deassert RTS_B:

- RTS_B remains asserted until the transfer is complete, even if the transmitter is disabled midway through a data transfer. See Transceiver driver enable using RTS_B for more information.
- If the receiver RTS functionality is enabled, the receiver automatically deasserts RTS_B if STAT[RDRF] is 1 or a start bit is detected that causes STAT[RDRF] to become 1.
- The receiver asserts RTS_B when STAT[RDRF] is 0 and has not detected a start bit that causes STAT[RDRF] to become 1. There is no impact if STAT[RDRF] is 1 already.
- Even if RTS_B is deasserted, the receiver continues to receive characters until the receive FIFO is overrun.
- If the receiver RTS functionality is disabled, the receiver's RTS_B remains deasserted.
- When RTS is driven by receiver, it will be negated when the receiver is disabled irrespective of the FIFO level.

68.5.2.6 Additional LPUART functions

68.5.2.6.1 Data modes

You can configure the LPUART transmitter and receiver to operate in 7-bit Data mode by writing 1 to CTRL[M7], 9-bit Data mode by writing 1 to CTRL[M], or 10-bit Data mode by writing 1 to BAUD[M10]. In 9-bit Data mode, there exists a ninth data bit and in 10-bit mode, there exists a tenth data bit.

When performing 8-bit writes to the transmit FIFO, the ninth and tenth bits are pushed into the FIFO from CTRL[T8] and CTRL[T9]. For coherent 8-bit writes, you must write to CTRL[T8] and CTRL[T9] before writing to Data (DATA)[7:0]. However, if the values in CTRL[T8] or CTRL[T9] do not need to change, it is not necessary to update CTRL[T8] and CTRL[T9] before every 8-bit write to Data (DATA).

When performing 16-bit or 32-bit writes to the transmit FIFO, all 10 bits are pushed into the transmit FIFO from the write data.

When performing 8-bit reads of the receive FIFO, the ninth and tenth bits are held in CTRL[R8] and CTRL[R9] but you must read them before reading Data (DATA). A 16-bit or 32-bit read of the receive FIFO returns all 10 bits in Data (DATA).

The 9-bit Data mode is typically used with parity to allow eight bits of data plus the parity in the ninth bit, or it is used with the address mark wake-up so that the ninth data bit can serve as the wake-up bit. The 10-bit Data mode is typically used with parity and address mark wake-up so that the ninth data bit can serve as the wake-up bit and the tenth bit can serve as the parity bit. In custom protocols, the ninth and/or tenth bits can also serve as software-controlled markers.

68.5.2.6.2 Idle length

An idle character is one where the start bit, all data bits, and stop bits are in the mark position (idle state, generally logic 1). You can configure CTRL[ILT] to start detecting an idle character from the previous start bit (any data bits and stop bits count for idle character detection) or from the previous stop bit.

You can also use CTRL[IDLECFG] to configure the number of idle characters that must be received before an idle line condition is detected. This field configures the number of idle characters that must be received before STAT[IDLE] becomes 1, STAT[RAF] becomes 0, and DATA[IDLINE] becomes 1 with the next received character.

CTRL[IDLECFG] also affects the idle line wake-up and idle match operations. When either the address match or match on/off operation is enabled, writing 1 to STAT[RWUID] causes any discarded characters to be treated as idle characters.

68.5.2.6.3 Loop mode

Enable Loop mode by setting CTRL[LOOPS] = 1 and CTRL[RSRC] = 0. You, sometimes, use Loop mode to check software, independent of connections in the external system, to help isolate system problems. In this mode, the transmitter output is internally connected to the receiver input and LPUART does not use the RXD pin.

Loop mode also internally connects the RTS_B output to the CTS_B input.

68.5.2.6.4 Single-Wire mode

Enable Single-Wire mode by setting CTRL[LOOPS] = 1 and CTRL[RSRC] = 1. Single-Wire mode implements a half-duplex serial connection. The receiver is internally connected to the transmitter output and TXD pin (the RXD pin is not used).

In Single-Wire mode, CTRL[TXDIR] controls the direction of serial data on the TXD pin. When CTRL[TXDIR] becomes 0, the TXD pin is an input to the receiver and the transmitter is temporarily disconnected from the TXD pin so that an external device can send serial data to the receiver. When CTRL[TXDIR] = 1, the TXD pin is an output that the transmitter drives. The internal loop back connection is disabled, and as a result, the receiver is unable to receive characters that the transmitter sends out.

68.5.2.7 Peripheral triggers

The connection of the LPUART peripheral triggers with other peripherals is chip-specific.

68.5.2.7.1 Output triggers

LPUART generates the following output triggers that can be connected to other peripherals on the chip:

- The transmit word trigger asserts at the end of each transmitted word and negates after 1-bit period.
- The transmit data trigger is identical to the TXD pin output, but without support for input trigger modulation.
- The receive word trigger asserts at the end of each received word that is written to the receive FIFO, for one oversampling clock period.
- The receive idle trigger asserts when STAT[IDLE] becomes 1, and negates when the next valid start bit is detected.

68.5.2.7.2 Input trigger

LPUART supports a peripheral input trigger that you can configure in one of the following ways:

- By enabling the CTS function: You can connect the input trigger (active high) instead of the CTS_B (active low) pin input. The input trigger must assert for longer than 1-bit clock period when the transmitter is idle, with data to send, to guarantee a new transmission.

- By making the input trigger modulate the transmit data output (trigger is logically ANDed with the TXD output): The input trigger is expected to be a free-running clock (carrier signal) that generates from a timer or PWM source with a frequency that is greater than the bit-clock frequency. The carrier signal must not toggle faster than the maximum supported bit time.
- By connecting the input trigger instead of the RXD pin input: The input trigger is expected to be generated from a receive data source, such as an analog comparator or external pin.

68.5.2.8 Infrared (IR) interface

LPUART provides the capability of transmitting narrow pulses to an IR LED and receiving narrow pulses, transforming them to serial bits, which are then sent to LPUART. The IrDA physical layer specification defines a half-duplex IR communication link for exchanging data. The full standard includes data rates up to 16 Mbit/s. The LPUART IrDA support is limited to SIR mode that supports data rates only between 2.4 kbit/s and 115.2 kbit/s.

LPUART has an infrared transmit encoder and a receive decoder. The infrared decoder converts the received character from the IrDA format to the NRZ format, which the receiver uses. It also has an OSR oversampling baud rate clock counter that filters noise and indicates when a 1 is received. LPUART transmits serial bits of data, which the infrared submodule encodes, to transmit a narrow pulse for every zero bit. No pulse is transmitted for every single bit. When receiving data, an IR photo diode (external to LPUART) detects the IR pulses. The IR receive decoder transforms them to CMOS levels. The infrared receive decoder then stretches the narrow pulses to get back to a serial bit stream that LPUART receives. You can invert the polarity of transmitted pulses and expected receive pulses so that a direct connection can be made to external IrDA transceiver modules that use active-high pulses.

The IR submodule receives its clock sources from LPUART. The submodule selects one of these clocks to generate either 1 ÷ OSR, 2 ÷ OSR, 3 ÷ OSR, or 4 ÷ OSR narrow pulses during transmission.

68.5.2.8.1 Infrared transmit encoder

The infrared transmit encoder converts serial bits of data from the transmit shift register to the TXD signal. A narrow pulse is transmitted for a 0 bit and no pulse is transmitted for a 1 bit. The narrow pulse is sent at the start of the bit with a duration of 1 ÷ OSR, 2 ÷ OSR, 3 ÷ OSR, or 4 ÷ OSR of a bit time. A narrow low pulse is transmitted for a 0 bit when CTRL[TXINV] is 0, while a narrow high pulse is transmitted for a 0 bit when CTRL[TXINV] is 1.

68.5.2.8.2 Infrared receive decoder

The infrared receive block converts data from the RXD signal to the receive shift register. A narrow pulse is expected for each 0 received and no pulse is expected for each 1 received. A narrow low pulse is expected for a 0 bit when STAT[RXINV] is 0, while a narrow high pulse is expected for a 0 bit when STAT[RXINV] is 1. This receive decoder meets the edge jitter requirement as defined by the IrDA serial infrared physical layer specification.

68.5.2.8.3 Start-bit detection

When STAT[RXINV] is 0, the first falling edge of the received character corresponds to the start bit. The infrared decoder resets its counter. At this time, the receiver also begins its start bit detection process. After the start bit is detected, the receiver synchronizes its bit times to this start bit time. For the rest of the character reception, the infrared decoder's counter and the receiver's bit time counter count independently of each other.

68.5.2.8.4 Noise filtering

The decoder ignores any rising edges detected during the first half of the infrared decoder counter, and can leave any pulses less than one oversampling baud clock as undetected. This is regardless of whether the pulse is seen in the first or second half of the count.

68.5.2.8.5 Low-bit detection

During the second half of the decoder count, a rising edge is decoded as 0, which is sent to the receiver. The decoder counter is also reset.

68.5.2.8.6 High-bit detection

At OSR oversampling baud rate clocks after the previous rising edge, if a rising edge is not seen, the decoder sends a 1 to the receiver.

If the next bit is 0, which arrives late, a low bit is detected according to Low-bit detection. The value sent to the receiver is changed from 1 to 0. Then, if a noise pulse occurs outside the receiver's bit time sampling period, the delay of a 0 is not recorded as noise.

68.5.2.9 Modes of operation

68.5.2.9.1 Low-Power modes

LPUART remains functional during low-power modes, provided CTRL[DOZEEN] is 0 and the LPUART functional clock is enabled. LPUART can generate an interrupt or DMA request to cause a wake-up from low-power modes.

You can configure LPUART to be disabled in low-power modes, when CTRL[DOZEEN] is 1. In this case, the transmitter and receiver finish transmitting and receiving the current word.

If LPUART is disabled in low-power modes, it can generate a wake-up via STAT[RXEDGIF] if the receiver detects an active edge.

NOTE

See the chip-specific information for specific low-power modes available on your chip.

68.5.2.9.2 Debug mode

LPUART remains functional in Debug mode.

68.5.2.10 Clocking

Table 667. Types of clocks

Clock	Description
Functional	Is asynchronous to the bus clock and can remain enabled in Low-Power modes to support transmit and/or receive functions, including low-power wake-up.
Bus	Is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPUART transmit and receive registers, including the FIFOs.

68.5.2.11 Reset

Table 668. Types of resets

Reset	Description
Chip	Enables the logic and registers for the LPUART transmitter and receiver to reset to their default states.
Software	Resets the LPUART logic and registers to their default states, except for Global (GLOBAL). GLOBAL[RST] controls the LPUART software reset.
FIFO	Implements write-only control fields that reset the transmit FIFO (FIFO[TXFLUSH]) and receive FIFO (FIFO[RXFLUSH]). After a FIFO is reset, that FIFO becomes empty.

68.5.2.12 Interrupts

The LPUART transmitter has two status fields that can optionally generate hardware interrupt requests. If STAT[TDRE] is 1, it indicates that there is room in the transmit FIFO to write another transmit character to Data (DATA). If CTRL[TIE] is 1, a hardware interrupt is requested when STAT[TDRE] is 1.

STAT[TC] indicates that the transmitter is finished transmitting all data, preamble, and break characters and is idle with TXD at the inactive level. This field is often used in systems with modems to determine when it is safe to turn off the modem. If CTRL[TCIE] is 1, a hardware interrupt is requested when STAT[TC] is 1. Instead of hardware interrupts, software polling may be used to monitor STAT[TDRE] and STAT[TC] if the corresponding CTRL[TIE] or CTRL[TCIE] field is 0.

When a program detects that STAT[RDRF] is 1, it gets the data from this field by reading Data (DATA). The field becomes 0 by reading Data (DATA).

STAT[IDLE] includes logic that prevents it from becoming 1 repeatedly when the RXD line remains idle for an extended period of time. STAT[IDLE] becomes 0 when you write 1 to it, and cannot become 1 again until the receiver has received at least one new character and has 1 as the value of STAT[RDRF].

If the associated error is detected in the received character that caused STAT[RDRF] to become 1, STAT[NF], STAT[FE], and STAT[PF] become 1 at the same time STAT[RDRF] becomes 1. These flags do not become 1 in overrun cases.

If STAT[RDRF] is already 1 when a new character is ready to be transferred from the receive shifter to the receive FIFO, STAT[OR] becomes 1, instead of the data along with any associated STAT[NF], STAT[FE], or STAT[PF] condition getting lost.

If the received character matches the contents of MATCH[MA1] and/or MATCH[MA2], then STAT[MA1F] and/or STAT[MA2F] become 1 at the same time that STAT[RDRF] becomes 1.

At any time, an active edge on the RXD serial data input pin causes STAT[RXEDGIF] to become 1. STAT[RXEDGIF] becomes 0 when you write 1 to it. This function depends on the receiver being enabled (the value of CTRL[RE] being 1).

68.5.2.13 DMA

68.5.2.13.1 DMA burst support

To support efficient DMA transfers to the transmit FIFO, two alias regions are implemented to support incrementing 8-bit, 16-bit, or 32-bit write accesses to the transmit FIFO:

- Transmit Command Burst (TCBR0 - TCBR127) is a 512-byte region that supports pushing 16-bit data into the transmit FIFO.
- Transmit Data Burst (TDBR0 - TDBR255) is a 1024-byte region that supports pushing zero extended 8-bit data into the transmit FIFO.

The aforementioned regions are contiguous, so a DMA transfer can start in Transmit Command Burst (TCBR0 - TCBR127) to initialize the transfer including address mark, idle word, or break character, and then complete the transfer in Transmit Data Burst (TDBR0 - TDBR255) with the data to transmit, without changing the transfer size.

The transmit FIFO block writes overflow the FIFO, but that does not signal an error. Do not perform 32-bit writes to Transmit Data Burst (TDBR0 - TDBR255) unless there are four empty slots in the transmit FIFO, and do not perform 16-bit writes to this register unless there are two empty slots in the transmit FIFO.

68.5.2.13.2 End-of-packet DMA transfers

The end-of-packet functionality is designed for serial interfaces where you may not know the size of the transfer in advance and the data is being pushed by an external device. The end-of-packet processing ensures that data does not become stranded in either the receive FIFO or the DMA receive buffer. Support for end-of-packet processing must be implemented in both the serial interfaces and DMA controller.

The condition that signals the end of packet is different for each serial interface, but the serial peripheral and DMA process it in the same way. For example, an idle line condition signals the UART end of packet, the Stop and/or Repeated Start condition signals the I2C end of packet, and PCS negation signals the SPI end of packet.

When the serial peripheral is configured to signal the end-of-packet condition to the DMA and the serial interface detects an end-of-packet condition, it asserts the DMA request for the receive FIFO irrespective of the watermark configuration. For larger watermark configurations, this ensures that the last few words of the transfer are first flushed from the receive FIFO.

The DMA then reads the contents of the receive FIFO, depending on the first word in the FIFO:

- If the receive FIFO is empty, the serial interface signals an end of packet condition to the DMA controller.
- If the receive FIFO is not empty, but the first word in the FIFO is the start of a new packet, data is not pulled from the receive FIFO and the serial interface signals an end-of-packet condition to the DMA controller.
- If the receive FIFO is not empty, and the first word in the FIFO is not the start of a new packet, the DMA transfers the receive data as normal.

Because the DMA may be transferring multiple words on each request, the end-of-packet condition persists until the DMA minor loop has completed and no additional data is pulled from the receive FIFO. The field that triggered the end-of-packet condition becomes 0 when the minor loop completes following the end of packet being signaled to the DMA controller.

When the DMA detects the end-of-packet condition, it writes all received words up to the end of packet into the system memory and saves the destination address for the word after the last valid data. The DMA then terminates the channel as if the major loop completed, including final offsets and optional interrupts, channel linking, and scatter-gather. You can, optionally, save the final destination address to the system memory. The final destination address is also available in the destination address register.

Because the DMA terminates the major loop, no servicing of the receive FIFO occurs until you or the hardware reconfigures the DMA (for example, channel linking or scatter-gather). You must minimize this delay to avoid receiver FIFO overrun. The automatic DMA end-of-packet processing is not recommended when there are only a few words transferred between end-of-packet conditions. This is because the DMA spends more time processing the end of packet than transferring the data. For example, the UART idle line length must be increased as needed to avoid an excessive number of idle conditions.

68.5.3 External signals

Table 669. External signals

Signal	Description	I/O
TXD	Transmit data: This pin is normally an output, but is an input (tristated) in Single-Wire mode whenever the transmitter is disabled or the transmit direction is configured for receive data.	I/O
RXD	Receive data	I
CTS_B	Clear-to-send	I
RTS_B	Request-to-send	O

68.5.4 Initialization

This module does not require initialization.

68.5.5 LPUART register descriptions

LPUART includes registers to control baud rate, select options, report status, and store transmit and receive data. Access to an address outside the valid memory map generates a bus error.

NOTE

Writing to a read-only (RO) register or reading a write-only (WO) register can cause bus errors. LPUART does not verify whether programmed values in the registers are correct; you must write valid values to them.

68.5.5.1 LPUART memory map

LPUART0 base address: 4011_0000h

LPUART1 base address: 4011_1000h

LPUART2 base address: 4011_2000h

LPUART3 base address: 4011_3000h

LPUART4 base address: 4017_1000h

LPUART5 base address: 4017_2000h

LPUART6 base address: 4017_3000h

LPUART7 base address: 4017_4000h

LPUART8 base address: 4019_9000h

LPUART9 base address: 4019_A000h

LPUART10 base address: 4019_B000h

LPUART11 base address: 4019_C000h

LPUART12 base address: 4019_D000h

LPUART13 base address: 4019_E000h

LPUART17 base address: 4032_6000h

LPUART18 base address: 4032_7000h

LPUART19 base address: 4032_8000h

LPUART20 base address: 4032_9000h

Fields

Field	Function
31-2 —	Reserved
1 RST	Software Reset Specifies whether the module is reset. This field resets all internal logic and registers, except Global (GLOBAL). The reset takes effect immediately and remains asserted until you negate it. There is no minimum delay required before clearing the software reset. 0b - Not reset 1b - Reset
0 —	Reserved

68.5.5.5 Pin Configuration (PINCFG)

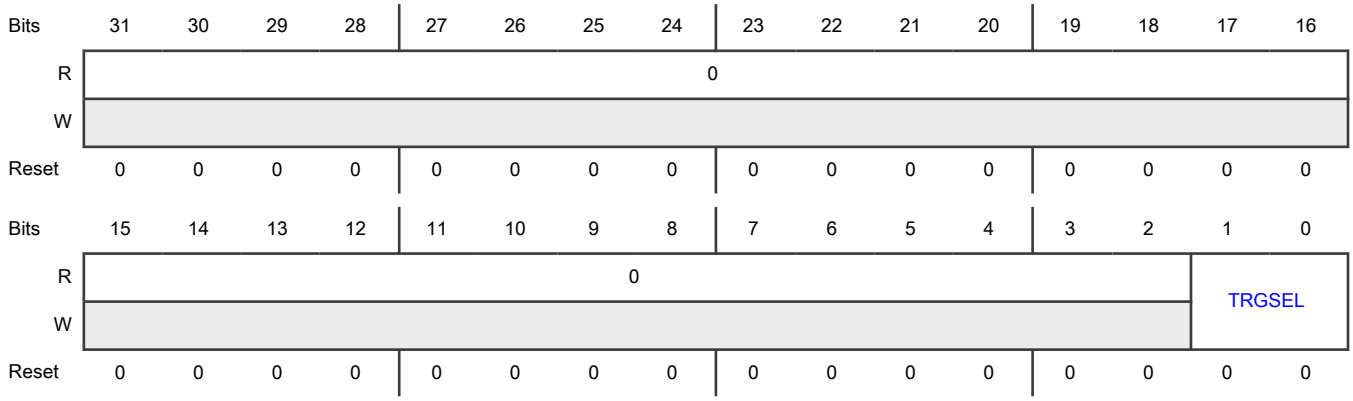
Offset

Register	Offset
PINCFG	Ch

Function

Enables the selection of input pins.

Diagram



Fields

Field	Function
31-2 —	Reserved
1-0 TRGSEL	Trigger Select Configures the input trigger usage. You must change the value of this field only when both the transmitter and receiver are disabled. 00b - Input trigger disabled 01b - Input trigger used instead of the RXD pin input 10b - Input trigger used instead of the CTS_B pin input 11b - Input trigger used to modulate the TXD pin output, which (after TXINV configuration) is internally ANDed with the input trigger

68.5.5.6 Baud Rate (BAUD)

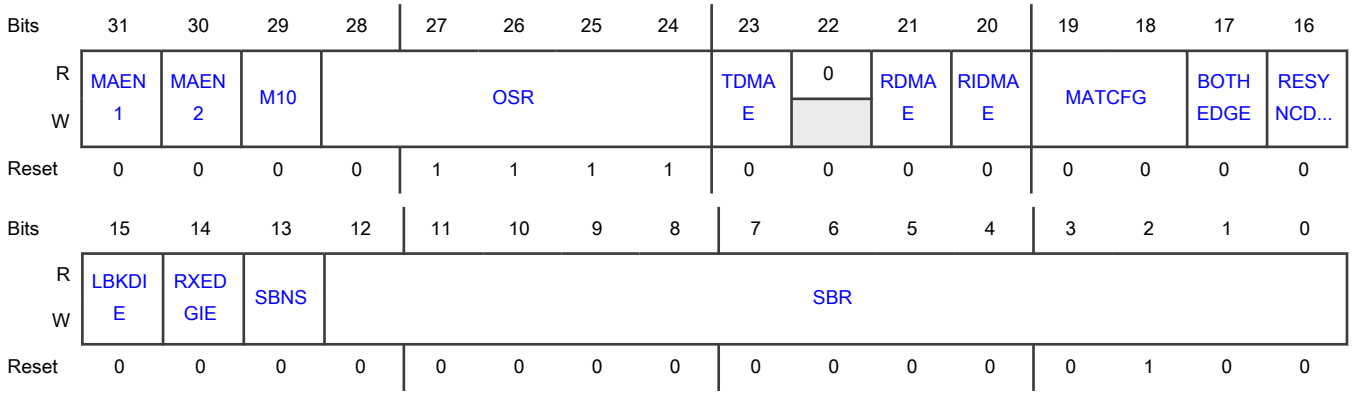
Offset

Register	Offset
BAUD	10h

Function

Configures the baud rate.

Diagram



Fields

Field	Function
31 MAEN1	Match Address Mode Enable 1 Enables automatic address matching or data matching mode for MATCH[MA1]. If this field is 0, normal operation takes place. 0b - Disable 1b - Enable
30 MAEN2	Match Address Mode Enable 2 Enables automatic address matching or data matching mode for MATCH[MA2]. If this field is 0, normal operation takes place. 0b - Disable 1b - Enable
29 M10	10-Bit Mode Select Causes the tenth bit to be a part of the serial transmission. You must change the value of this field only when both the transmitter and receiver are disabled. 0b - Receiver and transmitter use 7-bit to 9-bit data characters 1b - Receiver and transmitter use 10-bit data characters
28-24 OSR	Oversampling Ratio Configures the OSR of the receiver. You must change the value of this field only when both the transmitter and receiver are disabled. **NOTE** BAUD[OSR] results in an OSR of BAUD[OSR] + 1, for example, BAUD[OSR] = 0_0101b results in a final division by 6. 0_0000b - Results in an OSR of 16 0_0001b - Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0_0010b - Reserved 0_0011b - Results in an OSR of 4 (requires BAUD[BOTHEDGE] to be 1) 0_0100b - Results in an OSR of 5 (requires BAUD[BOTHEDGE] to be 1) 0_0101b - Results in an OSR of 6 (requires BAUD[BOTHEDGE] to be 1) 0_0110b - Results in an OSR of 7 (requires BAUD[BOTHEDGE] to be 1) 0_0111b - Results in an OSR of 8 0_1000b - Results in an OSR of 9 0_1001b - Results in an OSR of 10 0_1010b - Results in an OSR of 11 0_1011b - Results in an OSR of 12 0_1100b - Results in an OSR of 13 0_1101b - Results in an OSR of 14 0_1110b - Results in an OSR of 15 0_1111b - Results in an OSR of 16 1_0000b - Results in an OSR of 17 1_0001b - Results in an OSR of 18 1_0010b - Results in an OSR of 19 1_0011b - Results in an OSR of 20 1_0100b - Results in an OSR of 21 1_0101b - Results in an OSR of 22 1_0110b - Results in an OSR of 23 1_0111b - Results in an OSR of 24 1_1000b - Results in an OSR of 25 1_1001b - Results in an OSR of 26 1_1010b - Results in an OSR of 27 1_1011b - Results in an OSR of 28 1_1100b - Results in an OSR of 29 1_1101b - Results in an OSR of 30 1_1110b - Results in an OSR of 31 1_1111b - Results in an OSR of 32
23 TDMAE	Transmitter DMA Enable Enables STAT[TDRE] to generate a DMA request. 0b - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enable
22 —	Reserved
21 RDMAE	Receiver Full DMA Enable Enables STAT[RDRF] to generate a DMA request. 0b - Disable 1b - Enable
20 RIDMAE	Receiver Idle DMA Enable Enables STAT[IDLE] to generate a DMA request. If this field is 1, reading Data (DATA) when either DATA[RXEMPT] or DATA[IDLINE] is 1 generates an end-of-packet response until the completion of the DMA minor loop. During an end-of-packet response, reading Data (DATA) returns 0000_33FFh and does not pull data from the receive FIFO. STAT[IDLE] becomes 0 on completion of the minor loop, provided an end-of-packet response is generated and either the receive FIFO is empty or the receiver is active. 0b - Disable 1b - Enable
19-18 MATCFG	Match Configuration Configures the match addressing mode used. You must change the value of this field only when both the transmitter and receiver are disabled. 00b - Address match wake-up 01b - Idle match wake-up 10b - Match on and match off 11b - Enables RWU on data match and match on or off for the transmitter CTS input
17 BOTHEDGE	Both Edge Sampling Enables sampling of the received data on both edges of the baud rate clock, effectively doubling the number of times the receiver samples the input data for a given OSR. This field must be 1 for OSRs between x4 and x7 and is optional for higher OSRs. You must change the value of this field only when the receiver is disabled. If this field is 0, the receiver samples input data using the rising edge of the baud rate clock. If this field is 1, the receiver samples input data using the rising and falling edges of the baud rate clock. 0b - Rising edge 1b - Both rising and falling edges
16 RESYNCDIS	Resynchronization Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Disables resynchronization of the received data word when a data one followed by data zero transition is detected. You must change the value of this field only when the receiver is disabled. 0b - Enable 1b - Disable
15 LBKDIE	LIN Break Detect Interrupt Enable Enables STAT[LBKDIF] to generate hardware interrupt requests. If this field is 0, hardware interrupts from STAT[LBKDIF] (uses polling) are disabled. If this field is 1, hardware interrupts are requested when STAT[LBKDIF] is 1. 0b - Disable 1b - Enable
14 RXEDGIE	RX Input Active Edge Interrupt Enable Enables STAT[RXEDGIF] to generate interrupt requests. If this field is 0, hardware interrupts from STAT[RXEDGIF] are disabled. If this field is 1, hardware interrupts are requested when STAT[RXEDGIF] is 1. Changing the value of CTRL[LOOPS] or CTRL[RSRC] when this field (RXEDGIE) is 1 can cause STAT[RXEDGIF] to become 1. 0b - Disable 1b - Enable
13 SBNS	Stop Bit Number Select Determines whether data characters include one or two stop bits. You must change the value of this field only when both the transmitter and receiver are disabled. 0b - One stop bit 1b - Two stop bits
12-0 SBR	Baud Rate Modulo Divisor Sets the modulo divide rate for the baud rate generator. • If SBR is 0, baud rate generator is disabled. • If SBR is 1–8191, baud rate = baud clock ÷ ((OSR + 1) × SBR). You must update the 13-bit baud rate setting [SBR12:SBR0] only when both the transmitter and receiver are disabled (both CTRL[RE] and CTRL[TE] are 0).

68.5.5.7 Status (STAT)

Offset

Register	Offset
STAT	14h

Function

Provides the module status.

Fields

Field	Function
31 LBKDIF	LIN Break Detect Interrupt Flag Indicates whether a LIN break character is detected. This field becomes 1 when the LIN break detect circuitry is enabled and a LIN break character is detected. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag
30 RXEDGIF	RXD Pin Active Edge Interrupt Flag Indicates whether an active edge on the receive pin has occurred.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field becomes 1 whenever the receiver is enabled and an active edge (falling if STAT[RXINV] is 0; rising if STAT[RXINV] is 1) on the RXD pin occurs. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not occurred 1b - Occurred When writing 0b - No effect 1b - Clear the flag
29 MSBF	MSB First Specifies the first bit that is transmitted after the start bit. If this field is 0, LSB (bit 0) is the first bit transmitted after the start bit (which means, the first bit received after the start bit is identified as bit 0). If this field is 1, MSB (identified as bit 9, bit 8, bit 7, or bit 6) is the first bit that is transmitted, after the start bit, depending on the settings of CTRL[M], CTRL[PE], and BAUD[M10]. Writing 1 to this field reverses the order of the bits that are transmitted and received on the wire. This field does not affect the polarity of the bits, the location of the parity bit, or the location of the start or stop bits. You must change the value of this field only when both the transmitter and receiver are disabled. 0b - LSB 1b - MSB
28 RXINV	Receive Data Inversion Specifies whether receive data is inverted. Writing 1 to this field reverses the polarity of the received data input. You must change the value of this field only when the receiver is disabled. **NOTE** Writing 1 to this field inverts the RXD input for all cases: data bits, start and stop bits, break, and idle. 0b - Inverted 1b - Not inverted
27 RWUID	Receive Wake Up Idle Detect Controls, for CTRL[RWU] on idle character detection, whether the idle character that wakes up the receiver writes 1 to STAT[IDLE]. For address match wake-up, this field controls whether STAT[IDLE] = 1 when the address does not match. You must change the value of this field only when the receiver is disabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 0, during the Receive Standby state (CTRL[RWU] = 1), STAT[IDLE] does not become 1 upon detection of an idle character. During address match wake-up, STAT[IDLE] does not become 1 when an address does not match. If this field is 1, during the Receive Standby state (CTRL[RWU] = 1), STAT[IDLE] becomes 1 upon detection of an idle character. During address match wake-up, STAT[IDLE] becomes 1 when an address does not match. 0b - STAT[IDLE] does not become 1 1b - STAT[IDLE] becomes 1
26 BRK13	Break Character Generation Length Selects the longer transmitted break character length. The state of this field does not affect the detection of a framing error. You must change the value of this field only when the transmitter is disabled. You can send a break character by writing 1 to CTRL[SBK], or by writing the transmit FIFO when DATA[FRETSC] is 1 and DATA[R9T9] is 0. 0b - 9 to 13 bit times 1b - 12 to 15 bit times
25 LBKDE	LIN Break Detection Enable Enables LIN break detection. If this field is 0, LIN break detect is disabled, and only a normal break character can be detected. If this field is 1, LIN break detect is enabled and the LIN break character is detected at a length of 11 bit times (if CTRL[M] is 0), 12 bit times (if CTRL[M] is 1), or 13 bit times (if BAUD[M10] is 1). This field selects a longer break character detection length. When the field is 1, receive data is not stored in the receive FIFO. **NOTE** This field enables the LIN break detect circuit and disables writing receive data to FIFO. Therefore, it ignores all characters except a LIN break. 0b - Disable 1b - Enable
24 RAF	Receiver Active Flag Indicates whether the LPUART receiver is idle or active. This field becomes 1 when the receiver detects the beginning of a valid start bit, and the field becomes 0 automatically when the receiver detects an idle line. 0b - Idle, waiting for a start bit 1b - Receiver active (RXD pin input not idle)
23 TDRE	Transmit Data Register Empty Flag Indicates whether the transmit FIFO level is greater than, equal to, or less than the watermark.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	After the transmit FIFO is enabled, this field becomes 1 when the number of datawords in the transmit FIFO is equal to, or less than the number that WATER[TXWATER] indicates. To make the value of this field 0, write to it until the number of words in the transmit FIFO is greater than the number that WATER[TXWATER] indicates. After the transmit FIFO is disabled, this field becomes 1 to indicate that the FIFO level is less than the watermark. To make the value of this field 0 again, write to Data (DATA). This register is not affected by a character that is in the process of being transmitted; it is updated at the start of each transmitted character. 0b - Greater than watermark 1b - Equal to or less than watermark
22 TC	Transmission Complete Flag Indicates whether the transmitter is active. This field becomes 0 when a transmission is in progress or a preamble or break character is loaded; in other words, when the transmitter is active (sending data, a preamble, or a break). The field becomes 1 when the transmit buffer is empty and no data, preamble, or break character is being transmitted; in other words, when the transmission activity is complete. When this happens, the transmit data output signal becomes idle (logic 1). This field becomes 0 after you write to Data (DATA) to transmit new data, queuing a preamble by first writing 0 and then writing 1 to CTRL[TE], queuing a break character by writing 1 to CTRL[SBK]. 0b - Transmitter active 1b - Transmitter idle
21 RDRF	Receive Data Register Full Flag Indicates whether the receive FIFO level is less than, equal to, or greater than the watermark. This field becomes 1 when the number of datawords in the receive buffer is greater than the number that WATER[RXWATER] indicates and the receive FIFO is enabled. To write 0 to this field, read Data (DATA) until the number of datawords in the receive FIFO is equal to, or less than the number that WATER[RXWATER] indicates. When the receive FIFO is disabled, this field (RDRF) becomes 1 if the receive buffer (Data (DATA)) is full. To make this field 0, read Data (DATA). A character that is in the process of being received does not cause a change in this field until the entire character is received. Even if this field is 1, the character continues to be received until an overrun condition occurs after the entire character is received. 0b - Equal to or less than watermark 1b - Greater than watermark
20 IDLE	Idle Line Flag Indicates whether an idle line is detected. This field becomes 1 when the LPUART receive line becomes idle for a full character time after a period of activity. When CTRL[ILT] is 0, the receiver starts counting idle bit times after the start bit. If the receive character is all 1s, these bit times and the stop bit time count towards the full character time of logic high, 10 to 13 bit times, needed for the receiver to detect an idle line. After CTRL[ILT] becomes 1, the receiver does not start counting idle bit times until after the stop bits. The stop bits and any logic high bit times at the end

Table continues on the next page...

Table continued from the previous page...

Field	Function
	of the previous character do not count towards the full character time of logic high needed for the receiver to detect an idle line. For this field to become 0, write 1 to it. After the field becomes 0, you cannot write 1 to it again until after a new character is stored in the receive buffer or a LIN break character writes 1 to STAT[LBKDIF]. This field becomes 1 only once, even if the receive line remains idle for an extended period. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Idle line detected 1b - Idle line not detected When writing 0b - No effect 1b - Clear the flag
19 OR	Receiver Overrun Flag Indicates whether there is receive overrun. This field becomes 1 when you cannot prevent STAT[RDRF] from overflowing with data. The field becomes 1 immediately after the stop bit is completely received for the dataword that overflows the buffer and all the other error fields (STAT[FE], STAT[NF], and STAT[PF]) are prevented from becoming 1. The data in the shift register is lost, but the data already in the LPUART data registers is not affected. If STAT[LBKDE] is enabled and a LIN break is detected, this field becomes 1 if STAT[LBKDIF] is not 0 before the next data character is received. When this field is 1, no additional data is stored in the receive FIFO even if sufficient room exists. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No overrun 1b - Receive overrun (new LPUART data is lost) When writing 0b - No effect 1b - Clear the flag
18 NF	Noise Flag Indicates whether noise is detected in the received character of Data (DATA). The advanced sampling technique used in the receiver takes three samples in each of the received bits. If some of these samples disagree with the rest of the samples within any bit time in the frame, then noise is detected for that character. This field becomes 1 whenever the next character to be read from Data (DATA) is received with noise detected within the character.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - No noise detected 1b - Noise detected When writing 0b - No effect 1b - Clear the flag
17 FE	Framing Error Flag Indicates whether a framing error is detected. This field becomes 1 whenever the next character to be read from Data (DATA) is received with logic 0 detected where a stop bit was expected. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No framing error detected (this does not guarantee that the framing is correct) 1b - Framing error detected When writing 0b - No effect 1b - Clear the flag
16 PF	Parity Error Flag Indicates whether a parity error is detected. This field becomes 1 whenever the next character to be read from Data (DATA) is received when parity is enabled (CTRL[PE] is 1) and the parity bit in the received character does not agree with the expected parity value. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No parity error detected 1b - Parity error detected When writing 0b - No effect 1b - Clear the flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
15 MA1F	Match 1 Flag Indicates whether the received data is equal to MATCH[MA1]. This field becomes 1 whenever the next character to be read from Data (DATA) matches the value of MATCH[MA1]. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not equal to MA1 1b - Equal to MA1 When writing 0b - No effect 1b - Clear the flag
14 MA2F	Match 2 Flag Indicates whether the received data is equal to MATCH[MA2]. This field becomes 1 whenever the next character to be read from Data (DATA) matches the value of MATCH[MA2]. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not equal to MA2 1b - Equal to MA2 When writing 0b - No effect 1b - Clear the flag
13-10 —	Reserved
9-8 —	Reserved
7-2 —	Reserved
1 AME	Address Mark Enable Configures the location of the address mark when configured for MSB first transfers.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field has no effect when configured for LSB first and you must change the value of this field only when both the transmitter and receiver are disabled. If this field is 0, address mark in character is MSB. If this field is 1, the address mark is stored in Data (DATA) at MSB (or MSB-1 when the parity bit is enabled). In other words, the address mark in character is the last bit before the stop bit (or parity bit when enabled). 0b - Disable 1b - Enable
0 LBKFE	LIN Break Flag Enable Enables the LIN break flag to assert whenever a LIN break character is detected. Unlike STAT[LBKDE], this does not impact data being stored in the receive data buffer, but does cause STAT[LBKDIF] to become 1 whenever a LIN break is detected. Because a LIN break is longer than a normal character, the LIN break triggers a write to STAT[RDRF] with the data fields as 0 and STAT[FE] as 1. The character following the LIN break has DATA[LINBRK] as 1 to indicate that the previous character was a LIN break. You must change the value of this field only when both the transmitter and receiver are disabled. If this field is 1, the LIN break character is detected at a length of 11-bit times (if CTRL[M] is 0), 12 (if CTRL[M] is 1), or 13 (if BAUD[M10] is 1). 0b - Disable 1b - Enable

68.5.5.8 Control (CTRL)

Offset

Register	Offset
CTRL	18h

Function

Controls various optional features of the LPUART system.

You must write to the fields of this register only when both the transmitter and receiver are disabled.

Fields

Field	Function
31 R8T9	Receive Bit 8 Transmit Bit 9 Contains R8 and T9 that correspond to different functions. R8 is the ninth data bit received after you configure LPUART for 9-bit or 10-bit data formats. When reading 9-bit or 10-bit data, read R8 before reading Data (DATA). T9 is the tenth data bit transmitted after you configure LPUART for 10-bit data formats. When writing 10-bit data, write T9 before writing to Data (DATA). If T9 does not need to change from its previous value, such as when it is used to generate address mark or parity, then you need not write to it each time you write to Data (DATA). **NOTE** R8 is a read-only bit and T9 is a write-only bit; the value read is different from the value written.
30 R9T8	Receive Bit 9 Transmit Bit 8 Contains R9 and T8 that correspond to different functions. R9 is the tenth data bit received after you configure LPUART for 10-bit data formats. When reading 10-bit data, read R9 before reading Data (DATA). T8 is the ninth data bit transmitted after you configure LPUART for 9-bit or 10-bit data formats. When writing 9-bit or 10-bit data, write T8 before writing to Data (DATA). If T8 does not need to change from its previous value, such as when it is used to generate address mark or parity, then you need not write to it each time you write to Data (DATA). **NOTE** R9 is a read-only field and T8 is a write-only field; the value read is different from the value written.
29 TXDIR	TXD Pin Direction in Single-Wire Mode Determines the direction of data at the TXD pin, in Single-Wire mode, when LPUART is configured for a single-wire half-duplex operation (CTRL[LOOPS] and CTRL[RSRC] are 1). When writing 0 to this field, the transmitter finishes transmitting the current character (if any) before the receiver starts receiving data from the TXD pin.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Input 1b - Output
28 TXINV	Transmit Data Inversion Specifies whether transmit data is inverted. Writing 1 to this field reverses the polarity of the transmitted data output. This action inverts the TXD output for all cases: data bits, start and stop bits, break, and idle. 0b - Not inverted 1b - Inverted
27 ORIE	Overrun Interrupt Enable Enables STAT[OR] to generate hardware interrupt requests. When this field is 1, a hardware interrupt is requested. Use polling when OR interrupts are disabled. 0b - Disable 1b - Enable
26 NEIE	Noise Error Interrupt Enable Enables STAT[NF] to generate hardware interrupt requests. When this field is 1, a hardware interrupt is requested. Use polling when NF interrupts are disabled. 0b - Disable 1b - Enable
25 FEIE	Framing Error Interrupt Enable Enables STAT[FE] to generate hardware interrupt requests. When this field is 1, a hardware interrupt is requested. Use polling when FE interrupts are disabled. 0b - Disable 1b - Enable
24 PEIE	Parity Error Interrupt Enable Enables STAT[PF] to generate hardware interrupt requests. When this field is 1, a hardware interrupt is requested. Use polling when PF interrupts are disabled. 0b - Disable 1b - Enable
23 TIE	Transmit Interrupt Enable Enables STAT[TDRE] to generate interrupt requests if STAT[TDRE] is 1. 0b - Disable 1b - Enable
22	Transmission Complete Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
TCIE	Enables STAT[TC] to generate interrupt requests if STAT[TC] is 1. 0b - Disable 1b - Enable
21 RIE	Receiver Interrupt Enable Enables STAT[RDRF] to generate hardware interrupt requests if STAT[RDRF] is 1. 0b - Disable 1b - Enable
20 ILIE	Idle Line Interrupt Enable Enables hardware interrupts. This field enables STAT[IDLE] to generate interrupt requests. If this field is 0, hardware interrupts from STAT[IDLE] are disabled and polling is used, and if this field is 1, hardware interrupts are enabled when STAT[IDLE] is 1. 0b - Disable 1b - Enable
19 TE	Transmitter Enable Enables the LPUART transmitter. Using this field, you can also queue an idle preamble by first writing 0 and then writing 1 to this field. After this field becomes 0, the field reads 1 until the transmitter has completed the current character and the TXD pin is tristated. You can also queue a single idle character by writing to the transmit FIFO with DATA[FRETSC] and DATA[R9T9] = 1. 0b - Disable 1b - Enable
18 RE	Receiver Enable Enables the LPUART receiver. After you write 0 to this field, this field remains 1 until the receiver finishes receiving the current character (if any). 0b - Disable 1b - Enable
17 RWU	Receiver Wake-Up Control Specifies whether the LPUART receiver in standby is waiting for a wake-up condition. You can write 1 to this field to place the LPUART receiver in a Standby state. The field becomes 0 automatically when an RWU event occurs, that is, in case of an idle event when CTRL[WAKE] is 0 or an address match when CTRL[WAKE] is 1 and STAT[RWUID] is 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE You must write 1 to this field only when CTRL[WAKE] is 0 (wake-up on idle), if the channel is currently not idle. You can determine this by the value of STAT[RAF]. If the field is 1 to wake up an idle event and the channel is already idle, LPUART, possibly, discards the data. This is because the data must be received or a LIN break is detected after an Idle condition is detected before the IDLE flag is allowed to be reasserted. 0b - Normal receiver operation 1b - LPUART receiver in standby, waiting for a wake-up condition
16 SBK	Send Break Specifies whether queue break character(s) are to be sent. Writing 1 and then 0 to this field queues a break character in the transmit data stream. Additional break characters of 9 to 13 bits, or 12 to 15 bits if STAT[BRK13] is 1, and bit times of logic 0 are queued as long as this field is 1. Depending on the timing when this field is 1 and 0, relative to the character currently being transmitted, a second break character may be queued before you write 0 to this field. If the time taken to write 0 to this field is too long, for example, if the field does not become 0 by the end of the first break character, a second break character is sent. This is compared to queuing a break character through the transmit FIFO that guarantees only one break character is sent. You can also queue a single break character by writing to the transmit FIFO when DATA[FRETSC] is 1 and DATA[R9T9] is 0. 0b - Normal transmitter operation 1b - Queue break character(s) to be sent
15 MA1IE	Match 1 (MA1F) Interrupt Enable Enables the MA1F interrupt. 0b - Disable 1b - Enable
14 MA2IE	Match 2 (MA2F) Interrupt Enable Enables the MA2F interrupt. 0b - Disable 1b - Enable
13 —	Reserved
12 —	Reserved
11 M7	7-Bit Mode Select Specifies the data characters that the receiver and transmitter use.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	You must change the value of this field only after both the transmitter and receiver are disabled. 0b - 8-bit to 10-bit 1b - 7-bit
10-8 IDLECFG	Idle Configuration Configures the number of idle characters that must be received before you write 1 to STAT[IDLE]. 000b - 1 001b - 2 010b - 4 011b - 8 100b - 16 101b - 32 110b - 64 111b - 128
7 LOOPS	Loop Mode Select Selects Loop mode. After this field becomes 1, the RXD pin is disconnected from LPUART and the transmitter output is internally connected to the receiver input. The transmitter and receiver must be enabled to use the loop function. In Loop mode or Single-Wire mode, the transmitter outputs are internally connected to the receiver input (see CTRL[RSRC]). 0b - Normal operation: RXD and TXD use separate pins 1b - Loop mode or Single-Wire mode
6 DOZEEN	Doze Mode Enables LPUART in Doze mode. If this field is 1, LPUART remains active when not in Doze mode. 0b - Enable 1b - Disable
5 RSRC	Receiver Source Select Determines the source of the receiver shift register input if CTRL[LOOPS] is 1. This field has no effect unless CTRL[LOOPS] is 1. If this field is 0, internal Loopback mode is selected. LPUART does not use the RXD pin. Additionally, the CTS_B pin is not used and internally driven by the RTS_B output. If this field is 1, single-wire LPUART mode is selected where the TXD pin is connected to the transmitter output and receiver input.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Internal Loopback mode 1b - Single-wire mode
4 M	9-Bit Or 8-Bit Mode Select Specifies the data characters that the receiver and transmitter use. 0b - 8-bit 1b - 9-bit
3 WAKE	Receiver Wake-Up Method Select Determines which condition wakes up LPUART when CTRL[RWU] = 1 and BAUD[MATCFG] = 0 (this field must be 1 when BAUD[MATCFG] = 11): • Address mark in the bit preceding the stop bit (or bit preceding the parity bit when parity is enabled) of the received data character • An idle condition on the receive pin input signal If this field is 0, CTRL[RWU] is configured for idle line wake-up, and if this field is 1, CTRL[RWU] is configured with address mark wake-up. 0b - Idle 1b - Mark
2 ILT	Idle Line Type Select Determines when the receiver starts counting logic 1s as idle character bits. The count begins either after a valid start bit or the stop bit. If the count begins after the start bit, a string of logic 1s preceding the stop bit can cause false recognition of an idle character. Beginning the count after the stop bit avoids false idle character recognition, but requires properly synchronized transmissions. **NOTE** In case you write 1 to this field, a logic 0 is automatically shifted after a received stop bit, therefore resetting the idle count. 0b - After the start bit 1b - After the stop bit
1 PE	Parity Enable Enables hardware parity generation and checking. If parity is enabled, the bit immediately before the stop bit is treated as the parity bit. 0b - Disable 1b - Enable
0 PT	Parity Type Selects the type of parity, even or odd, if parity is enabled (CTRL[PE] = 1):

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Odd parity means that the total number of logic 1 bits in the data character, including the parity bit, is odd. • Even parity means that the total number of 1s in the data character, including the parity bit, is even. 0b - Even parity 1b - Odd parity

68.5.5.9 Data (DATA)

Offset

Register	Offset
DATA	1Ch

Function

Supports 8-bit, 16-bit, or 32-bit writes, each type of write performing a separate function. An 8-bit write to DATA[7:0] pushes {CTRL[R8T9], CTRL[R9T8], DATA[7:0]} the transmit FIFO with TSC clear. A 16-bit or 32-bit write pushes the data written into the FIFO and does not update the value of CTRL[R8T9] or CTRL[R9T8].

Reads and writes of this register are also involved in the automatic flag clearing mechanisms for some of the LPUART status fields.

NOTE

Reads return the contents of the read-only receive FIFO and writes go to the write-only transmit FIFO, making this register work as a set of two separate registers.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	NOISY	PARITYE	FRETSC	RXEMPT	IDLINE	LINBRK	R9T9	R8T8	R7T7	R6T6	R5T5	R4T4	R3T3	R2T2	R1T1	R0T0
W																
Reset	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 —	Reserved
15 NOISY	Noisy Data Received Indicates whether the current received dataword contained in DATA[R9:R0] is received with noise. 0b - Received without noise 1b - Received with noise
14 PARITYE	Parity Error Indicates whether the current received dataword contained in DATA[R9:R0] is received with a parity error. 0b - Received without a parity error 1b - Received with a parity error
13 FRETSC	Frame Error Transmit Special Character Specifies the way the dataword is received. For reads, this field indicates that the current received dataword contained in DATA[R9:R0] is received with a frame error. For writes, the field indicates that a break or idle character is to be transmitted instead of the contents in DATA[T9:T0]. T9 indicates a break character when it is 0 and indicates an idle character when it is 1. The contents of DATA[T8:T0] must be 0. 0b - Received without a frame error on reads or transmits a normal character on writes 1b - Received with a frame error on reads or transmits an idle or break character on writes
12 RXEMPT	Receive Buffer Empty Indicates whether the receive buffer contains valid data. This field becomes 1 when there is no data in the receive buffer. The field does not consider data in the receive shift register. 0b - Valid data 1b - Invalid data and empty
11 IDLINE	Idle Line Indicates whether the receiver line was idle before receiving the character in DATA[9:0]. It can be read as “1” on the first character when the receiver is first enabled. The difference between this field and STAT[IDLE] is that, STAT[IDLE] flag does not set on an idle line after the receiver is first enabled, it needs to receive a character before it can become set, whereas this field does not have this limitation and can be set on the first character received if an idle line is detected beforehand. 0b - Not idle 1b - Idle
10	LIN Break

Table continues on the next page...

Table continued from the previous page...

Field	Function
LINBRK	Indicates whether the receiver line detected a LIN break before receiving the character in DATA[9:0]. This field requires the value of STAT[LBKDIF] to be 1. If this field is 0, the LIN break detect circuitry is disabled. 0b - Not detected 1b - Detected
9 R9T9	Read receive FIFO bit 9 or write transmit FIFO bit 9
8 R8T8	Read receive FIFO bit 8 or write transmit FIFO bit 8
7 R7T7	Read receive FIFO bit 7 or write transmit FIFO bit 7
6 R6T6	Read receive FIFO bit 6 or write transmit FIFO bit 6
5 R5T5	Read receive FIFO bit 5 or write transmit FIFO bit 5
4 R4T4	Read receive FIFO bit 4 or write transmit FIFO bit 4
3 R3T3	Read receive FIFO bit 3 or write transmit FIFO bit 3
2 R2T2	Read receive FIFO bit 2 or write transmit FIFO bit 2
1 R1T1	Read receive FIFO bit 1 or write transmit FIFO bit 1
0 R0T0	Read receive FIFO bit 0 or write transmit FIFO bit 0

68.5.5.10 Match Address (MATCH)

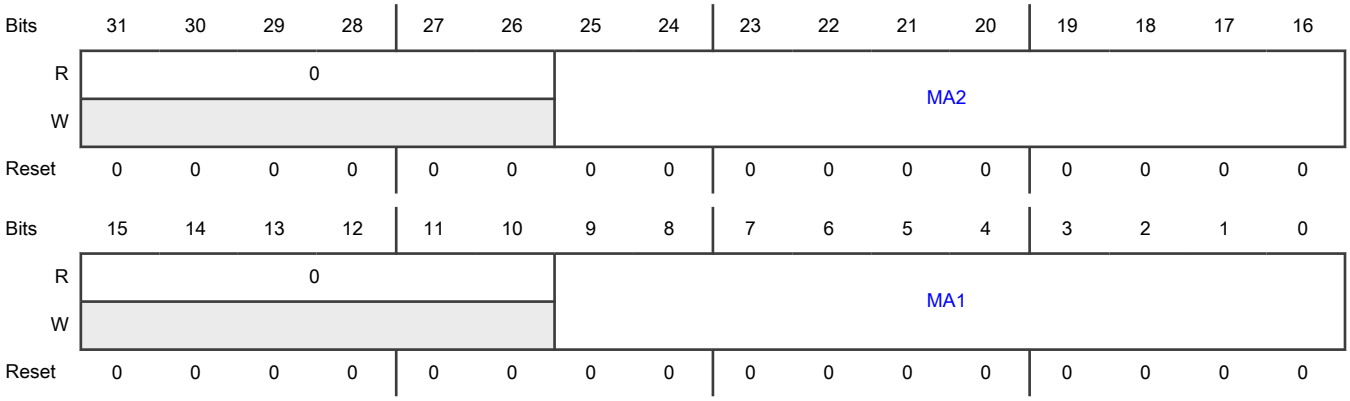
Offset

Register	Offset
MATCH	20h

Function

Provides addresses for address matching during the receiver operation.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-16 MA2	Match Address 2 Is compared to input data addresses when the most significant bit is 1 and the associated Baud Rate (BAUD) field is 1. If a match occurs, the data that follows is transferred to Data (DATA). If a match fails, the data that follows is discarded. You must write to MATCH[MA1] and MATCH[MA2] only when the associated Baud Rate (BAUD) field is 0.
15-10 —	Reserved
9-0 MA1	Match Address 1 Is compared to input data addresses when the most significant bit is 1 and the associated Baud Rate (BAUD) field is 1. If a match occurs, the data that follows is transferred to Data (DATA). If a match fails, the data that follows is discarded. You must write to MATCH[MA1] and MATCH[MA2] fields only when the associated field in Baud Rate (BAUD) is 0.

68.5.5.11 MODEM IrDA (MODIR)

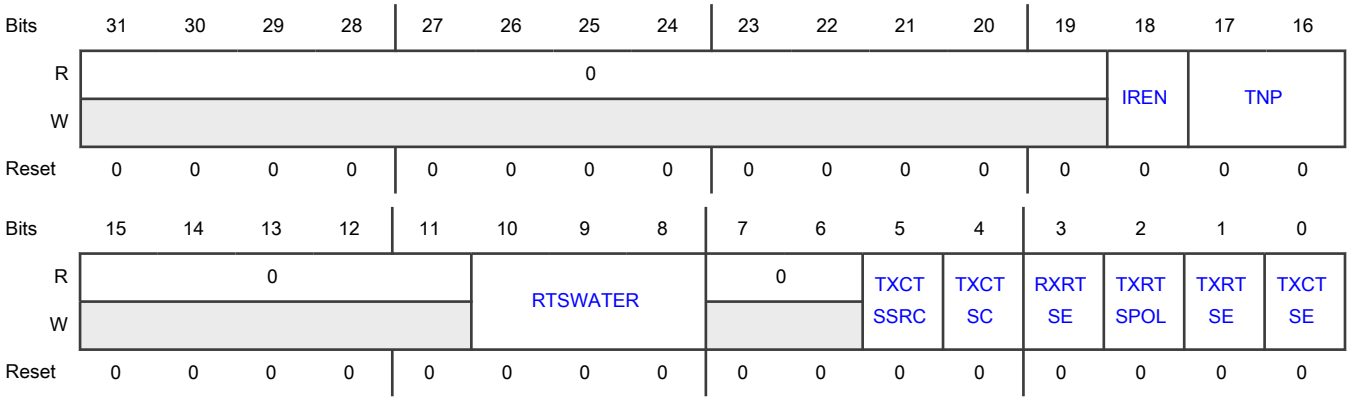
Offset

Register	Offset
MODIR	24h

Function

Controls options for setting the MODEM configuration.

Diagram



Fields

Field	Function
31-19 —	Reserved
18 IREN	IR Enable Enables IR modulation and demodulation. You must change the value of this field only when both the transmitter and receiver are disabled. 0b - Disable 1b - Enable
17-16 TNP	Transmitter Narrow Pulse Specifies whether LPUART transmits a 1 ÷ OSR, 2 ÷ OSR, 3 ÷ OSR, or 4 ÷ OSR narrow pulse when the IR pulse is enabled. You must change the value of this field only when both the transmitter and receiver are disabled. The IR pulse width must be configured to less than half of the OSR. Common pulse widths are 3 ÷ 16, 1 ÷ 16, 1 ÷ 32, or 1 ÷ 4 of the bit length. You can configure these by selecting the appropriate OSR and pulse width. 00b - 1 ÷ OSR 01b - 2 ÷ OSR 10b - 3 ÷ OSR 11b - 4 ÷ OSR
15-11 —	Reserved
10-8	Receive RTS Configuration

Table continues on the next page...

Table continued from the previous page...

Field	Function
RTSWATER	Configures the assertion and negation of the receiver's RTS_B output. The receiver's RTS_B output negates when the number of empty words in the receive FIFO is greater or equal to the value of this field. If this field is 0, the RTS_B pin negates when the receive FIFO is full. For the purpose of receive RTS_B generation, the number of words in the receive FIFO updates when a start bit is detected. This supports additional latency between RTS_B negation and the external transmitter ceasing transmission. If both receive RTS_B and address or data matching is enabled, RTS_B could assert at the end of a character if there exists no match. You must change the value of this field only when the receiver is disabled.
7-6 —	Reserved
5 TXCTSSRC	Transmit CTS Source Configures the source of the CTS input. 0b - The CTS_B pin 1b - An internal connection to the receiver address match result
4 TXCTSC	Transmit CTS Configuration Configures whether the CTS state or input is checked or sampled at the start of each character or only when the transmitter is idle. 0b - Sampled at the start of each character 1b - Sampled when the transmitter is idle
3 RXRTSE	Receiver RTS Enable Allows the RTS output to control the CTS input of the transmitting device to prevent receiver overrun. You must change the value of this field only when the receiver is disabled. If this field is 0, the receiver has no effect on RTS. If this field is 1, RTS is deasserted if STAT[RDRF] is 1 or a start bit is detected that causes STAT[RDRF] to become 1. RTS is asserted if STAT[RDRF] is 0 and has not detected a start bit that causes STAT[RDRF] to become 1. **NOTE** Do not write 1 to both MODIR[RXRTSE] and MODIR[TXRTSE]. 0b - Disable 1b - Enable
2 TXRTSPOL	Transmitter RTS Polarity Controls the polarity of the transmitter RTS. This field does not affect the polarity of the receiver RTS that remains negated in the active-low state unless MODIR[TXRTSE] is 1. You must change the value of this field only when the transmitter is disabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Active low 1b - Active high
1 TXRTSE	Transmitter RTS Enable Controls the operation of RTS before and after a transmission. You must change the value of this field only when the transmitter is disabled. If this field is 0, the transmitter has no effect on RTS, and if this field is 1, a character is placed into an empty transmit shift register. RTS asserts 1-bit time before the start bit is transmitted and deasserts 1-bit time after all characters in the transmitter FIFO and shift register are completely sent, including the last stop bit. 0b - Disable 1b - Enable
0 TXCTSE	Transmitter CTS Enable Enables the operation of the transmitter. You can write 1 to this field irrespective of the states of MODIR[TXRTSE] and MODIR[RXRTSE]. If this field is 1, the transmitter checks the state of the CTS signal each time it is ready to send a character. If CTS is asserted, the character is sent. If CTS is deasserted, the TXD signal remains in the mark state and transmission is delayed until CTS is asserted. Changes in CTS, when a character is being sent, do not affect its transmission. 0b - Disable 1b - Enable

68.5.5.12 FIFO (FIFO)

Offset

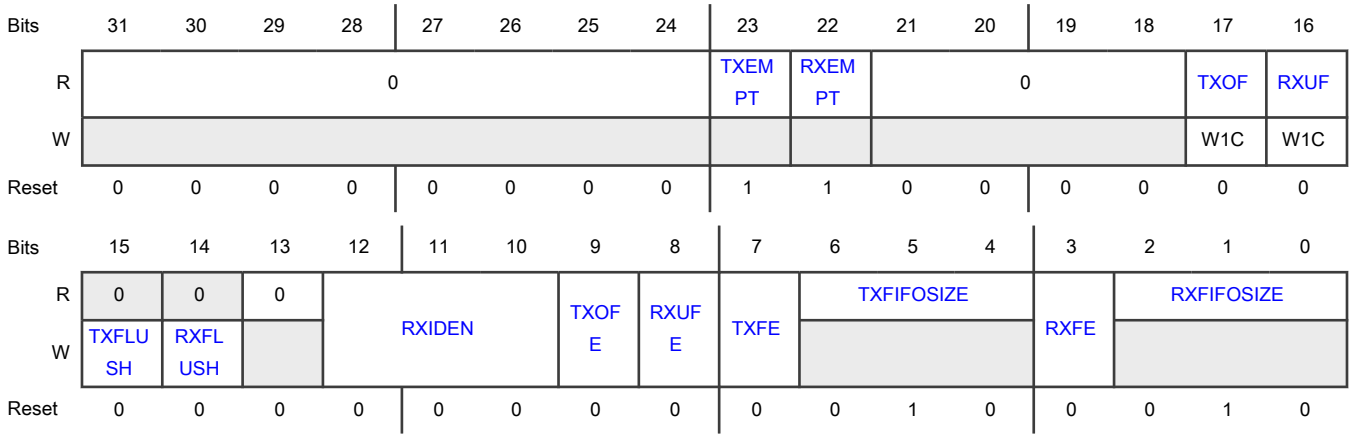
Register	Offset
FIFO	28h

Function

Provides you the ability to turn on and turn off the FIFO functionality.

This register also provides you the size of the FIFO that has been implemented. You can read this register at any time and must write to it only when CTRL[RE] and CTRL[TE] are 0 and the FIFO is empty.

Diagram



Fields

Field	Function
31-24 —	Reserved
23 TXEMPT	Transmit FIFO Or Buffer Empty Indicates whether the transmit buffer is empty. This field becomes 1 when there is no data in the transmit FIFO or buffer. The field does not consider data in the transmit shift register. 0b - Not empty 1b - Empty
22 RXEMPT	Receive FIFO Or Buffer Empty Indicates whether the receive buffer is empty. This field becomes 1 when there is no data in the receive FIFO or buffer. The field does not consider data in the receive shift register. 0b - Not empty 1b - Empty
21-18 —	Reserved
17 TXOF	Transmitter FIFO Overflow Flag Indicates whether more data has been written to the transmit FIFO than it can hold. If this field is 0, no transmit FIFO overflow has occurred since the last time the field was cleared, and if this field is 1, at least one transmit FIFO overflow has occurred since the last time the field was cleared. This field becomes 1 regardless of the value of FIFO[TXOFE]. However, an interrupt is issued to the host only if FIFO[TXOFE] is 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - No overflow 1b - Overflow When writing 0b - No effect 1b - Clear the flag
16 RXUF	Receiver FIFO Underflow Flag Indicates whether more data has been read from the receive FIFO than was present. If this field is 0, no receive FIFO underflow has occurred since the last time the field was cleared, and if this field is 1, at least one receive FIFO underflow has occurred since the last time the field was cleared. This field becomes 1 regardless of the value of FIFO[RXUFE]. However, an interrupt is issued to the host only if FIFO[RXUFE] is 1. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No underflow 1b - Underflow When writing 0b - No effect 1b - Clear the flag
15 TXFLUSH	Transmit FIFO Flush Causes all data that is stored in the transmit FIFO to be flushed. If you write 0 to this field, no flush operation occurs, and if you write 1 to this field, all data in the transmit FIFO or buffer clears out. This does not affect data in the transmit shift register. 0b - No effect 1b - All data flushed out
14 RXFLUSH	Receive FIFO Flush Causes all data that is stored in the receive FIFO to be flushed. If you write 0 to this field, no flush operation occurs, and if you write 1 to this field, all data in the receive FIFO or buffer clears out.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This does not affect data in the receive shift register. 0b - No effect 1b - All data flushed out
13 —	Reserved
12-10 RXIDEN	Receiver Idle Empty Enable Enables STAT[RDRF] to become 1 when the receiver is idle for a number of idle characters and the FIFO is not empty. 000b - Disable STAT[RDRF] to become 1 because of partially filled FIFO when the receiver is idle 001b - Enable STAT[RDRF] to become 1 because of partially filled FIFO when the receiver is idle for one character 010b - Enable STAT[RDRF] to become 1 because of partially filled FIFO when the receiver is idle for two characters 011b - Enable STAT[RDRF] to become 1 because of partially filled FIFO when the receiver is idle for four characters 100b - Enable STAT[RDRF] to become 1 because of partially filled FIFO when the receiver is idle for eight characters 101b - Enable STAT[RDRF] to become 1 because of partially filled FIFO when the receiver is idle for 16 characters 110b - Enable STAT[RDRF] to become 1 because of partially filled FIFO when the receiver is idle for 32 characters 111b - Enable STAT[RDRF] to become 1 because of partially filled FIFO when the receiver is idle for 64 characters
9 TXOFE	Transmit FIFO Overflow Interrupt Enable Enables FIFO[TXOF] to generate an interrupt to the host. 0b - Disable 1b - Enable
8 RXUFE	Receive FIFO Underflow Interrupt Enable Enables FIFO[RXUF] to generate an interrupt to the host. 0b - Disable 1b - Enable
7 TXFE	Transmit FIFO Enable Enables the transmit FIFO. If this field is 0, the transmit buffer operates as a FIFO of depth equal to 1 dataword, regardless of the value in FIFO[TXFIFOSIZE]. Both CTRL[TE] and CTRL[RE] must be 0 before you change the value of this field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 1, the built-in FIFO structure for the transmit buffer is enabled. FIFO[TXFIFOSIZE] indicates the size of the FIFO structure. 0b - Disable 1b - Enable
6-4 TXFIFOSIZE	Transmit FIFO Buffer Depth Indicates the maximum number of transmit datawords (transmit FIFO buffer depth) that can be stored in the transmit buffer. 000b - 1 001b - 4 010b - 8 011b - 16 100b - 32 101b - 64 110b - 128 111b - 256
3 RXFE	Receive FIFO Enable Enables the receive FIFO. If this field is 0, the receive buffer operates as a FIFO of depth equal to 1 dataword, regardless of the value in FIFO[RXFIFOSIZE]. Both CTRL[RE] and CTRL[TE] must be 0 before you change the value of this field. If this field is 1, the built-in FIFO structure for the receive buffer is enabled. FIFO[RXFIFOSIZE] indicates the size of the FIFO structure. 0b - Disable 1b - Enable
2-0 RXFIFOSIZE	Receive FIFO Buffer Depth Indicates the maximum number of receive datawords (receive FIFO buffer depth) that can be stored in the receive buffer before an overrun occurs. 000b - 1 001b - 4 010b - 8 011b - 16 100b - 32 101b - 64 110b - 128 111b - 256

68.5.5.13 Watermark (WATER)

Offset

Register	Offset
WATER	2Ch

Function

Provides the ability to set a programmable threshold for notification, or sets the programmable thresholds to indicate that transmit data can be written or receive data can be read.

You may read this register at any time but must write to it only when CTRL[TE] is 0.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0				TXCOUNT				0				TXWATER			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-28 —	Reserved
27-24 RXCOUNT	Receive Counter Indicates the number of datawords in the receive FIFO or buffer. If a dataword is being received in the receive shift register, it is not included in the count. This value may be used in conjunction with FIFO[RXFIFOSIZE] to calculate the room left in the receive FIFO or buffer.
23-19 —	Reserved
18-16 RXWATER	Receive Watermark Generates an interrupt or a DMA request if the number of datawords in the receive FIFO or buffer is greater than the value of this field. For proper operation, the value of this field must be less than the size of the receive FIFO or buffer, as indicated by FIFO[RXFIFOSIZE] and FIFO[RXFE].

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-12 —	Reserved
11-8 TXCOUNT	Transmit Counter Indicates the number of datawords in the transmit FIFO or buffer. If a dataword is being transmitted to the transmit shift register, it is not included in the count. This value may be used in conjunction with the value of FIFO[TXFIFOSIZE] to calculate the room left in the transmit FIFO or buffer.
7-3 —	Reserved
2-0 TXWATER	Transmit Watermark Generates an interrupt or a DMA request when the number of datawords in the transmit FIFO or buffer is equal to or less than the value of this field. For proper operation, the value of this field must be less than the size of the transmit buffer or FIFO, as indicated by FIFO[TXFIFOSIZE] and FIFO[TXFE].

68.5.5.14 Data Read-Only (DATARO)

Offset

Register	Offset
DATARO	30h

Function

Indicates the first entry in the receive FIFO, but does not pull data from the FIFO.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-16 —	Reserved
15-0 DATA	Receive Data Indicates the first entry from the receive FIFO. This register has the same functionality as that of Data (DATA).

68.5.5.15 Transmit Command Burst (TCBR0 - TCBR127)

Offset

For a = 0 to 127:

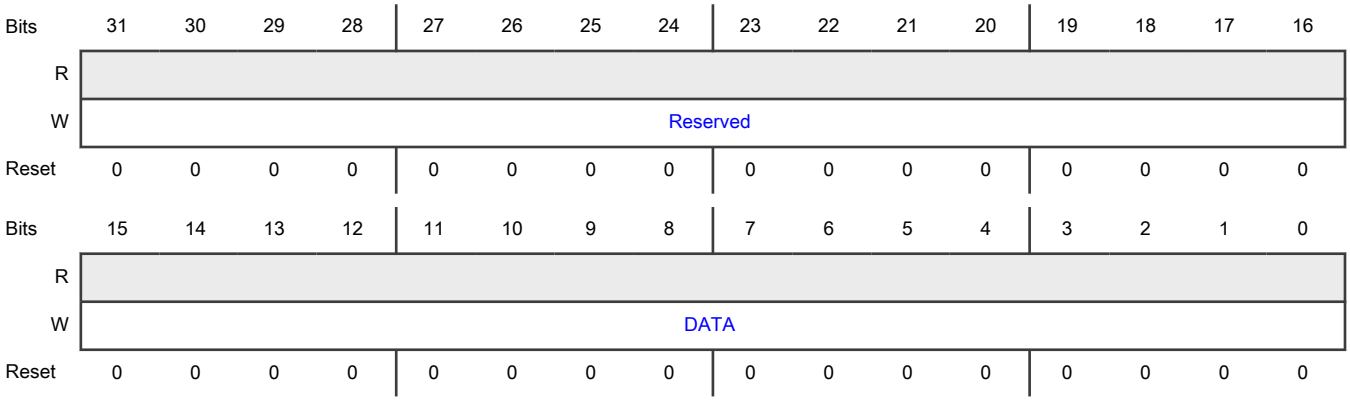
Register	Offset
TCBRa	200h + (a × 4h)

Function

Acts as an alias of Data (DATA), designed to support incrementing burst transfers to the transmit FIFO by a DMA controller, using aligned 8-bit, 16-bit, or 32-bit writes. The size of this register is 512 bytes:

- An aligned 32-bit write in this region pushes one entry into the transmit FIFO.
- An aligned 16-bit write in this region to TCBR*x*[15:0] pushes one entry into the transmit FIFO.
- An 8-bit write in this region to TCBR*x*[7:0] updates DATA[7:0], but does not push the data into the transmit FIFO.
- An 8-bit write in this region to TCBR*x*[15:8] pushes the data written to DATA[15:8] plus the previously written DATA[7:0] into the transmit FIFO.
- An 8-bit or 16-bit write in this region to TXBR*x*[31:16] is ignored.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 DATA	Data Enables writing data to Data (DATA).

68.5.5.16 Transmit Data Burst (TDBR0 - TDBR255)

Offset

For a = 0 to 255:

Register	Offset
TDBRa	400h + (a × 4h)

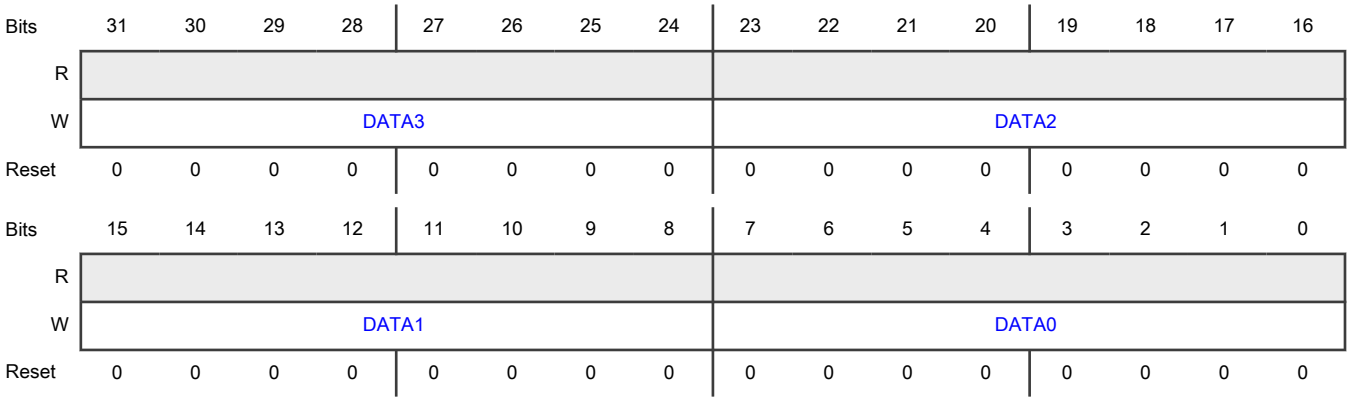
Function

Acts as an alias of Data (DATA), designed to support incrementing burst transfers to the transmit FIFO by a DMA controller using 8-bit, 16-bit, or 32-bit writes. The size of this register is 1024 bytes:

- An aligned 32-bit write in this region pushes four DATA byte entries into the transmit FIFO (DATA0 byte first). The register access is extended by three wait states.
- An aligned 16-bit write in this region to either half of a 32-bit word pushes two DATA byte entries into the transmit FIFO (DATA0 or DATA2 first). The register access is extended by one wait state.
- An 8-bit write in this region pushes one DATA byte entry into the transmit FIFO.

Byte writes to Data (DATA) use the contents of CTRL[R9T8] for the ninth data bit, CTRL[R8T9] for the tenth data bit, and zero extend DATA[FRETSC].

Diagram



Fields

Field	Function
31-24 DATA3	Data3 Enables writing of data to Data (DATA).
23-16 DATA2	Data2 Enables writing of data to Data (DATA).
15-8 DATA1	Data1 Enables writing of data to Data (DATA).
7-0 DATA0	Data0 Enables writing of data to Data (DATA).

I3C3	SYSCON1.I3C_ASYNC_WAKEUP_CTRL[IRQ_EN3]	I3C3.SINTSET[MATCHED]

69.2 Overview

I3C is a communications processor that improves upon the use and power of I2C, and provides an alternative to SPI for mid-speed applications.

The I3C bus protocol supports:

- In-band interrupts (IBI): these interrupts move from target to controller without extra wires, and the controller knows which target sent the interrupt
- Common command codes (CCC)
- Dynamic addressing
- Multi-controller and multi-drop
- Hot-Join (HJ)
- I2C compatibility

I3C supports all required and many optional features of the MIPI Alliance Specification for I3C, v1.0 and v1.1, except for ternary data rates (HDR-TSP and HDR-TSL). See Features, Target Capabilities (SCAPABILITIES), and Target Capabilities 2 (SCAPABILITIES2) for more information.

69.2.1 Block diagram

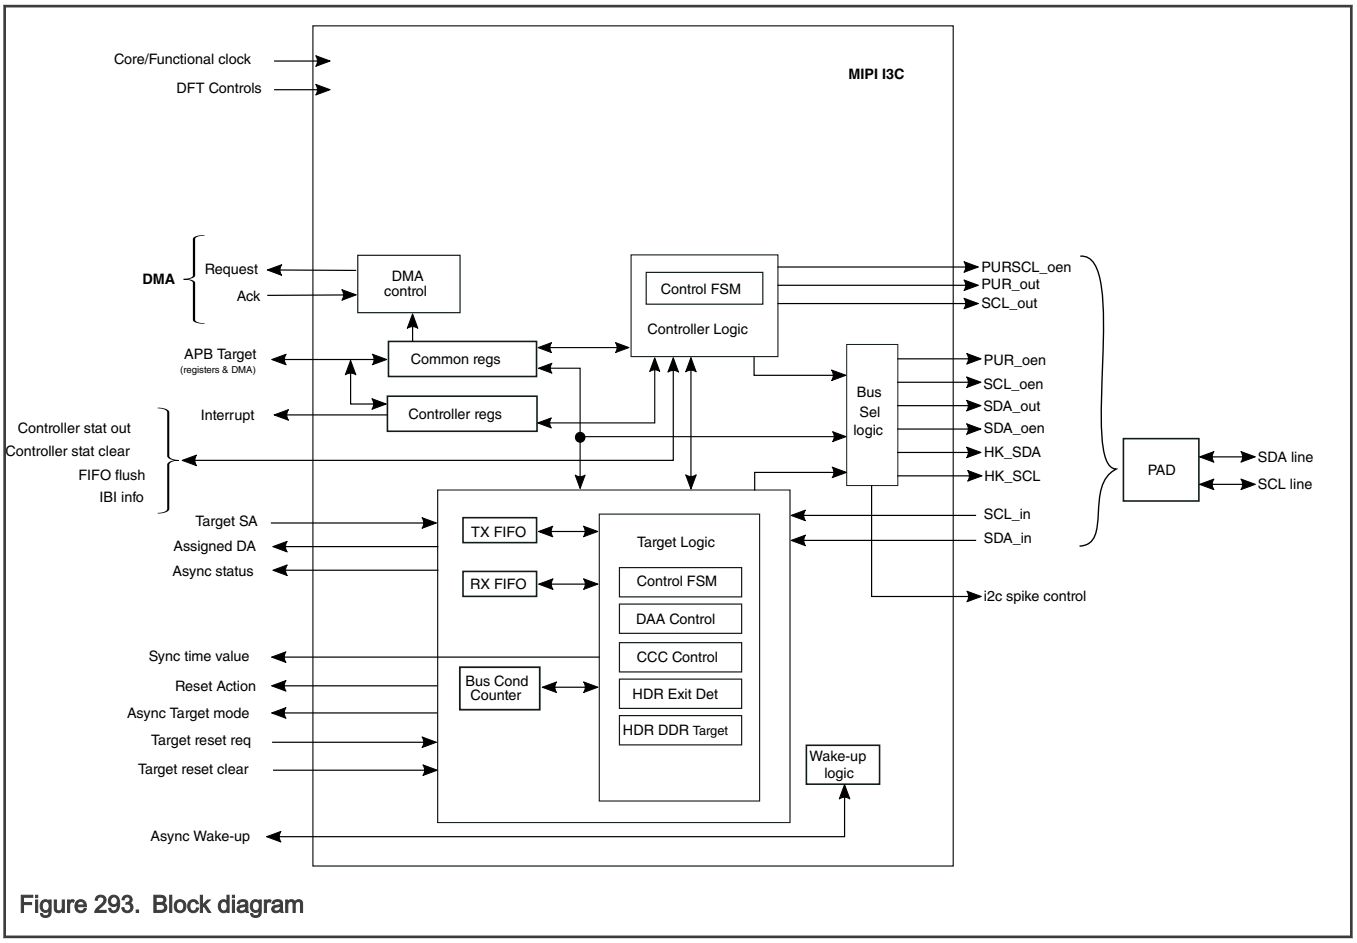

Figure 293. Block diagram

69.2.2 Features

- Two-wire multidrop bus that is capable of up to 12.5 MHz clock speeds with up to 11 devices:
  - Uses standard pads with 4 mA drive.
  - Dynamically assigns target addresses, and targets do not require static addresses (SAs). However, targets can have an I2C static address assigned at startup, so the target can operate on an I2C bus. By default, I3C supports 7-bit I2C-style addresses.
  - Allows targets to use the inbound SCL clock as the peripheral clock (instead of the clock from the controller) so that devices can have slow or inaccurate clocks internally.
  - Allows simple targets, such as temperature sensors, to have no internal clock.
  - I3C controller supports handoff from Open-Drain to Push-Pull mode for ACK to data transfer.
  - Generally, the controller terminates the read, but for I3C, the target can also end the read.
- IBIs that allow targets to send notifications to a controller:
  - Can be equivalent to a separate GPIO, but can also be directly data-bearing.
  - Can be prioritized. When multiple targets send interrupts to a controller at the same time, the order is resolved. Dynamic addresses (DAs) establish the priority of the targets, so the controller controls the priority of the targets.

    Targets with lower-value DAs are higher-priority level IBIs.

  - Can start interrupts even when the controller is not active on the bus. A free-running clock is not required, but starting an interrupt requires a Bus Available condition.
  - Can resolve an initial event via a time-stamping option, not requiring an interrupt.
- Built-in commands for applications created in software or firmware by using the register interface maintained in a separate space. These commands do not collide with normal controller-to-target messages and:
  - Control bus behavior, modes and states, low-power state, inquiries, and more.
  - Have an extra room for new built-in commands for other groups.
- Organized forms of multicontroller modes that are secondary controllers using clean handoffs between different controllers.
- Hot-Join onto I3C bus allows devices to connect to the bus later than when the bus starts. This:
  - Enables a device or module to access the I3C bus after power up or when physically inserted onto the I3C bus.
  - Provides a clean method for notification when new devices or modules access the I3C bus.
- I3C can use both I2C and I3C buses:
  - I3C supports specific legacy I2C devices on the bus.
  - I3C target devices can operate on I2C buses.
  - In I2C controller mode, it supports only Push-Pull mode on the SCL line.
  - A reset output is available for I2C mode SW reset for application usage. Asserted when the module is an I2C target and gets a I2C software General command from a controller. See the chip-specific section, for usage if this is available.
- Higher data rate modes are available:
  - I3C has a high data rate: double data rate (HDR-DDR) mode, which is double the data rate of SDR .
  - Only the controller and the specific targets, which are capable and configured to work with HDR-DDR, support the higher data rate (the other targets can ignore it).

I3C supports most of the I3C features (see Target Capabilities (SCAPABILITIES) and Target Capabilities 2 (SCAPABILITIES2)), except for the ternary data rates (HDR-TSP and HDR-TSL), HDR-BT modes, and peer-to-peer messaging.

69.3 Functional description

69.3.1 Operating modes

This section describes all functional operation modes of the I3C module.

69.3.1.1 Target and controller roles for I3C

The I3C protocol defines these roles for devices on the I3C bus:

- Main controller: initially configures the I3C bus and serves as the first active controller
- Secondary controller: accepts the controller role from any active controller to become the new active controller (the secondary controller may then pass the controller role along: either back to the previous active controller, or on to any other controller-capable device)
- Target: responds to commands from any I3C controller
- I2C target: responds to compatible commands from any I3C controller

The I3C peripheral contains both controller and target components and can be configured to be either controller or target, or as target with secondary controller capability. However, if I3C is chosen to be a controller, then the I3C peripheral supports Target mode to facilitate handoffs to multiple controllers.

In general, any I3C controller can be a controller or a target because a controller becomes a target when giving over control to another controller. The only exceptions to this rule occur when using point-to-point communication or when using a controller that never shares controllership.

69.3.1.1.1 Controller requirements

Controller mode uses software that supports the requirements of the controller (including as a secondary controller):

- Managing the enter dynamic address assignment (ENTDAA) assigning dynamic addresses (DAs) to each target. The I3C peripheral supports this process but requires you to make choices.
- Driving the serial data (SDA) signal in both Open-Drain and Push-Pull modes. After START command, SDA is in Open-Drain mode and after Repeated START command, it is in Push-Pull mode:
  - SDA is subject to arbitration because both controller and target can drive the SDA line (arbitration is also useful for handoff from controller to target).
  - The ninth bit of SDA controller write data is an odd parity bit.
- Building a table of targets and their capabilities to control which actions and commands may be sent to the targets.
- Managing requests such as IBI and controller requests (handoff).
- Adjusting clock speed or write-to-read timing to match the limitations of the target. This adjustment can be done in hardware using dividers and uneven duty cycles, but you must decide how.
- Adjusting the maximum data length.
- Being a target after the controller role handoff to another controller-capable device.

The controller needs an accurate clock capable of running at a frequency that is the multiple of a frequency between 11 MHz and 12.5 MHz. Following are the possible clock frequencies:

- 24 MHz (multiple of 12 MHz)
- 25 MHz (multiple of 12.5 MHz)

If required to use a lower I3C SCL value, for example as small as 5 MHz (although the lower value does not support a mixed bus system):

- The controller clock can be a multiplier of that value.
- A lower SCL can also be achieved using a higher PPBAUD value.

69.3.1.1.2 I3C target acts like I2C target on I3C buses

If the target is assigned an I2C static address, the I3C target acts like an I2C device when it first powers on. If the I3C target is placed on an I2C bus with an I2C controller, then the I3C target stays in I2C mode and operates normally. The software is aware that the I3C target is in I2C mode because:

- There has not been an interrupt (see SSTATUS[DACHG]) indicating that a dynamic address was assigned.

For full I2C support of Fast mode (Fm) and Fast-mode Plus (Fm+), the pads must support a 50-ns spike filter. This filter must be turned off when the I3C 7Eh broadcast address is received (indicating an I3C controller). You can turn off the spike filters via hardware using the raw net indicating that the address was received, or via software. I3C does not need a 50-ns spike filter to operate on an I2C bus. Therefore, the spike filter is not a requirement for the I3C peripheral.

Depending on the configuration, the module supports most I2C features. See Target Capabilities (SCAPABILITIES) and Target Capabilities 2 (SCAPABILITIES2) for more information.

69.3.1.1.3 How a target rejoins the I3C bus

When a target tries to rejoin the I3C bus following a power-up or hard reset, the target needs a new dynamic address (DA). The target can rejoin the I3C bus in these ways:

- If the DA is lost, Hot-Join is used.

- If the DA is retained in the peripheral (for example, with state retention flip-flops), SCONFIG[OFFLINE] is used.

When SCONFIG[SLVENA] is 1, SCONFIG[OFFLINE] may become 1. This setting causes the peripheral to rejoin the bus safely. It does so by ensuring that the I3C bus is not in HDR mode, using the same approach as TE0 or TE1 exit. The peripheral waits for the HDR exit pattern from the controller, or for 60 µs of SCL and SDA lines not changing, whichever occurs first.

After using SCONFIG[OFFLINE], the I3C peripheral cannot safely use IBI until SSTATUS[STOP] becomes 1. This status ensures that the next START is safe to use for IBI.

If the application has to perform an IBI, it must wait for SSTATUS[STOP] to become 1, or for SCL and SDA lines to remain high for 200 µs. You can perform this process using the SSTATUS and SINTSET controls:

- If Target Status (SSTATUS) indicates that the bus is not busy and the peripheral interrupts on START or STOP, use a timer to measure 200 µs. If the timer finishes with no START or STOP, it is safe to use IBI.
- If a START causes an interrupt, then the timer must be turned off and the application must wait for a STOP.
- If a STOP causes an interrupt, it is safe to use IBI.

69.3.1.2 Using the I3C controller for I2C and I3C

The I3C controller operates with the following set of built-in capabilities with the application flow:

- Built-in enter dynamic address assignment (ENTDAA) mechanism to simplify the assignment of dynamic addresses to targets. This feature is used when set dynamic address from static address (SETDASA) is not available.

  NOTE

  When SETDASA CCC is available, use SETDASA CCC before using ENTDAA CCC; all targets without assigned dynamic addresses respond to ENTDAA CCC.

- Request for START + address with IBI support, including both I2C and I3C modes.
- SDR write flow via FIFO, with automatic parity in I3C and ACK or NACK detection in I2C.
- SDR read flow via the FIFO, with an automatic NACK generator for I2C, and optional use of a terminate generator for I3C.
- Request for Repeated START + address or STOP when finished with the previous request, including both I2C and I3C.
- Auto-IBI mode, which responds immediately to a target-initiated IBI and can be used when in Sleep or Deep Sleep mode.
- Special message mode for SDR and DDR to simplify DMA use.
- Automated SCL, SDA, pullup, and High-Keeper controls.
- I2C and I3C frequency and duty cycle configurations from functional clock.

  NOTE

  You must configure Controller Configuration (MCONFIG) and Controller In-band Interrupt Registry and Rules (MIBIRULES) before using the controller.

69.3.1.3 Protocol modes and states

The following modes are activated in I3C:

- I2C mode is the default mode on startup:
  - If no I2C static address is used, this mode has no effect other than to track frames looking for I3C transitional frames.
  - If an I2C static address is used, the device can interact with the I2C bus controller using the address.
- When in I2C mode, I3C Transitory Frame mode occurs whenever the I3C broadcast address is received (7Eh). In particular:
  - This mode occurs when 7Eh is broadcast followed by SETDASA from the controller. If there is a static address match, the target is assigned a dynamic address and it enters I3C SDR mode.

- This mode occurs when 7Eh is broadcast followed by ENTDAA from the controller. If the target can send a 48-bit provisioned ID (48b ID), a dynamic address is assigned, and the target enters I3C SDR mode.
- If a Hot-Join arbitrated event occurs (sending 02h when the controller generates another address such as 7Eh), there is a conceptual Hot-Join mode. ENTDAA or SETDASA sets a dynamic address to resolve the event, and the target enters I3C SDR mode.

NOTE

An I3C target can operate as a normal I2C target only when it has a static address. Otherwise, it matches nothing in I2C and waits for the aforementioned events.

- I3C SDR mode is the standard mode after I3C activates, which is defined by a dynamic address being assigned. This mode is the resting mode of I3C, and all devices are normally in SDR mode:
  - RSTDAA CCC causes an exit from SDR mode and a return to I2C mode. This transition is not normally used.

    RSTDAA can be issued to ensure that all I3C targets participate in an upcoming dynamic address assignment process, before the I3C controller starts assigning the target address.
  - SETNEWDA does not affect the SDR mode; it only changes the dynamic address of an I3C device that already had a dynamic address assigned.
  - When in SDR mode, the device ignores messages to or from its original I2C static address.
- The I3C CCC command submode of type Direct or Broadcast. Following are the options to exit the CCC:
  - Exit the Broadcast CCC submode by a Repeated START or by a STOP.
  - Exit the Direct CCC submode by a 7Eh broadcast address after a Repeated START or by a STOP.
  - I3C dynamic address assignment (DAA) CCC command enters DAA mode. This mode is a special mode for dynamic addressing. Use STOP to exit. If a target has a dynamic address, the command is ignored.
- I3C SETDASA CCC command enters Static Address Match submode, which allows matching the static address of the device (if any). The command is ignored when a target has a dynamic address, or when the target in I2C mode has no static address.

NOTE

The special point-to-point address is also matched.

- I3C HDR modes are activated by ENTHDR*n* CCC commands, where *n* represents the type of HDR (0 to 7). This mode is valid until an HDR exit pattern is detected, irrespective of whether HDR mode for a target is supported.

  Exit-pattern detection must always be on to prevent errors. Alternatively, you could set it to be activated only on ENTHDR.
- A special HDR-DDR syntax is used for transmitting CCC in the HDR-DDR protocol.
- Internal states such as IBI or no-IBI and Low-Power mode are flagged internally (see SSTATUS[EVDET] for more information). These states are exported to the application and affect the engine to restrain it from performing a prohibited operation.

69.3.1.4 Address match

For an address match to occur, the target matches the I3C broadcast address and either the I2C-style static address or I3C dynamic address (see Table 673).

The address match is inactive (just listening) for all Repeated START commands and also for the START command, unless an IBI, CR, or Hot-Join has been activated. If inactive, it simply tries to match. If not matched, it waits for a Repeated START or STOP command. If an IBI, CR, or Hot-Join has been activated, the arbitration mechanism is used for START (but never for a Repeated START).

When matching the 7Eh broadcast address, it looks for a CCC until the next Repeated START or STOP command.

Table 673. Address match conditions

For	Match condition occurs when	Notes
I3C broadcast address	The address is 111 1110b (written as 7Eh).	
I2C-style static address	• The device has a static address. • The device is not in I3C mode.	When in I3C mode, the address matches only until the ENTDAA, SETDASA, or SETAASA command has a dynamic address assigned. SETDASA matches the static address or the special one-controller-to-one-target point-to-point address.
I3C dynamic address	ENTDAA or SETDASA assigns it, or SETNEWDA modifies it.	

69.3.1.5 I3C from low power mode and wake-up

A wake-up interrupt is available to bring the I3C module out of low power mode.

This interrupt works in both Controller and Target mode of operation as described below.

69.3.1.5.1 Controller mode

In Controller mode, I3C works with 2 clocks.

- Host interface clock for accessing registers and DMA
- Functional clock (FCLK) for controller logic operation and generating SCL

The Functional clock can be switched off to keep the I3C controller in low power mode if there is no data to be sent by the host and the i3C bus is in idle state (SDA = 1).

Before switching off the clock, take the below steps.

- Ensure that you enable the Controller mode MCONFIG[MSTENA] = 01b.
- Ensure that the bus is in the idle state.
- Switch off the Functional Clock.

If any agent on the bus pulls the SDA line low and at the SoC level the ENABLE bit of the I3C SDA interrupt is set to 1, then the interrupt goes high to inform the SoC logic to switch on the FCLK again.

69.3.1.5.2 Target mode

In Target mode, I3C works with only the Host interface clock (for accessing registers and DMA)

The main target control logic works on the external SCL clock.

The Host interface clock can be switched off to keep the I3C Target in low-power mode.

Before switching off the clock, take these steps.

- Ensure that you configure the Target mode, MCONFIG[MSTENA] = 00b along with all other normal target configuration as required.
- Clear the interrupts in Target Status (SSTATUS) after handling them.
- Enable DA matched interrupt in SINTSET[MATCHED].
- The host can now stop the Host interface clock to enter low power mode.

The interrupt asserts when any address match happens, either DA or SA or group address with this target.

The host then resumes the Host interface clock to serve and clear the interrupt.

69.3.2 Operations

This section describes the operations of the module.

69.3.2.1 Reading and writing I2C messages using the normal method

1. Set up interrupts using the following fields of Controller Interrupt Set (MINTSET):
   - MCTRLDONE: Indicates when the module completes an MCTRL request.
   - COMPLETE: Indicates when data is finished sending or being received.
   - RXPEND: Used for read operations. Works with Controller Data Control (MDATACTRL) to set the FIFO trigger. You can also use this field to allow DMA to read out data.
   - TXNOTFULL: Used for write operations. Works with Controller Data Control (MDATACTRL) to set the FIFO trigger. You can also use this field to allow DMA to supply data.
   - IBIWON: Indicates that an IBI, CR, or HJ has won the arbitration on a header address.
   - Additionally, Controller Errors and Warnings (MERRWARN) indicates the causes of errors and warnings.
2. Configure the following fields in Controller Control (MCTRL) simultaneously:
   a. Write 1 to REQUEST (EmitStartAddr).
   b. Write 1 to TYPE (I2C).
   c. Configure IBIRESP to respond to IBIs in your chosen manner.
   d. Write 1 to DIR for read, or write 0 for write.
   e. Write the static address of the I2C target to ADDR.
   f. Configure RDTERM to the maximum length for read operations, to auto-terminate, or set it to STOP as the data is read out. For example, write 1 (with MCTRL[REQUEST] = 0) to stop after the next character.
3. Write or read the data.
   - For write operations, write to Controller Write Data Byte (MWDATAB) for each byte before the last byte, and then write to Controller Write Data Byte End (MWDATABE) for the last byte:
     — You can perform or start this operation before setting up interrupts.
     — If there is more data than the FIFO can hold, use the TXNOTFULL interrupt based on the trigger level. This interrupt allows the application to provide more data or to use DMA.
   - For read operations, wait for RXPEND, and then read out data via Controller Read Data Byte (MRDATAB). DMA may also be used.
4. After message transfer is complete (MSTATUS[COMPLETE] = 1), the message may end with a STOP condition, or a new message may start with a Repeated START condition:
   a. Write 2 to MCTRL[REQUEST] (EmitStop to STOP). Then wait for the MCTRLDONE status to be asserted for its completion. (When sending STOP in I2C mode, MCONFIG[ODSTOP] and MCTRL[TYPE] must be 1.)
   b. Write 1 to MCTRL[REQUEST] (EmitStartAddr to restart). IBI is not possible in this case.

NOTE

I2C Fm and I2C Fm+ modes are supported for legacy I2C devices as per the I3C standard specifications. See I2C configuration to meet timing requirements for Fm and Fm+ modes for more information.

69.3.2.2 Reading and writing I3C messages using the normal methods (SDR and HDR-DDR)

The normal method for I3C is the same as the method for I2C with a few differences:

1. Set up interrupts using the following fields of Controller Interrupt Set (MINTSET):
   - MCTRLDONE: Indicates when the I3C module completes an MCTRL request.
   - COMPLETE: Indicates when data is finished sending or being received.
   - RXPEND: Used for read operations. Works with Controller Data Control (MDATACTRL) to set the FIFO trigger. You can also use it to allow DMA to read out bytes.
   - TXNOTFULL: Used for write operations. Works with Controller Data Control (MDATACTRL) to set the FIFO trigger. You can also use it to allow DMA to supply bytes.
   - IBIWON: Indicates that an IBI, CR, or HJ has won the arbitration on a header address.
   - Additionally, Controller Errors and Warnings (MERRWARN) indicates the causes of errors and warnings.
2. Set up Controller Control (MCTRL).
   - Option 1: Configure the following fields of Controller Control (MCTRL) simultaneously in this way:
     a. Write 1 to REQUEST (EmitStartAddr).
     b. Write 0 to TYPE for I3C Single Data Rate (SDR) mode or write 2 for Double Data Rate (DDR) mode.
     c. Configure IBIRESP to respond to IBIs in your chosen manner.
     d. Write 1 to DIR for read, or write 0 for write.
     e. Write the dynamic address of the I3C target to ADDR.
     f. For read operations, you can configure RDTERM to the maximum length to terminate automatically.
     g. For write operations, prewriting the data (MWDATAB or MWDATAH) is preferred to ensure that there are no time delays waiting for the data.

        For DMA with MCTRL, use either Controller Write Byte Data 1 (to Bus) (MWDATAB1) or Controller Write Halfword Data (to Bus) (MWDATAH1).

     NOTE

     HDR-DDR mode requires writing an 8-bit command value for read or write. This value must be written into the TX FIFO via Controller Write Data Byte (MWDATAB). The END field is not used for this byte.

   - Option 2: This option is preferred when stopped (bus free condition) in SDR mode, and not in HDR-DDR mode. It allows any target to issue an IBI and avoids collisions with an IBI address. Also, it is faster (when the MSB of the dynamic address is always 0).

     Configure the following fields of Controller Control (MCTRL) in this way:
     a. Write 1 to REQUEST (EmitStartAddr). No prewritten transmit data can be in the FIFO.
     b. Write 0 to TYPE (I3C).
     c. Configure IBIRESP to respond to IBIs in your chosen manner.
     d. Write 0 to DIR.
     e. Write 7Eh to ADDR.
     f. Wait for MCTRLDONE (via interrupt, for example), then proceed as in option 1. The option 2 method has advantages for IBIs when 7Eh is sent on START (but not on Repeated START conditions).
3. Write or read the data.
   - For write operations, write to MWDATAB for each byte before the last byte, and then write to Controller Write Data Byte End (MWDATABE) for the last byte. For HDR-DDR, the byte with END must be even (second, fourth, sixth, and so on) because DDR uses byte pairs:

— You can perform or start this operation before step 1 (REQUEST = 1) of the option 1 method, but not before the option 2 method.

— If there is more data than the FIFO can hold, use the TXNOTFULL interrupt based on the trigger level. This interrupt allows the application to provide more data or to use DMA.

- For read operations, wait for RXPEND, and then read out data via Controller Read Data Byte (MRDATAB) or Controller Read Data Halfword (MRDATAH). DMA may also be used. When using DMA, read using the same registers.

4. After message transfer is complete (MSTATUS[COMPLETE] = 1), the message may be ended with STOP (or EXIT in HDR mode). Alternatively, a new message may be started with a Repeated START (or HDR-Restart in HDR mode):
   - In SDR mode, write 2 to MCTRL[REQUEST] (EmitStop to STOP). Then wait for the MCTRLDONE status to be asserted for its completion.
   - For HDR mode, write 6 to MCTRL[REQUEST] (ForceExit) to end HDR mode. Then wait for the MCTRLDONE status to be asserted for its completion. When sending the HDR exit pattern, MCONFIG[ODSTOP] must be 0.
   - Write 1 to MCTRL[REQUEST] (EmitStartAddr to start another message). IBI is not possible in this case.

69.3.2.3 Determining bus types and modes

The settings of MCTRL[TYPE] and MCTRL[REQUEST] determine bus types and modes.

Table 674. Determining bus types and modes

Value of MCTRL[TYPE]	Meaning when MCTRL[REQUEST] = 1 (EmitStartAddr)	Meaning when MCTRL[REQUEST] = 2 (EmitStop)	Meaning when MCTRL[REQUEST] = 6 (ForceExit)
0	SDR mode of I3C	SDR mode of I3C	Exit pattern
1	Standard I2C protocol	Standard I2C protocol	Reserved
2	The bus enters DDR mode (7E and then ENTHDR0), if the module is not in DDR mode already. The first byte written to the transmit FIFO must be a command and already in the FIFO. To end DDR mode, use ForceExit.	Reserved	Target reset
3	If not already in HDR-BT, the bus automatically enters BT mode (7E and then ENTHDR3). You must also configure the MHDRBTCFG register for multilane and CMD rules.	Reserved	Reserved

Table 675. Deriving the dynamic address

Value of MCTRL[TYPE]	Meaning when MCTRL[REQUEST] = 4 (ProcessDAA)
0	The dynamic address is derived from MWDATAB[VALUE]; in case of a NACK, ProcessDAA continues to the next 7E/R request.
1	Reserved
2	The dynamic address is derived from MWDATAB[VALUE]; in case of a NACK, a STOP condition is sent after the assignment.
3	Reserved

69.3.2.4 Sending a CCC to I3C targets

The normal common command code (CCC) method uses an I3C write operation with an address of 7Eh (the CCC is the first byte):

- For broadcast type, any remaining bytes are sent with the CCC. This operation ends with a STOP or a Repeated START and 7Eh.
- For direct type, only the CCC byte is sent (or by a CCC and a defining byte, if required by the CCC).

  These bytes are followed by a Repeated START and the address of the I3C target (for SETDASA, this address is its I2C static address). This sequence may be repeated with more Repeated START conditions and addresses until done. It may end in STOP or a Repeated START and 7Eh. After the Repeated START and target address, the values are read or written depending on the CCC.
- I3C provides interrupts (by hardware) for unhandled and handled CCC when received by the target. Its state is reflected in Target Status (SSTATUS).

I3C controllers require to emit a single START, 7E/W sequence with both SCL high and SCL low half periods at full open-drain timing (for example, 200 ns). This sequence allows I3C targets acting as I2C legacy devices to turn off their I2C 50-ns spike filters, if they have them.

NOTE

START, 7E/W is a notation indicating a START command, followed by the 7Eh broadcast address and then by a write command.

After that sequence, addresses following START may be sent with Open-Drain Low (for example, 200 ns) but high of Push-Pull timing (for example, 40 ns). The I3C controller must emit this START, 7E/W sequence with MCONFIG[ODHPP] = 0. ODHPP is Open-Drain High period at Push-Pull speeds, and MCONFIG[ODHPP] is usually 1.

NOTE

- MCONFIG[ODHPP] is ignored when sending a message to an I2C legacy device on an I3C bus.
- Each Repeated START is a new EmitStart request. This request can be chained by an interrupt or pushed by a message model using DMA.

69.3.2.5 IBI handling

An IBI occurs when a target sends its address after a START, and that address is numerically the lowest. That is, it is lower than the address sent by the controller and addresses sent by any other targets. When the controller sends 7Eh, the controller always loses the arbitration.

The IBI can occur unexpectedly when any new START (not a Repeated START) is sent. The IBI can also occur in response to a target pulling SDA low. This condition can occur in one of these ways:

- The controller has set the request to AutoIBI mode, so the IBI occurs automatically. The controller sends 7Eh to allow the target to win the arbitration.
- The application receives the SLVSTART (target START request) interrupt, so it sends 7Eh.

The IBI response is configured by MCTRL[IBIRESP], which can be set to:

- NACK (always reject the IBI).
- ACK (always accept the IBI):
  - You must configure Controller In-band Interrupt Registry and Rules (MIBIRULES) so that the engine knows whether IBI bytes follow.
  - If IBI bytes follow (also known as IBI mandatory byte), then the COMPLETE field does not become 1 when IBIWON becomes 1. RXPEND becomes 1 for one or more bytes in the receive FIFO. When the last byte is received, then the COMPLETE field becomes 1. The controller automatically stops IBI data after 9 bytes (including the mandatory data byte). MCTRL[RDTERM] can be used with MCTRL[REQUEST] = 0 to end the process of receiving data sooner. I3C

supports address ACK to mandatory byte transition during IBI from Open_Drain (controller acknowledges the target address) to Push Pull (target sends SDR data).

— I3C target supports up to 7 bytes (maximum limit is defined by IBIEXT1[MAX]) of extended IBI data following a mandatory data byte. Extended data to send, if any, is present in Extended IBI Data 1 (IBIEXT1) and Extended IBI Data 2 (IBIEXT2).

- Manual (allow the decision to be made by the application on a case-by-case basis):
  — The application rewrites it when stopped, pending an IBI.
  — The application can ACK or NACK the IBI based on the IBI address defined in MSTATUS.
  — This mode selects whether there is an IBI byte when accepting the IBI request from targets.

Accurate timestamping of I3C target data is supported in I3C though Async mode 0. In I3C Asynchronous Timing Control mode, a target device timestamp event occurs within that target. The target notifies the controller about the event by generating an IBI.

69.3.2.6 Assigning dynamic addresses to I3C devices

If dynamic addresses (DAs) are all assigned below 40h (7-bit values from 3Fh down to 03h, except where not allowed), then MIBIRULES[MSB0] can be 1. This setting optimizes the START timing. When dynamic addresses are assigned, you must program Controller In-band Interrupt Registry and Rules (MIBIRULES) based on which I3C target uses IBI bytes (present in SIDEXT[BCR]).

Any SETDASA assignments can be performed via the normal CCC model. These assignments cannot be performed when using the static address for the directed part.

There is a built-in mechanism to process ENTDAA mode:

1. Set up interrupts using the following fields of Controller Interrupt Set (MINTSET):
   - MCTRLDONE: Indicates when a target has sent its ID and BCR or DCR, and a new DA is needed.
   - COMPLETE: Indicates when DAA is done (NACKed by all targets).
   - RXPEND: Indicates the reading of the IDs of the targets. You can also use this field to allow DMA to read out bytes.
   - IBIWON: Indicates when an IBI has occurred (normally there are no IBI conditions when assigning dynamic addresses to the I3C device).
   - Additionally, Controller Errors and Warnings (MERRWARN) indicates the causes of errors and warnings.
2. Configure Controller Control (MCTRL):
   a. Write 4 to MCTRL[REQUEST] (ProcessDAA).
   b. Set MCTRL[IBIRESP] to IBI response, if possible. If not possible, set to the first target assignment.
3. Wait for the MCTRLDONE interrupt when reading ID using the RXPEND interrupt. If MSTATUS[STATE] = 5 (DAA mode) and MSTATUS[BETWEEN] = 1, it is waiting to write a dynamic address:
   a. Write the dynamic address into Controller Write Data Byte (MWDATAB) using bits 6:0, such as 14h for DA = 7'h14.
   b. Write 4 to MSTATUS[STATE] (ProcessDAA again). This option writes the DA, then moves to the next DA.
   c. If MSTATUS[COMPLETE] = 1 and MSTATUS[STATE] = 0, then all targets are assigned.
   d. If MSTATUS indicates NACK after writing a new DA, the DA is not accepted by the target. The next step is to write 2 to MCTRL[REQUEST] (EmitStop) and start over. It is also acceptable to write 4 to MCTRL[REQUEST] (ProcessDAA again).

69.3.2.7 Using Controller Message mode

Controller Message mode is intended for use with DMA although Message mode can also be used by the processor. In Message mode, all writes are to the same location, including control and data. Reads occur from an associated location.

NOTE

The data writes for Message mode work in the same way as the halfword access registers, Controller Write Data Halfword (MWDATAH) and Controller Read Data Halfword (MRDATAH).

To send a message via Single Data Rate (SDR), follow these steps (from DMA or processor):

1. Write the control request to Controller Write Message Control in SDR mode (MWMSG_SDR_CONTROL). This request includes the following items:
   - The address.
   - I2C or I3C.
   - Read or write.
   - The count of bytes to process.
   - How to end (on STOP or ready for Repeated START).
2. Process the data:
   - For write operations, write the rest of the data to Controller Write Message Data in SDR mode (MWMSG_SDR_DATA). Use the DMA trigger (or interrupt) to keep the transmit FIFO full, and the controller stops using the data when it has already consumed the number of bytes configured in the LEN field.
   - For read operations, a DMA trigger (or interrupt) indicates when the RX FIFO is ready to be read out via Controller Read Message in SDR mode (MRMSG_SDR).
3. Select the in-band interrupt (IBI) behavior in MCTRL[IBIRESP].
4. Use END type STOP (MCTRL[REQUEST] = 2) with a zero-length message or by using Controller Control (MCTRL). To exit Message mode with the original message, use END type STOP (MCTRL[REQUEST] = 2) with a zero-length message or by using the MCTRL register.

To send a message via Double Data Rate (DDR), follow these steps (from DMA or processor):

1. Write the control request to Controller Write Message in DDR mode: First Control Word (MWMSG_DDR_CONTROL). This request includes:
   - The count of byte pairs.
   - How to end the message (through HDR exit or to wait for HDR restart).
2. Write the second control data to MWMSG_DDR_CONTROL. This second write includes:
   - The address.
   - Read or write.
   - The 7-bit command value.
3. Process the data:
   - For write operations, write the rest of the data to MWMSG_DDR_DATA. Use the DMA trigger (or interrupt) to keep the transmit FIFO full, and the controller stops using the data when the program count MWMSG_DDR_CONTROL register reaches 0.
   - For read operations, a DMA trigger (or interrupt) indicates when the receive FIFO is ready to be read out.
4. Select in-band interrupt (IBI) behavior in MCTRL[IBIRESP].
5. Use END type exit (MCTRL[REQUEST] = 6) with a zero-length message or by using the MCTRL register to exit DDR Message mode with the original message.

69.3.2.8 Handing off controllership to another target and getting it back

To hand off controllership, the controller can perform either of the following actions:

- Wait for a controller request (CR) (that is, MSTATUS[IBIWON] = 1 interrupt), indicating that the CR is using MSTATUS[IBITYPE].
- Push the request manually.

In either case, the controller sends a GETACCMST request, which is a directed GET informing the target that it is being assigned controllership. If the target accepts this request, it returns its dynamic address in bits 7:1 and the negative parity of its dynamic address in bit 0. A STOP must be issued, and MCONFIG[MSTENA] must be set to 2 (switching to Target mode).

To gain controllership, the target sends a CR using Target Control (SCTRL):

- If MCONFIG[MSTENA] is 2, the GETACCCR CCC is ACKed.
- If MCONFIG[MSTENA] is not 2, the GETACCCR CCC is NACKed.

After controllership is granted, MSTATUS[NOWMASTER] becomes 1. The application must enable MINTSET[NOWMASTER], so the application is interrupted when a controllership transfer occurs.

69.3.2.9 Controller engine flow diagram

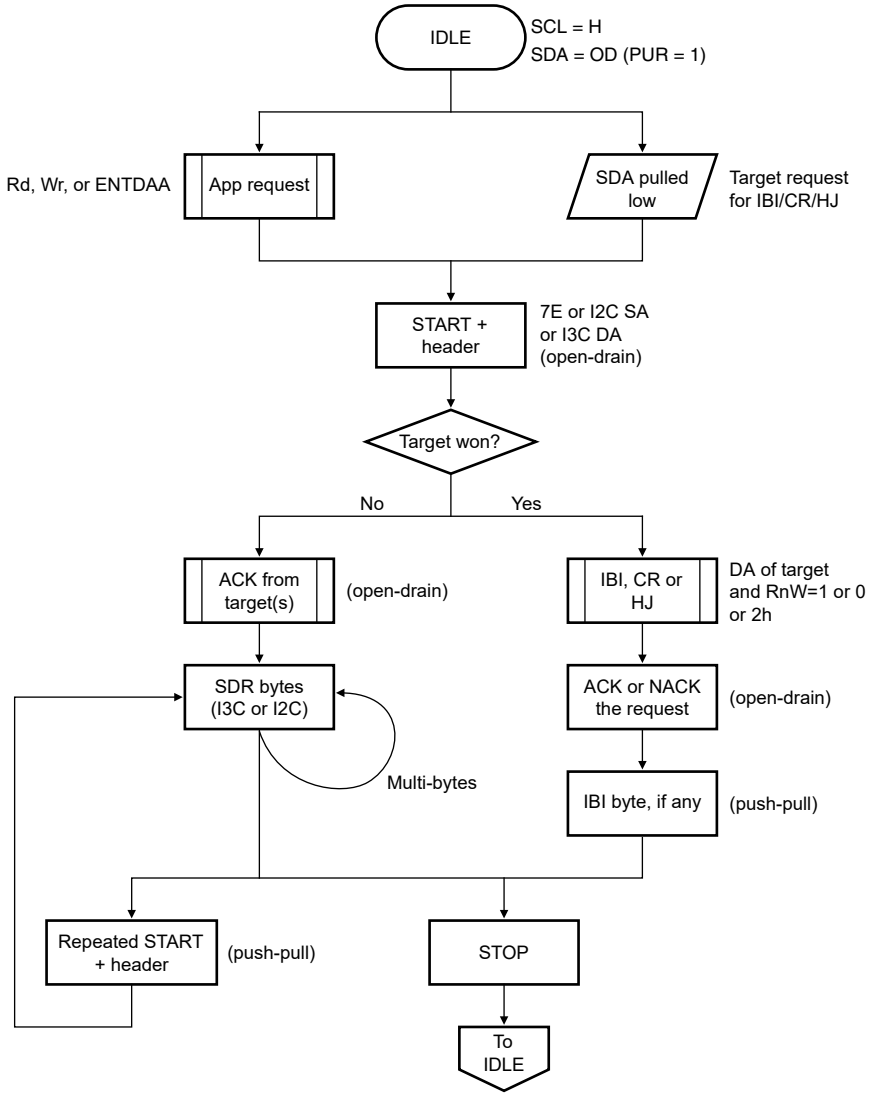

Figure 294. Controller engine flow diagram for SDR (HDR flow progresses from SDR bytes)

69.3.2.10 Target receives data from controller

When the address match is valid for the target dynamic address and the type is W (write from controller), the target ACKs the address. It does so unless some condition prevents it, such as a full buffer. On ACK, the Write state is entered. Once ACKed, it waits for each complete data byte. This process occurs in two steps:

1. Eight bits are clocked in and stored in the next buffer location when in the Write state.
2. On the ninth bit:
   - In I3C mode, the W9TH state (in I3C, the ninth data bit written by the controller is the parity of the preceding eight data bits) is used and the parity is checked. The buffer is marked as complete with or without a parity error.
   - In I2C mode, the W9TH state (in I2C, the ninth data bit written by the controller is an ACK by the target) is used and the data is ACKed and stored.

When the address match is valid for the 7Eh broadcast address, the target acknowledges it. After first data completion, it sets the in_ccc broadcast or direct flag (based on bit 7 of the command). If recognized, it parses the command, setting that bit as well. The recognized commands are for dynamic address work and modes. The CCC and DAA blocks handle the workload afterward. If not supported, then the commands are passed up to the system.

69.3.2.11 Target sends data to controller

When the address match is valid for the target dynamic address, and the type is R (read by controller), the target ACKs the address. The target does so unless there is no data waiting for the read. On ACK, the Read state is entered.

After being ACKed, it emits the data byte at a time, with the ninth bit using the R9TH state. In I2C, the ninth data bit from target to controller is an ACK by the controller. In I3C, this bit allows the target to end a read, and allows the controller to abort a read:

- In I3C mode, the T bit is emitted to allow the device to indicate whether this byte is the last. If it is not the last byte, the controller may terminate the read via the T bit.
- In I2C mode, the ninth bit allows the controller to terminate via NACK, or else it allows the read to continue via ACK. On completion of each byte read, the "done" signal is pulsed to get the next byte.

If the read is terminated by the controller unexpectedly (abort in I3C, NACK before END marked), the application is notified.

69.3.3 Clocking

The controller works on the following primary clocks:

- The system clock, which controls access to the memory-mapped registers.
- A functional clock (FCLK), which is used to generate the SCL clock rate on the I2C or I3C bus.

I3C supports adjusting clock frequency and accuracy via Target Time Control Clock (STCCLOCK).

FCLK is used to check conditions such as bus availability, bus free for IBI, or HJ:

- To determine the Bus Available condition for IBI, the target needs a clock to generate the ~1 µs timing. To support this requirement, a slow clock (CLK_SLOW) is provided to save on power.
- I3C supports a counter field, SCONFIG[BAMATCH], to calculate the Bus Available condition. BAMATCH provides the count of the slow clock . This field counts 1 µs or more to allow an IBI to drive SDA low when the controller is free. The I3C module controls the maximum width and maximum values.

I3C supports a timeout when stalled for too long in a frame. This timeout occurs when:

- The transmit FIFO or receive FIFO is not handled and the bus is stuck in the middle of a message.
- No STOP is issued and the bus is between messages.
- IBI manual is used and no decision is made.

69.3.4 Reset

- Global or system reset fed into the module: Everything is reset by this global or system reset. Release is assumed to be synchronized with the system clock. It is not synchronized with SCL or SDA. These signals must not be active when the reset is released; otherwise, I3C enters Hot-Join mode and remains inactive.
- Software reset

69.3.5 Interrupts

This section describes all the interrupts (IRQs) that this module generates. All status interrupts are updated in Controller Status (MSTATUS) and Target Status (SSTATUS).

Supported interrupts occur:

- For pending IBI, CR, or Hot-Join that have been sent by a target.
- When a CCC is received and is handled by the module (SSTATUS[CHANDLED]).
- When an error or warning has occurred, such as data underrun, data overrun, parity error, HDR-DDR, or CRC error.

A wake-up interrupt is also available to bring the I3C module out of low power mode. See I3C from low power mode and wake-up .

69.4 External signals

Table 676. External signals

Signal	Description	Direction
SCL	Serial clock	Input or output
SDA	Serial data	Input or output
PUR	Pull up resistance. There is an internal pullup resistance on SDA, which the I3C controls. If the internal pullup is not enough, PUR can control an external pullup resistance on SDA actively. See the chip-specific I3C information on whether this external pullup is available on your chip.	Output

69.5 Initialization

69.5.1 Controller configuration

Certain configuration is performed when initializing this module. Controller Configuration (MCONFIG) controls the frequencies, duty cycle, optimizations for performance, and other parameters.

Table 677. Configuration for module initialization

Configuration parameter		Description
MSTENA	Controller enable	Determines whether the peripheral starts in Controller mode (main controller in I3C terms) or starts in Target mode (and switches to Controller mode later).
HKEEP	High-Keeper	Determines how the high-keeper (weak pullup) is implemented, depending on the device capabilities.
PPBAUD	Push-Pull baud	Sets the push-pull frequency as a divider from the FCLK (alternative clock fed to the peripheral). This frequency sets the SCL half-clock period baseline (used at least for the high time of SCL).

Table continues on the next page...

Table 677. Configuration for module initialization (continued)

Configuration parameter		Description
		The formula for SCL in Push-Pull mode using PPBAUD and PPLOW is: SCL frequency (in MHz) = FCLK ÷ ((2 + 2 × PPBAUD) + PPLOW) If PPLOW is 0, then SCL high = SCL low (in ns) = (1 + PPBAUD) × 1000 ÷ FCLK (in MHz) Examples: • If FCLK = 24 MHz, then PPBAUD = 0 yields 12 MHz (42.67 ns per half period) • If FCLK = 50 MHz, then PPBAUD = 1 yields 12.5 MHz (20 + 20 = 40 ns per half period)
PPLOW	Push-Pull low	Changes the duty cycle for Push-Pull. It indicates how many more FCLK cycles to use for low. The formula for SCL in Push-Pull mode using PPBAUD and PPLOW is: SCL frequency (in MHz) = FCLK ÷ ((2 + 2 × PPBAUD) + PPLOW) If PPLOW is a nonzero value, then: • SCL high (in ns) = (1 + PPBAUD) × 1000 ÷ FCLK (in MHz) • SCL low (in ns) = (1 + PPBAUD + PPLOW) × 1000 ÷ FCLK (in MHz) For example, when FCLK is 50 MHz, PPBAUD is 1, and PPLOW is 1, then the periods are: • (1 + 1) × 1000 ÷ 50 = 20 + 20 = 40 ns high • (1 + 1 + 1) × 1000 ÷ 50 = 20 + 20 + 20 = 60 ns low This timing is equivalent to 10 MHz SCL, but this timing maintains the 40 ns high needed; therefore, I2C devices do not see the high periods. **NOTE** The PPLOW value does not have any impact on Open-Drain mode and I2C mode SCL rate calculations.
ODBAUD	Open-Drain baud	Determines the number of PPBAUD periods to make up one I3C Open-Drain half-clock baseline. If ODHPP is 0, the ODBAUD half-clock time period = (ODBAUD + 1) × PPBAUD high period. If ODHPP is 0, the formula for SCL in Open-Drain mode is: SCL (in MHz) = FCLK ÷ (2 + 2 × PPBAUD) × (ODBAUD + 1) Target to get open-drain half-clock period is 200 ns. For example: • If PPBAUD yields 12.5 MHz (40 ns per PPBAUD period), then ODBAUD = 4 can be used to get 200 ns. See ODHPP for details on short high and long low. • If PPBAUD = 1, FCLK = 50 MHz, and ODBAUD = 4, then open-drain SCL = 50 ÷ (2 + 2 × 1) × 5 = 2.5 MHz.
ODHPP	Open-Drain High Push-Pull	Optional field that allows the I3C open drain to be long low and short high. The high period of SCL is the PPBAUD period. This period leaves enough time for the pullup resistor to pull the SDA high when SCL is low. It is also quick when SCL is high and there are no changes happening. ODBAUD low half-clock time period = (ODBAUD + 1) × PPBAUD high period.

Table continues on the next page...

Table 677. Configuration for module initialization (continued)

Configuration parameter		Description
		ODBAUD high half-clock time period = PPBAUD high period If ODHPP is 1, the formula for SCL in Open-Drain mode is: SCL (in MHz) = FCLK ÷ (1 + PPBAUD) × (ODBAUD + 1) + (1 + PBAUD) For example: • If PPBAUD produces 12.5 MHz (40 ns per PPBAUD period), then ODBAUD = 4 and ODHPP = 1. These settings provide a high period of 40 ns and a low period of 200 ns. • If PPBAUD = 1, FCLK = 50 MHz, and ODBAUD = 4, then open-drain SCL = 50 ÷ (1 + 1) × 5 + (1 + 1) = 4.16 MHz.
I2CBAUD	I2C Baud	Indicates the number of ODBAUD periods that are required to communicate with I2C devices (MCTRL[TYPE] = 2 or MWMSG_SDR_CONTROL[I2C] = 1). For example, if ODBAUD gives 200 ns, and the goal is Fm+ (Fast Mode, 1 MHz), then the sum must be 1 µs. I2CBAUD acts differently for odd and even values. For example: • If I2CBAUD = 3, it gives three ODBAUD periods low and two ODBAUD periods high. • If I2CBAUD = 4, it gives three ODBAUD periods for low and three ODBAUD periods for high. • Also, if I2CBAUD = 3, this yields 200 × 3 = 600 ns and 200 × 2 = 400 ns, with the sum 600 + 400 = 1000 ns = 1 µs.
SKEW	Skew	The normal SDA skew from SCL is handled by using the time for the SCL to reach its pad and return. This time is normally 2 ns to 5 ns (or sometimes more). If the skew is too fast, then add more delay. The skew allows specifying the number of FCLK to insert.

Additional optimizations:

- Use MIBIRULES[MSB0] to obtain faster start header times. If the controller application assigns all I3C dynamic addresses to be less than 40h (it does not have MSB set), you can write 1 to MIBIRULES[MSB0]. When the controller emits 7Eh (broadcast) and a target does not drive the first bit low, the rest of the header can be at push-pull speeds. This speed is two times faster or more, depending on optimizations.
- Auto-emit 7Eh speeds up the frame when used with MIBIRULES[MSB0]. It allows the processor to sleep when the frame starts automatically (in response to a target).

69.5.2 Interrupt service flow

Set up interrupts for Controller Status (MSTATUS) in Controller Interrupt Set (MINTSET).

Set up interrupts for Target Status (SSTATUS) in Target Interrupt Set (SINTSET).

69.6 Application information

69.6.1 I2C configuration to meet timing requirements for Fm and Fm+ modes

I2C Fm and I2C Fm+ modes are supported according to the I3C standard specifications.

Table 678 shows the configuration for Fm mode, where frequency is close to 400 kHz but timing requirement is not met (T_{SU_STA} is not met) because the actual value is 600 ns. Rest of the requirements are met per the I2C specifications in the chip data sheet.

Table 679 shows the configuration for Fm mode, where all timing requirements are met.

Table 678. Configuration for Fm mode with not all timing requirements met

FCLK	PPBAUD	ODBAUD	I2CBAUD	SCL frequency	Timing requirement status
24 MHz	0	4	11	370 kHz	T_{SU_STA} - 353 ns

Table 679. Configuration for Fm mode with all timing requirements met

FCLK	PPBAUD	ODBAUD	I2CBAUD	SCL frequency	Timing requirement status
24 MHz	1	2	9	363 kHz	All requirements met per the I2C specifications in the chip data sheet

Table 680 shows the configuration for Fm+ mode, where the frequency is close to 1 MHz. In this case, the T_{SU_STA} timing requirement is not met because the actual value is 260 ns. Rest of the requirements are met per the I2C specifications in the chip data sheet.

Table 681 shows the configuration for Fm+ mode, where all timing requirements are met. To meet all the timing specifications, frequency may differ from 1 MHz. Use the configurations listed in Table 681.

Table 680. Configuration for Fm+ mode with not all timing requirements met

FCLK	PPBAUD	ODBAUD	I2CBAUD	SCL frequency	Timing requirement status
24 MHz	0	4	3	960 kHz	T_{SU_STA} - 228 ns

Table 681. Configuration for Fm+ mode with all timing requirements met

FCLK	PPBAUD	ODBAUD	I2CBAUD	SCL frequency	Timing requirement status
24 MHz	0	3	6	749 kHz	All requirements met per the I2C specifications in the chip data sheet

NOTE

The controller module provides an option to slow down the clock for standard speed mode to support legacy I2C standard targets as well (although this option may not necessarily meet the exact timing requirement of the standard mode according to the standard I2C timing specification).

For the timing requirements under consideration, see the "I3C timing requirements when communicating with I2C legacy devices" table in the MIPI I3C v1.1.1 specification available on www.mipi.org.

69.7 I3C register descriptions

Writing to a read-only (RO) register, except to Controller Interrupt Mask (MINTMASKED), causes bus errors. This module does not verify whether programmed values in the registers are correct. You must ensure that valid programmed values are written.

However, the peripheral ignores writes to RO registers and returns 0 for reads from WO or nonexistent registers. It requires all 32-bit registers to be read and written as 32-bit and aligned to 32 bits. The peripheral uses the advanced peripheral bus (APB: AMBA 3 APB Protocol Specification v1.0); therefore, the peripheral does not know whether partial read or write operations (less than 32 bits) are used.

69.7.2 Controller Configuration (MCONFIG)

Offset

Register	Offset
MCONFIG	0h

Function

Controls all controller states when the controller operation is enabled. You must not change this register during an active transaction.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	PPLOW				PPBAUD				Reserved	ODSTOP	HKEEP		DISTO	0	MSTENA	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-28 I2CBAUD	I2C Baud Rate Specifies the I2C low and high times in ODBAUD counts. See I2CBAUD in Controller configuration.
27-25 SKEW	Skew Specifies the number of FCLK counts for an SDA change after SCL for I3C push-pull. This skew is in addition to the roundtrip of the SCL line from the pad back to the module (6 ns or more): • SKEW is normally not needed, so assign SKEW = 0. • SKEW is only used if SDA is not naturally skewing from an SCL change. • I2C automatically skews SDA (but not PUR) to match I2C rules. Use the following values: • In I2C Controller mode (MCONFIG[MSTENA] = 11b) — SKEW > 0 when clock stretching feature is not required. — SKEW = 0 when clock stretching feature is required. • In I3C Controller mode, use SKEW = 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
24 ODHPP	Open-drain High Push-Pull Enables ODHPP. If you write 0 to this field, open-drain SCL high half-clock period is the same as the open-drain low SCL half period. If you write 1 to this field, open-drain high SCL half-lock period is one PPBAUD count for I3C messages. This setting is faster and works for I3C devices. Any legacy I2C devices on the bus do not see the SCL high level at all (less than the spike filter period). For open-drain timing, check upon the first 7Eh broadcast allowing I3C peripherals acting as I2C legacy devices to turn off their I2C 50-ns spike filters. See Sending a CCC to I3C targets for more information. 0b - Disable 1b - Enable
23-16 ODBAUD	Open-drain Baud Rate Specifies the open-drain baud rate. ODBAUD is configured in terms of number of PPBAUD counts - 1. This field must not be 0; this setting is not the same as push-pull. See Controller configuration for more information. The open-drain baud rate is usually 200 ns (see I2CBAUD for I2C counts). When used with MCONFIG[ODHPP], this setting produces 250 ns per clock in I3C. In this case, if MCONFIG[PPBAUD] provides 12 MHz, then one PPBAUD count is half of 12 MHz, or 41.67 ns. To obtain a rate around 200 ns, use a value of 5 - 1 = 4 for ODBAUD.
15-12 PPLOW	Push-Pull Low Acts as an adder for push-pull low to create a duty cycle with a longer low period, with up to 15 more FCLK cycles low than high. PPLOW = 0 produces a 50/50 duty cycle.
11-8 PPBAUD	Push-Pull Baud Rate Specifies the push-pull baud rate. The number of FCLK counts makes each push-pull low and normally high period. PPBAUD = 0 when run at 1/2 input FCLK speed. For example, a 24 MHz FCLK produces a 12 MHz SCL because each FCLK is SCL low or SCL high. MCONFIG[PPLOW] has an effect on the duty cycle. For example, 24 MHz with 50/50 duty cycle is 12 MHz. However, when PPLOW adds three more low beats, the push-pull baud rate becomes 4.8 MHz (from 24 MHz or 5 beats).
7 —	Reserved
6 ODSTOP	Open-drain Stop Enables open-drain stop. If you write 0 to this field, open-drain stop is disabled. ODSTOP must be disabled when sending an HDR exit pattern. If you write 1 to this field, open-drain stop is enabled. STOP condition is emitted at open-drain speeds even for I3C messages. In legacy devices, this feature can ensure that the legacy devices see the STOP condition. 0b - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enable
5-4 HKEEP	High-Keeper Indicates how High-Keeper is supported. If this field is 00b, use pull-up resistor (PUR). No separate pin_HK_SDA or pin_HK_SCL is used. Only pin_PUR_oena is used for SDA. The pin_SCL_oena pin is held high in this mode, SCL clock is push-pull, and pin_SCL_out toggles, which is the actual clock. If this field is 01b, High-Keeper controls are in place; pin_HK_SDA or pin_HK_SCL (High-Keeper) controls are used. SCL may use an HK or that signal (pin_HK_SCL) may only OR into pin_SCL_oena. The pin_HK_SDA pin is used as well for SDA high keeper, along with pin_PUR_oena. Use HKEEP = 10b or 11b for I2C modes. Use HKEEP = 00b or 01b for I3C modes. **NOTE** Your chip may not support any or all High-Keeper methods. You must check the availability of High-Keeper methods. 00b - None 01b - WIRED_IN 10b - PASSIVE_SDA (I2C mode, no clock stretches mode). SDA is open drain, and will be Hi-Z (high-impedance) for Bus Free (IDLE) and hold. The pin pin_HK_SDA is not used in this option, only a combination of SDA_oena and pin_PUR_oena are used. SCL is push-pull. The pin pin_HK_SCL is not used in this option, only pin_SCL_oena is used. Since the controller does not support multi-controller mode, there is no need to have open-drain SCL for I2C. For a single controller application, the controller's SCL output can be a push-pull driver design if there are no devices on the bus which would stretch the clock. 11b - PASSIVE_ON_SDA_SCL. For I2C clock stretching mode, where both SCL and SDA are open-drain. Open-Drain on both SDA and SCL, can Hi-Z (high-impedance) both for Bus Free (IDLE), and can Hi-Z SDA for hold. Does not support multi-controller mode, SCL open-drain is only to support clock stretching.
3 DISTO	Disable Timeout Disables the timeout that produces application errors. If the controller is left in a state other than Stopped for more than 100 µs (because 10 kHz is the slowest allowed I3C speed), the timeout sends a MERRWARN interrupt. To prevent the MERRWARN interrupt during development or testing, write 1 to DISTO to disable the timeout. In systems that support timeouts, timeout is disabled automatically during debug. To obtain a clock configuration with 100 µs timeout, see SCONFIG[BAMATCH]. 0b - Enabled 1b - Disabled
2	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
1-0 MSTENA	Controller Enable Indicates whether the controller is enabled and the states it can use. If this field is 0b, the controller is disabled. The module can only use Target mode. If this field is 1b, the controller is enabled. When used upon start-up, this module is the main controller by default. I3C controls the bus unless the controller is handed off. When this happens, MSTENA must become 2 so that it has the capability to become the controller again. Performing the handoff means emitting the GETACCMST CCC command. If the command is accepted, I3C emits a STOP condition and sets this field to 2 (or 0). If this field is 10b, I3C is controller-capable, but is operating as a target now. When used from the start, I3C starts as a target, but is prepared to switch to Controller mode. To switch to this mode, the target emits a controller request (CR) or receives a GETACCMST CCC command and accepts it (to switch on the STOP condition). Legacy I2C—if this field is 11b, I2C Controller mode uses an open-drain clock (to allow clock stretching) and relies on passive pull-up resistors (PURs) on both SCL and SDA. This mode uses only I2CBAUD. START requests can only be made for I2C type, and I3C requests are not accepted. If there are only I2C targets on the bus and no clock stretching, use type 1 instead. Type 1 has a push-pull SCL clock, which is faster and uses less power. 00b - CONTROLLER_OFF 01b - CONTROLLER_ON 10b - CONTROLLER_CAPABLE 11b - I2C_CONTROLLER_MODE

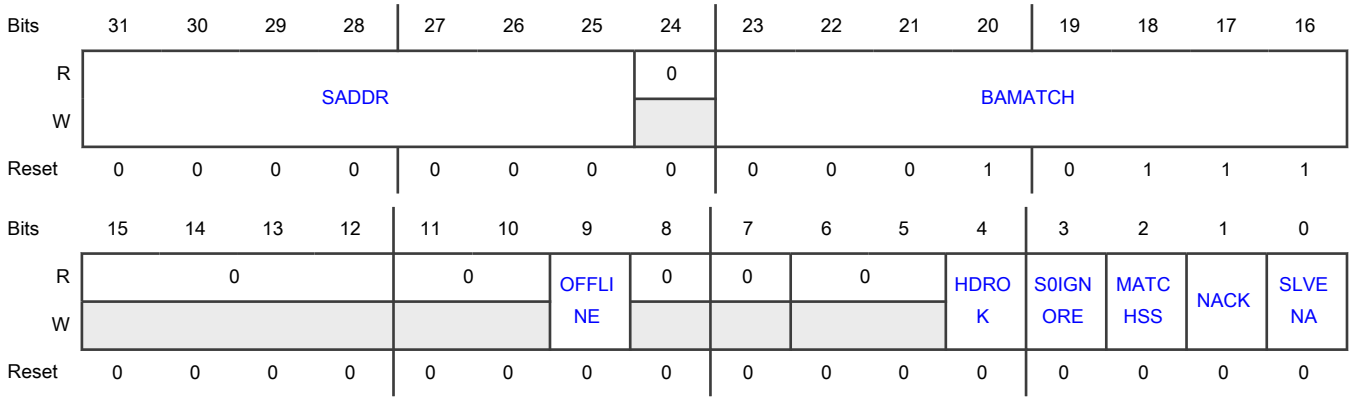
69.7.3 Target Configuration (SCONFIG)

Offset

Register	Offset
SCONFIG	4h

Function
Contains fields that must be configured before the module is activated.

Diagram



Fields

Field	Function
31-25 SADDR	Static Address Sets the I2C 7-bit static address, which otherwise must be 0.
24 —	Reserved
23-16 BAMATCH	Bus Available Match Specifies the bus available condition match value for the current slow clock. BAMATCH provides the count of the slow clock to count out 1 µs (or more). The BAMATCH should be set as (slowClk(MHz) - 1) to generate a 1 µs clock cycle. Use BAMATCH = 1 to generate 1 µs clock cycle if slow clock is 1 MHz. A value of 0 would not give a correct match indication. The default value applies to the default slow clock setting of the chip. If the I3C slow clock is updated to a new value, BAMATCH must be updated, too. When I3C operates in Controller mode, BAMATCH is used to generate a 1 µs clock cycle basic time to count 100 µs timeout. When I3C operates in Target mode, BAMATCH allows the IBI to drive SDA low when the controller is not doing so.
15-12 —	Reserved
11-10 —	Reserved
9 OFFLINE	Offline Enables wait to ensure that the bus is not in HDR mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field is 1 when SCONFIG[SLVENA] is 1, then I3C waits for either 60 µs of bus quiet or an HDR exit pattern. This waiting ensures that the bus is not in HDR mode, and so can safely monitor the next activity in Single Data Rate (SDR) mode. 0b - Disable 1b - Enable
8 —	Reserved
7 —	Reserved
6-5 —	Reserved
4 HDROK	HDR OK Enables HDR OK. If you write 1 to this field, it allows HDR-DDR and/or HDR-BT messaging, if available, by writing 1 to the corresponding SIDEXT[BCR] field to indicate HDR is available, and the corresponding GETCAPS field for DDR and/or BT bit permitting use. This is a deprecated field; use the SIDEXT[BCR] field instead. 0b - Disable HDR OK 1b - Enable HDR OK
3 S0IGNORE	Ignore TE0 or TE1 Errors Ignores TE0 or TE1 errors. If you write 1 to this field, the target does not detect TE0 or TE1 errors, so it does not lock up waiting on an exit pattern. You must not use this setting when the bus does not use HDR mode. 0b - Do not ignore TE0 or TE1 errors 1b - Ignore TE0 or TE1 errors
2 MATCHSS	Match Start or Stop Enables matched START, that is Repeated START, or STOP condition. If you write 1 to this field, SINTSET[START] and SINTSET[STOP] become 1 only when SSTATUS[MATCHED] is 1. This setting allows the START and STOP fields to be used to detect the end of a message to or from this target. **NOTE** SSTATUS[START] does not assert for START of transaction if SCONFIG[MATCHSS] = 1. SSTATUS[START] only asserts for Repeated Start within that transaction, because SSTATUS[START] only asserts after SSTATUS[MATCHED] occurs, which is after START of transaction. 0b - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enable
1 NACK	Not Acknowledge Controls the ACK or NACK capability. If you write 1 to this field, the target rejects all requests, except for a CCC broadcast. NACK = 1 must be used with caution because the controller may decide that the target is missing, if NACK is overused. 0b - Always disable NACK mode 1b - Always enable NACK mode (works normally)
0 SLVENA	Target Enable Enables the target. If you write 0 to this field, the target ignores the I2C or I3C bus. If you write 1 to this field, the target can operate on the I2C or I3C bus. You must not write 1 to this field before registers such as Target Configuration (SCONFIG), Target ID Part Number (SIDPARTNO), Target ID Extension (SIDEXT), and others are configured because these registers affect the data to and from the controller. Target enable is configured just once before the bus comes up. If target enable is used at other times, SCAPABILITIES[IBI_MR_HJ] must be 1 before writing 1 to SLVENA so that the device does not see a START or STOP condition incorrectly. 0b - Disable 1b - Enable

69.7.4 Target Status (SSTATUS)

Offset

Register	Offset
SSTATUS	8h

Function

Indicates the sticky status for interrupts, states, and modes related to the I3C bus. Not all fields of the register are used if the module only acts as a target. The fields are divided into current activity, interrupt maskable actions, and then states and modes on the bus.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	1	0	1	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-30 TIMECTRL	Time Control Indicates whether time control is enabled, and in which mode. 00b - NO_TIME_CONTROL (no time control is enabled) 01b - SYNC_MODE (Synchronous mode is enabled) 10b - ASYNC_MODE (Asynchronous standard mode (0 or 1) is enabled) 11b - BOTHSYNCASYNC (both Synchronous and Asynchronous modes are enabled)
29-28 ACTSTATE	Activity State from Common Command Codes (CCC) Indicates the activity state from CCC. 00b - NO_LATENCY (normal bus operations) 01b - LATENCY_1MS (1 ms of latency) 10b - LATENCY_100MS (100 ms of latency) 11b - LATENCY_10S (10 seconds of latency)
27 HJDIS	Hot-Join Disabled Indicates whether hot-join is disabled. When hot-join is disabled, CTRL requests are not responded to. 0b - Enabled 1b - Disabled
26 —	Reserved
25 MRDIS	Controller Requests Disable Indicates whether controller requests are disabled. When controller requests are disabled, CTRL requests are not responded to.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Enabled 1b - Disabled
24 IBIDIS	In-Band Interrupts Disable Indicates whether in-band interrupts are disabled. When in-band interrupts are disabled, CTRL requests are not responded to. 0b - Enabled 1b - Disabled
23-22 —	Reserved
21-20 EVDET	Event Details Indicates current details of the last (EVENT = 1) or pending event. 00b - NONE (no event or no pending event) 01b - NO_REQUEST (request is not sent yet; either there is no START condition yet, or is waiting for Bus-Available or Bus-Idle (HJ)) 10b - NACKed (not acknowledged, request sent and rejected); I3C tries again 11b - ACKed (acknowledged; request sent and accepted), so done (unless the time control data is still being sent)
19 —	Reserved
18 EVENT	Event Flag Indicates, for a target, whether a pending in-band interrupt (IBI), controller request (CR), or hot-join (HJ) has been sent as requested. See the upper status register fields for details. This field becomes 1 only when acknowledged by a controller. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No event occurred 1b - IBI, CR, or HJ occurred When writing 0b - No effect 1b - Clear the flag
17 CHANDLED	Common Command Code Handled Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates whether an HDRMATCH CCC is being handled by I3C. This field is for notification only, but it may result in updates to this register. **NOTE** This field behaves differently for register reads and writes. When reading 0b - CCC handling not in progress 1b - CCC handling in progress When writing 0b - No effect 1b - Clear the flag
16 HDRMATCH	High Data Rate Command Match Flag Indicates whether the HDR command matched the I3C dynamic address of this device. The HDR command is available as the first byte, with RXPEND = 1. The MSB of the command byte indicates whether it is a read or a write command. If the HDR command is a read, and there are to-bus bytes waiting, then the command is ACKed and the data is sent back. Otherwise, the HDR command is NACKed. **NOTE** When this field is 1, you must check SSTATUS[ERRWARN] because the HPAR error may occur after signaling this HDR command. The parity occurs after the destination address and command. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Did not match 1b - Matched the I3C dynamic address When writing 0b - No effect 1b - Clear the flag
15 ERRWARN	Error Warning Indicates that an error or warning has occurred, such as data underrun, data overrun, parity error, HDR-DDR CRC error, or other error or warning condition (see Target Errors and Warnings (SERRWARN) for more information).
14 CCC	Common Command Code Flag Indicates whether a CCC has been received, and is not handled by I3C. There are two types of common command codes: • Broadcast CCC, which corresponds with RXPEND, and the first byte is the CCC (command).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Direct CCC, which may never be directed to this device. If the direct CCC is directed to this device, then TXSEND or RXPEND are triggered, and RXPEND contains the command. **NOTE** This field behaves differently for register reads and writes. When reading 0b - CCC not received 1b - CCC received When writing 0b - No effect 1b - Clear the flag
13 DACHG	Dynamic Address Change Flag Indicates an occurrence of dynamic address (DA) change. Actual DA can be seen in the DYNADDR register. If this field is 1, DA change is detected. The target DA has been assigned, reassigned, or reset (lost) and is now in the state of being valid or none. This field is also used when the MAP auto feature is configured, changing one or more MAP items. See DYNADDR and MAPCTRL*n* for more information. DYNAADDR for the main DA (0) indicates whether the last change was because of Auto-MAP. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No DA change detected 1b - DA change detected When writing 0b - No effect 1b - Clear the flag
12 TXNOTFULL	Transmit Buffer Not Full Indicates that the transmit buffer is not full. If DMA is enabled for transmitting, then it is also signaled to provide more data. To-bus buffer or FIFO can accept more data to be transmitted. For all but external FIFOs, this process uses SDATACTRL[TXTRIG], which defaults to "not full". 0b - Transmit buffer full 1b - Transmit buffer not full
11 RX_PEND	Received Message Pending Indicates whether a received message is pending. The field indicates when a message from the controller that is not being handled by I3C (not a CCC message) is received. I3C processes such messages internally. For all but external FIFOs, this process uses SDATACTRL[RXTRIG], which

Table continues on the next page...

Table continued from the previous page...

Field	Function
	defaults to "not empty". If DMA is enabled for receiving, then DMA is signaled as well. This field automatically becomes 0 if data is read (from FIFO and non-FIFO sources). 0b - No received message pending 1b - Received message pending
10 STOP	Stop Flag Indicates whether the Stopped state is detected. The STNOTSTOP state also indicates when the module is in Stop mode. A fast STOP and START combination may not trigger the Stop status. In that case, the Start status is always set. If this field is 1, it indicates that the Stop state was present on the bus since the bus was last cleared. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No Stopped state detected 1b - Stopped state detected When writing 0b - No effect 1b - Clear the flag
9 MATCHED	Matched Flag Indicates whether an incoming header matched the I3C dynamic or I2C static address (if any) of this device since the bus was last cleared. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Header not matched 1b - Header matched When writing 0b - No effect 1b - Clear the flag
8 START	Start Flag Indicates whether a START or Repeated START was detected after this flag was last cleared. This flag is not usually needed, but can be used for wake events.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag
7 —	Reserved
6 STHDR	Status High Data Rate Indicates whether the I3C bus is in HDR-DDR mode, regardless of whether HDR mode is supported by this module, and regardless of whether the message is intended for this module or some other module. 0b - I3C bus not in HDR-DDR mode 1b - I3C bus in HDR-DDR mode
5 STDAA	Status Dynamic Address Assignment Indicates whether the I3C bus is in Enter Dynamic Address Assignment (ENTDAA) mode, regardless of whether this bus target has a dynamic address. 0b - Not in ENTDAA mode 1b - In ENTDAA mode
4 STREQWR	Status Request Write Indicates whether the REQ in process is SDR write data from the controller to this bus target (or all targets), but not in ENTDAA mode. See status high data rate (STHDR) for double data rate (DDR) handling. 0b - Not an SDR write 1b - SDR write data from the controller, but not in ENTDAA mode
3 STREQRD	Status Request Read Indicates whether the REQ in process is an SDR read from this target. See status high data rate (STHDR) for double data rate (DDR) handling. 0b - Not an SDR read 1b - SDR read from this target or an IBI is being pushed out
2	Status Common Command Code Handler

Table continues on the next page...

Table continued from the previous page...

Field	Function
STCCCH	Indicates whether a CCC message is being handled automatically. 0b - No CCC message handled 1b - Handled automatically
1 STMSG	Status Message Indicates whether the bus target is busy (listening to the bus traffic or responding). If STNOSTOP = 1, STMSG is 0 when a nonmatching address is seen, until the next Repeated START or STOP condition occurs. 0b - Idle 1b - Busy
0 STNOTSTOP	Status not Stop Indicates the status of the bus. If this field is 0, I3C is in a STOP condition. If this field is 1, the bus is busy (has activity). Other fields of this register may also be set when busy. STNOTSTOP can also become 1 after a TE0 or TE1 error, when I3C is waiting for an exit pattern. 0b - In STOP condition 1b - Busy

69.7.5 Target Control (SCTRL)

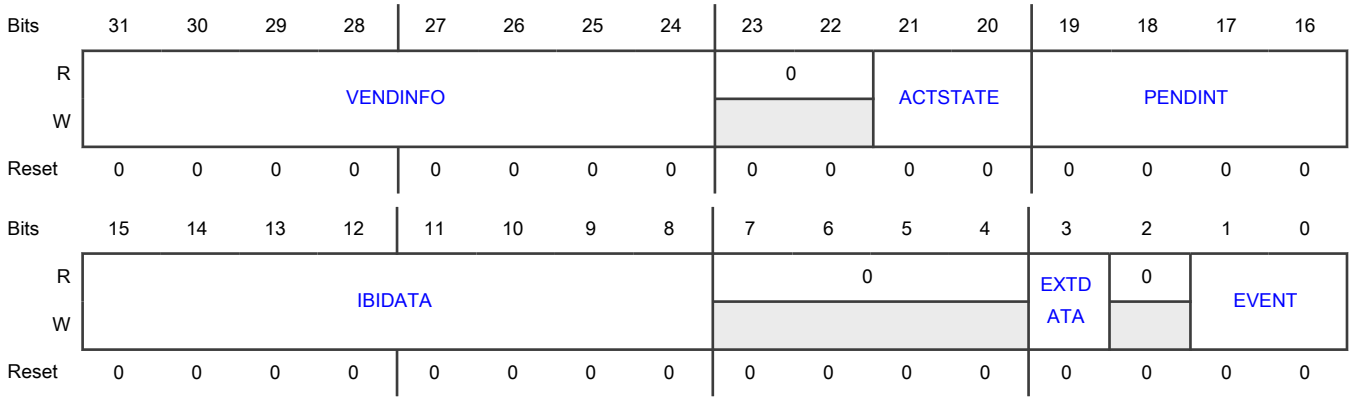
Offset

Register	Offset
SCTRL	Ch

Function

Contains controls for the active use of the I3C bus (for example, event generation such as interrupts to the controller). Only if I3C is configured to support various special operations for the target, this register is used to activate those operations. These events include IBI and GETSTATUS fields (except the protocol error, which is automatically set).

Diagram



Fields

Field	Function
31-24 VENDINFO	Vendor Information Controls vendor information that the GETSTATUS CCC returns. You must set this field to the Vendor Reserved field that the GETSTATUS CCC returns. The application must maintain the vendor information because the controller reads this field. If this field is not configured, then the GETSTATUS field always returns 0.
23-22 —	Reserved
21-20 ACTSTATE	Activity State of Target Controls the activity state of the target. You must set this field to the activity state of the target that the GETSTATUS CCC command returns as activity mode. The application must maintain the activity state because the controller reads this field. If you do not configure the activity state, then the GETSTATUS command always returns 0.
19-16 PENDINT	Pending Interrupt Specifies whether an IBI interrupt is pending. You must set this field to the pending interrupt that the GETSTATUS CCC command returns. The application must maintain the pending interrupt because the controller reads this field. If PENDINT = 0: • The GETSTATUS command returns 1 if an IBI interrupt is pending. • The GETSTATUS field returns 0 if an IBI interrupt is not pending.
15-8 IBIDATA	In-Band Interrupt Data Controls the data byte accompanying the IBI, if the module is enabled for IBI. If SCTRL[IBIDATA] is enabled, then IBI is required.
7-4 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
3 EXTDATA	Extended Data Enables extended data. After IBIDATA is emitted, extended data is acquired from IBIEXT1 and IBIEXT2, if configured. If extended data is used with time control, the data follows the time information. See IBIEXT1[MAX] for more information. 0b - Disable 1b - Enable
2 —	Reserved
1-0 EVENT	Event Requests an event. If this field is 0b, it indicates Normal mode, in which if this field becomes 0 from a nonzero value and event processing has not yet started, the event processing is canceled. However, event processing is not canceled if it has already started. If this field is 1b, an IBI is pushed onto the I3C bus. If there is data associated with the IBI, the data is read from SCTRL[IBIDATA]. If time control is enabled, this data includes any time-control-related bytes. Additionally, SCTRL[IBIDATA][7] becomes 1 automatically (as is required for time control). The IBI interrupt occurs after the first (mandatory) IBIDATA, if any. If this field is 10b, a controller request is started; the meaning depends on SIDEXT[BCR] configured in I3C. If this field is 11b, a hot-join (HJ) request is started, which is used when the device is powered on after the I3C bus is already powered up. It is also used when the device is connected using hot-insertion methods (the device is powered up when it is physically inserted in the powered-up I3C bus). The HJ waits for Bus Idle, and SCTRL[EVENT] = HOT_JOIN_REQUEST must be set before the target enable (SCONFIG[SLVENA]). If this field is a nonzero value, it requests an event. After the request, SSTATUS[EVENT] and SSTATUS[EVDET] show the status as it progresses. After completion, this field automatically returns to 0. After this field becomes a nonzero value, you can write only 0 it (to cancel) until the event processing is finished. 00b - NORMAL_MODE 01b - IBI 10b - CONTROLLER_REQUEST 11b - HOT_JOIN_REQUEST

69.7.6 Target Interrupt Set (SINTSET)

Offset

Register	Offset
SINTSET	10h

Function

Sets interrupt enables for select Target Status (SSTATUS) fields. Reading this register (SINTSET) returns the status of the interrupt enable:

- To activate an interrupt enable, write 1 to its corresponding field in this register (SINTSET).
- To disable an interrupt, write 1 to its corresponding field in Target Interrupt Clear (SINTCLR). Writing 0 to the interrupt enable in this register (SINTSET) does not disable the interrupt.

The Interrupt registers allow the masking of interrupt sources. They also allow the checking of which interrupts are activated. The normal method is to enable an interrupt, and then after the interrupt occurs, clear the interrupt either by writing to Target Status (SSTATUS) or by performing an action on the corresponding data register. The interrupt is level-held, meaning the interrupt stays set until the cause is cleared by some method. The module prevents races; if a new event occurs, that new event is not lost:

- SINTSET sets interrupt enables for Target Status (SSTATUS) fields. Reading the SINTSET register returns the status of the interrupt enables.
- SINTCLR clears interrupt enables for the SSTATUS fields.
- SINTMASKED returns the value of the SSTATUS fields ANDed with their interrupt enables.

Fields

Field	Function
31-20 —	Reserved
19 —	Reserved
18 EVENT	Event Interrupt Enable Enables event interrupts. This field indicates, for a target, whether a pending in-band interrupt (IBI), controller request (CR), or hot-join (HJ) has been sent as requested. The field is configured to support events. See SSTATUS[EVDET] for more information.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
17 CHANDLED	Common Command Code (CCC) Interrupt Enable Enables CCC interrupts. This field specifies whether CCC is being handled by I3C. Target Status (SSTATUS) shows new results. You can use this field to track when activity states and masks on events (for example, IBIs) occur. The field is used for CCCs that are enabled. 0b - Disable 1b - Enable
16 DDRMATCHED	Double Data Rate Interrupt Enable Enables DDR match for read or write command. This field indicates when DDR matches for read or write command, and the field is used only if HDR is enabled. 0b - Disable 1b - Enable
15 ERRWARN	Error or Warning Interrupt Enable Enables error or warning interrupts. This field indicates whether an error or warning has occurred, such as data underrun, data overrun, parity error, or HDR-DDR CRC error, or any other error or warning condition. See Target Errors and Warnings (SERRWARN) for cause of error. Only available for errors related to configured features. 0b - Disable 1b - Enable
14 CCC	Common Command Code (CCC) Interrupt Enable Enables CCC interrupts. This field indicates whether a CCC has been received, and is not handled by I3C. For CCCs that the block does not handle, RXPEND also interrupts, and SSTATUS[STREQRD] indicates that it is a CCC sending a read request. 0b - Disable 1b - Enable
13 DACHG	Dynamic Address Change Interrupt Enable Enables dynamic address change interrupts: interrupt on dynamic address defined (SETDASA or ENTDAA) or lost (RSTDAA). See Controller Dynamic Address (MDYNADDR) for more information.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
12 TXSEND	Transmit Interrupt Enable Enables transmit interrupts. This field indicates whether to-bus buffer or FIFO can accept more data to be transmitted. The corresponding interrupt occurs when the controller requests data to read from this target. This interrupt occurs on the first request (header) as well as when it is ready for more data. The corresponding interrupt occurs when the controller requests data to be read from this target. If this interrupt is for a FIFO, it triggers on the transmit emptiness trigger. If this interrupt is for DMA, then it indicates message end (DMA end or termination). 0b - Disable 1b - Enable
11 RXPEND	Receive Interrupt Enable Enables receive interrupts. This field specifies when a message from the controller that is not being handled by the module is received. For example, where data is consumed by hardware directly when it goes into the FIFO (excludes CCCs being handled automatically). If this interrupt is for a FIFO, it indicates a receive fullness trigger. If this interrupt is for DMA, then it indicates message end. 0b - Disable 1b - Enable
10 STOP	Stop Interrupt Enable Enables stop interrupts. This field detects the Stopped state present on the bus since the bus was last cleared. Use SINTSET[START] as the preferred interrupt when needed. This interrupt may not trigger for a quick STOP and START combination because it relates to the state of being stopped. 0b - Disable 1b - Enable
9 MATCHED	Match Interrupt Enable Enables match interrupts. Incoming header matched the I3C dynamic or I2C static address of this device since the bus was last cleared. If configured and if no dynamic address is set, this interrupt is also for matching a header on an I2C static address. See Controller Dynamic Address (MDYNADDR) for related information. 0b - Disable 1b - Enable
8	Start Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
START	Enables start interrupts. A START or Repeated START (such as wakeup) is seen after this field last became 0. See SINTSET[STOP] for related information. 0b - Disable 1b - Enable
7-0 —	Reserved

69.7.7 Target Interrupt Clear (SINTCLR)

Offset

Register	Offset
SINTCLR	14h

Function

Clears interrupt enables for select Target Status (SSTATUS) fields. To clear an interrupt enable, write 1 to the corresponding field in this register (SINTCLR). Writing 0 has no effect.

69.7.9 Target Errors and Warnings (SERRWARN)

Offset

Register	Offset
SERRWARN	1Ch

Function

Contains errors and warnings from I3C and I2C protocols. This includes internal issues such as overrun and underrun, detected errors and conditions like parity errors, CRC errors, and read terminations by the controller. See SSTATUS[ERRWARN] and SINTSET[ERRWARN] for related information.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-22 —	Reserved
21 —	Reserved
20-18 —	Reserved
17 OWRITE	Over-Write Error Flag Indicates that Target Write Data Byte (SWDATAB) or Target Write Data Byte End (SWDATABE) was written to when full. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No overwrite error 1b - Overwrite error When writing 0b - No effect 1b - Clear the flag
16 OREAD	Over-Read Error Flag Indicates that Target Read Data Byte (SRDATAB) was read for more bytes than were available, by the application. This field also indicates over-read errors for Target Read Data Halfword (SRDATAH), if it is enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - No over-read error 1b - Over-read error When writing 0b - No effect 1b - Clear the flag
15-14 —	Reserved
13 —	Reserved
12 —	Reserved
11 S0S1	TE0 or TE1 Error Flag Indicates whether a TE0 or TE1 error occurred and the target is locked and waiting for an HDR exit pattern. Writing 1 to S0S1 causes I3C to release the lock, but this method must be used with great care. S0S1 becomes 0 automatically when an exit pattern is detected, so writing 1 to S0S1 must be used under controlled circumstances to avoid problems. Before starting to operate normally after this error, I3C waits for a START (or Repeated START) or STOP state. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No TE0 or TE1 error occurred 1b - TE0 or TE1 error occurred When writing 0b - No effect 1b - Clear the flag
10 HCRC	HDR-DDR CRC Error Flag Indicates whether an HDR-DDR CRC error occurred on a message from the controller. Error reasons include an HDR restart and an exit being issued before an HDR-DDR message from the controller has finished. This error calls into question the data from the entire DDR command frame.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - No HDR-DDR CRC error occurred 1b - HDR-DDR CRC error occurred When writing 0b - No effect 1b - Clear the flag
9 HPAR	HDR Parity Error Flag Indicates when an HDR parity error or framing error on a message from the controller occurs. The corresponding command or data that has the error is usually in the RX buffer, which can be read using Target Read Data Byte (SRDATAB). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No HDR parity error 1b - HDR parity error When writing 0b - No effect 1b - Clear the flag
8 SPAR	SDR Parity Error Flag Indicates when an SDR parity error on a message from the controller occurs. This error also sets the GETSTATUS protocol error field (which becomes 0 after a GETSTATUS read). For read operations, this field becomes 1 when a read abort (timeout) occurs because of the controller not driving clock for more than 100 µs during an SDR read. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No SDR parity error 1b - SDR parity error When writing 0b - No effect 1b - Clear the flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-5 —	Reserved
4 INVSTART	Invalid Start Error Flag Indicates an invalid condition with SCL falling before SDA falls, so there is no start. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No invalid start error 1b - Invalid start error When writing 0b - No effect 1b - Clear the flag
3 TERM	Terminated Error Flag Indicates when the controller terminates a read from a target, if an END is not set by the target (on the same read or the previous read). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No terminated error 1b - Terminated error When writing 0b - No effect 1b - Clear the flag
2 URUNNACK	Underrun and Not Acknowledged (NACKed) Error Flag Indicates when the internal to-bus buffer or FIFO is underrun in the read header and so the module NACKed the header. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No underrun; not acknowledged error 1b - Underrun; not acknowledged error When writing

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No effect 1b - Clear the flag
1 URUN	Underrun Error Flag Indicates when the internal to-bus buffer or FIFO is underrun during data read (the application is not providing the data fast enough). The END field or register must be used if the read was the last one. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No underrun error 1b - Underrun error When writing 0b - No effect 1b - Clear the flag
0 ORUN	Overrun Error Flag Indicates when the internal from-bus buffer or FIFO has overrun (arrival of too many characters that you cannot process fast enough). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No overrun error 1b - Overrun error When writing 0b - No effect 1b - Clear the flag

69.7.10 Target DMA Control (SDMACTRL)

Offset

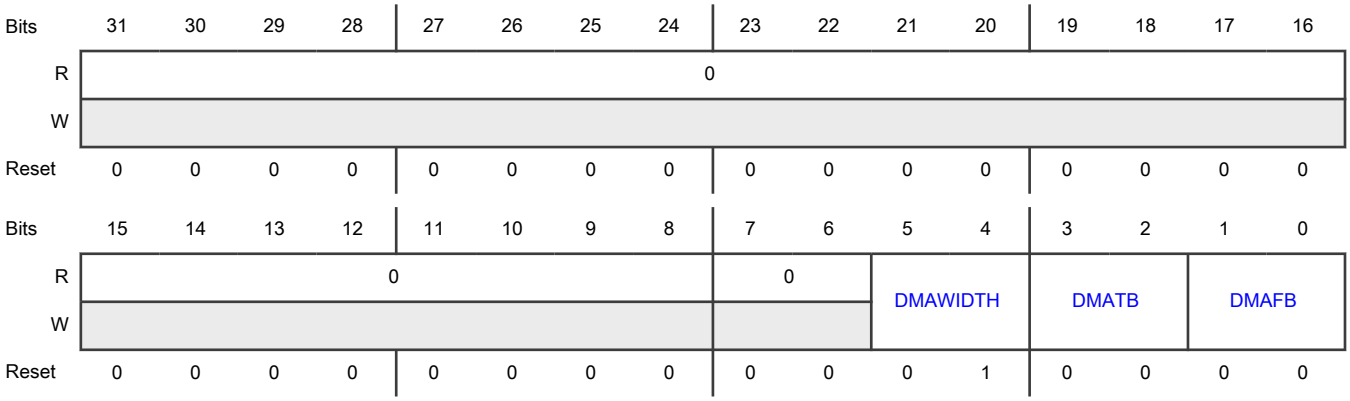
Register	Offset
SDMACTRL	20h

Function

Allows DMA to be used for inbound and outbound messages. This register is limited in value for target use because the target must be reactive. These are the two common use case models:

- To avoid an overrun in from-bus collection: if SCONFIG[MATCHSS] becomes 1, then the processor enables the interrupts for START and STOP and enables the DMA to collect the data. The START or STOP interrupt only occurs after a message is directed to the target (MATCHED is 1). The DMA copied data can then be examined.
- To perform larger reads from the to-bus: I3C and I2C reads are preceded by a write that indicates what will be read (or in response to an IBI from the target). Because of this process, the DMA can be used to push through the data:
  - For I3C, the processor must manage the last value, unless the DMA moves wider words and is able to write 1 to the END field. These values are 16-bit values when in Byte mode or 32-bit values when in Halfword mode.
  - For I2C, the controller determines the last value, so the DMA may end early or run out when the controller expects more values.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-6 —	Reserved
5-4 DMAWIDTH	Width of DMA Operations Indicates the width of DMA operations, if configured to allow halfword data accesses. 00b,01b - Byte 10b - Halfword (16 bits) (this value ensures that two bytes are available in the FIFO) 11b - Reserved
3-2 DMATB	DMA Write (To-Bus) Trigger Enables DMA writes. If this field is enabled, it starts a request DMA on a transmit trigger (see Target Data Control (SDATACTRL)). DMATB requests until full, unless the DMA is set up as a trigger. DMATB becomes 0 when MSTATUS[ERRWARN] becomes 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If you write 1b to this field, DMA is enabled for one frame (ended by DMA or terminated). DMATB automatically becomes 0 after a STOP or repeated START. See SCONFIG[MATCHSS] for more information. If you write 10b to this field, DMA is enabled until turned off. The value must only be used with Controller Message mode. 00b - DMA not used 01b - DMA enabled for one frame 10b - DMA enabled until turned off. Recommended mode, instead of 01b, to enable DMA. This setting provides better software control. 11b - Reserved
1-0 DMAFB	DMA Read (From-Bus) Trigger Enables DMA reads. If this field is enabled, DMAFB requests DMA on receive trigger (see SDATACTRL). It requests until empty, unless the DMA is set up as a trigger. This field becomes 0 when SSTATUS[ERRWARN] becomes 1. If this field is 1b (DMA is enabled for one frame), it automatically becomes 0 on STOP or repeated START. See SCONFIG[MATCHSS] for more information. **NOTE** Do not enable DMA after a transaction starts. It must be enabled only when enabling the target and interrupts to avoid any kind of RX FIFO overrun. 00b - DMA not used 01b - DMA enabled for one frame 10b - DMA enabled until turned off. Recommended mode, instead of 01b, to enable DMA. This setting provides better software control. 11b - Reserved

69.7.11 Target Data Control (SDATACTRL)

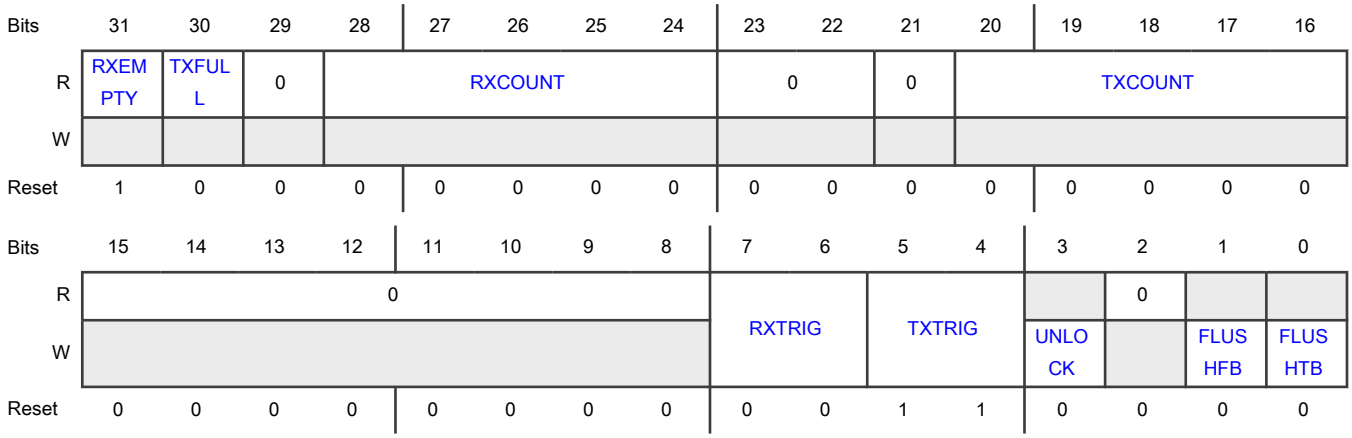
Offset

Register	Offset
SDATACTRL	2Ch

Function

Assists in data control when no FIFO is used. Also assists in data control of FIFO when the FIFO is available (regardless of size) allowing some control over the FIFO behavior. This register controls when to interrupt based on fullness or emptiness of a buffer or FIFO. It also controls behavior related to width, when the buffer or FIFO is not 1 byte wide.

Diagram



Fields

Field	Function
31 RXEMPTY	Receive is Empty Indicates whether the receive FIFO or buffer is empty. 0b - Not empty 1b - Empty
30 TXFULL	Transmit is Full Indicates whether the transmit FIFO or buffer is full. 0b - Not full 1b - Full
29 —	Reserved
28-24 RXCOUNT	Count of Entries in Receive Contains the count of entries in the receive FIFO or buffer. Entry size for SDR and HDR-DDR is in bytes.
23-22 —	Reserved
21 —	Reserved
20-16 TXCOUNT	Count of Entries in Transmit Contains the count of entries waiting in the TXFIFO. This count is the number of entries that the application has written to the transmit FIFO that have not yet gone onto the bus. Entry size for SDR and HDR-DDR is in bytes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-8 —	Reserved
7-6 RXTRIG	Receive Trigger Level Indicates the trigger level for receive fullness when using a FIFO. The field affects the RXPEND interrupt. 00b - Trigger when not empty (default) 01b - Trigger when 1/4 or more full 10b - Trigger when 1/2 or more full 11b - Trigger when 3/4 or more full
5-4 TXTRIG	Transmit Trigger Level Indicates the trigger level for transmit emptiness when using a FIFO. The field affects the TXNOTFULL interrupt. 00b - Trigger when empty 01b - Trigger when 1/4 full or less 10b - Trigger when 1/2 full or less 11b - Default (trigger when 1 less than full or less)
3 UNLOCK	Unlock Indicates whether the RXTRIG and TXTRIG fields can be changed on a write. This field must be 1 in the same cycle while writing to TXTRIG or RXTRIG. 0b - Cannot be changed 1b - Can be changed
2 —	Reserved
1 FLUSHFB	Flush From-Bus Buffer or FIFO Not normally used. **NOTE** Before using FLUSHFB, disable the DMA (SDMACTRL[DMAFB] = 0). Then use FLUSHFB to flush the FIFO and then re-enable the DMA. 0b - No action 1b - Flush the buffer
0 FLUSHTB	Flush To-Bus Buffer or FIFO Indicates when the controller terminates a to-bus (read) message prematurely.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE Before using FLUSHTB, disable the DMA (SDMACTRL[DMATB] = 0). Then use FLUSHTB to flush the FIFO and then re-enable the DMA. 0b - No action 1b - Flush the buffer

69.7.12 Target Write Data Byte (SWDATAB)

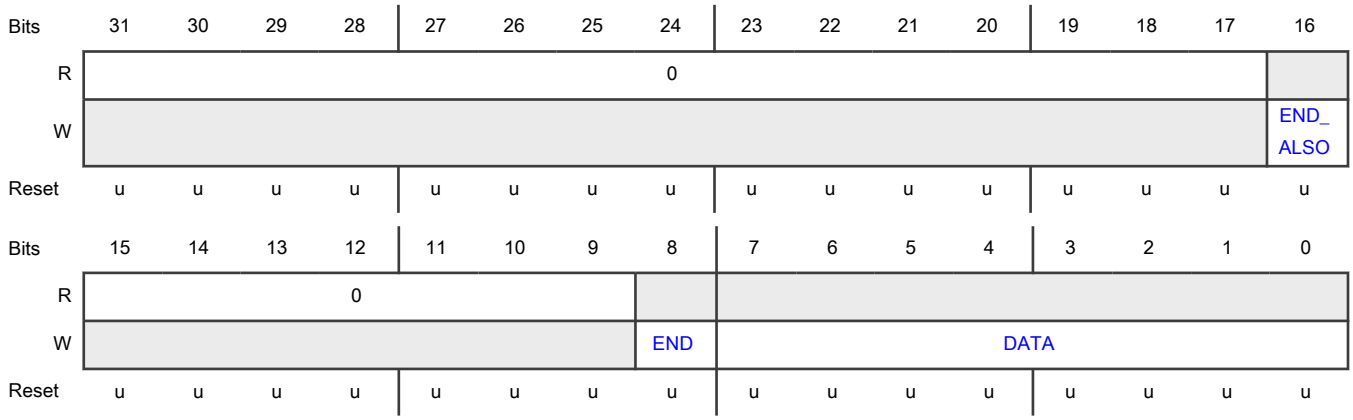
Offset

Register	Offset
SWDATAB	30h

Function

Allows writing a byte to the bus (to the controller) unless an external FIFO is used. Writing a byte requires a byte plus an end-of-data (last) marker bit. A byte must not be written unless there is room, indicated by SSTATUS[TXNOTFULL] = 1.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 END_ALSO	End Also Marks the last byte of the message. This field is required for I3C, but is optional for I2C. If this field is 0, it indicates that there are more bytes in the message.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	For HDR-DDR, the byte with END_ALSO must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs. 0b - Not the end 1b - End
15-9 —	Reserved
8 END	End Marks the last byte of the message. If this field is 0, it indicates that there are more bytes in the message. This field is required for I3C, but is optional for I2C. For HDR-DDR, the byte with END must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs. 0b - Not the end 1b - End
7-0 DATA	Data Indicates the data byte to be sent to the controller.

69.7.13 Target Write Data Byte End (SWDATABE)

Offset

Register	Offset
SWDATABE	34h

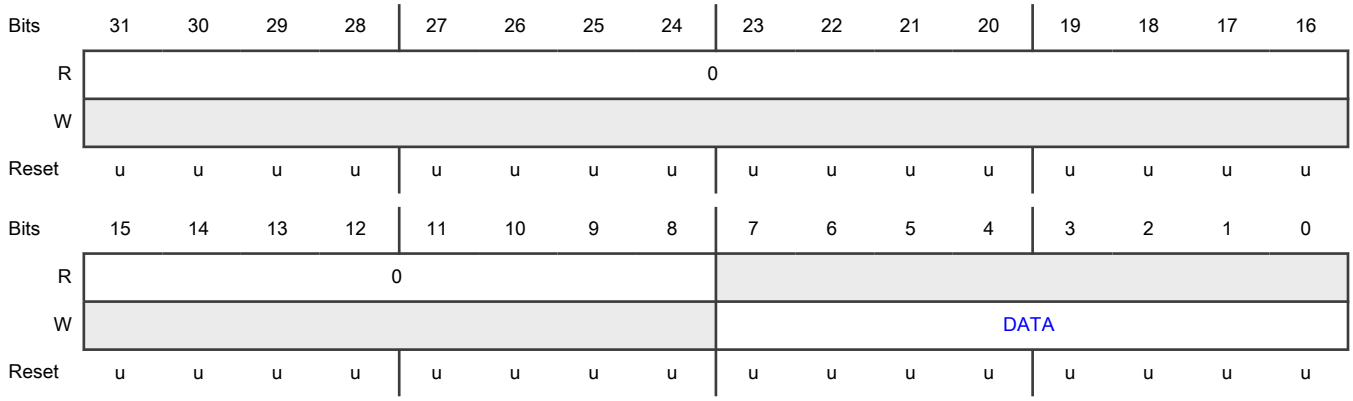
Function

Allows writing a byte to the bus (to the controller) unless an external FIFO is used.

Unlike Target Write Data Byte (SWDATAB), writing a byte only requires the byte itself, and is marked as end-of-data (last byte). A byte must not be written unless there is room, indicated by SSTATUS[TXNOTFULL] = 1.

For HDR-DDR, the byte with the END must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 DATA	Data Indicates the data byte to be sent to the controller.

69.7.14 Target Write Data Halfword (SWDATAH)

Offset

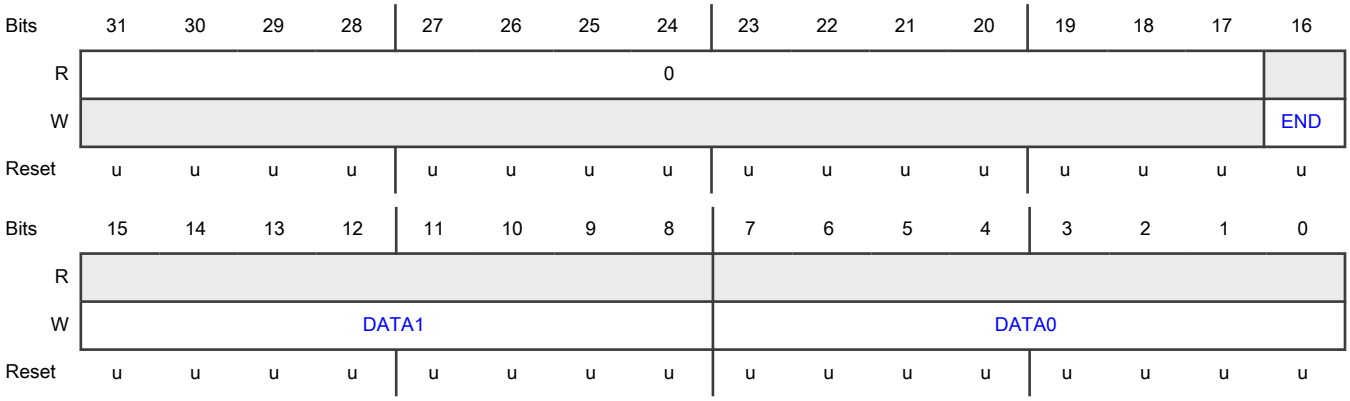
Register	Offset
SWDATAH	38h

Function

Allows writing a halfword (pair of bytes) to the bus unless an external FIFO is used. The low byte is followed by the high byte. The 16th bit marks the end; that is, the last byte of the halfword is the end.

An end-of-data (last) marker bit is allowed (or must be 0). A halfword must not be written unless there is room for both, as indicated by the use of transmit FIFO level trigger or SDATACTRL[TXCOUNT].

Diagram



Fields

Field	Function
31-17 —	Reserved
16 END	End of Message Marks the last byte of the message. This field always marks DATA1 as the end. The field is required for I3C, but is optional for I2C. If this field is 0, it indicates that there are more bytes in the message. For HDR-DDR, the byte with the END must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs. 0b - Not the end 1b - End
15-8 DATA1	Data 1 Indicates the second byte to be sent to the controller.
7-0 DATA0	Data 0 Indicates the first byte to be sent to the controller.

69.7.15 Target Write Data Halfword End (SWDATAHE)

Offset

Register	Offset
SWDATAHE	3Ch

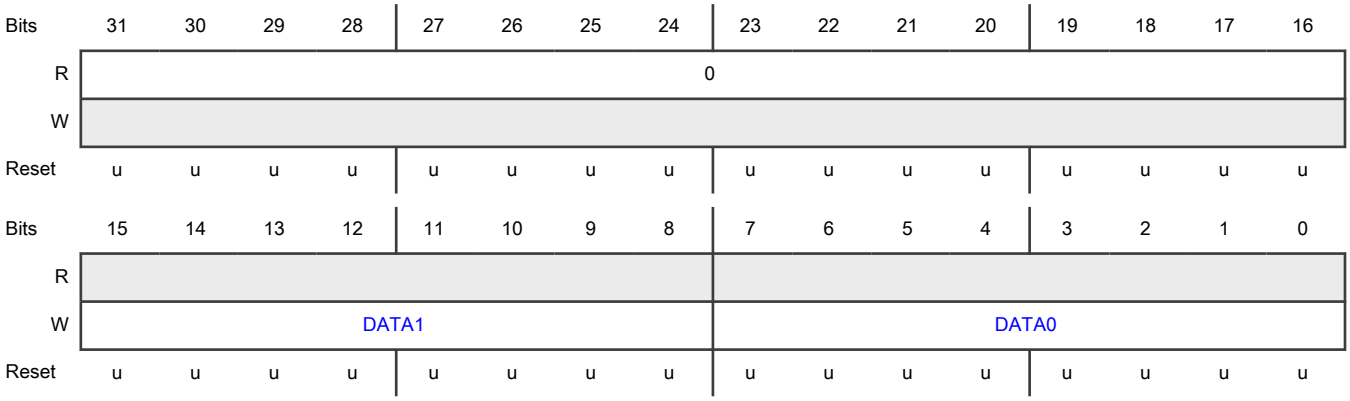
Function

Allows writing a halfword of data, which is the end (the last byte of the halfword is the end). The target writes the halfword (byte pair) in the same way it writes to Target Write Data Halfword (SWDATAH), but marks the second byte as end-of-data (last byte).

For HDR-DDR, the byte with the END must be even (second, fourth, sixth, and so on) because DDR uses byte pairs.

A halfword must not be written unless there is room for both, as indicated by the use of transmit FIFO level trigger or SDATACTRL[TXCOUNT].

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 DATA1	Data 1 Indicates the second byte to be sent to the controller.
7-0 DATA0	Data 0 Indicates the first byte to be sent to the controller.

69.7.16 Target Read Data Byte (SRDATAB)

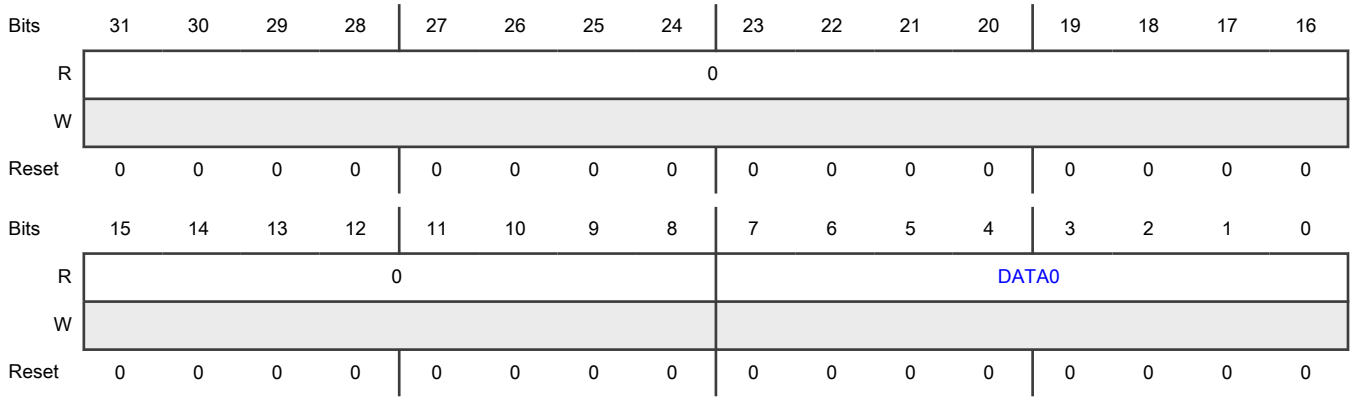
Offset

Register	Offset
SRDATAB	40h

Function

Allows reading a byte from the bus (controller). A byte must not be read unless there is data waiting, as indicated by SSTATUS[RX_PEND] = 1.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 DATA0	Data 0 Indicates the byte read from the controller.

69.7.17 Target Read Data Halfword (SRDATAH)

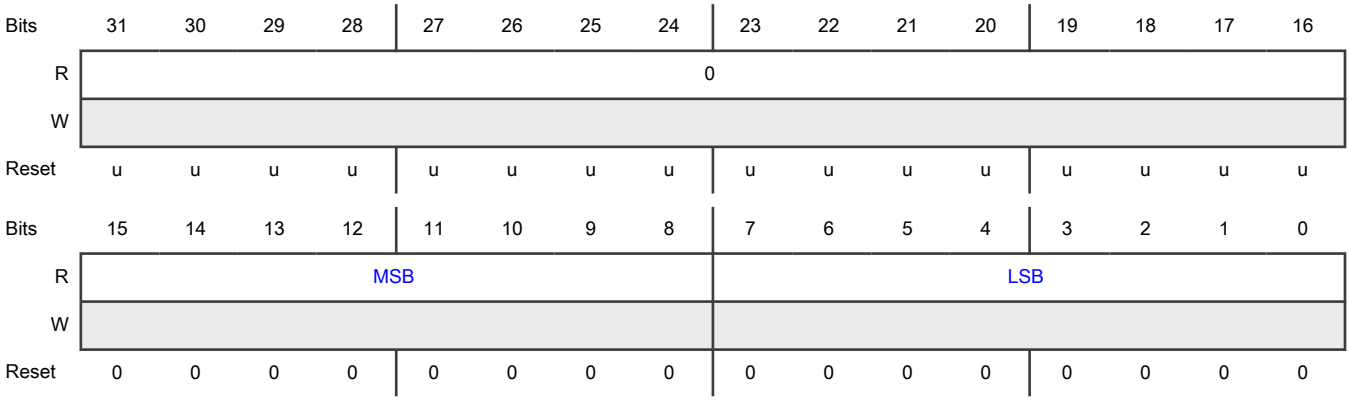
Offset

Register	Offset
SRDATAH	48h

Function

Allows reading a halfword (byte pair) written by the target after an SDR read or DAA or DDR. This register is used only when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively. A halfword must not be read unless there are at least two bytes of data waiting, as indicated by the use of receive FIFO level trigger or SDATACTRL[RXCOUNT].

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 MSB	High Byte Indicates the second byte read from the target.
7-0 LSB	Low Byte Indicates the first byte read from the target.

69.7.18 Target Write Data Byte (SWDATAB1)

Offset

Register	Offset
SWDATAB1	54h

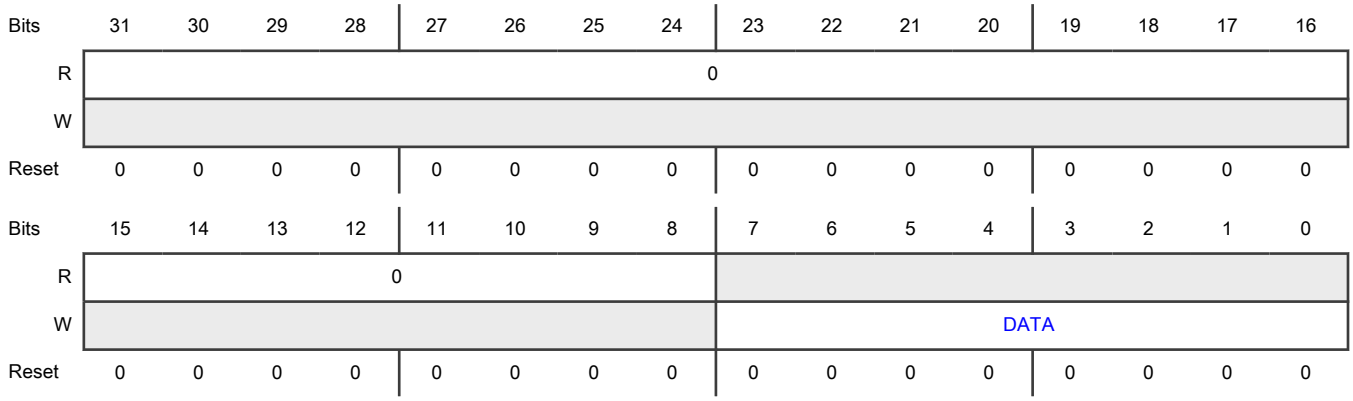
Function

Allows writing a single byte to the bus (to the controller) in a way that only bits 7:0 are used.

This register is intended to be used by DMAs (the upper bytes of the APB word are ignored).

A byte must not be written unless there is room, as indicated by SSTATUS[TXNOTFULL] = 1.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 DATA	Data Indicates the byte to be sent to the controller.

69.7.19 Target Write Data Halfword (SWDATAH1)

Offset

Register	Offset
SWDATAH1	54h

Function

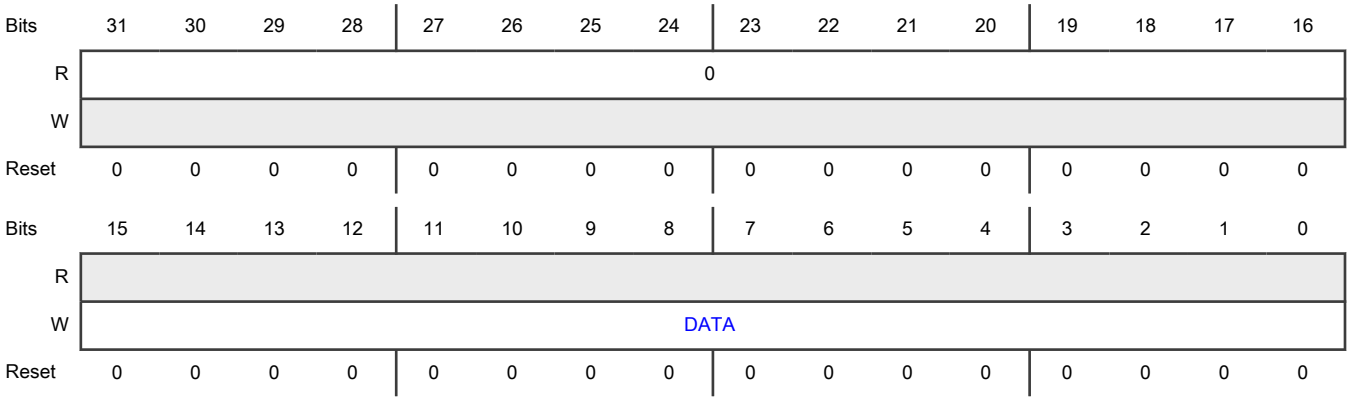
Shares the same address as Target Write Data Byte (SWDATAB1), and SDMACTRL[DMAWIDTH] determines which one is set.

This register allows writing a single-byte pair (halfword) to the bus (to the controller) in a way that only bits 15:0 are used.

This register is intended for use by DMAs, which do not format the upper part of the APB word.

A halfword must not be written unless there is room, as indicated by SSTATUS[TXNOTFULL] = 1.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 DATA	Data Indicates the byte pair (halfword) to be sent to the controller.

69.7.20 Target Capabilities 2 (SCAPABILITIES2)

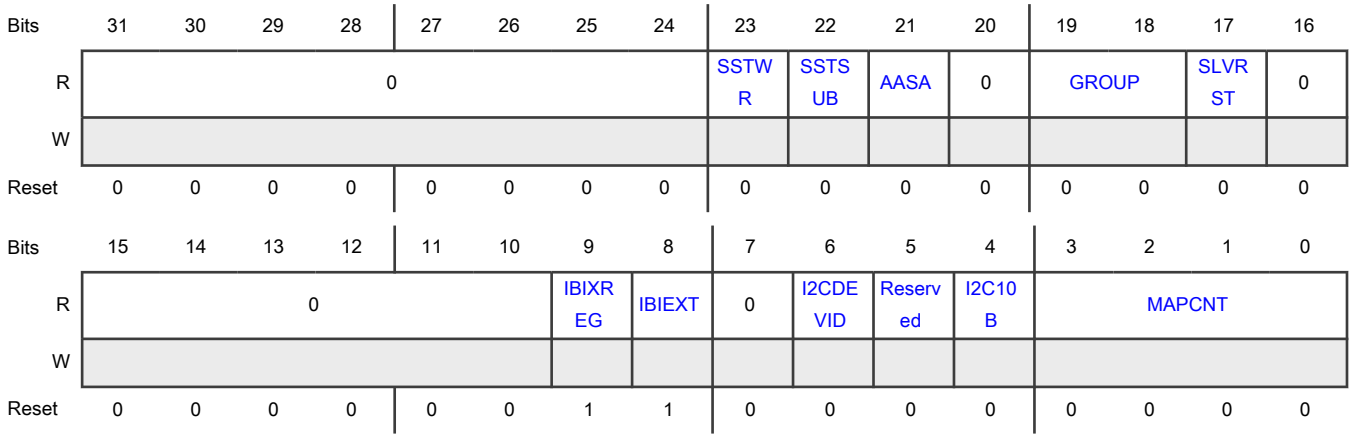
Offset

Register	Offset
SCAPABILITIES2	5Ch

Function

Indicates which features are available and supported in this module, including controller and target capabilities, HDR modes, and others.

Diagram



Fields

Field	Function
31-24 —	Reserved
23 SSTWR	Target-Target(s)-Tunnel Write Capable Indicates whether target-target(s)-tunnel is write capable. 0b - Not write capable 1b - Write capable
22 SSTSUB	Target-Target(s)-Tunnel Subscriber Capable Indicates whether target-target(s)-tunnel is subscriber capable. 0b - Not subscriber capable 1b - Subscriber capable
21 AASA	SETAASA Supports the set static address as dynamic address CCC (SETAASA) feature. 0b - SETAASA not supported 1b - SETAASA supported
20 —	Reserved
19-18 GROUP	Group Indicates whether v1.1 group addressing is supported. Groups use mapping, so MAPCNT must be the same or greater than GROUP. 00b - v1.1 group addressing not supported 01b - One group supported

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - Two groups supported 11b - Three groups supported
17 SLVRST	Target Reset Indicates whether v1.1 target reset is supported. 0b - Not supported 1b - Supported
16 —	Reserved
15-10 —	Reserved
9 IBIXREG	In-Band Interrupt Extended Register Supports extended registers for IBIs. This field indicates whether Extended IBI Data 1 (IBIEXT1) is available. Extended IBI Data 2 (IBIEXT2) is available if IBIEXT1[MAX] > 3. 0b - Not supported 1b - Supported
8 IBIEXT	In-Band Interrupt EXTDATA Supports SCTRL[EXTDATA] to allow data beyond the mandatory data byte (MDB) for IBIs. 0b - Not supported 1b - Supported
7 —	Reserved
6 I2CDEVID	I2C Device ID Indicates whether I2C device ID is supported. 0b - Not supported 1b - Supported
5 —	Reserved
4 I2C10B	I2C 10-bit Address Supports 10-bit I2C address in MAP 1. If this field is 1, MAPCNT must be 1 or greater.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not supported 1b - Supported
3-0 MAPCNT	Map Count Indicates the number of maps that are allowed. If there is no mapping, this field is 0. (DYNADDR is used to add more static and/or dynamic addresses to act as virtual targets.)

69.7.21 Target Capabilities (SCAPABILITIES)

Offset

Register	Offset
SCAPABILITIES	60h

Function

Indicates which features are available and supported in this module, including controller and/or target capabilities, HDR modes, and others.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31 DMA	Direct Memory Access Indicates whether DMA is supported. 0b - Not supported 1b - Supported

Table continues on the next page...

Table continued from the previous page...

Field	Function
30 INT	Interrupts Indicates whether interrupts are supported. 0b - Not supported 1b - Supported
29-28 FIFORX	FIFO Receive Indicates the size of receive (from-bus) FIFO. **NOTE** Controller and target use the same receive FIFO, so size is the same for the controller receive FIFO as well. FIFO size of SDR and HDR-DDR is in bytes. 00b - Two or three 01b - Four 10b - Eight 11b - 16 or larger
27-26 FIFOTX	FIFO Transmit Indicates the size of transmit (to-bus) FIFO. **NOTE** Controller and target use the same transmit FIFO, so size is the same for the controller transmit FIFO as well. FIFO size of SDR and HDR-DDR is in bytes. 00b - Two 01b - Four 10b - Eight 11b - 16 or larger
25-23 EXTFIFO	External FIFO Indicates whether external FIFOs are enabled. If they are not enabled, then check FIFOTX and FIFORX for the internal FIFO. 000b - No external FIFO available 001b - Standard available or free external FIFO 010b - Request track external FIFO All other values are reserved.
22 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
21 TIMECTRL	Time Control Specifies whether any time-control type is supported. 0b - No time control supported 1b - At least one time-control type supported
20-16 IBI_MR_HJ	In-Band Interrupts, Controller Requests, Hot-Join Events Indicates which events (IBI, CR, and HJ) are allowed. For example, if this field is 00011b, IBI (bit 0) and IBI_HAS_DATA (bit 1) functionality are both enabled. 0_0000b - Application cannot generate IBI, CR, or HJ 1_xxxxb - Application can use SCONFIG[BAMATCH] for bus-available timing x_1xxxb - Application can generate a Hot-Join event x_x1xxb - Application can generate a controller request for a secondary controller x_xx1xb - When bit 0 = 1, the IBI has data from the SCTRL register x_xxx1b - Application can generate an IBI
15-12 CCCHANDLE	Common Command Codes Handling Indicates what manages CCC between I3C and the application. 0000b - All handling features disabled 1xxxb - GETSTATUS CCC returns the value of SCTRL[VENDINFO] x1xxb - GETSTATUS CCC returns the values of SCTRL[PENDINT] and SCTRL[ACTSTATE] xx1xb - The I3C module manages maximum read and write lengths, and max data speed xxx1b - The I3C module manages events, activities, status, HDR, and if enabled for it, ID and static-address-related items
11-10 SADDR	Static Address Indicates how the static address is managed. 00b - No static address 01b - Static address is fixed in hardware 10b - Hardware controls the static address dynamically (for example, from the pin strap) 11b - SCONFIG register supplies the static address
9 MASTER	Controller Specifies whether controller capability is supported. 0b - Not supported 1b - Supported
8	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
7-6 HDRSUPP	High Data Rate Support Indicates which HDR modes are supported. 00b - No HDR modes supported 01b - DDR mode supported All other values are reserved.
5-2 IDREG	ID Register Indicates which ID features are available in the configurable registers. 0000b - All ID register features disabled 1xxxb - A Bus Characteristics Register (BCR) is available x1xxb - A Device Characteristic Register (DCR) is available xx1xb - An ID Random field is available xxx1b - ID Instance is a register; used if there is no PARTNO register
1-0 IDENA	ID 48b Handler Indicates what handles the 48-bit ID value. 00b - Application 01b - Hardware 10b - Hardware, but the I3C module instance handles ID 48b 11b - A part number register (PARTNO)

69.7.22 Target Dynamic Address (SDYNADDR)

Offset

Register	Offset
SDYNADDR	64h

Function

Fills with the assigned address after the controller has assigned it via SETDASA or ENTDAA CCC commands. It clears if the RESETDAA CCC is used. The current validity state is also indicated through SSTATUS[DAVALID], which can be used to interrupt the processor. The DCAUSE field can be used to determine the changes, if enabled.

NOTE

If mapped addresses are enabled, you can access them through the SMAPCTRL*n* registers.

The first dynamic address (DA[0]) may be written irrespective of whether the mapping is enabled, if configured to allow writes used to restore the DA after a power-down (an ultra-low power state that loses power to peripherals but retains the DA somewhere else). This is not required if state-retention flops are used for the DA. This mechanism only allows writes when target is disabled

(and is ignored otherwise). If the controller uses RSTDAA or SETNEWDA, then it overrides this mechanism and yields to the controller-assigned DA. When enabling the target, SCONFIG[OFFLINE] must be 1. This waits for evidence that the bus is not in I3C HDR mode and exits when an HDR exit pattern is seen or when 60 µs has expired. This makes it safe to monitor START and STOP. If the application needs to do an IBI, then the application must either wait for a STOP (see STATUS) or make sure that 200 µs have gone by with no activity (no START or STOP) before the application emits the IBI.

The MAPIDX or MAPSA model allows writing additional DAs (and SAs) into a list (the number in the list is preconfigured); any DA or SA with DAVALID = 0 are never matched. The additional DAs may be based on the bridge target CCC or done by a move (read current DA and then copy into the upper map, and then invalidate the 0 map) when matching ENTDAA over and over. Any mapped location can be invalidated by writing MAPIDX and DAVALID = 0. The mapped ones are not reset by the RSTDA CCC (see Target Message Map Address (SMSGMAPADDR)).

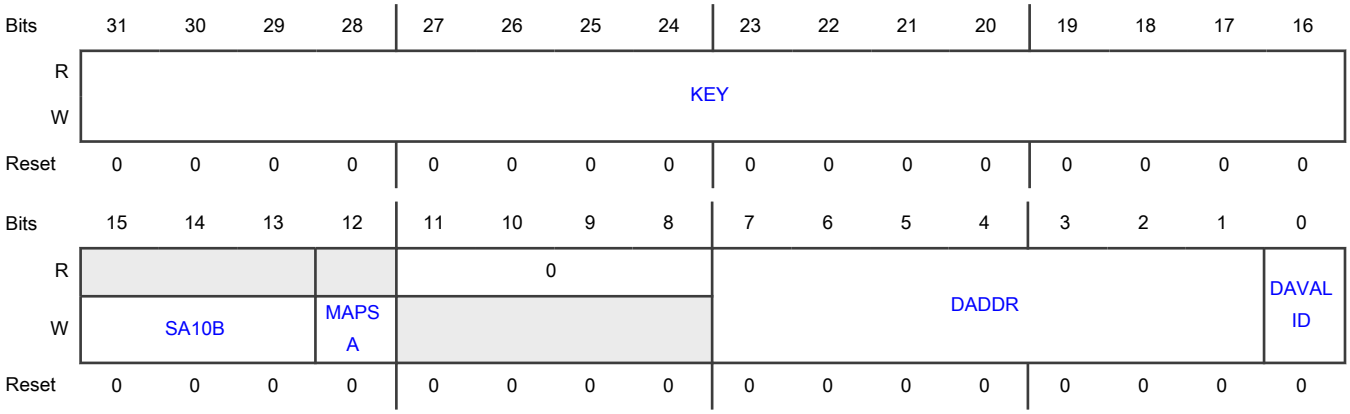
To copy the base DA to the mapped set, you must perform the configuration to allow it; otherwise it leads to distinct mechanisms:

- If used in I3C mode, a base DA is required, so the last one must not be cleared (or writing a dynamic address with DAVALID = 1 is necessary).

NACK/ACK of mapped DAs/SAs: The register also permits specific DAs (above the base) to NACK or ACK writes or reads, such as for bridges when the endpoint is busy. The NACK must not be set for too long, or the controller may consider the target in an error state. The model is to write with KEY = A731h and the MAPIDX and DAVALID to select ACK or NACK.

Mapping: If MAPIDX ≠ 0 and KEY = 0, then the next read returns details on the static or dynamic address at that location. If the read does not have MAPIDX ≠ 0, then it is not an acceptable location.

Diagram



Fields

Field	Function
31-16 KEY	Key Specifies the value of KEY. Must be set to A4D9h to write to the DADDR field (and 1 to the DAVALID field). Write only when a target is not enabled (for restoring after power-down sleep with auto-restore). The mapped locations and base may be written when a target is enabled, but do not write when there are transactions on the I3C bus. KEY reads back 1 if overwritten, else KEY is 0 if assigned by the controller including when the controller changes it. If address mapping is allowed, then writing with KEY = CB19h is used to clear the base DA.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If mapping is allowed, then writing with the key of A731h means that MAPIDX indicates which mapped address to set to ACK or NACK, such that DAVALID = 1 if ACK, DAVALID = 0 if NACK. This allows having the address refuse write and read requests when NACK. When using read back from map index (write with MAPIDX ≠ 0, KEY = 0, read) bit [16] = 1 if NACK, else 0.
15-13 SA10B	10-Bit Static Address Stores a 10-bit static address composed of {SA10B,DADDR}, if not 0 when MAPSA is set. Only one static address may be stored this way, and it must be MAPIDX == 1.
12 MAPSA	Map a Static Address Sets a static address into the list if MAPSA = 1 on a write with MAPIDX ≠ 0; otherwise, a dynamic address is used.
11-8 —	Reserved
7-1 DADDR	Dynamic Address Specifies the dynamic address (DA). This is the assigned dynamic address when DAVALID is 1 and is a static address if the MAPSA field is 1.
0 DAVALID	Dynamic Address Valid Determines whether a dynamic address is assigned. This field is 1 for ACK and 0 for NACK when using the A731h KEY. 0b - DANOTASSIGNED: a dynamic address is not assigned 1b - DAASSIGNED: a dynamic address is assigned

69.7.23 Target Maximum Limits (SMAXLIMITS)

Offset

Register	Offset
SMAXLIMITS	68h

Function

Indicates the limits set by the controller (or the originally requested limits). The maximum limits are not enabled in the hardware design, including maximum read and write lengths. If the maximum read and write lengths are enabled, then the current setting (including the default request) shows up in this register (SMAXLIMITS).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-28 —	Reserved
27-16 MAXWR	Maximum Write Length Indicates the maximum write length, which must be between 8 to 4095 (saturation). The application must not set the maximum write length to a higher value than the maximum write length set by the controller.
15-12 —	Reserved
11-0 MAXRD	Maximum Read Length Indicates the maximum read length, which must be between 16 to 4095 (saturation). The application must not set the maximum read length to a higher value than the maximum read length set by the controller.

69.7.24 Target ID Part Number (SIDPARTNO)

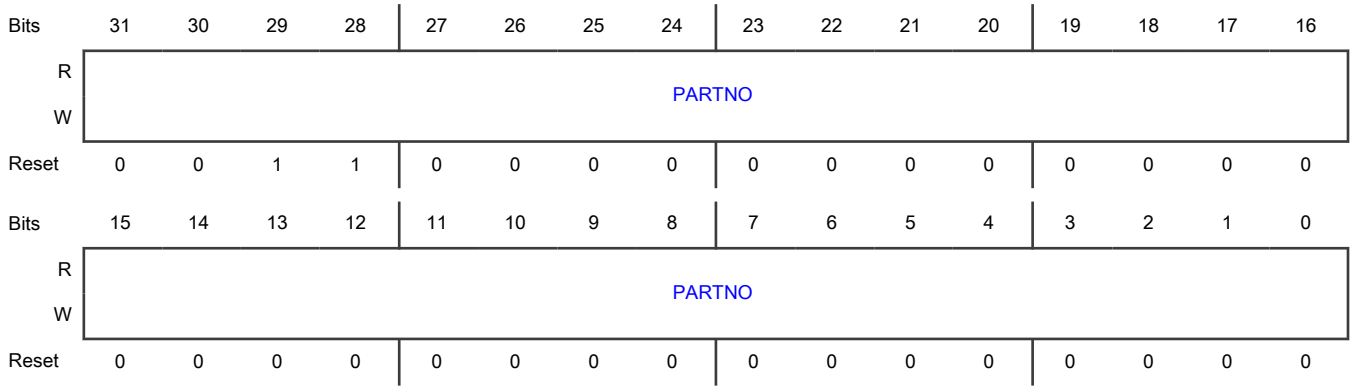
Offset

Register	Offset
SIDPARTNO	6Ch

Function

Allows you to write the ID part number. You must write a nonzero value into the PARTNO field because 0 is not valid.

Diagram



Fields

Field	Function
31-0 PARTNO	Part Number

69.7.25 Target ID Extension (SIDEXT)

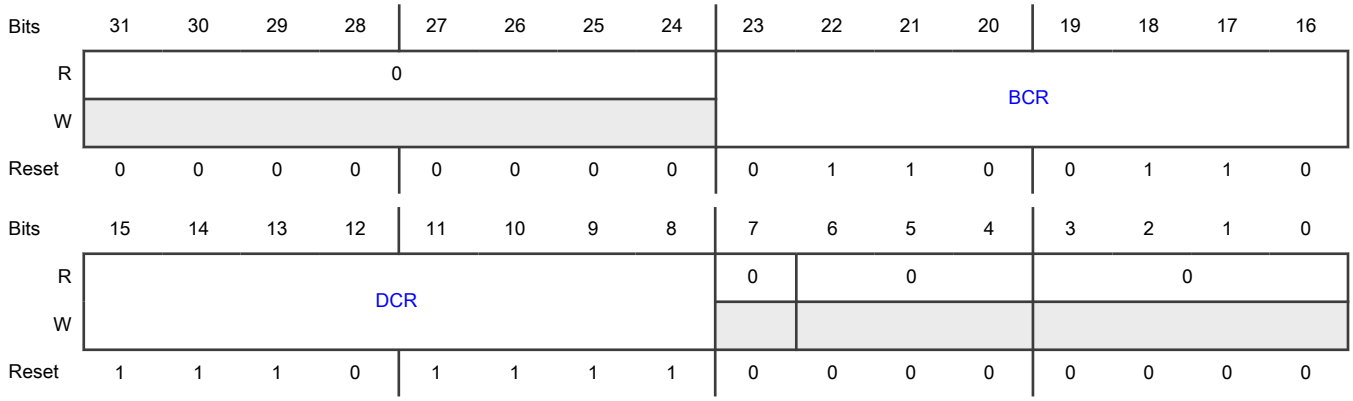
Offset

Register	Offset
SIDEXT	70h

Function

Allows you to write the ID extension of DCR and/or BCR.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 BCR	Bus Characteristics Register Sets the value for BCR, if this field is configured. Otherwise, the default value is considered. This field controls features such as secondary controller and slow-speed requirements.
15-8 DCR	Device Characteristic Register Sets the value for DCR, if this field is configured. Otherwise, the default value is considered.
7 —	Reserved
6-4 —	Reserved
3-0 —	Reserved

69.7.26 Target Vendor ID (SVENDORID)

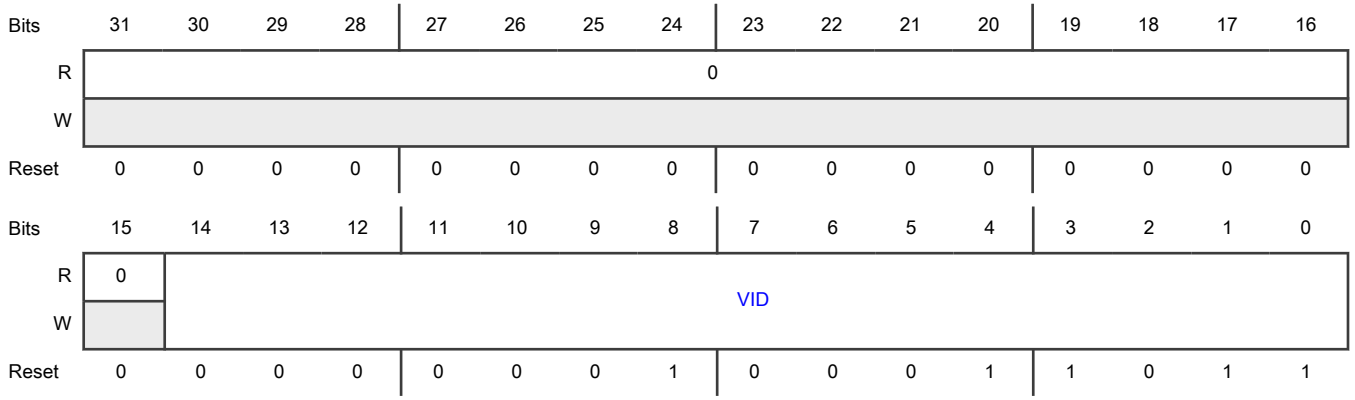
Offset

Register	Offset
SVENDORID	74h

Function

Allows you to write the vendor ID. The default value is the chip vendor ID, and is set from the constant field. When using the chip vendor ID, the part number (PARTNO) does not collide with other uses. The MIPI vendor ID is available to all companies (MIPI membership is not required). To get a vendor ID, make a request at the mipi.org website.

Diagram



Fields

Field	Function
31-15 —	Reserved
14-0 VID	Vendor ID Configures the 15-bit MIPI vendor ID. If not configured, the default value is considered.

69.7.27 Target Time Control Clock (STCCLOCK)

Offset

Register	Offset
STCCLOCK	78h

Function

Allows you to dynamically set the time control clock and accuracy information. The clock frequency and accuracy are constants set by the hardware. If the clock can be adjusted (that is, divided) or if the accuracy could vary with knowable information, then the clock may be set via this register, which must be updated whenever the clock source is changed.

Diagram

Fields

Field	Function
31-16 —	Reserved
15-8 FREQ	Clock Frequency Indicates the clock frequency in 0.5 MHz steps. For example, a value of 20 in this field indicates a frequency of 10 MHz. Default set by parameters if configured.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-0 ACCURACY	Clock Accuracy Indicates the clock accuracy in 1/10ths of %. For example, a value of 15 indicates an accuracy of 1.5%. Default set by parameters if configured.

69.7.28 Target Message Map Address (SMSGMAPADDR)

Offset

Register	Offset
SMSGMAPADDR	7Ch

Function

Allows you to determine which address is matched when STATUS[MATCHED] = 1. This register is used when the DYNADDR register builds a list of extra DAs or SAs to match. It holds the last three matches.

Diagram

11-8 —	Reserved
7-6 —	Reserved
5 —	Reserved
4 —	Reserved
3-0 —	Reserved

69.7.30 Controller Control (MCTRL)

Offset

Register	Offset
MCTRL	84h

Function

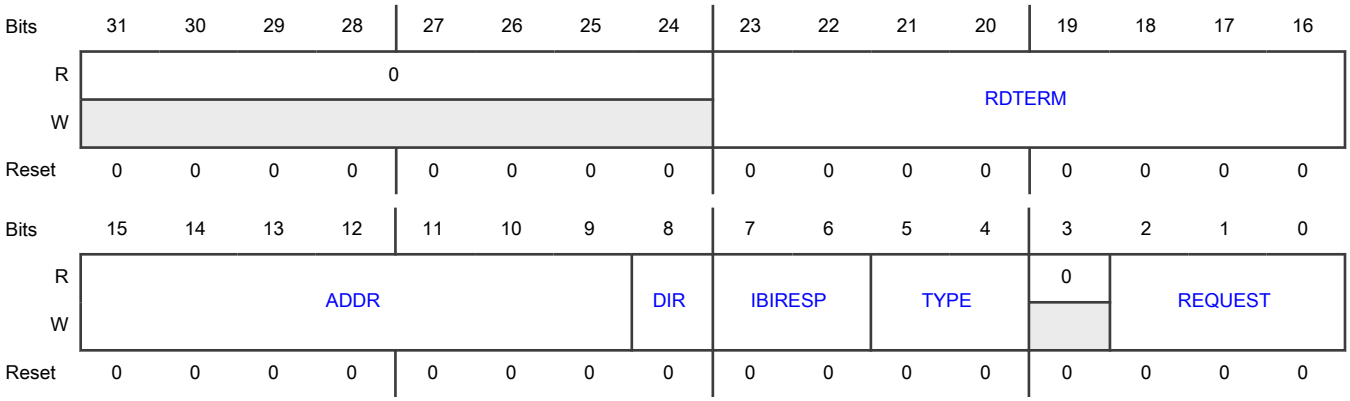
Starts activities on the I3C or I2C bus (see the MWMSG registers). A request cannot be changed when a message is in progress; the REQUEST field becomes 0 automatically.

You must write to MCTRL fields as per use case or as mentioned in Operating modes. Bit read and write checking may not work independently.

NOTE

If MCONFIG[MSTENA] is configured for I2C Controller mode (legacy I2C), only REQUEST = 1 and REQUEST = 2 are accepted. Also, fields are constrained to I2C-supported fields.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 RDTERM	Read Terminate Counter Determines when to terminate a read operation: • For I2C, this field controls when to NACK a read. • For I3C, this field can be used to terminate (end) a read: — If RDTERM is 0, it has no effect. — If RDTERM is 1, the read terminates after the next character.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	— If RDTERM is 2, the read terminates after the next two characters. The field supports up to 255 characters. In DDR mode, RDTERM terminates the read based on word counts (for DDR) instead of byte counts (for SDR). The field self-clears when MSTATUS[COMPLETE] becomes 1. **NOTE** You may write 1 to this field anytime, but a value greater than 1 must be written when starting EmitStartAddress.
15-9 ADDR	Address Indicates the type of address: I3C dynamic address or I2C static address. Some values are not allowed based on the bus that is used (I3C or I2C).
8 DIR	Direction Indicates the direction, write or read. 0b - Write 1b - Read
7-6 IBIRESP	In-Band Interrupt Response Indicates the response to use when you get an IBI from START, and when to force using an IBI ACK NACK request when completing a manual IBI. Completion of a manual IBI means that the target DA is known, and so the mandatory byte (or not) is specified by the application when acknowledging. This field is also used when a message is emitted in Message mode using the MWMSG_SDR or MWMSG_DDR registers. If an IBI with MDB (mandatory byte) is ACKed, the controller limits it to a maximum of eight more bytes after the MDB. RDTERM = 1 can be used with REQUEST = NONE to terminate data from a target sooner. If this field is 0b, it indicates ACK (acknowledge). When REQUEST = 1 (EmitStartAddr) or REQUEST = 7 (AutoIBI), Controller In-band Interrupt Registry and Rules (MIBIRULES) decides whether to ACK with mandatory byte. When REQUEST = 3 (IBIAckNack), ACK with no mandatory byte. If this field is 1b, it indicates NACK (reject) or no acknowledgement. If this field is 10b, it indicates acknowledge with mandatory byte. When REQUEST = 1 or REQUEST = 7, ignore Controller In-band Interrupt Registry and Rules (MIBIRULES). Do not use this setting unless only targets with a mandatory byte can cause an IBI. When REQUEST = 3, ACK with mandatory byte. If this field is 11b, it indicates manual. When REQUEST = 1 or REQUEST = 7, stop and wait for a decision using the IBI ACK NACK request. When REQUEST = 3, this field is reserved. **NOTE** A CR and HJ always cause IBIRESP to become 3 (manual) so the application must decide. 00b - ACK (acknowledge) 01b - NACK (reject) 10b - Acknowledge with mandatory byte

Table continues on the next page...

Table continued from the previous page...

Field	Function
	11b - Manual
5-4 TYPE	Bus Type with EmitStartAddr Works with REQUEST to determine the bus type. See Determining bus types and modes for more information. The following values are valid only if REQUEST is 1. 00b - I3C 01b - I2C 10b - DDR 11b - Reserved
3 —	Reserved
2-0 REQUEST	Request Emits the requested operation when performing in pieces, instead of performing by message. You must check Controller Status (MSTATUS) because some requests can only be made in some states. For example, the system cannot enter SDR mode from DDR mode, and it cannot use an incorrect request in DAA mode. If this field is 0b, it indicates that no request is present (NONE). The REQUEST field returns to NONE after finishing a request. Controller Status (MSTATUS) indicates the state of the controller. See AutoIBI mode. NONE is written as 0 only in these cases: when writing 1 to MCTRL[RDTERM] (to stop a read in progress) or when configuring MCTRL[IBIRESP] for MSG use. If this field is 1b, it emits START with address and direction (EMITSTARTADDR), either from Stopped state or in the middle of a single data rate (SDR) message. If from Stopped state (Idle), then EmitStart may be prevented by an event (such as IBI, CR, HJ). In this case, an appropriate interrupt is signaled. EmitStart can be resubmitted. If this field is 10b, it emits a STOP on bus (EMITSTOP). Must be in SDR mode. In DAA mode, emitting STOP exits DAA mode. If this field is 11b, it indicates manual IBI ACK or NACK (IBIACKNACK). When MCTRL[IBIRESP] indicates a hold on an IBI to allow a manual decision, this request completes it. The field uses MCTRL[IBIRESP] to provide the information. If this field is 100b, and if currently not in DAA mode, it emits START, 7E, ENTDAA sequence, and then emits 7E/R to process the first target (PROCESSDAA). Stops just before the new dynamic address (DA) is to be emitted. The DA is written using Controller Write Data Byte (MWDATAB), then process DAA is requested again to write the new address, and then it starts the next unless marked to STOP. An MSTATUS indicating NACK means DA was not accepted (for example, parity error). If PROCESSDAA is NACKed on the 7E/R request, meaning no more targets need a DA, then a COMPLETE is signaled (along with DONE) and a STOP issued. If TYPE = 2 or 3, the DA is assigned and then it emits a STOP (instead of starting a new 7E/R request). If TYPE = 1 or 3, then the DA is taken from the ADDR field (bits 6:0). If this field is 110b, it emits an exit pattern from any state (force exit and target reset). End DDR mode (including MSGDDR), including a STOP afterward. If MCTRL[TYPE] is 2, perform a target reset action

Table continues on the next page...

Table continued from the previous page...

Field	Function
	(RSTACT can prevent the reset in the target). Target reset may follow immediately after RSTACT CCC or STOP. If this field is 111b, the target is held in a Stopped state, but autoemits a START, 7E sequence when the target holds SDA low for an IBI (AUTOIBI). Actual IBI handling is defined by MCTRL[IBIRESP]. 000b - NONE 001b - EMITSTARTADDR 010b - EMITSTOP 011b - IBIACKNACK 100b - PROCESSDAA 101b - Reserved 110b - Force Exit and Target Reset 111b - AUTOIBI

69.7.31 Controller Status (MSTATUS)

Offset

Register	Offset
MSTATUS	88h

Function

Indicates the controller status, including which events cause interrupts. The peripherals share the IRQ (called parallel-to-target status).

Because a peripheral can either be in Controller or Target mode, but not both at the same time, only one (target or controller peripheral) can cause the IRQ. If there is an IRQ and the peripheral is a controller, then this register (MSTATUS) indicates the status.

If there is an IRQ and the peripheral is a target, then Target Status (SSTATUS) indicates the status.

This register self-clears if the COMPLETE field becomes 1.

If the MCONFIG register is configured only for I2C, some states and fields never remain active (for example, DAA or IBI).

Diagram

Fields

Field	Function
31 —	Reserved
30-24 IBIADDR	IBI Address Indicates the address of: • The IBI when MSTATUS[IBITYPE] = 1. • The CR, when MSTATUS[IBITYPE] = 2. • 7'h2 when HJ, when MSTATUS[IBITYPE] = 3.
23-20 —	Reserved
19 NOWMASTER	Module is now Controller Flag Indicates whether the module is now a controller. That is, it was previously a target, and controllership acceptance was requested from the previous controller and controllership was accepted. The reverse operation (controller becomes a target) does not need an interrupt because the application grants it through the GETACCMST CCC. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not a controller 1b - Controller When writing 0b - No effect 1b - Clear the flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
18-16 —	Reserved
15 ERRWARN	Error or Warning Indicates whether an error occurred, such as improper register use, overrun, or underrun of FIFO or buffer, or invalid parity or CRC in a DDR read. See Controller Errors and Warnings (MERRWARN) for more information. 0b - No error or warning 1b - Error or warning
14 —	Reserved
13 IBIWON	In-Band Interrupt (IBI) Won Flag Indicates whether an IBI, CR, or HJ has won the arbitration on a header address, regardless of whether it was NACKed or ACKed. Arbitration requires manual intervention for CR and HJ, and optionally requires it for IBI if MCTRL[IBIRESP] = 3 (manual). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No IBI arbitration won 1b - IBI arbitration won When writing 0b - No effect 1b - Clear the flag
12 TXNOTFULL	TX Buffer or FIFO Not Full Indicates whether the buffer, FIFOm, or message register can accept another byte or halfword. FIFO uses trigger level. If DMA is enabled for transmitting, it transfers data as long as it is not full. 0b - Receive buffer or FIFO full 1b - Receive buffer or FIFO not full
11 RXPEND	RXPEND Indicates whether a message is being received from a target and bytes are in the input buffer or FIFO: • When using a FIFO, this message is at least one FIFO trigger's worth (a minimum of one byte in the FIFO). • When DMA is enabled for receiving, the DMA is signaled. RXPEND becomes 0 when the data is read.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No receive message pending 1b - Receive message pending
10 COMPLETE	Complete Flag Indicates whether a message is complete: • With MWMSG_SDR or MWMSG_DDR, the COMPLETE condition occurs when MWMSG_SDR_CONTROL[LEN] or MWMSG_DDR_CONTROL[LEN] reaches 0. • When MCTRL[REQUEST] = 1 (EmitStartAddr), this COMPLETE condition occurs after the end of a write operation, or after a read operation has terminated or ended. • With an IBI (AutoIBI or EmitStartAddr), the COMPLETE condition occurs at the end of IBI data (if any). **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not complete 1b - Complete When writing 0b - No effect 1b - Clear the flag
9 MCTRLDONE	Controller Control Done Flag Indicates whether the module has completed an MCTRL request. MCTRLDONE automatically becomes 0 when writing a new control. If MCTRL[REQUEST] = 1 (EmitStartAddr), MCTRLDONE becomes 1 when the address goes out (and is ACKed, NACKed, or ended in an IBI). If ACKed, MSTATUS[COMPLETE] becomes 1 after the write or read data is complete. If MCTRL[REQUEST] = 4 (ProcessDAA), MCTRLDONE becomes 1 when the module is ready to emit the dynamic address (DA) for the target, or when no more targets are ACKing. This condition can be determined by using the MSTATUS[BETWEEN] and MSTATUS[STATE] fields. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not done 1b - Done When writing 0b - No effect 1b - Clear the flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
8 SLVSTART	Target Start Flag Indicates whether a target is or was requesting a START by holding SDA low. Handling starts automatically when MCTRL[REQUEST] = 7 (AutoIBI). **NOTE** This field behaves differently for register reads and writes. When reading 0b - Target not requesting START 1b - Target requesting START When writing 0b - No effect 1b - Clear the flag
7-6 IBITYPE	In-Band Interrupt (IBI) Type Indicates the type of IBI of the last event that won the arbitration, whether the interrupt was ACKed, NACKed, or pending. 00b - NONE (no IBI: this status occurs when MSTATUS[IBIWON] becomes 0) 01b - IBI 10b - CR 11b - HJ
5 NACKED	Not Acknowledged Indicates whether the last start and address sequence was NACKed (was not ACKed by the addressed target). 0b - Not NACKed 1b - NACKed (not acknowledged)
4 BETWEEN	Between Indicates whether the controller is active between messages or dynamic address assignments (DAA). It is active when: • MSTATUS[STATE] is MSGSDR, DDR, or DAA, or NORMACT, and the state is between messages or DAAs. It is expecting a new message or DAA to start (or STOP or exit). • MSTATUS[STATE] is NORMACT. The module is waiting for the transmit FIFO to be not empty or the receive FIFO to be not full. 0b - Inactive (for other cases) 1b - Active
3 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
2-0 STATE	State of the Controller Indicates the current controller state. If this field is 0b, it indicates that the controller is idle (the bus has stopped.) If this field is 1b, it indicates target request. The bus has stopped but a target is holding SDA low. When using auto-emit IBI (MCTRL[REQUEST] = 7), the controller does not remain in this state. If this field is 10b, it indicates entry into Single Data Rate Message mode, using MWMSG_SDR. If this field is 11b, it indicates entry into normal active SDR mode, using MCTRL, MWDATA*n*, and MRDATA*n* registers. The controller remains in this state until a STOP is issued. If this field is 100b, it indicates entry into Double Data Rate Message mode, using MWMSG_DDR or the normal method with DDR. The controller remains in the DDR state until the controller exits using EXIT (emitting the Exit pattern). If this field is 101b, it indicates entry into Dynamic Address Assignment (ENTDAA) mode. If this field is 110b, it indicates wait for an IBI ACK/NACK decision. If this field is 111b, it indicates receiving an IBI. This state is used after IBI, CR, or HJ has won an arbitration. The IBIRCV state is also used for IBI mandatory byte (if any) and any bytes that follow. 000b - IDLE (bus has stopped) 001b - SLVREQ (target request) 010b - MSGSDR 011b - NORMACT 100b - MSGDDR 101b - DAA 110b - IBIACK 111b - IBIRCV

69.7.32 Controller In-band Interrupt Registry and Rules (MIBIRULES)

Offset

Register	Offset
MIBIRULES	8Ch

Function

Contains the rules for using IBI, and keeps a registry of the targets that use the IBI byte.

This register defines the IBI mandatory byte rules for the targets and determines which targets do (or do not) have a mandatory byte.

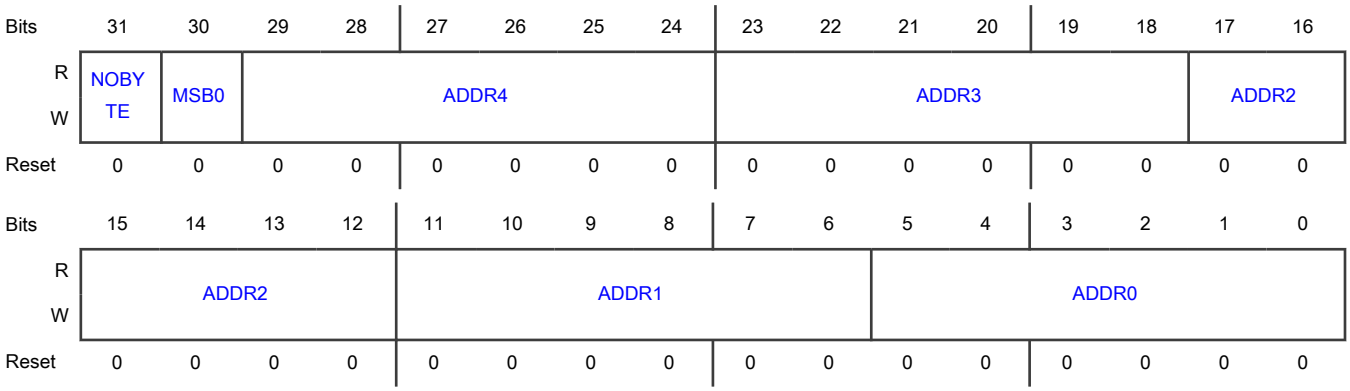
Concerning ADDR*n* fields: The address has 6 bits. Assuming that MIBIRULES[MSB0] = 1, the most significant bit of each address is 0. In this case, each address is 7 bits (usually written as A7 to A1) and A7 must be 0. If the application does not use that optimal convention, the "manual" method of IBI ACK handling must be used (see MCTRL[IBIRESP] for more information).

By default, the ADDR*n* values indicate the targets with a mandatory byte. If MIBIRULES[NOBYTE] = 1, the ADDR*n* values indicate targets that do not have a mandatory IBI byte.

NOTE

A7 = 0 is only needed for targets that use IBI. For legacy I2C devices, A7 can use any valid value because I2C devices cannot cause an IBI.

Diagram



Fields

Field	Function
31 NOBYTE	No IBI byte Specifies whether the ADDR*n* fields refer to targets with or without a mandatory IBI byte. 0b - With mandatory IBI byte 1b - Without mandatory IBI byte
30 MSB0	Most Significant Address Bit is 0 Specifies whether MSB is 0 for all I3C dynamic addresses. Assigning 1 to this field allows the START header to be optimized. 0b - MSB is not 0 1b - MSB is 0
29-24 ADDR4	ADDR4 Specifies the address of the target with or without mandatory IBI byte. If 0, then the address does not apply.
23-18 ADDR3	ADDR3 Specifies the address of the target with or without mandatory IBI byte. If 0, then the address does not apply.
17-12 ADDR2	ADDR2 Specifies the address of the target with or without mandatory IBI byte. If 0, then the address does not apply.

Table continues on the next page...

Table continued from the previous page...

Field	Function
11-6 ADDR1	ADDR1 Specifies the address of the target with or without mandatory IBI byte. If 0, then the address does not apply.
5-0 ADDR0	ADDR0 Specifies the address of the target with or without mandatory IBI byte. If 0, then the address does not apply.

69.7.33 Controller Interrupt Set (MINTSET)

Offset

Register	Offset
MINTSET	90h

Function

Returns the status of the interrupt enables when read. This register sets interrupt enables for select fields in Controller Status (MSTATUS):

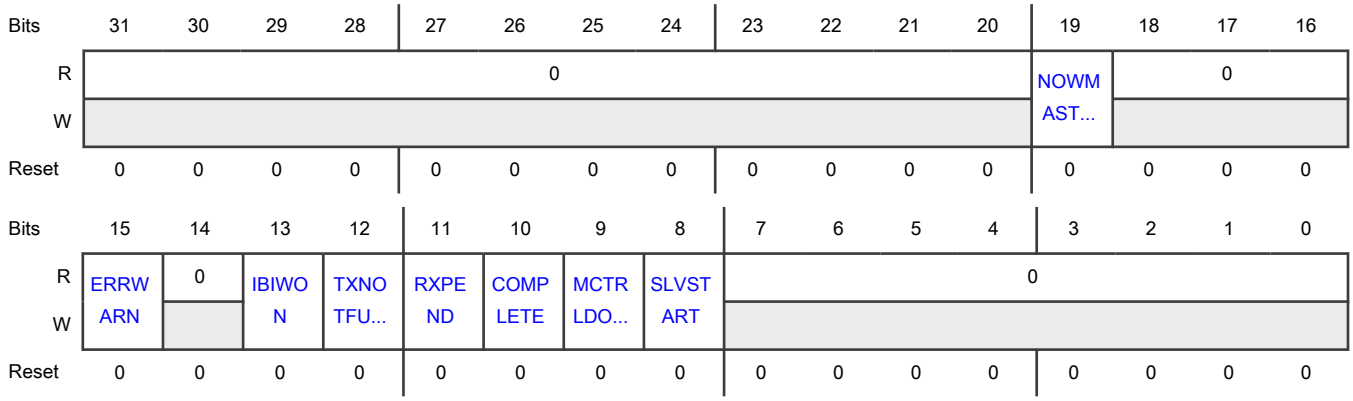
- To activate an interrupt enable, write 1 to its corresponding field.
- To disable an interrupt enable, write 1 to the appropriate field in Controller Interrupt Clear (MINTCLR). Writing 0 to the interrupt enable in MINTSET does not disable the interrupt.

The interrupt registers allow masking of interrupt sources as well as checking which interrupts are activated in Controller Status (MSTATUS). The normal method is to enable an interrupt and then after that interrupt fires, clear the interrupt either by writing to Controller Status (MSTATUS) or via an action on the corresponding data register. The interrupt is level-held, meaning that the interrupt remains 1 until the cause is cleared by some method. The module prevents races; if a new event comes in, that new event is not lost.

These interrupts are parallel to Target Interrupt Set (SINTSET) and Target Interrupt Clear (SINTCLR), and only one interrupt set is active depending on the state (controller or target operation):

- MINTSET: Sets interrupt enables for MSTATUS fields. Reading the MINTSET register returns the status of the interrupt enables.
- MINTCLR: Clears interrupt enables for MSTATUS fields.
- MINTMASKED: Returns the value of the MSTATUS fields ANDed with their interrupt enables.

Diagram



Fields

Field	Function
31-20 —	Reserved
19 NOWMASTER	Now Controller Interrupt Enable Enables the corresponding interrupt to indicate whether the module is now a controller (now this I3C module is a controller). That is, it was previously a target; controllership acceptance was requested from the previous controller and it was accepted. 0b - Disable 1b - Enable
18-16 —	Reserved
15 ERRWARN	Error or Warning (ERRWARN) Interrupt Enable Enables the corresponding interrupt to indicate whether an error occurred, such as improper register use, overrun or underrun of FIFO or buffer, or invalid parity or CRC in a DDR read. 0b - Disable 1b - Enable
14 —	Reserved
13 IBIWON	IBI Won Interrupt Enable Enables the corresponding interrupt to indicate whether an IBI, CR, or HJ has won the arbitration on a header address, regardless of whether it was NACKed or ACKed. 0b - Disable 1b - Enable
12	Transmit Buffer/FIFO Not Full Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
TXNOTFULL	Enables the corresponding interrupt to indicate whether the buffer, FIFOm, or message register can accept another byte or halfword. 0b - Disable 1b - Enable
11 RXPEND	Receive Pending Interrupt Enable Enables the corresponding interrupt to indicate whether a message is being received from a target and bytes are in the input buffer or FIFO.
10 COMPLETE	Completed Message Interrupt Enable Enables the corresponding interrupt to indicate whether a message is complete. 0b - Disable 1b - Enable
9 MCTRLDONE	Controller Control Done Interrupt Enable Enables the corresponding interrupt to indicate whether the module has completed an MCTRL request. 0b - Disable 1b - Enable
8 SLVSTART	Target Start Interrupt Enable Enables the corresponding interrupt to indicate whether a target is or was requesting a START by holding SDA low. 0b - Disable 1b - Enable
7-0 —	Reserved

69.7.34 Controller Interrupt Clear (MINTCLR)

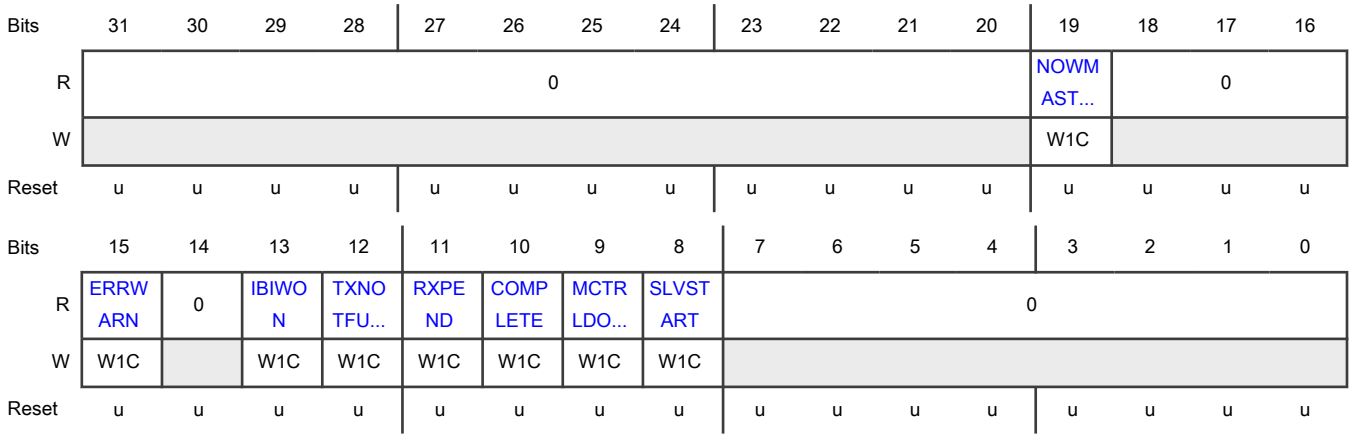
Offset

Register	Offset
MINTCLR	94h

Function

Clears interrupt enables for select fields in Controller Status (MSTATUS). Writing 1 clears the corresponding interrupt enable. Writing 0 has no effect.

Diagram



Fields

Field	Function
31-20 —	Reserved
19 NOWMASTER	NOWCONTROLLER Interrupt Enable Clear Flag Clears the corresponding NOWCONTROLLER interrupt enable. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No effect 1b - Interrupt enable cleared When writing 0b - No effect 1b - Clear the flag
18-16 —	Reserved
15 ERRWARN	ERRWARN Interrupt Enable Clear Flag Clears the corresponding ERRWARN interrupt enable. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No effect 1b - Interrupt enable cleared

69.7.36 Controller Errors and Warnings (MERRWARN)

Offset

Register	Offset
MERRWARN	9Ch

Function

Contains errors and warnings. When any errors or warnings are not 0, then MSTATUS[ERRWARN] is 1.

Parallel-to-target ERRWARN:

- In Controller mode, use this register (MERRWARN).
- In Target mode, use Target Errors and Warnings (SERRWARN).

The error fields in both registers (MERRWARN and SERRWARN) are similar in meaning.

Diagram

Fields

Field	Function
31-22 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
21 —	Reserved
20 TIMEOUT	Timeout Error Flag Indicates an error caused by the module stalling for too long in a frame. This stalling occurs when: • The transmit FIFO or receive FIFO is not handled, and the bus is stuck in the middle of a message. • No STOP is issued after data transfer (there is a gap between messages). • IBI manual is used and no decision has been made. The maximum stall period is 10 kHz or 100 µs. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
19 INVREQ	Invalid Request Error Flag Indicates an error caused by an invalid use of a request: • Not using IBI ACK NACK when stopped in manual hold for IBI acknowledgment. • Using a request other than ForceStop or ForceExit when in a message. Other requests are valid when the message is done. • Other mismatched uses (for example, IBI ACK NACK in normal states). **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
18 MSGERR	Message Error Flag Indicates an error caused by:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• Trying to write to or read from the MWMSG_SDR register when in a DDR message. • Trying to write to or read from the MWMSG_DDR register when in an SDR message. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
17 OWRITE	Overwrite Error Flag Indicates an error caused by trying to write to Controller Write Data Byte (MWDATAB) when the FIFO is full. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
16 OREAD	Overread Error Flag Indicates an error caused by: • Trying to read from Controller Read Data Byte (MRDATAB) when the FIFO is empty. • Trying to read from the MRMSG_SDR register or the MRMSG_DDR register when no message has yet started. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No effect 1b - Clear the flag
15-13 —	Reserved
12 —	Reserved
11 —	Reserved
10 HCRC	High Data Rate CRC Error Flag Indicates that a cyclic redundancy check (CRC) error occurred from a DDR read. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
9 HPAR	High Data Rate Parity Flag Indicates a parity error from a DDR read, including a bad preamble on a read. This does not stop the read because it is not safe to terminate; the read data may become misframed. Ends on a run of 1 second. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
8-5 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 TERM	Terminate Error Flag Indicates an error when this controller terminates a target read because the read exceeded the count for the message. This error is valid only when using the MWMSG_SDR or MWMSG_DDR register. If you write to the MWMSG_SDR or MWMSG_DDR register, this field automatically becomes 0. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
3 WRABT	Write Abort Error Flag Indicates an error caused by the I2C target NACKing the write data, terminating the message. For example, the controller is writing in I2C and the target NACKed the write. If you write to the MCTRL register, this field automatically becomes 0. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
2 NACK	Not Acknowledge Error Flag Indicates an error caused by the target or targets NACKing (not acknowledging) the last address. If 7Eh is the address, then it indicates all targets NACKed the last address. If you write to the MCTRL register, this field automatically becomes 0. **NOTE** In HDR mode, this error occurs when an address is not accepted (as opposed to NACKed). **NOTE** This field behaves differently for register reads and writes. When reading

Table continues on the next page...

Field	Function
	0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
1 URUN	Underrun Error Flag Indicates an underrun for HDR-BT. This error occurs when attempting to write from an empty transmit FIFO. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No effect 1b - Clear the flag
0 —	Reserved

69.7.37 Controller DMA Control (MDMACTRL)

Offset

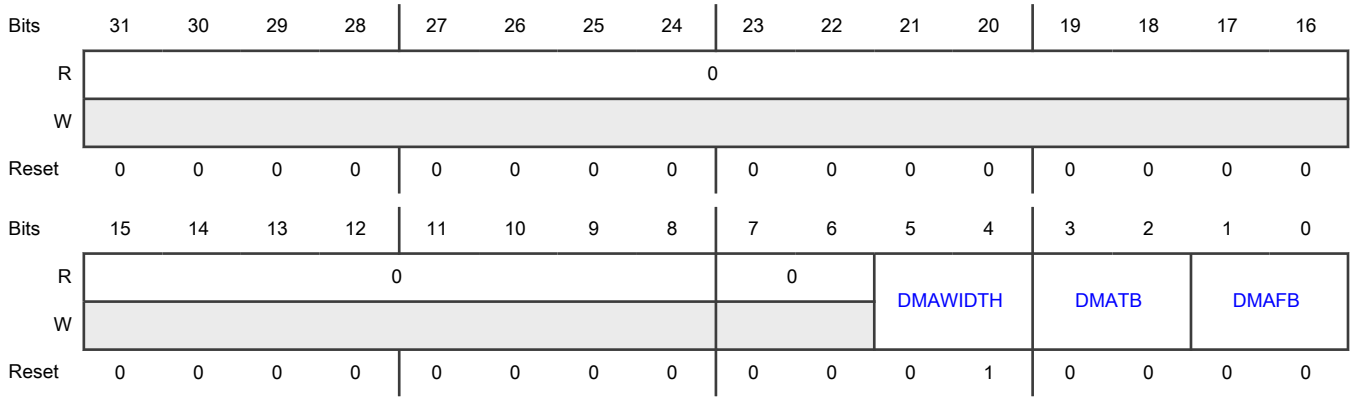
Register	Offset
MDMACTRL	A0h

Function

Allows DMA to be used for inbound and outbound messages. DMA is much more useful for a controller than for a target because the controller directs the bus traffic and actions. DMA can be used with a controller in these ways:

- Push or pull data for MCTRL[REQUEST] = 1 (EmitStartAddr) request written by the processor.
- Implementing message mode, completely controlled by DMA.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-6 —	Reserved
5-4 DMAWIDTH	DMA Width Specifies the data width of DMA operations. The halfword (16 bits) setting ensures that two bytes are free or available in FIFO. 00b,01b - Byte 10b - Halfword (16 bits) 11b - Reserved
3-2 DMATB	DMA to Bus Represents the DMA write (to-bus) trigger. When DMATB = 1 or DMATB = 2, I3C requests DMA when a transmit trigger occurs (see Controller Data Control (MDATACTRL)). I3C requests until full, unless the DMA is set up as a trigger. DMAFB becomes 0 when MSTATUS[ERRWARN] = 1. If this field is 1b, STOP or repeated START causes DMATB to become 0 (see SCONFIG[MATCHSS]). Normally, DMA enable must be used only in Controller Message mode. 00b - DMA not used 01b - Enable DMA for one frame (ended by DMA or terminated) 10b - Enable DMA until DMA is turned off. Recommended mode, instead of 01b, to enable DMA. This setting provides better software control. 11b - Reserved
1-0	DMA from Bus

Table continues on the next page...

Table continued from the previous page...

Field	Function
DMAFB	Represents the DMA read (from-bus) trigger. When DMAFB = 1 or DMAFB = 2, I3C requests DMA when a receive trigger occurs (see Controller Data Control (MDATACTRL)). I3C requests until empty unless the DMA is set up as a trigger. DMAFB becomes 0 when MSTATUS[ERRWARN] = 1. If this field is 1b, STOP or Repeated START causes DMAFB to automatically become 0 (see SCONFIG[MATCHSS]). **NOTE** Do not enable DMA after a transaction starts. It must be enabled only when enabling the controller and interrupts to avoid any kind of RX FIFO overrun. 00b - DMA not used 01b - Enable DMA for one frame 10b - Enable DMA until DMA is turned off. Recommended mode, instead of 01b, to enable DMA. This setting provides better software control. 11b - Reserved

69.7.38 Controller Data Control (MDATACTRL)

Offset

Register	Offset
MDATACTRL	ACh

Function

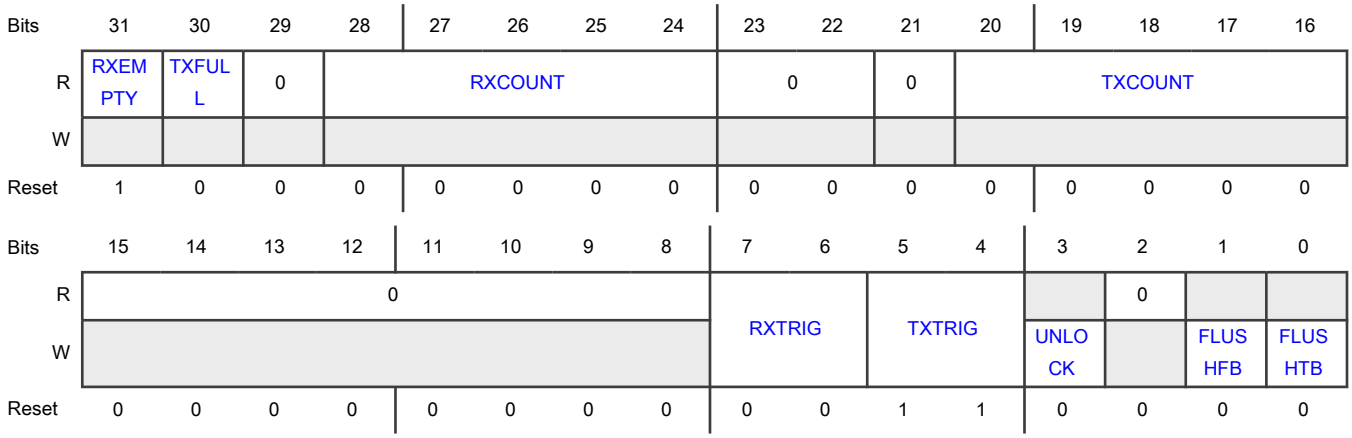
Assists in data control when there is no FIFO. This register also assists the FIFO when FIFO is available (regardless of size), and this assistance allows some control over the FIFO behavior. In particular, the register provides control over when to interrupt when a particular state of fullness or emptiness is reached. It also controls behavior related to width, when the width is not 1 byte wide.

This register acts as an alias of Target Data Control (SDATACTRL).

NOTE

When flushing a FIFO if DMA is in use, disable the DMA channel first. You must not use FIFO flush when a message (in that direction) is in flight.

Diagram



Fields

Field	Function
31 RXEMPTY	Receive is Empty Indicates whether the receive FIFO or buffer is empty. 0b - Not empty 1b - Empty
30 TXFULL	Transmit is Full Indicates whether the transmit FIFO or buffer is full. 0b - Not full 1b - Full
29 —	Reserved
28-24 RXCOUNT	Receive Entry Count Contains the count of entries in the receive FIFO or buffer. Entry size for SDR and HDR-DDR is in bytes.
23-22 —	Reserved
21 —	Reserved
20-16 TXCOUNT	Transmit Entry Count Contains the count of entries waiting in the TXFIFO. This count is the number of entries that the application has written to the transmit FIFO that have not yet gone onto the bus. Entry size for SDR and HDR-DDR is in bytes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-8 —	Reserved
7-6 RXTRIG	Receive Trigger Level Indicates the trigger level for receive fullness when using a FIFO. This field affects the RXPEND interrupt. 00b - Trigger when not empty (default) 01b - Trigger when 1/4 full or more 10b - Trigger when 1/2 full or more 11b - Trigger when 3/4 full or more
5-4 TXTRIG	Transmit Trigger Level Indicates the trigger level for transmit emptiness when using a FIFO. This field affects the TXNOTFULL interrupt. 00b - Trigger when empty 01b - Trigger when 1/4 full or less 10b - Trigger when 1/2 full or less 11b - Trigger when 1 less than full or less (default)
3 UNLOCK	Unlock Unlocks the functionality so that the RXTRIG and TXTRIG fields can be changed on a write. This field must be 1 (unlocked) in the same cycle when writing to TXTRIG or RXTRIG. If this field is 0 (locked), RXTRIG and TXTRIG fields cannot be changed on a write. 0b - Locked 1b - Unlocked
2 —	Reserved
1 FLUSHFB	Flush From-Bus Buffer or FIFO Flushes from-bus buffer or FIFO. You normally do not use this field. **NOTE** Before using FLUSHFB, disable the DMA (MDMACTRL[DMAFB] = 0). Then use FLUSHFB to flush the FIFO and then re-enable the DMA. 0b - No action 1b - Flush the buffer
0	Flush To-Bus Buffer or FIFO

Table continues on the next page...

Table continued from the previous page...

Field	Function
FLUSHTB	Flushes to-bus buffer or FIFO. This field is used when the controller terminates a to-bus message (read) prematurely. **NOTE** Before using FLUSHTB, disable the DMA (MDMACTRL[DMATB] = 0). Then use FLUSHTB to flush the FIFO and then re-enable the DMA. 0b - No action 1b - Flush the buffer

69.7.39 Controller Write Data Byte (MWDATAB)

Offset

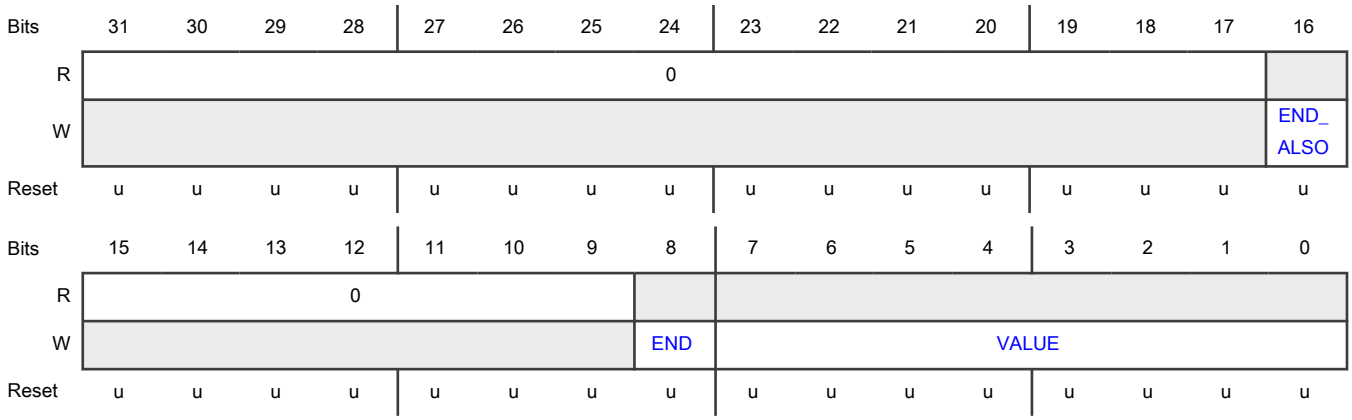
Register	Offset
MWDATAB	B0h

Function

Allows writing bytes to send onto the bus. This register is used only when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

This register acts as an alias of Target Write Data Byte (SWDATAB).

Diagram



Fields

Field	Function
31-17 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
16 END_ALSO	End of Message ALSO Indicates end of message, used to end an outbound message normally. Every message must indicate when it is the last message to be sent. This method can be used with the MDATABE register. This field is required for I3C and is optional for I2C. For HDR-DDR, the byte with END_ALSO must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs. If this field is 0, more bytes are assumed to be in the message. If this field is 1, the END bit marks the last byte of the message. 0b - Not the end 1b - End
15-9 —	Reserved
8 END	End of Message Indicates the end of a message. This field is required for I3C and is optional for I2C. For HDR-DDR, the byte with the END must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs. If this field is 0, more bytes are assumed to be in the message. If this field is 1, the END bit marks the last byte of the message. 0b - Not the end 1b - End
7-0 VALUE	Data Byte Represents the byte written to the target (stored in transmit FIFO): • I3C computes the parity. • I2C manages the ACK or NACK.

69.7.40 Controller Write Data Byte End (MWDATABE)

Offset

Register	Offset
MWDATABE	B4h

Function

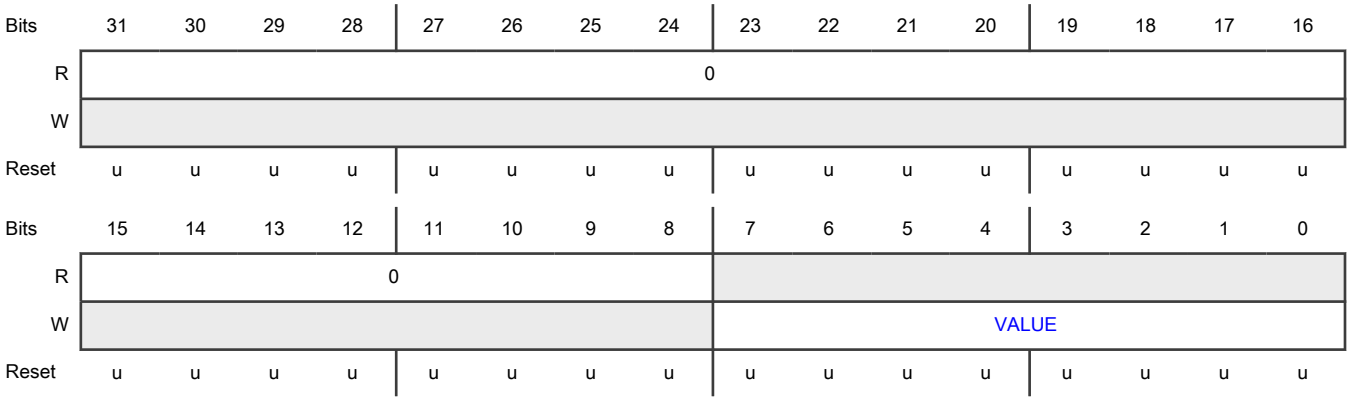
Allows writing the last byte to send onto the bus. This register is used only when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

This register acts as an alias of Target Write Data Byte End (SWDATABE).

NOTE

MWDATABE can also indicate END using bit 8.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 VALUE	Data Represents the last byte written to the target (stored in transmit FIFO): • I3C computes the parity. • I2C manages the ACK or NACK.

69.7.41 Controller Write Data Halfword (MWDATAH)

Offset

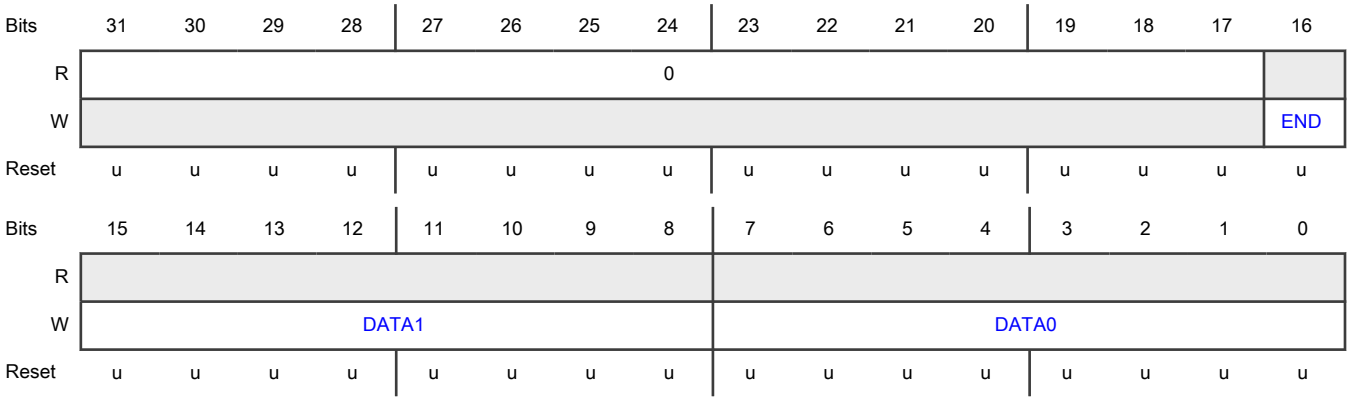
Register	Offset
MWDATAH	B8h

Function

Allows writing a halfword (pair of bytes) to the bus unless an external FIFO is used, sending the low byte followed by the high byte. An end-of-data (last) marker bit is allowed (or must be 0). A halfword must not be written unless there is room for both, as indicated by the use of transmit FIFO level trigger or MDATACTRL[TXCOUNT].

This register acts as an alias of Target Write Data Halfword (SWDATAH).

Diagram



Fields

Field	Function
31-17 —	Reserved
16 END	End of Message Indicates the end of a message. For this register, this field always marks DATA1 as the end. This field is required for I3C and is optional for I2C. For HDR-DDR, the byte with the END must be an even byte (second, fourth, sixth, and so on) because DDR uses byte pairs. If this field is 0, more bytes are assumed to be in the message. If this field is 1, the END bit marks the last byte of the message. 0b - Not the end 1b - End
15-8 DATA1	Data Byte 1 Represents the second byte that is sent to the target (written to transmit FIFO).
7-0 DATA0	Data Byte 0 Represents the first byte that is sent to the target (written to transmit FIFO).

69.7.42 Controller Write Data Halfword End (MWDATAHE)

Offset

Register	Offset
MWDATAHE	BCh

Function

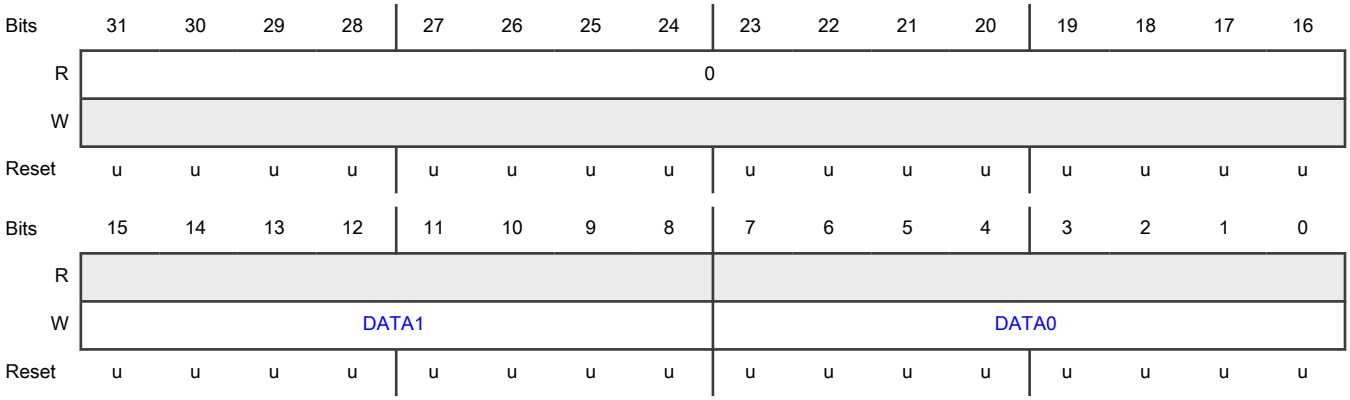
Allows writing a halfword of data, which is the end (the last byte of the halfword is the end). The target writes the halfword (byte pair) in the same way as it does to Controller Write Data Halfword (MWDATAH), but marks the second byte as end-of-data (last byte).

For HDR-DDR, the byte with the END must be even (second, fourth, sixth, and so on) because DDR uses byte pairs.

You must not write a halfword unless there is room for both, as indicated by the use of transmit FIFO level trigger or MDATACTRL[TXCOUNT].

This register acts as an alias of Target Write Data Halfword End (SWDATAHE).

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 DATA1	Data Byte 1 Represents the second byte that is sent to the target (written to transmit FIFO).
7-0 DATA0	Data Byte 0 Represents the first byte that is sent to the target (written to transmit FIFO).

69.7.43 Controller Read Data Byte (MRDATAB)

Offset

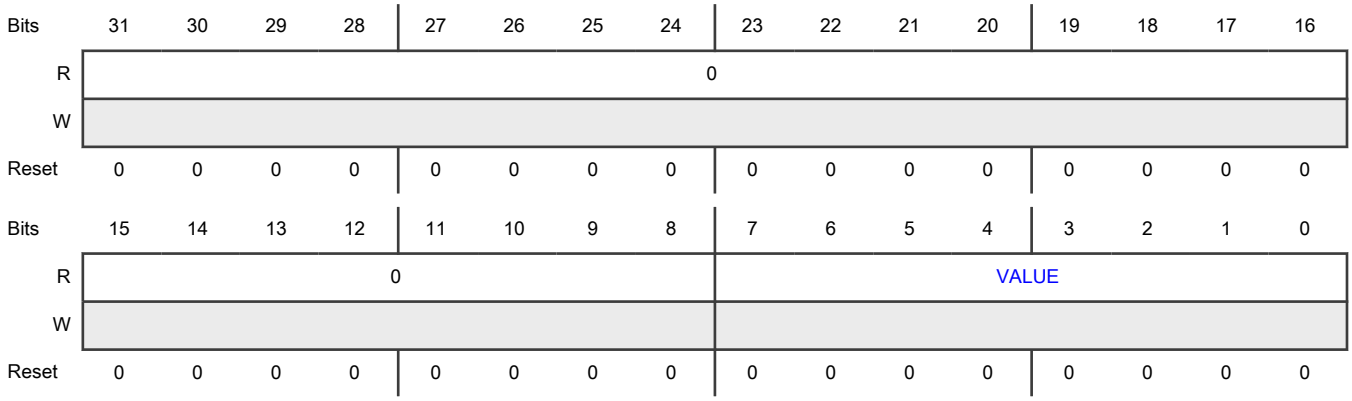
Register	Offset
MRDATAB	C0h

Function

Allows reading bytes written by the target after an SDR read, or DAA or DDR. This register is used only when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

This register acts as an alias of Target Read Data Byte (SRDATAB).

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 VALUE	Value Represents the byte read from the controller (and written by the target).

69.7.44 Controller Read Data Halfword (MRDATAH)

Offset

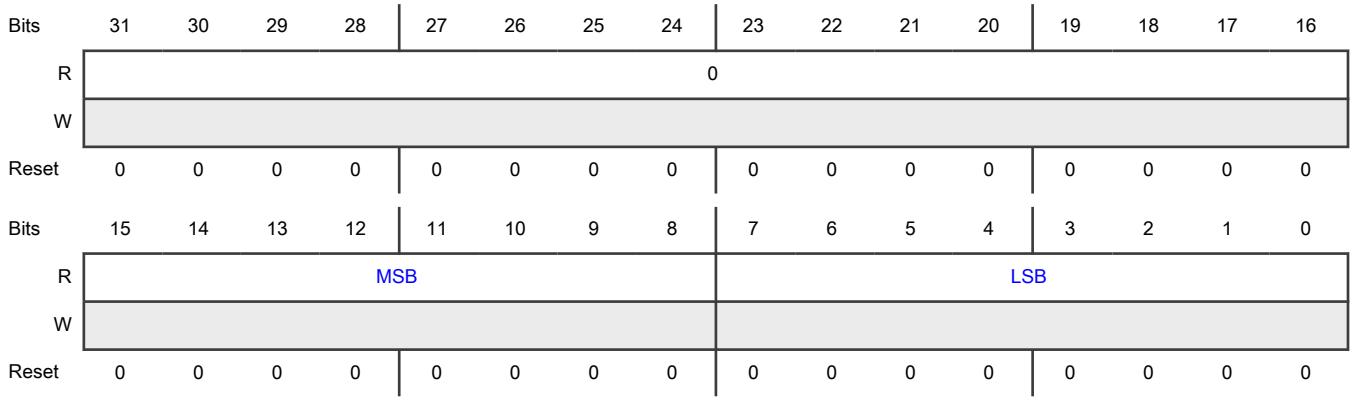
Register	Offset
MRDATAH	C8h

Function

Allows reading a halfword (byte pair) written by the target after an SDR read or DAA or DDR. This register is used only when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

A halfword must not be read unless there are at least two bytes of data waiting, as indicated by the receive FIFO level trigger or MDATACTRL[RXCOUNT].

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 MSB	High Byte Represents the second byte read from the controller (and written by the target).
7-0 LSB	Low Byte Represents the first byte read from the controller (and written by the target).

69.7.45 Controller Write Byte Data 1 (to Bus) (MWDATAB1)

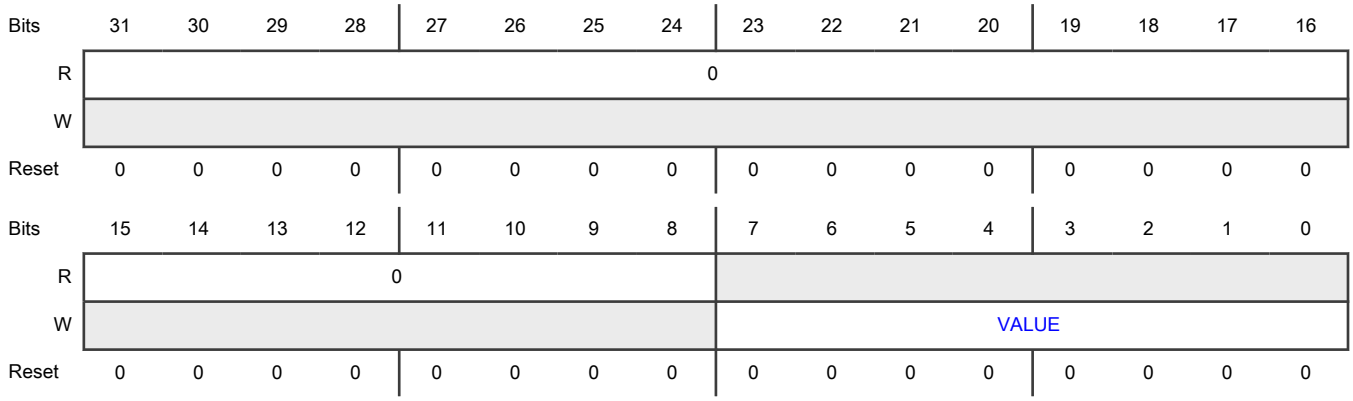
Offset

Register	Offset
MWDATAB1	CCh

Function

Allows writing bytes to send onto the bus, and is intended for DMAs that do not clear the upper bits of the word. This register does not have the END bits and is only used when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 VALUE	Value Represents the byte to write out. The I3C module computes the parity for I3C, or manages the ACK or NACK for I2C.

69.7.46 Controller Write Halfword Data (to Bus) (MWDATAH1)

Offset

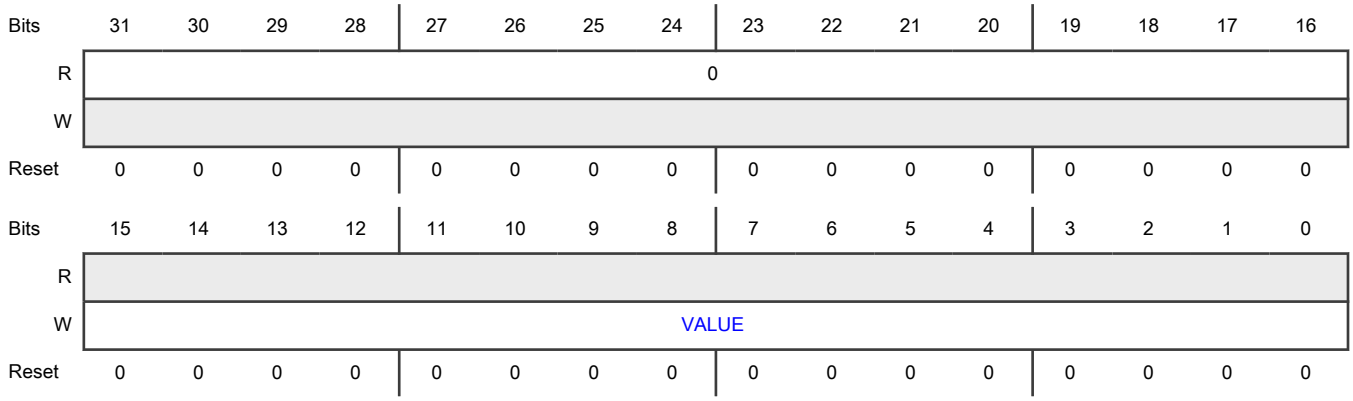
Register	Offset
MWDATAH1	CCh

Function

Allows writing a byte pair (halfword) to send onto the bus, and is intended for DMAs that do not clear the upper bits of the word. It does not have the END bits as present in Controller Write Data Halfword (MWDATAH). This register is only used when using Controller Control (MCTRL) to start the message. If MWMSG_SDR or MWMSG_DDR is used to start a message, that interface must be used exclusively.

MWDATAH1 shares the same address as MWDATAB1. MDMACTRL[DMAWIDTH] determines which one is set.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 VALUE	Value Represents the byte to write out. The I3C module computes the parity for I3C, or manages the ACK or NACK for I2C.

69.7.47 Controller Write Message Control in SDR mode (MWMSG_SDR_CONTROL)

Offset

Register	Offset
MWMSG_SDR_CONTROL	D0h

Function

Allows setting up and writing 16-bit words in Single Data Rate (SDR) mode. The MWMSG_SDR_ register is modal and has two modes—control and data:

- For the first write to set up a new message, this register functions as the MWSMSG_SDR_CONTROL register.
- For subsequent writes, this register functions as MWMSG_SDR_DATA.
- The control information is not pipelined. You must write to control information registers for a start and do not write to them until data is sent.

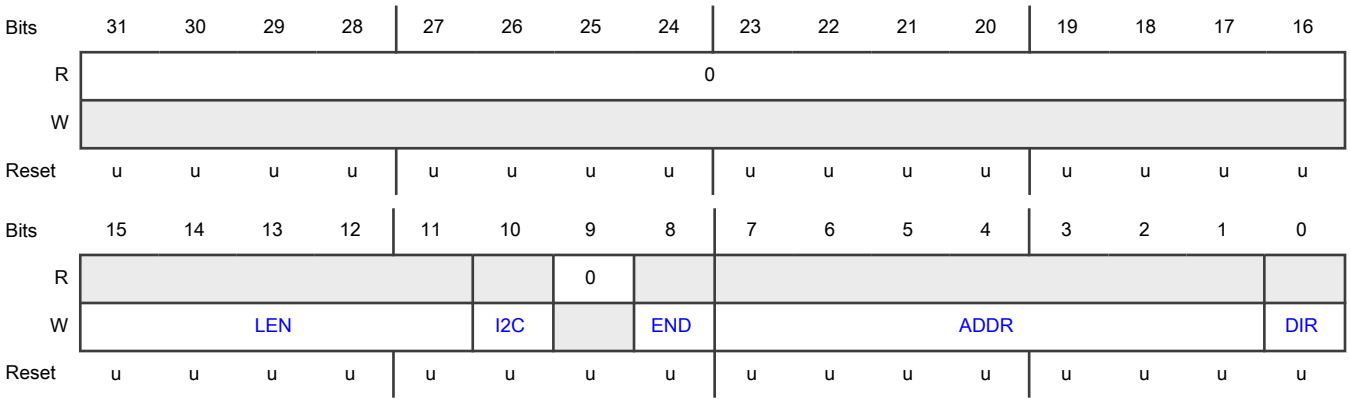
When not in the middle of a message, the MWMSG_SDR_CONTROL register is used to start a new message (or emit a STOP). After starting a message, the MWMSG_SDR_DATA register is used until the length (see the LEN field) counts down, or until data with END = 1 is used.

The MWMSG_SDR_CONTROL register is written with the 16-bit control word if currently stopped or after the end of the previous message. If MSTATUS[STATE] = 2 (MSGSDR) and MSTATUS[BETWEEN] = 0, the register (at this offset address) functions as the MWMSG_SDR_DATA register. Otherwise, this register (at this offset address) functions as the MWMSG_SDR_CONTRL register, as long as MSTATUS[STATE] is not in another mode.

The control word contains the byte length (6-bit), address, direction, and how it ends (stop, ready for next, continuation with more length). If the command is START and an event (IBI, CR, HJ) occurs, MCTRL[IBIRESP] is used to determine action, and the corresponding interrupt occurs. In that case, the message is restarted.

The MWMSG_SDR_CONTROL and MWMSG_SDR_DATA registers are only targeted for DMA operations, but the processor can also write to the MWMSG_SDR_CONTROL register (instead of using MCTRL and MxDATAB).

Diagram



Fields

Field	Function
31-16 —	Reserved
15-11 LEN	Length Indicates the byte length of the message. If LEN = 0, then only END is used (and it does not use the address if stopped). LEN = 1 must not be used. The minimal LEN size is 2 bytes (LEN = 2).
10 I2C	I2C Specifies whether the message is I2C or I3C. 0b - I3C message 1b - I2C message
9 —	Reserved
8 END	End of SDR Message Indicates the end of SDR message. MSTATUS[COMPLETE] = 1 when done. The end can happen: • Before LEN bytes are read in I3C mode, if a target ends sooner. • Before LEN bytes are written in I2C mode, if a target NACKs. If this field is 0, the SDR message ends waiting for a new SDR message (issues a Repeated START for a new message). If this field is 1, the SDR message ends at the STOP.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not the end 1b - End
7-1 ADDR	Address Contains the address to be written.
0 DIR	Direction 0b - Write 1b - Read

69.7.48 Controller Write Message Data in SDR mode (MWMSG_SDR_DATA)

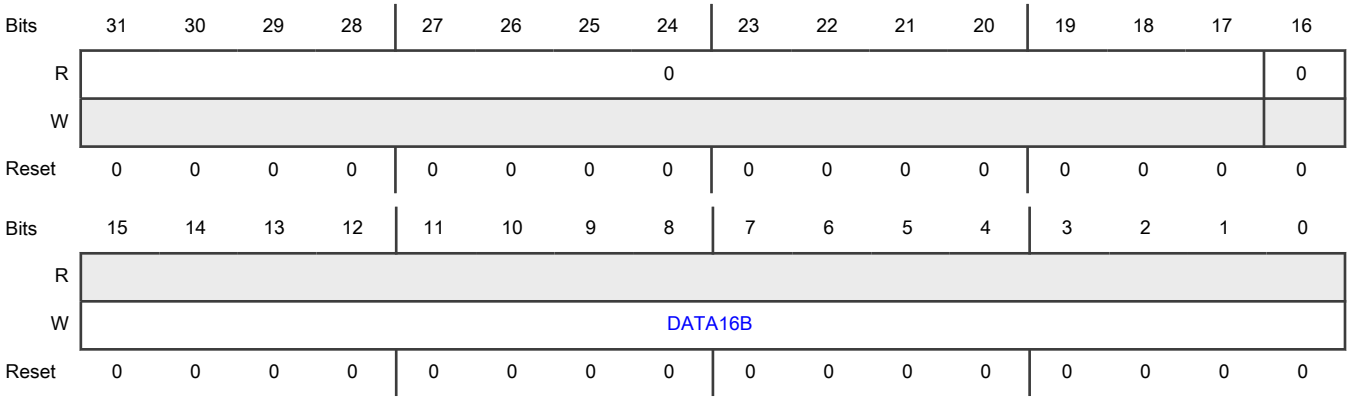
Offset

Register	Offset
MWMSG_SDR_DATA	D0h

Function

Contains the 16-bit word to be written in Single Data Rate (SDR) mode. This register functions in a way similar to MWMSG_SDR_CONTROL.

Diagram



Fields

Field	Function
31-17 —	Reserved

Table continues on the next page...

Table continued from the previous page...

16 —	Reserved
15-0 DATA16B	Data

69.7.49 Controller Read Message in SDR mode (MRMSG_SDR)

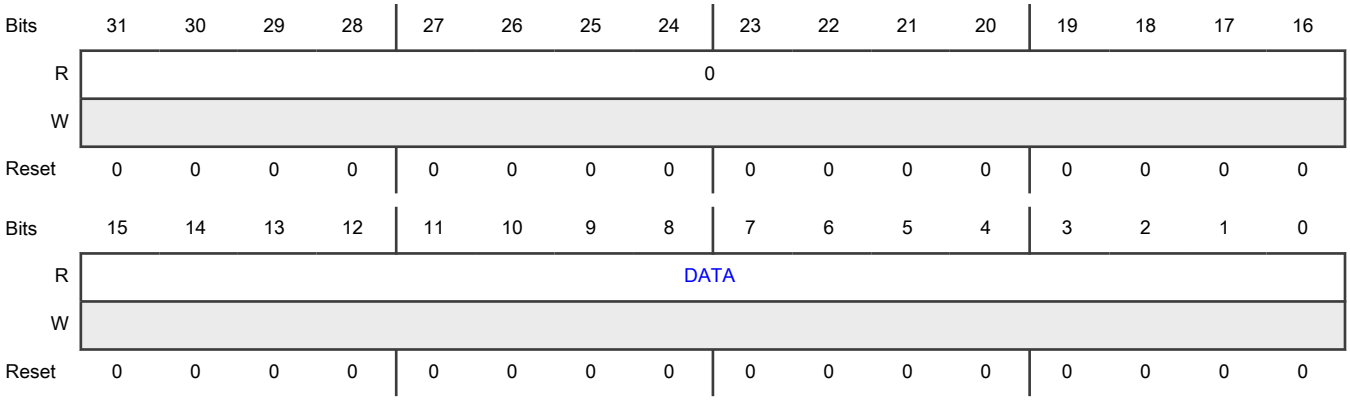
Offset

Register	Offset
MRMSG_SDR	D4h

Function

Allows reading 16-bit words from a target in SDR Message mode. The MRMSG_SDR register is used to read 16-bit words from an active message started with MWMSG_SDR. These words are intended to be read by DMA.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 DATA	Data Contains the 16-bit word read from the target: • If the length (LEN) is an odd number, the upper byte is 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• If the target ends before LEN is finished, the module treats the read as completed. • If the target is not done before LEN is finished and END is not a continuation, the read is terminated.

69.7.50 Controller Write Message in DDR mode: First Control Word (MWMSG_DDR_CONTROL)

Offset

Register	Offset
MWMSG_DDR_CONTROL	D8h

Function

Allows setting up and writing 16-bit words in DDR mode. The register has three modes:

- The first write to set up a new message functions as the MWSMSG_DDR_CONTROL register.
- The second write contains the functions as shown in the MWMSG_DDR_CONTROL2 register.
- For subsequent writes, this register functions in a way similar to Controller Write Message Data in DDR mode (MWMSG_DDR_DATA).
- The control information is not pipelined. You must write to control information registers for a start and do not write to them until data is sent.

When not in the middle of a message, the MWMSG_DDR_CONTROL register is used to start a new message (or emit a STOP). After starting a message, the MWMSG_DDR_DATA register is used until the length (see LEN field) counts down or until data with END = 1 is used.

The MWMSG_DDR_CONTROL register is written with the 16-bit control word if currently stopped or after the end of the previous message. If MSTATUS[STATE] = 4 (MSGDDR) and MSTATUS[BETWEEN] = 0, then the register (at this offset address) functions as the MWMSG_DDR_DATA register. Otherwise, this register (at this offset address) functions as the MWMSG_DDR_CONTROL register, as long as MSTATUS[STATE] is not in another mode.

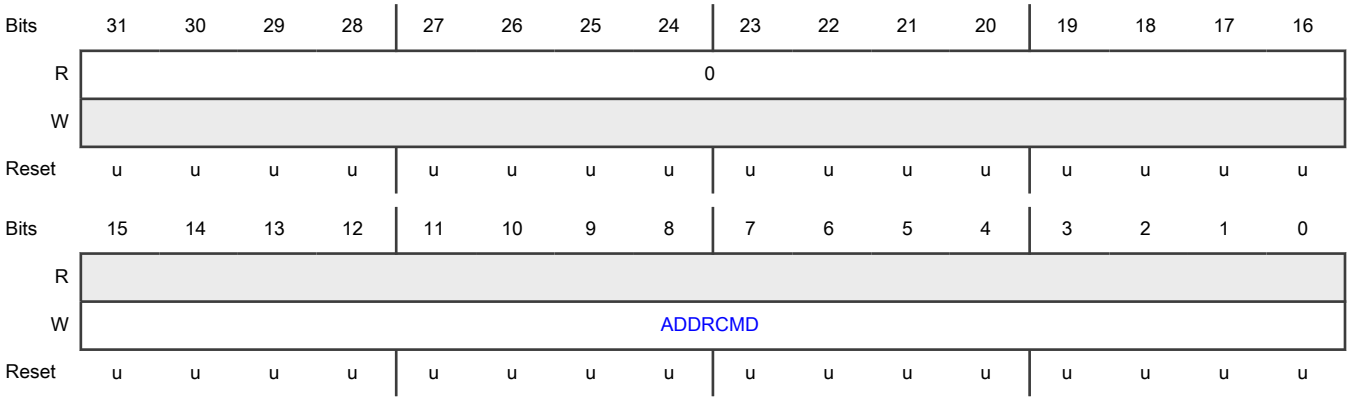
The main control word contains the 16-bit word length and how it ends (stop, ready for next, continuation with more length). Then the command word contains the command and address for read or write. If the command is START and an event (IBI, CR, HJ) occurs, MCTRL[IBIRESP] is used to determine action, and the corresponding interrupt occurs. In that case, the message is restarted.

The MWMSG_DDR_CONTROL, MWMSG_DDR_CONTROL2, and MWMSG_DDR_DATA registers are only targeted for DMA operations, but the processor can also write to the MWMSG_DDR_CONTROL register (instead of using MCTRL and MxDATAB).

NOTE

The module handles preamble, parity, and CRC.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 ADDRCMD	Address Command Indicates the first data write after control write, with LEN ≠ 0. This is formatted as: • Bits 15:9: target address to read or write • Bit 8: reserved, must be 0 • Bit 7: 1 if read, 0 if write • Bits 6:0: CMD as 7-bit value, always for controller

69.7.51 Controller Write Message in DDR Mode Control 2 (MWMSG_DDR_CONTROL2)

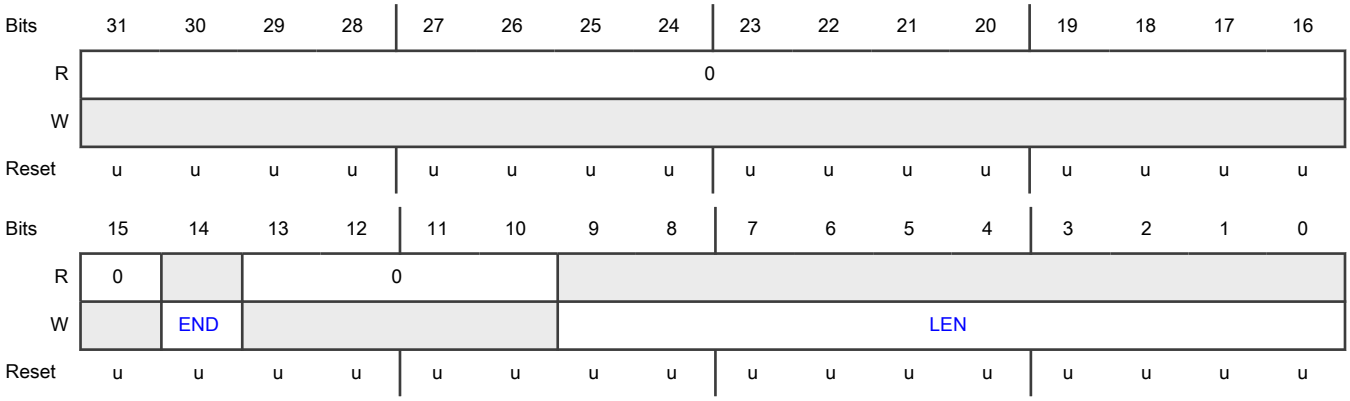
Offset

Register	Offset
MWMSG_DDR_CONTROL2	D8h

Function

Contains the second control word instructions with the length of message and end.

Diagram



Fields

Field	Function
31-16 —	Reserved
15 —	Reserved
14 END	End of Message Indicates the end of DDR message. MSTATUS[COMPLETE] becomes 1 when done. The end can happen before LEN bytes are read if the target ends sooner. If this field is 0, DDR message ends waiting for a new DDR message (issues an HDR restart for the new message). If this field is 1, DDR message ends on HDR exit. 0b - Not the end 1b - End
13-10 —	Reserved
9-0 LEN	Length of Message Contains the length of the message (including the command) in halfwords, up to 2046 bytes. If LEN = 0, then only END is applied: • For reads, + 1 for the CRC. For example, to read 4 bytes (2 halfwords), use 1 + 2 + 1 for CMD + 2 halfwords + CRC. • For writes, LEN is the number of halves of data bytes + 1 (for command).

69.7.52 Controller Write Message Data in DDR mode (MWMSG_DDR_DATA)

Offset

Register	Offset
MWMSG_DDR_DATA	D8h

Function

Contains the 16-bit word to be written in DDR mode. This register functions in a way similar to Controller Write Message in DDR mode: First Control Word (MWMSG_DDR_CONTROL).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

69.7.53 Controller Read Message in DDR mode (MRMSG_DDR)

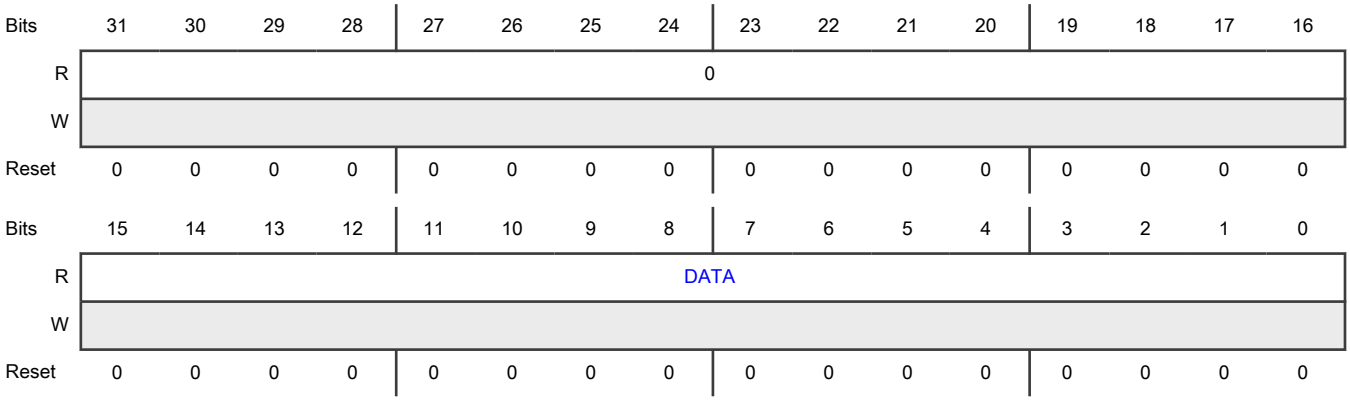
Offset

Register	Offset
MRMSG_DDR	DCh

Function

Allows reading 16-bit words from a target in DDR Message mode from an active message started with MWMSG_DDR. These words are intended to be read by DMA.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 DATA	Data Contains the 16-bit word read from a target. The first byte is the LSB, and is in DATA[7:0]. The second byte is the MSB, and is in DATA[15:8]: • If the target ends before the entire length of the message (MWMSG_DDR[LEN]) is read, the module considers the DATA read as completed. In I3C mode, the target can indicate the end of message (the last byte). Otherwise, the controller terminates the message if the message is more than the controller can accept. • If the target has not yet finished sending DATA before the entire length of the message (MWMSG_DDR[LEN]) is read and END is not a continuation, the DATA read is terminated.

69.7.54 Controller Dynamic Address (MDYNADDR)

Offset

Register	Offset
MDYNADDR	E4h

Function

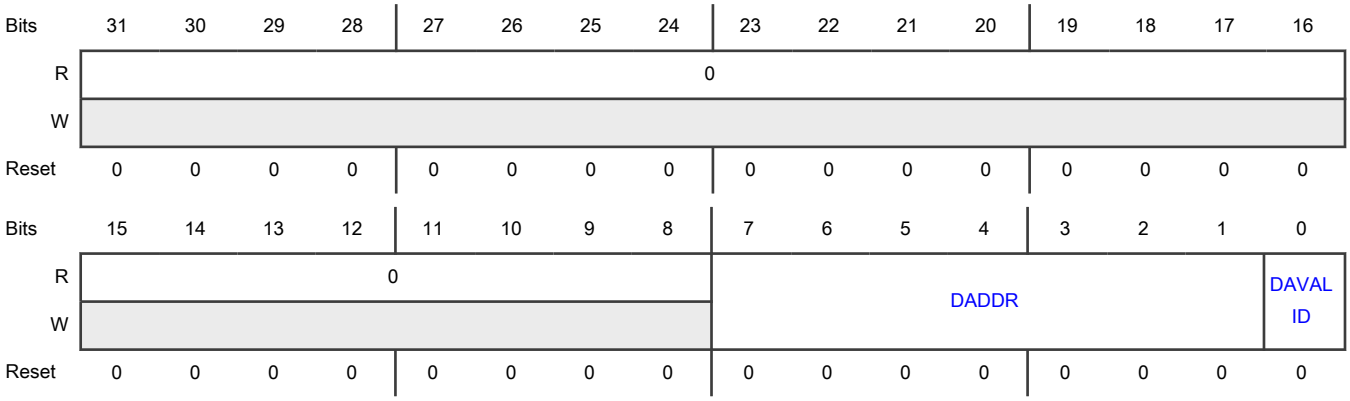
Allows the I3C module to write its own dynamic address (DA) when the module changes from Controller mode to Target mode.

If this device is the main controller (the controller during bus initialization), then the device may use this mechanism to assign itself its DA. When the device hands off control to a secondary controller, it becomes a target itself. This DA must be written before switching to Target mode and must not be changed once in Target mode (it is not clock-safe to do so). It must be written with a valid address value in DADDR if DAVALID = 1.

NOTE

The main controller also uses DEFSLVS CCC to define the target addresses, including itself. This mechanism is how secondary controllers know this address. If the controller is not the main controller, then this mechanism must not be used.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-1 DADDR	Dynamic Address Contains the assigned dynamic address when DAVALID = 1.
0 DAVALID	Dynamic Address Valid 0b - No valid DA assigned 1b - Valid DA assigned

69.7.55 Map Feature Control 0 (SMAPCTRL0)

Offset

Register	Offset
SMAPCTRL0	11Ch

Function

Provides map feature control.

The SMAPCTRL*n* registers are named SMAPCTRL0, SMAPCTRL1, and so on based on the number of mapped addresses. MAPCTRL0 represents the primary DA or SA with SMAPCTRL1 onwards being the mapped addresses.

The features of the SMAPCTRL*n* registers depend on configuration. SMAPCTRL0 acts differently, as described in this chapter.

In general, this mechanism is intended to replace the DYNADDR register for all MAP-related uses.

When using the Auto-MAP and DASA or AASA, the slot is changed from SA to DA. If the controller then issues RSTDAA, the application must rewrite the static addresses and enable them because they are marked disabled.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Signal multiplexing	IOPCTL	External signals and pin multiplexing IO PAD controller

70.1.1 Module instances

This device contains two instances of the INPUTMUX module.

Table 683. INPUTMUX instances

	INPUTMUX0	INPUTMUX1
Located	VDD2_COMP	VDD1_SENSE
Access	CPU0, HiFi4, EZH-V, eDMA0, eDMA1	CPU1, HiFi1, EZH-V, eDMA2, eDMA3

70.2 Overview

INPUTMUX provides signal routing options for internal peripherals. Some peripheral inputs are multiplexed to multiple input sources. The sources can be external pins, interrupts, output signals of other peripherals, or other internal signals.

NOTE

Depending on the package, not all inputs from external pins are available.

70.2.1 Block diagram

Figure 295 shows a generic input multiplexer arrangement with n inputs.

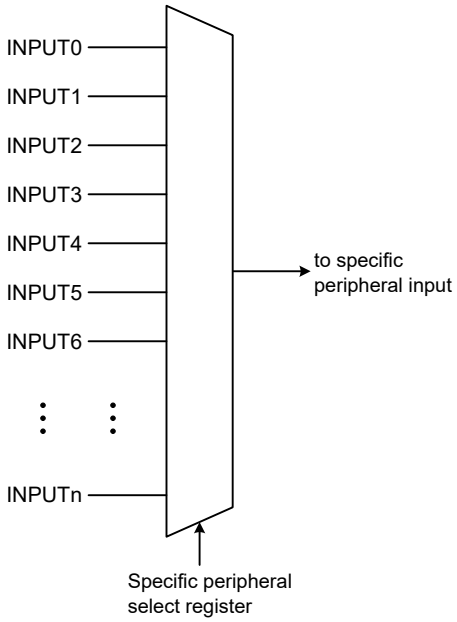

Figure 295. Generic input multiplexing

70.2.2 Features

- Configures the inputs to the SCT module.
- Configures the inputs to the asynchronous CTIMER modules.
- Configures the inputs to the HiFi1 and HiFi4.
- Configures the inputs to the LP_FLEXCOMM and FLEXIO modules.
- Configures the inputs to the EZH-V
- Configures the inputs to the PINT modules.
- Configures the inputs to ADC0 module.
- Configures the inputs to the FREQME module.

70.3 Functional description

The INPUTMUX implements a number of input multiplexers that select one of many inputs to be routed to a specific input signal for a given peripheral. This is used to allow user configuration of data paths between internal modules and/or external pins on the device. For every module input (output from the INPUTMUX), there is a register that selects the input to use, where the register name and description provide details on the module input controlled by each register. The input signal/pin options for each of the multiplex are configurable, and can vary from each other. See register descriptions for the details on the input signal/pin options used for each INPUTMUX output in Memory map and register definition.

70.3.1 Clocking

Table 684. INPUTMUX clock

Clock	Description
Module clock (clk_and_reset_pclk)	Functions the module and controls the access to the registers.

After the INPUTMUX is configured, no clock is needed to function the module, you can disable the clocks by:

- Writing 1 to the CLKCTL0_PSCCTL3_CLR[INPUTMUX0] to disable the clock to the INPUTMUX0.
- Writing 1 to the CLKCTL1_PSCCTL1_CLR[INPUTMUX1] to disable the clock to the INPUTMUX1.

70.3.2 Reset

The following table shows the INPUTMUX registers reset caused by RSTCTL module:

Table 685. INPUTMUX related reset

Write 1 to	Reset
RSTCTL0_PRSTCTL4[INPUTMUX0] or RSTCTL0_PRSTCTL4_SET[INPUTMUX0]	• INPUTMUX0_HiFi4_INTERRUPT0-INPUTMUX0_HiFi4_INTERRUPT26 • INPUTMUX0_LP_FLEXCOMM0_TRIG-INPUTMUX0_FLEXCOMM13_TRIG • INPUTMUX0_CTIMER0_CAP0-INPUTMUX0_CTIMER4_CAP3 • INPUTMUX0_CTIMER0_TRIG-INPUTMUX0_CTIMER4_TRIG • INPUTMUX0_FREQME_TRIG0-INPUTMUX0_FREQME_TRIG1 • INPUTMUX0_EZHV_TRIG0-INPUTMUX0_EZHV_TRIG7 • INPUTMUX0_FLEXIO_TRIG0-INPUTMUX0_FLEXIO_TRIG3
RSTCTL3_PRSTCTL1[INPUTMUX1] or RSTCTL3_PRSTCTL1_SET[INPUTMUX1]	• INPUTMUX1_HiFi1_INTERRUPT0-INPUTMUX1_HiFi1_INTERRUPT26 • INPUTMUX1_LP_FLEXCOMM17_TRIG-INPUTMUX1_LP_FLEXCOMM20_TRIG • INPUTMUX1_ADC0_TRIG0-INPUTMUX1_ADC0_TRIG1 • INPUTMUX1_CTIMER5_CAP0-INPUTMUX1_CTIMER7_CAP3 • INPUTMUX1_CTIMER5_TRIG-INPUTMUX1_CTIMER7_TRIG
RSTCTL0_PRSTCTL2[SCT0] or RSTCTL0_PRSTCTL2_SET[SCT0]	• SCT0 module • INPUTMUX0_SCT0_TRIG0-INPUTMUX0_SCT0_TRIG6
RSTCTL0_PRSTCTL4[PINT0] or RSTCTL0_PRSTCTL4_SET[PINT0]	• PINT0 module • INPUTMUX0_PINT0_TRIG0-INPUTMUX0_PINT0_TRIG7
RSTCTL1_PRSTCTL0[PINT1] or RSTCTL1_PRSTCTL0_SET[PINT1]	• PINT1 module • INPUTMUX1_PINT1_TRIG0-INPUTMUX1_PINT1_TRIG3

70.3.3 Interrupts

This module has no interrupts.

70.4 External signals

The INPUTMUX has no dedicated pins. Multiplexer inputs from external pins work independently of any other function assigned to the pin as long as no analog function is enabled.

Table 686. INPUTMUX pin description

Pins	Peripheral	Section
Any existing pin on PIO0, PIO1, PIO8 and PIO10	Pin interrupts 0 to 7	See INPUTMUX
PIO0_28	FREQME	See INPUTMUX
SCT_GPIN[0:7] pin functions selected from IOPCTL register	SCT	See SCT

70.6.1.5 LP_FLEXCOMM Input Connections (LP_FLEXCOMM0_TRIG - LP_FLEXCOMM13_TRIG)

Offset

For a = 0 to 13:

Register	Offset
LP_FLEXCOMMa_TRIG	200h + (a × 20h)

Function

Selects the LP_FLEXCOMM trigger inputs.

NOTE

When TRIGIN field is configured as 1100b to select PINT0 boolean pattern-match output as input trigger and this LP_FLEXCOMM is used as LPUART, the related CFG field of PINT0.PMCFG register must not be configured as 111b (Event).

71.1.1 Module instances

This device has four eDMA controllers:

Table 688. eDMA instances

	eDMA0, eDMA1	eDMA2, eDMA3
Located in	VDD2_COMP	VDD1_SENSE
Core access	CPU0, HiFi4, EZH-V, eDMA0, eDMA1	CPU1, HiFi1, EZH-V, eDMA2, eDMA3
Channel numbers	16	8

71.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

71.1.3 Module DMA requests enable

All the module DMA requests are disabled by default, you can enable them by SYSCON registers.

Table 689. Module DMA requests enable

DMA requests of eDMA instance	Enabled by register
eDMA0	SYSCON0.EDMA0_EN0-SYSCON0.EDMA0_EN3
eDMA1	SYSCON0.EDMA1_EN0-SYSCON0.EDMA1_EN3
eDMA2	SYSCON1.EDMA2_EN0-SYSCON1.EDMA2_EN3
eDMA3	SYSCON1.EDMA3_EN0-SYSCON1.EDMA3_EN3

71.2 Overview

The enhanced direct memory access (eDMA) controller is capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes:

- A DMA engine that performs:
  - Source address and destination address calculations
  - Data-movement operations
- Local memory containing transfer control descriptors for each of the 16 channels

NOTE

The terminology in this chapter has been updated to align with NXP's inclusive language standards, as shown in the table below.

71.2.1 Block diagram

Figure 296 illustrates the components of the eDMA system, including the eDMA module (engine).

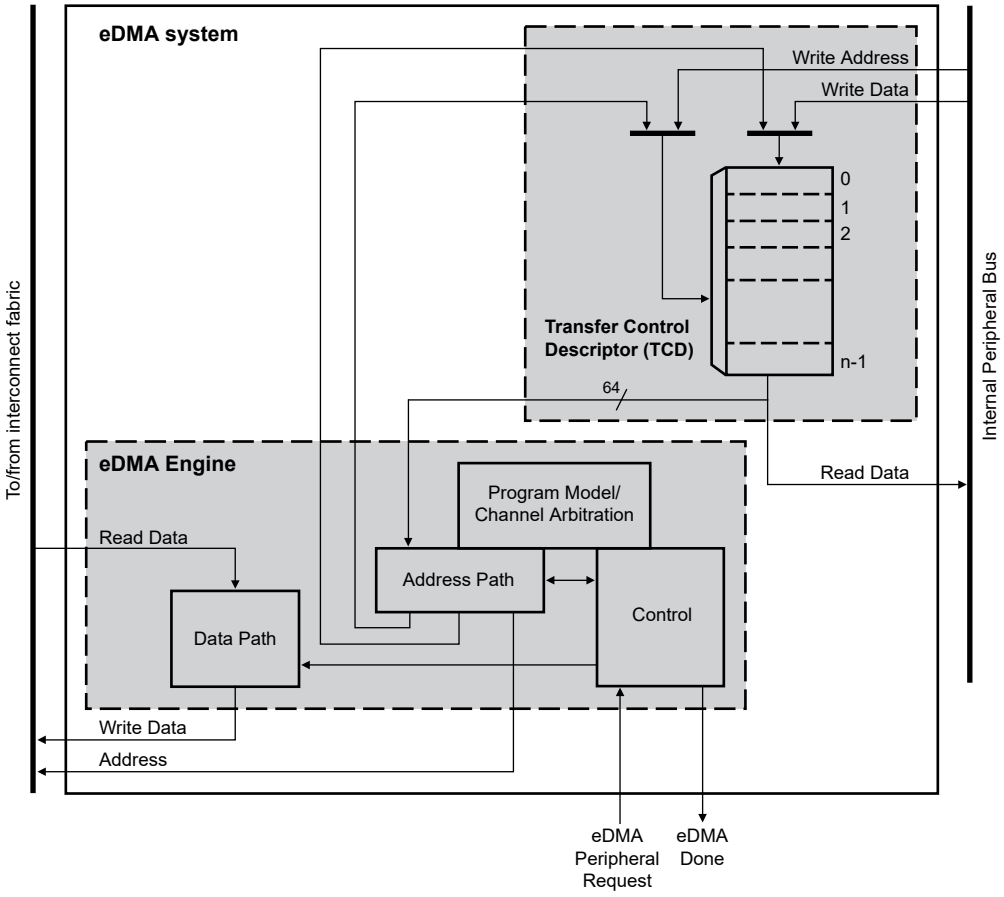

Figure 296. Block diagram

71.2.2 Block parts

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer control descriptor local memory.

The eDMA engine is further partitioned into four submodules:

Table 691. eDMA engine submodules

Submodule	Function
Address path	This block: • Implements a primary channel and secondary (preempt) channel • Manages all initiator bus-address calculations All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the primary channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by CH*n*_PRI[ECP]) where a large data transfer can be preempted to minimize the time another channel is blocked from execution. When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for the TCD*n*_{SADDR, DADDR, CITER} back to local memory. If the major iteration count is exhausted, additional processing is performed, including the final address pointer updates, reloading the TCD*n*_CITER field, and a possible fetch of a new TCD*n* from memory as part of a scatter/gather operation. See Dynamic scatter/gather for more details.
Data path	This block implements the bus initiator read/write data path. It includes a data buffer and the necessary multiplex logic to support any required data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output. The address and data path modules directly support the 2-stage pipelined internal bus. The address path module represents the first stage of the bus pipeline (address phase), and the data path module implements the second stage of the pipeline (data phase).
Program model/channel arbitration	This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus. The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).
Control	This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has been moved from the source to the destination. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-bit data and the destination is 32-bit data, the eDMA performs two reads, then one 32-bit write.

The transfer control descriptor local memory is further partitioned into:

Table 692. Transfer control descriptor memory

Submodule	Description
Memory controller	This logic implements the required dual-ported controller, and manages accesses from the eDMA engine as well as references from the internal peripheral bus. In simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
Memory array	TCD storage for each channel's transfer profile.

71.2.3 Features

The eDMA is a highly programmable data-transfer engine optimized to minimize any required intervention from the host processor. It is intended for use in applications where the data size to be transferred is statically known and is not defined within the transferred data itself. The eDMA module features:

- All data movement via dual-address transfers: read from source, write to destination
  - Programmable source and destination addresses and transfer size
  - Support for complex address calculations
- 16-channel implementation that performs complex data transfers with minimal intervention from a host processor
  - Internal data buffer, used as temporary storage for all transfers
  - Connections to the crossbar switch for bus driving the data movement
- TCD organized to support two-deep, nested transfer operations
  - 32-byte TCD stored in local memory for each channel
  - An inner data transfer loop defined by a minor byte transfer count
  - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
  - Explicit software initiation
  - Initiation via a channel-to-channel linking mechanism for continuous transfers
  - Peripheral-paced hardware requests, one per channel
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via programmable interrupt requests
  - One interrupt per channel, which can be asserted at completion of major iteration count
  - Programmable error terminations per channel that are logically summed together to form one error interrupt to the interrupt controller
- Programmable support for scatter/gather DMA processing
- Support for complex data structures

In the discussion of this module, *n* is used to reference the channel number.

71.3 Functional description

The operation of eDMA is described in the following subsections.

71.3.1 Modes of operation

The eDMA operates in the following modes:

Table 693. Modes of operation

Mode	Description
Normal	In Normal mode, eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with eDMA. A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the TCD. The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.
Debug	eDMA operation is configurable in Debug mode via the control register: • If CSR[EDBG] is cleared to 0, eDMA continues to operate. • If CSR[EDBG] is set to 1, eDMA stops transferring data. If Debug mode is entered when a channel is active, eDMA continues operation until the channel retires.

71.3.2 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments.

As shown in the following diagram, the first segment involves the channel activation:

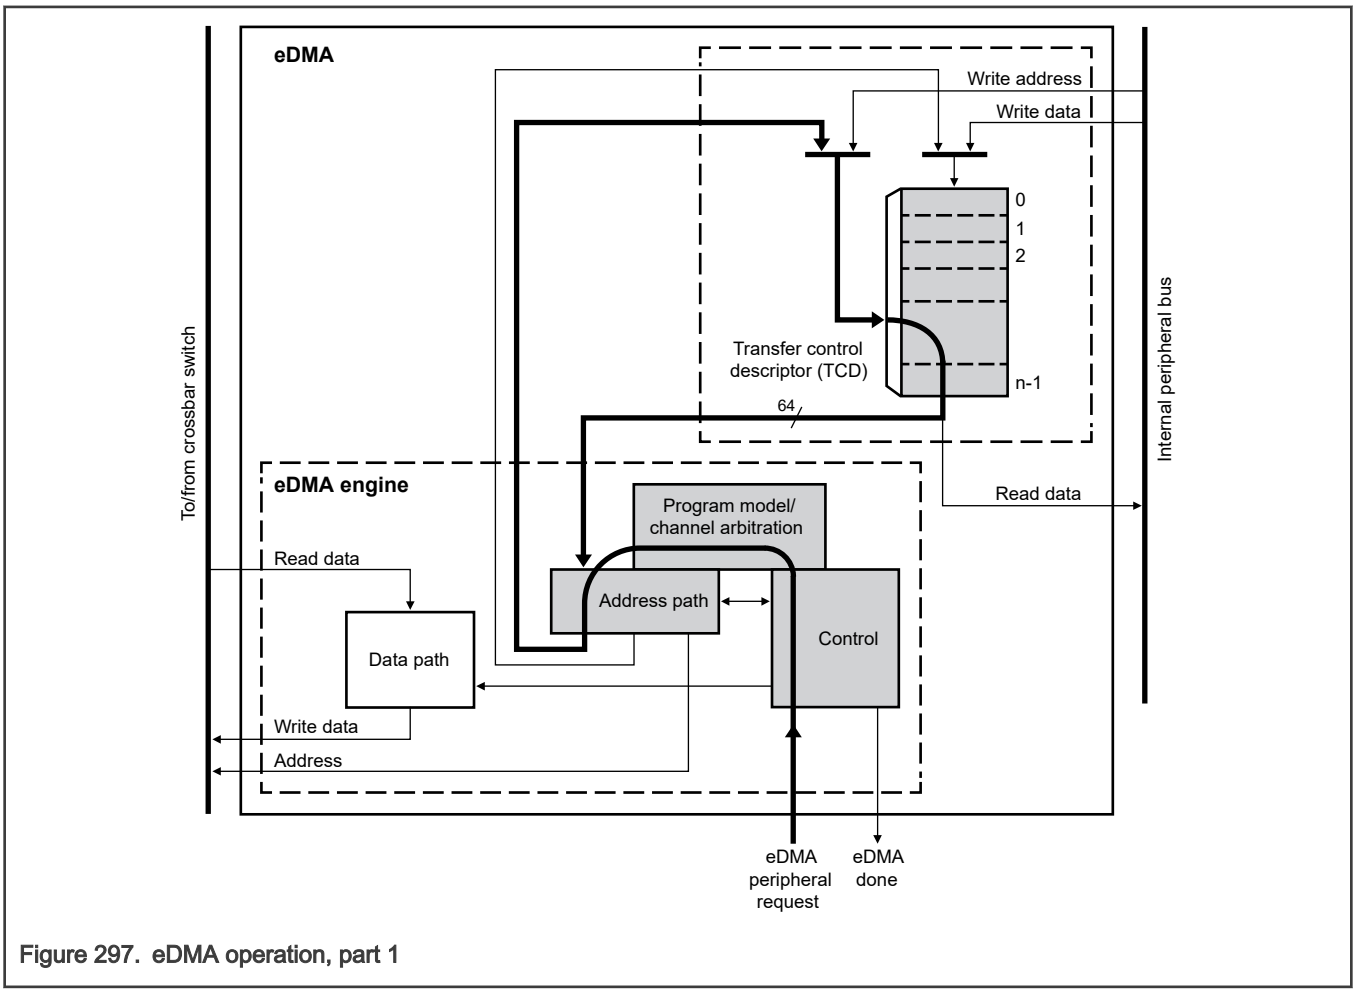

Figure 297. eDMA operation, part 1

This example uses the assertion of the eDMA peripheral request signal to request service for channel *n*. Channel activation via software and the TCD*n*_CSR[START] field follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration.

In the next cycle, the channel arbitration begins using fixed-priority plus the optional round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the required address to access the local memory for TCD*n*. Next, the TCD memory is accessed and the required descriptor is read from the local memory and then loaded into the eDMA engine address path's primary or secondary channel execution registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path registers.

The following diagram illustrates the second part of the basic data flow:

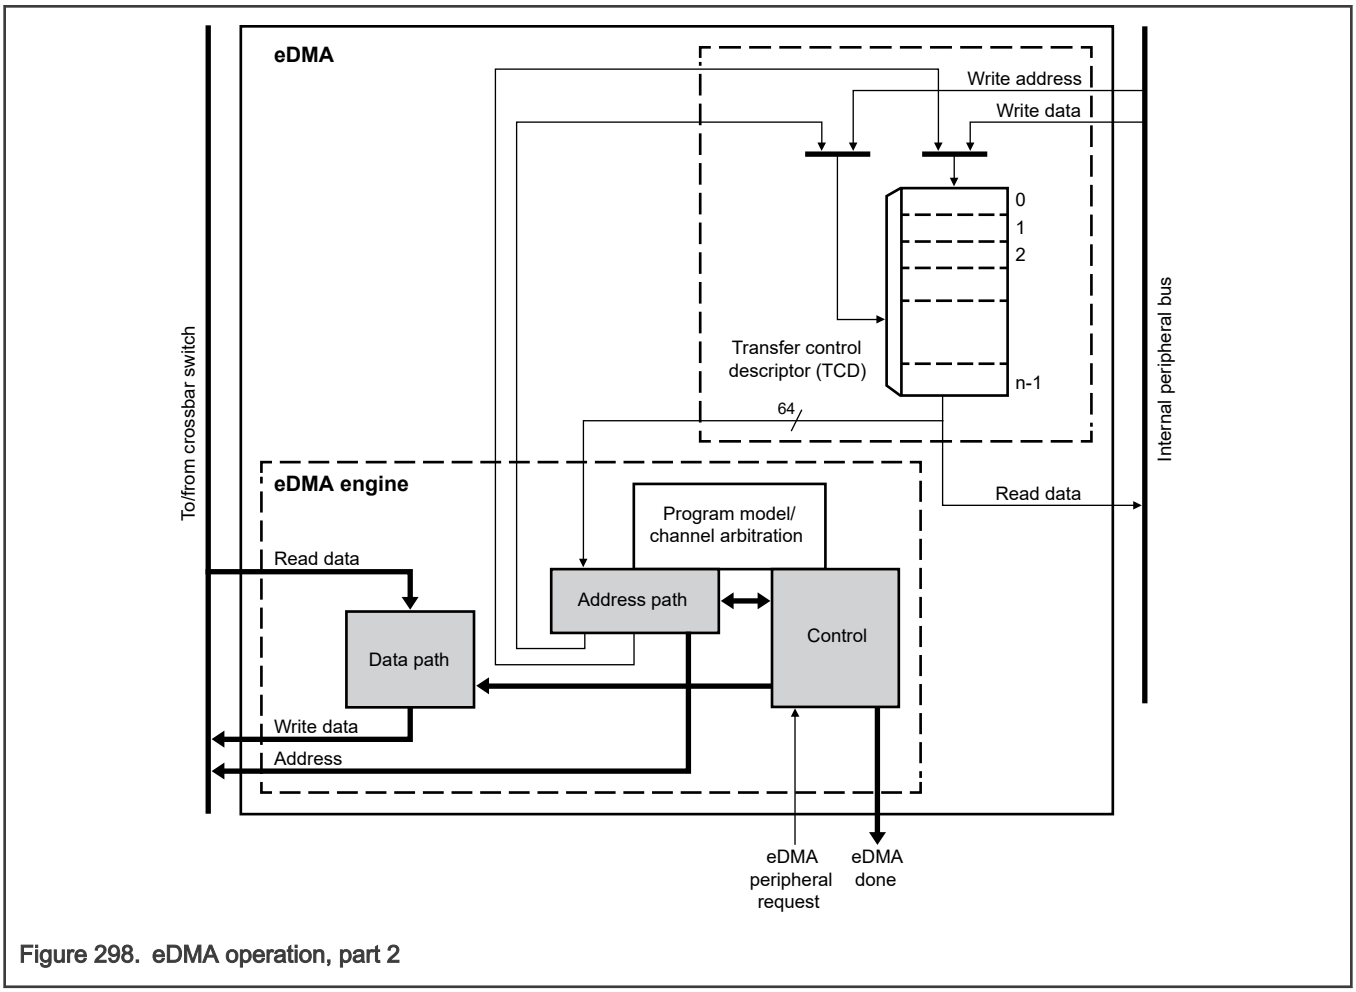

Figure 298. eDMA operation, part 2

The modules associated with the data transfer (address path, data path, and control) go through the required sequence of source reads and destination writes to perform the actual data movement. The source reads are initiated, and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the byte count, NBYTES, has been transferred.

After NBYTES of data has been moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs the required updates to certain fields in the appropriate TCD (for example, SADDR, DADDR, CITER). If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER field. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor (if scatter/gather is enabled). The updates to the TCD memory and the assertion of an interrupt request are shown in the following diagram.

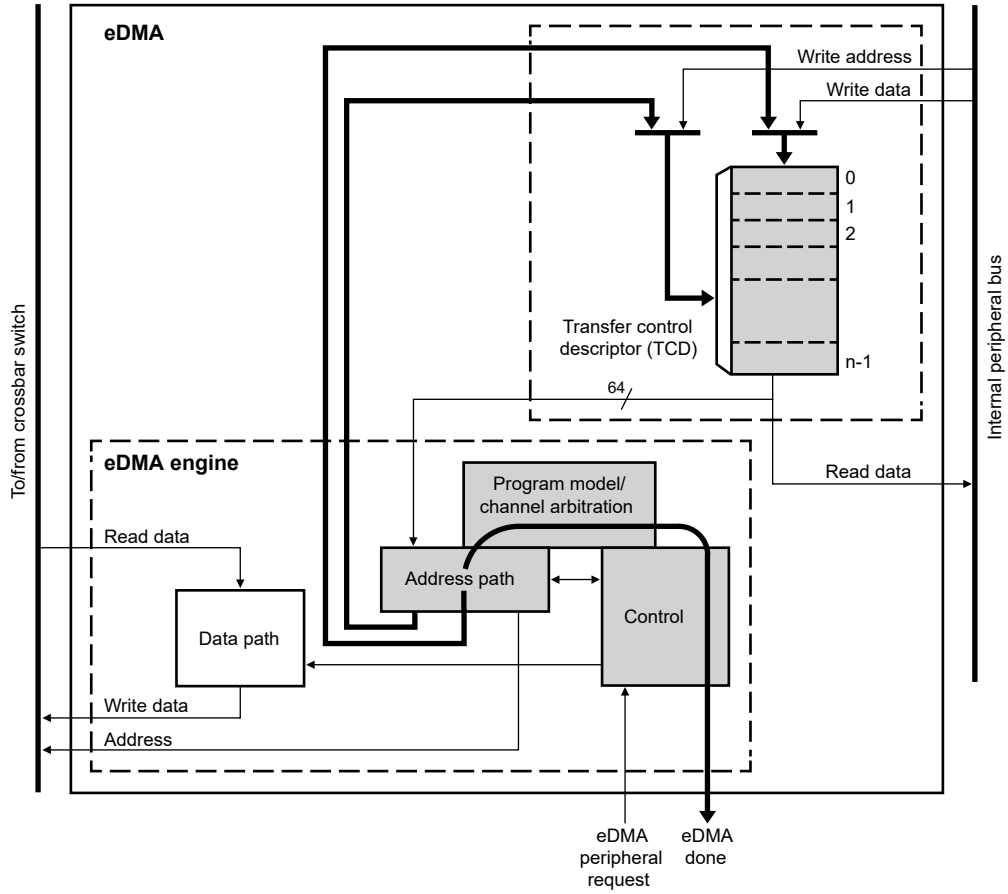

Figure 299. eDMA operation, part 3

71.3.3 Fault reporting and handling

Channel errors are reported in the Error Status register (CHn_ES) and can be caused by any of the following:

- A configuration error, which is an illegal setting in the transfer control descriptor
- An active channel canceled via a "cancel transfer with error" hardware or software request
- An error termination to a bus initiator read or write cycle

A configuration error is reported when an inconsistent state is represented by one of these factors:

- Starting source or destination address
- Source or destination offsets
- Minor loop byte count
- Transfer size

Each of these possible causes is detailed below:

- The addresses and offsets must be aligned on zero-modulo-transfer-sized boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size.

NOTE

To aid in debugging, set the Halt After Error field in the DMA's Control Status register, CSR[HAE]. Upon any error condition, the DMA is halted after the error is recorded. The DMA remains halted and does not process any channel service requests. After the error is fixed, the DMA may be enabled again by clearing the Halt field, CSR[HALT].

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (TCDn_DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn_CITER[ELINK] field does not equal the TCDn_BITER[ELINK] field.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, are reported as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion if properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system bus error occurs, the channel terminates after the next transfer. Due to pipeline effect, the next transfer is already in progress when the bus error is received by the eDMA. If a bus error occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

The occurrence of any error causes the eDMA engine to stop normal processing of the active channel immediately (it goes to its error processing states and the transaction to the system bus still has pipeline effect), and the appropriate channel field in the eDMA error register is set to 1. At the same time, the details of the error condition are loaded into the Error Status register (CHn_ES). The major loop complete indicators, setting the transfer control descriptor DONE flag, and the possible assertion of an interrupt request are not affected when an error is detected.

After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

The error status fields are read-only. These error indicators are sticky and cannot be cleared. They show the last recorded error until the DMA is reset. CHn_ES[ERR] is used to determine if a new error condition exists. This field is the logical OR of each channel's error interrupt field (ERR).

After the software has resolved all errors and cleared all of the error interrupt fields, the MP_ES[VLD] is cleared to 0 but the cause of the last error is still indicated.

71.3.4 Channel preemption

The eDMA uses a priority vector value to determine the highest priority channel requesting service.

The priority vector is a combination of:

1. the channel's group priority, CHn_GRPRI
2. the channel's priority level, CHn_PRI[APL]

It can be considered a number composed of these concatenated priority levels: CHn_GRPRI : CHn_PRI[APL]

Priority vector = ((CHn_GRPRI << 8) + (CHn_PRI[APL] << 5) + CH_NUM)

A channel requesting service with the highest priority vector value will receive the next execution slot.

An execution slot is available:

1. immediately if the eDMA is idle
2. when an active channel retires
3. when valid preemption conditions exist

NOTE

Preemption is strictly priority based. Preemption is not bound by a specific group number as defined by CHn_GRPRI.

Channel preemption is enabled on a per-channel basis by setting the CHn_PRI[ECP] field. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher-priority channel. After the preempting channel has completed all of its minor loop data transfers, the preempted channel is restored and resumes execution.

After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended, and the higher-priority channel is serviced. Nested preemption, that is, attempting to preempt a preempting channel, is not supported. After a preempting channel begins execution, it cannot be preempted.

A channel's ability to preempt another channel can be disabled by setting CHn_PRI[DPA] to 1. When a channel's preempt ability is disabled, that channel cannot suspend a lower-priority channel's data transfer, regardless of the lower-priority channel's ECP setting. This allows for a pool of low-priority, large-data-moving channels to be defined.

You can configure these low-priority channels to not preempt each other, thus preventing a low-priority channel from consuming the preempt slot normally available to a true high-priority channel. When you enable round-robin channel arbitration mode (CSR[ERCA] is set to 1), any channel with a priority level equal to 0 (CHn_PRI[APL] = 0) has preemption disabled and cannot preempt another channel.

71.3.5 Clocking

The following table describes the clock sources:

Table 694. Clocks

Clock	Description
hclk	Clock used for the DMA engine
ipg_clk	Clock used for the DMA programming model
dma_ram_clk	Clock used for the TCD RAMs

71.3.6 Interrupts

Software can enable the interrupt for each channel for the following events:

1. The major loop is half complete (INTHALF)
2. The major loop is complete (INTMAJOR)
3. A configuration error occurs (EEI)

71.4 External signals

This module has no external signals.

71.5 Initialization

The following sections discuss initialization of the eDMA and programming considerations.

71.5.1 eDMA initialization

To initialize the eDMA:

1. Write to the MP_CSR if a configuration other than the default is wanted.
2. Write the channel priority levels to the CHn_PRI registers and group priority levels to the CHn_GRPRI registers if a configuration other than the default is wanted.

3. Enable error interrupts in the CHn_CSR[EEI] registers if they are wanted.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the CHn_CSR[ERQ] registers.
6. Request channel service via either:
   - Software: setting TCDn_CSR[START]
   - Hardware: target device asserting its eDMA peripheral request signal

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields, as shown in Table 695, for the selected channel into its internal address path module.

As the TCD is read, the first transfer is initiated on the internal bus, unless a configuration error is detected. Transfers from the source, defined by TCDn_SADDR, to the destination, defined by TCD_DADDR, continue until the number of bytes specified by TCDn_NBYTES are transferred.

When the transfer is complete, the eDMA engine's local TCDn_SADDR, TCDn_DADDR, and TCDn_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, then eDMA executes further post-processing, such as interrupts, major loop channel linking, and scatter/gather operations, if enabled.

Table 695. TCD control and status (TCDn_CSR) fields

TCDn_CSR field name	Description
START	Control field to start the channel explicitly when using a software-initiated DMA service (automatically cleared by hardware)
EEOP	Control field to enable end-of-packet processing
ESDA	Control field to enable storing of the destination address to system memory after the major loop completes
DREQ	Control field to disable hardware-initiated DMA service requests after major loop completion
BWC	Control field for throttling the bandwidth control of a channel
ESG	Control field to enable the scatter-gather feature
INTHALF	Control field to enable interrupt when major loop is half-complete
INTMAJOR	Control field to enable interrupt when major loop completes

Table 696. Channel control and status (CHn_CSR) fields

CHn_CSR field name	Description
ACTIVE	Status field indicating the channel is currently in execution
DONE	Status field indicating major loop completion (cleared by software when a channel begins execution)
EEI	Control field to enable error interrupts
EARQ	Control field to enable external, asynchronous wakeup event in conjunction with the ERQ field
ERQ	Control field to enable hardware service requests

The following figure shows how each DMA request initiates one minor-loop transfer, or iteration, without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

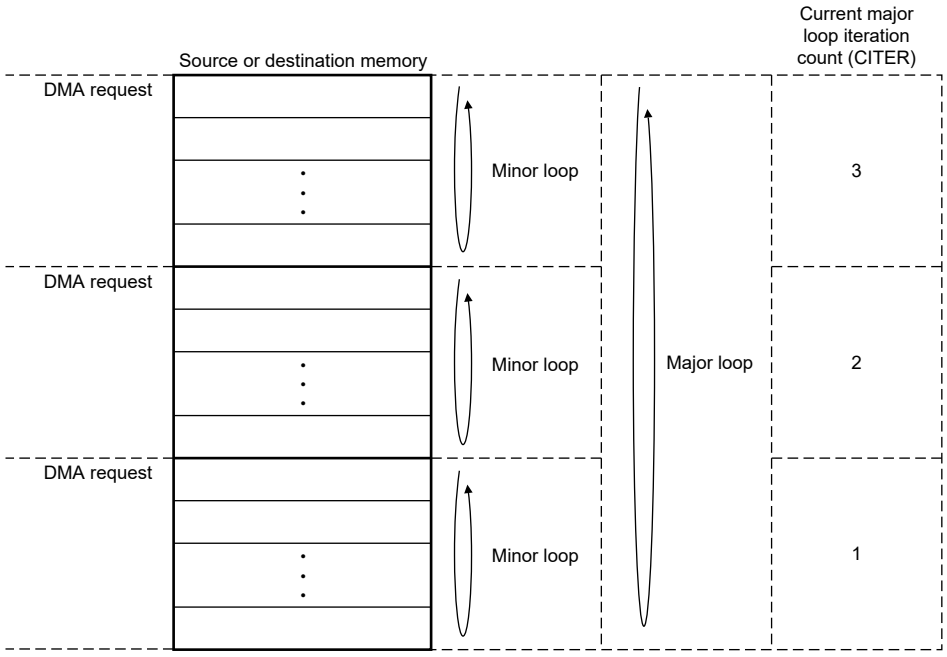

Figure 300. Example of multiple loop iterations

The following figure lists the memory array terms and how the TCD settings are related.

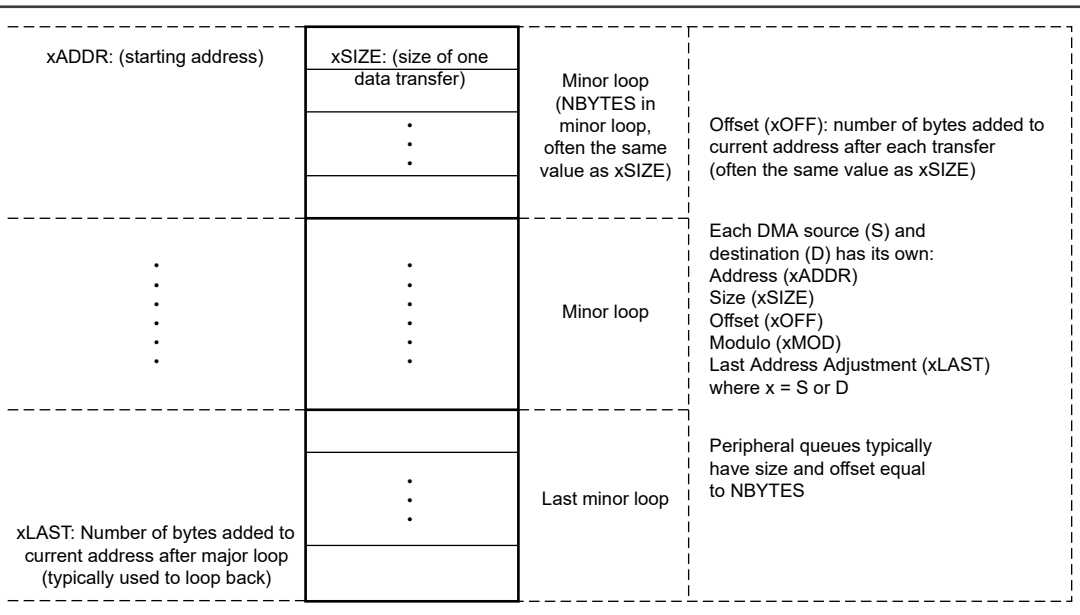

Figure 301. Memory array terms

71.5.2 eDMA arbitration

The eDMA uses a layered arbitration scheme composed of multiple priority levels. The eDMA uses a fixed-priority arbitration scheme with optional round-robin arbitration under specific conditions. The priorities are evaluated in the following order:

Table 697. eDMA arbitration priorities

Priority	Scheme	Description
1 (Highest)	Arbitration group priority	Each channel is assigned an arbitration group via the CHn_GRPRI registers. Priority is given to the highest value (31 being the highest possible value) down to the lowest value (zero, the default).
2	Channel priority	Each channel is assigned a channel priority level via the CHn_PRI registers. The channel priority is a relative priority level within an arbitration group. Priority is given to the highest value (seven being the highest possible value) down to the lowest value (zero, the default). Channel priorities within each arbitration group need not be unique. If multiple channels have the same channel priority level, the channel number will be used to determine priority as defined in row three.
3	Channel number	When two or more channels have the same arbitration group priority and channel priority, the channel number (CHn_NUM) is used to determine the highest priority. Priority is given to the highest channel number. Lowest priority is channel 0. The channel numbers are static and cannot be changed in the programmer's model.
4 (Lowest)	Round-robin	When round-robin is enabled, any channel configured for round-robin operation has lowest priority within an arbitration group. Round-robin is enabled by setting the MP_CSR[ERCA] field to 1. After being enabled, channels with a channel priority of zero (CHn_PRI=0) will use round-robin arbitration. Round-robin arbitration will rotate the channel selection among the channels requesting service with CHn_PRI=0 within the arbitration group. Any non-zero channel within the arbitration group will continue to use fixed-priority arbitration, and if requesting service will be selected over any round-robin channels.

For fixed arbitration, the overall priority can be considered a number composed of three concatenated priority levels: CHn_GRPRI:CHn_PRI:CH_NUM. The largest number has the highest priority and the lowest number has the lowest priority.

For round-robin arbitration, the priority number is CHn_GRPRI:0:X. The module rotates through the CHn_PRI=0 channels requesting service without regard to priority among these channels. Any channel within the arbitration group for which CHn_PRI is greater than 0 will be serviced before the round-robin channels.

71.5.3 Programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data.

The channel number causing the error is recorded in the Error Status register (CHn_ES). If the error source is not removed before the next activation of the problematic channel, the error is detected and recorded again. Setting the halt after error field, CSR[HAE], will halt the DMA and prevent recurrence of the error.

71.5.4 Arbitration mode considerations

This section discusses arbitration considerations for eDMA.

71.5.4.1 Fixed group arbitration, fixed channel arbitration

In this mode, eDMA selects for execution the channel service request from the highest-priority channel in the highest-priority group. If eDMA is programmed so that the channels within a high-priority group have a high number of requests or large data transfers, that group may consume all the bandwidth of the eDMA controller. That is, no lower-priority groups are serviced if there is always at least one DMA request pending on a channel in the highest-priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly.

71.5.4.2 Fixed group arbitration, round-robin channel arbitration

The highest-priority group with a request is serviced. Lower-priority groups are serviced if no pending requests exist in the higher-priority groups.

Within each group, channels are serviced starting with the highest non-zero channel priority. For all channels with a channel priority programmed to 0, selection begins with the highest channel number requesting service and then rotates through to the lowest channel number requesting service. The round-robin channel arbitration can provide a fairness mechanism to lower-priority channels.

This scenario could cause the same bandwidth consumption problem as indicated in Fixed group arbitration, fixed channel arbitration, but all the channels in the highest-priority group will be serviced. Service latency is short on the highest-priority group, but could potentially be very much longer as the group priority decreases.

71.5.5 Performing DMA transfers

This section presents examples on how to perform DMA transfers with the eDMA.

71.5.5.1 Single request

To perform a simple transfer of n bytes of data with one activation, set the major loop to one (TCD*n*_CITER = TCD*n*_BITER = 1). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the CH*n*_CSR[DONE] field is set to 1 and an interrupt is generated if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop transferring 16 bytes per iteration. The source memory has a byte-wide memory port located at 0x1000. The destination memory has a 32-bit port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source, and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```
TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
```

```
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA= -16
TCDn_CSR[INTMAJ] = 1
TCDn_CSR[START] = 1 (should be written last after all other fields have been initialized)
All other TCDn fields = 0
```

This generates the following event sequence:

1. User write to the TCD*n*_CSR[START] field requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes:
   - CH*n*_CSR[DONE] = 0
   - TCD*n*_CSR[START] = 0
   - CH*n*_CSR[ACTIVE] = 1
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
   a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
   b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
   c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
   d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
   e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
   f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
   g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
   h. Write 32 bits to location 0x200C → last iteration of the minor loop → major loop complete.
6. The eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 1 (TCD*n*_BITER).
7. The eDMA engine writes: CH*n*_CSR[ACTIVE] = 0, CH*n*_CSR[DONE] = 1, CH*n*_INT[INT] = 1.
8. The channel retires and the eDMA goes idle or services the next channel.

71.5.5.2 Multiple requests

The following example transfers 32 bytes via two hardware requests, but is otherwise the same as the previous example. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop, transferring 16 bytes per iteration. After the channel's hardware requests are enabled via the CHn_CSR[ERQ] register field, the target device initiates channel service requests.

```
TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32
```

This would generate the following sequence of events:

1. First hardware (eDMA peripheral) requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: CH*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, CH*n*_CSR[ACTIVE] = 1.

4. eDMA engine reads: channel TCD*n* data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
    a. Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
    b. Write 32 bits to location 0x2000 → first iteration of the minor loop.
    c. Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
    d. Write 32 bits to location 0x2004 → second iteration of the minor loop.
    e. Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
    f. Write 32 bits to location 0x2008 → third iteration of the minor loop.
    g. Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
    h. Write 32 bits to location 0x200C → last iteration of the minor loop.
6. eDMA engine writes: TCD*n*_SADDR = 0x1010, TCD*n*_DADDR = 0x2010, TCD*n*_CITER = 1.
7. eDMA engine writes: CH*n*_CSR[ACTIVE] = 0.
8. The channel retires, which concludes one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware (eDMA peripheral) requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: CH*n*_CSR[DONE] = 0, TCD*n*_CSR[START] = 0, CH*n*_CSR[ACTIVE] = 1.
12. eDMA engine reads: Channel TCD data from local memory to internal register file.
13. The source-to-destination transfers are executed as follows:
    a. Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
    b. Write 32 bits to location 0x2010 → first iteration of the minor loop.
    c. Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
    d. Write 32 bits to location 0x2014 → second iteration of the minor loop.
    e. Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
    f. Write 32 bits to location 0x2018 → third iteration of the minor loop.
    g. Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
    h. Write 32 bits to location 0x201C → last iteration of the minor loop → major loop complete.
14. eDMA engine writes: TCD*n*_SADDR = 0x1000, TCD*n*_DADDR = 0x2000, TCD*n*_CITER = 2 (TCD*n*_BITER).
15. eDMA engine writes: CH*n*_CSR[ACTIVE] = 0, CH*n*_CSR[DONE] = 1, CH*n*_INT[INT] = 1.
16. The channel retires, which concludes with the major loop complete. The eDMA goes idle or services the next channel.

71.5.5.3 Using the modulo feature

The modulo feature of the eDMA allows implementation of a circular data queue in which the size of the queue is a power of 2. xMOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature. Modulo addressing applies to cases where the minor loop offset is enabled; that is, the upper address bits remain the same after the minor loop offset is added to the source or destination address.

The following table shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value but the 28 upper address bits (0x1234567*x*) retain their original value. In this example, the source address is set to 0x12345670, the offset is set to four bytes, and the MOD field is set to four, which allows for a 2^4 byte (16 byte) queue size.

Table 698. Modulo example

Transfer number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670
6	0x12345674

71.5.6 Monitoring transfer descriptor status

This section discusses how to monitor eDMA status.

71.5.6.1 Testing for minor loop completion

There are two methods to test for minor loop completion when using software-initiated service requests.

1. The first method is to read the TCDn_CITER field and test for a change.
2. The second method, extracted from the sequence shown below, is to test the TCDn_CSR[START] field and the CHn_CSR[ACTIVE] field. The minor-loop-complete condition is indicated by both fields reading 0 after TCDn_CSR[START] is set to 1. Polling the CHn_CSR[ACTIVE] field only may be inconclusive because the active status may be missed if the channel execution is short in duration.

The CHn_CSR and TCDn_CSR status fields execute the following sequence for a software-activated channel:

Stage	TCDn_CSR field	CHn_CSR fields		State
	START	ACTIVE	DONE	
1	1	0	0	Initiate channel service request via software.
2	0	1	0	Channel is executing.
3a	0	0	0	Channel has completed the minor loop and is idle.
3b	0	0	1	Channel has completed the major loop and is idle.

The best method to test for minor-loop completion when using hardware-initiated (that is, peripheral-initiated) service requests is to read the TCDn_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status fields execute the following sequence for a hardware-activated channel:

Stage	TCDn_CSR field	CHn_CSR fields		State
	START	ACTIVE	DONE	
1	0	0	0	Initiate channel service request via hardware (peripheral request asserted).
2	0	1	0	Channel is executing.
3a	0	0	0	Channel has completed the minor loop and is idle.
3b	0	0	1	Channel has completed the major loop and is idle.

For both activation types, the major-loop-complete status is explicitly indicated via the CHn_CSR[DONE] field.

The TCDn_CSR[START] field is cleared to 0 automatically when the channel begins execution, regardless of how the channel activates.

71.5.6.2 Reading the transfer descriptors of active channels

The eDMA reads back the true TCDn_SADDR, TCDn_DADDR, and TCDn_NBYTES values if they are read when a channel executes. The true values of SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file, and not the values in the TCD local memory for that channel. The addresses, SADDR and DADDR, and NBYTES (which decrements to zero as the transfer progresses), can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

71.5.6.3 Checking channel preemption status

A preemptive situation is one in which a preempt-enabled channel is executing and a higher-priority request becomes active. When round-robin channel arbitration mode is enabled, all channels with their channel priority set to 0 lose their preempt ability. Channel priorities of 0 are treated as equal, that is, they are constantly rotating, when round-robin arbitration mode is enabled.

The CHn_CSR[ACTIVE] field for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended when the preempting channel executes one major loop iteration. If two CHn_CSR[ACTIVE] fields are set simultaneously in the global TCD map, a higher-priority channel is actively preempting a lower-priority channel.

71.5.7 Channel linking

Channel linking (or chaining) is a mechanism in which one channel sets the TCDn_CSR[START] field of another channel (or itself), thus initiating a service request for that channel. When properly enabled, the eDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCDn_CITER[ELINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, using an initial field setting of:

```
MP_CSR[GCLC] = 1
TCDn_CITER[ELINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJORELINK] = 1
TCDn_CSR[MAJORLINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12_CSR[START] field
2. Minor loop done → set TCD12_CSR[START] field
3. Minor loop done → set TCD12_CSR[START] field
4. Minor loop done, major loop done→ set TCD7_CSR[START] field

When minor loop linking is enabled (TCDn_CITER[ELINK] = 1), the TCDn_CITER[CITER] field uses a nine-bit vector to form the current iteration count. When minor loop linking is disabled (TCDn_CITER[ELINK] = 0), the TCDn_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCDn_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

NOTE

The TCDn_CITER[ELINK] field and the TCDn_BITER[ELINK] field must be equal — if they are not, a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop halfway done interrupt point.

The following table summarizes how a DMA channel can link to another DMA channel, that is, use another channel's TCD, at the end of a loop.

Table 699. Channel linking parameters

Wanted link behavior	TCD control field name	Description
Link at end of minor loop	TCDn_CITER[ELINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	TCDn_CITER[LINKCH]	Link channel number when linking at end of minor loop (current iteration)
Link at end of major loop	TCDn_CSR[MAJORELINK]	Enable channel-to-channel linking on major loop completion
	TCDn_CSR[MAJORLINKCH]	Link channel number when linking at end of major loop

71.5.8 Dynamic programming

This section provides recommended methods to change the programming model during channel execution.

Steps for channel linking:

1. Set GCLC = 1
2. For linking after major loop complete:
   a. Set MAJORLINKCH = target channel number
   b. Set MAJORELINK = 1, enable the major loop link
   c. Upon major loop completion (CITER decrements to 0), the link will be made.
3. For linking on minor loop completion:
   a. Set LINKCH = target channel number
   b. Set ELINK = 1, enable the minor loop link
   c. Set the beginning iteration count to the same values; LINKCH = target channel and ELINK = 1,
   d. Upon minor loop completion (that is, after each service request except when the major loop is complete) the link will be made.

71.5.8.1 Dynamically changing the channel priority

To change group or channel priority levels:

1. Halt the DMA by writing 1 to the CSR[HALT] field.
2. Change the group or channel priorities as wanted.
3. Enable normal DMA operations by writing 0 to the CSR[HALT] field.

71.5.8.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCDn_CSR[MAJORELINK] field during channel execution (see the diagram in TCD structure). This field is read from the TCD local memory at the end of channel execution, thus allowing you to enable the feature during channel execution.

Because you are allowed to change the configuration during execution, you need a coherency model. Consider the scenario where you attempt to execute a dynamic channel link by enabling the TCDn_CSR[MAJORELINK] field at the same time the eDMA engine is retiring the channel. TCDn_CSR[MAJORELINK] would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

We recommend that you use the following coherency model when executing a dynamic channel link request.

1. Write 1 to the TCDn_CSR[MAJORELINK] field.
2. Read back the TCDn_CSR[MAJORELINK] field.
3. Test the TCDn_CSR[MAJORELINK] request status:
   - If TCDn_CSR[MAJORELINK] = 1, the dynamic link attempt was successful.
   - If TCDn_CSR[MAJORELINK] = 0, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCDn_CSR[MAJORELINK] field to 0 on any writes to a channel's TCDn_CSR[7:0] after that channel's CHn_CSR[DONE] field is set to 1, indicating the major loop is complete.

NOTE

You must clear the CHn_CSR[DONE] field to 0 before writing to the TCDn_CSR[MAJORELINK] field. The CHn_CSR[DONE] field is cleared to 0 automatically by the eDMA engine after a channel begins execution.

71.5.8.3 Dynamic scatter/gather

Scatter/gather is the process of automatically loading a new TCD into a channel. It allows a DMA channel to use multiple TCDs; this enables a DMA channel to scatter the DMA data to multiple destinations or gather it from multiple sources. When scatter/gather is enabled and the channel has finished its major loop, a new TCD is fetched from system memory and loaded into that channel's descriptor location in the eDMA programmer's model, thus replacing the current descriptor.

Because you are allowed to change the configuration during execution, you need a coherency model. Consider the scenario where you attempt to execute a dynamic scatter/gather operation by enabling the TCDn_CSR[ESG] field at the same time the eDMA engine is retiring the channel. The TCDn_CSR[ESG] field would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods are recommended for executing a dynamic scatter/gather request. Whenever the TCDn_CSR is written, the TCD local memory controller forces the TCDn_CSR[ESG] field to 0 on any writes to a channel's TCDn_CSR[7:0] after that channel's CHn_CSR[DONE] field has been set to 1, indicating the major loop is complete. If attempting to set the ESG, ensure the DONE field is cleared to 0.

NOTE

You must clear the CHn_CSR[DONE] field to 0 before writing the TCDn_CSR[ESG] or TCDn_CSR[ESG] fields. The CHn_CSR[DONE] field is cleared to 0 automatically by the eDMA engine after a channel begins execution and is set to 1 upon major loop completion.

71.5.8.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request.

When the TCDn_CSR[MAJORELINK] field is 0, the TCDn_CSR[MAJORLINKCH] field is not used by the eDMA. In this case, the TCDn_CSR[MAJORLINKCH] bits may be used for other purposes. This method uses the TCDn_CSR[MAJORLINKCH] field as a TCDn_CSR identification (ID).

When the descriptors are built, write a unique TCDn_CSR ID in the TCDn_CSR[MAJORLINKCH] field for each TCDn_CSR associated with a channel using dynamic scatter/gather.

1. Write a 1 to the TCDn_CSR[DREQ] field. Should a dynamic scatter/gather attempt fail, setting the TCDn_CSR[DREQ] field to 1 will prevent future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST final offset value.
2. Write the TCDn_DLAST_SGA field with the scatter/gather address.
3. Write a 1 to the TCDn_CSR[ESG] field.
4. Read back the 16-bit TCDn_CSR control/status field.
5. Test the TCDn_CSR[ESG] request status and TCDn_CSR[MAJORLINKCH] value:
   - If ESG = 1, the dynamic scatter/gather attempt was successful.
   - If ESG = 0 and the MAJORLINKCH (ID) did not change, the dynamic scatter/gather attempt was not successful (the channel was already retiring).
   - If ESG = 0 and the MAJORLINKCH (ID) changed, the dynamic scatter/gather attempt was successful (the new TCDn_CSR's ESG value cleared the ESG field to 0).

71.5.8.3.2 Method 2 (channel using major loop channel linking)

For a channel using major loop channel linking, the coherency model described here may be used for a dynamic scatter/gather request. This method uses the TCDn_DLAST_SGA field as a TCD identification (ID).

1. Write a 1 to the TCDn_CSR[DREQ] field. Should a dynamic scatter/gather attempt fail, setting the DREQ field to 1 will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (DADDR) that was calculated using a scatter/gather address (written in the next step) instead of a DLAST final offset value.
2. Write the TCDn_DLAST_SGA field with the scatter/gather address.
3. Write a 1 to the TCDn_CSR[ESG] field.
4. Read back the TCDn_CSR[ESG] field.
5. Test the TCDn_CSR[ESG] request status:
   - If ESG = 1, the dynamic scatter/gather attempt was successful.
   - If ESG = 0, read the 32-bit TCDn_DLAST_SGA field.
   - If ESG = 0 and the TCDn_DLAST_SGA did not change, the dynamic scatter/gather attempt was not successful (the channel was already retiring).
   - If ESG = 0 and the TCDn_DLAST_SGA changed, the dynamic scatter/gather attempt was successful (the new TCDn_CSR's ESG value cleared the ESG field to 0).

71.5.9 Lockstep

This chip contains an eDMA Checker which, when enabled, operates in Lockstep mode with the primary eDMA, executing the exact same transfer profiles. The eDMA Checker checks to ensure the primary eDMA is operating correctly. A block diagram is shown below.

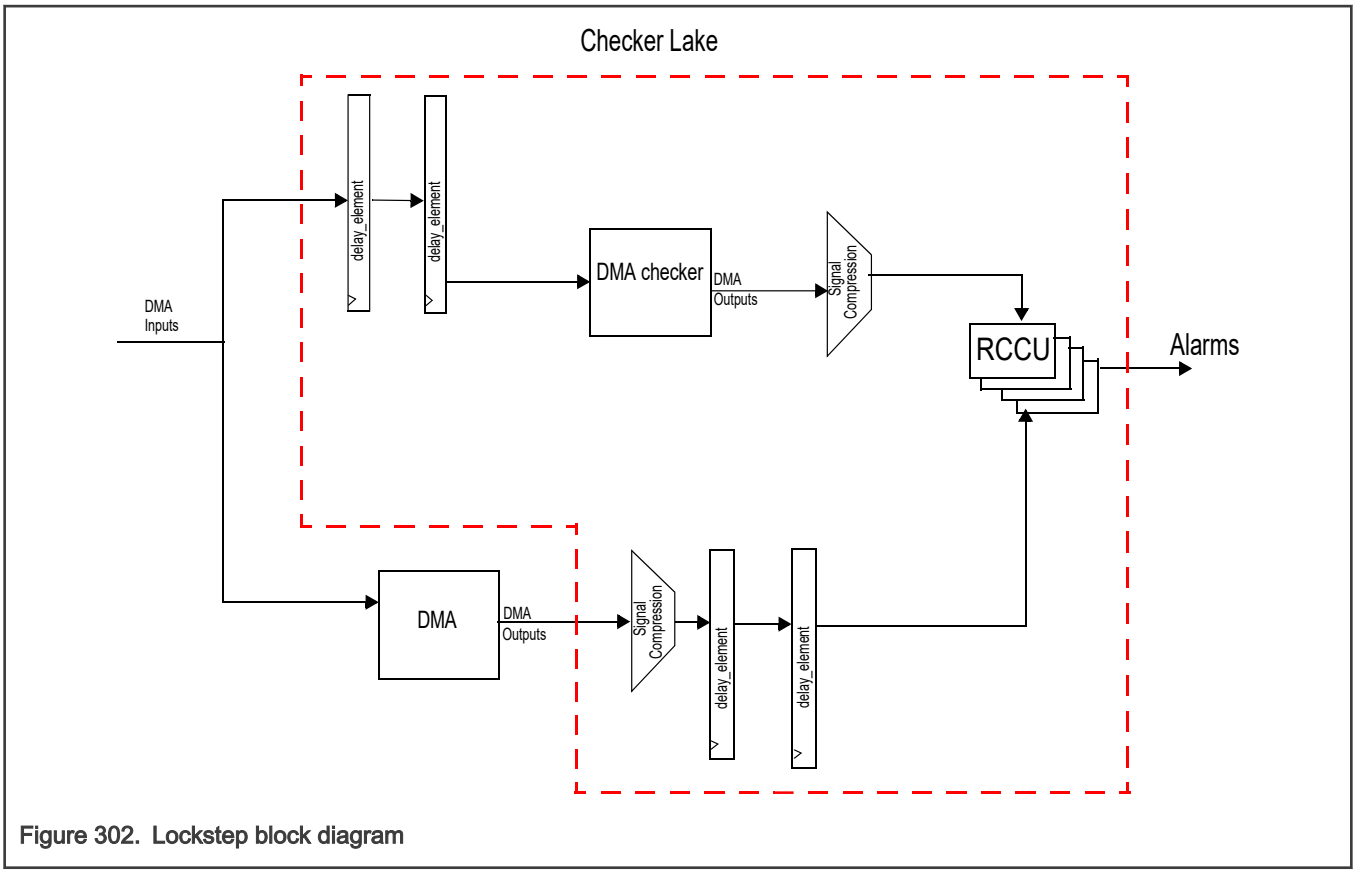

Figure 302. Lockstep block diagram

Initialization

To prevent the eDMA Checker from generating a false comparison error after power-on-reset, the eDMA's data output buffer must be initialized prior to enabling the Checker. To initialize the eDMA data output buffer, the eDMA must perform one or more 32-bit data transfers using any data value.

Errors

To handle source-address errors (SAE), perform the following steps.

1. Fix the addressing error.
2. Clear the ERR bit in the appropriate Channel Error Status (CH0_ES - CH15_ES). Management Page Error Status (MP_ES) indicates the presence, location, and type of the last recorded channel error.
3. Start the channel in a normal fashion.

71.5.10 Suspend/resume a DMA channel with active hardware service requests

The DMA allows you to move data from memory or peripheral registers to another location in memory or to peripheral registers without CPU interaction. After the DMA and peripherals are configured and active, it is rare but supported to suspend a peripheral's service request dynamically. In this scenario, there are certain restrictions to disabling a DMA hardware service request. For coherency, you must follow a specific procedure.

71.5.10.1 Suspend an active DMA channel

To suspend an active DMA channel:

1. Stop the DMA service request at the peripheral first. Confirm it has been disabled by reading back the appropriate register in the peripheral.

2. Check the DMA's Hardware Request Status (MP_HRS) to ensure there is no service request to the DMA channel being suspended. Then disable the hardware service request by clearing the ERQ field to 0 on the appropriate DMA channel.

For example, assume the SPI is set as a initiator for transmitting data via a DMA service request when the TXFIFO has an empty slot. The DMA will transfer the next command and data to the TXFIFO upon the request. If you need to suspend the DMA/SPI transfer loop, perform the following steps:

1. Disable the DMA service request at the SPI.
2. Ensure there is no DMA service request from the SPI by verifying that MP_HRS[HRS] is 0 for the appropriate channel. If no service request is present, disable the DMA channel by clearing the channel's ERQ field to 0. If a service request is present, wait until the request has been processed and the HRS field reads 0.

71.5.10.2 Resume a DMA channel

To resume a DMA channel:

1. Enable the DMA service request on the appropriate channel by setting its ERQ field to 1.
2. Enable the DMA service request at the peripheral.

71.6 Memory map and register definition

The eDMA programming model is partitioned into three parts:

1. The first part defines a number of registers providing overall control functions and is known as the management page.
2. The second part corresponds to the channel (CH) control, status, and configuration.
3. The third part corresponds to the local TCD memory.

TCD memory

Each channel requires a 32-byte transfer control descriptor for defining the data movement operation. Each TCDn definition is presented as 11 registers of 16 or 32 bits. See EDMA_TCD register descriptions for details.

TCD initialization

Prior to activating a channel, you must initialize its TCD with the appropriate transfer profile.

TCD structure

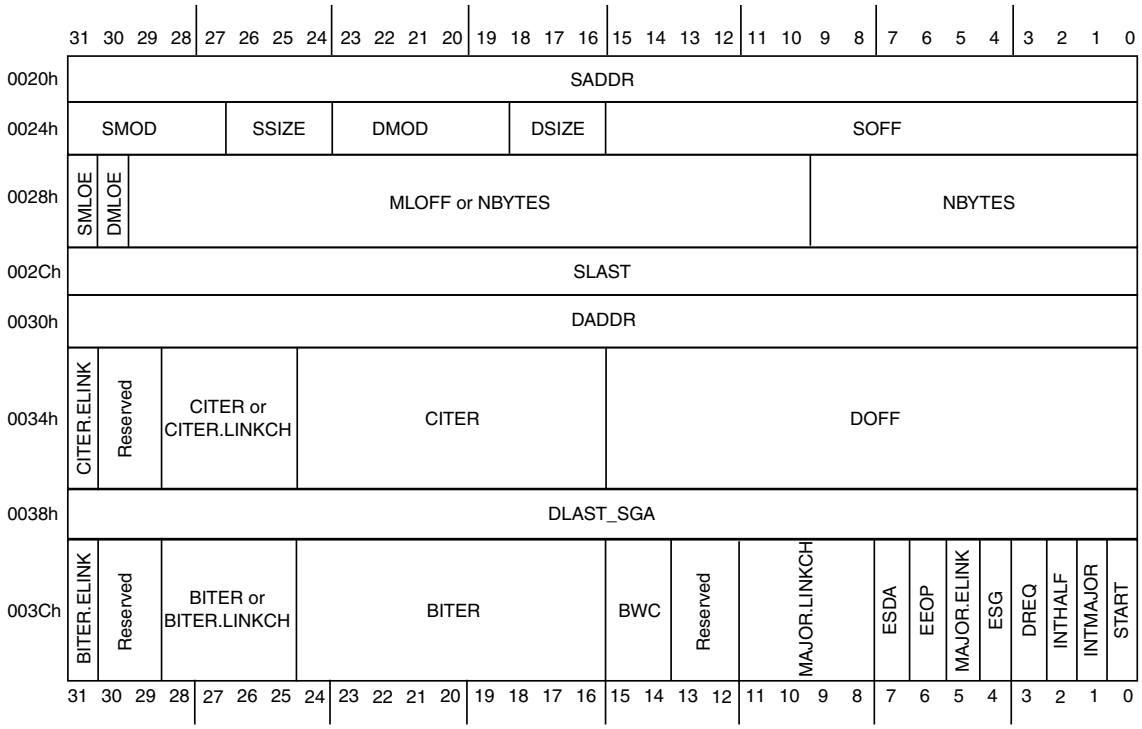

Figure 303. TCD structure

Accesses to reserved memory and fields

- Reading reserved fields in a register returns the value of zero.
- Writes to reserved fields in a register are ignored.
- Reading or writing a reserved memory location generates a bus error.

71.6.1 EDMA_MP register descriptions

71.6.1.1 EDMA_MP memory map

DMA0 base address: 4014_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Management Page Control (MP_CSR)	32	RW	0031_0000h
4h	Management Page Error Status (MP_ES)	32	R	0000_0000h
8h	Management Page Interrupt Request Status (MP_INT)	32	R	0000_0000h
Ch	Management Page Hardware Request Status (MP_HRS)	32	R	0000_0000h
100h - 13Ch	Channel Arbitration Group (CH0_GRPRI - CH15_GRPRI)	32	RW	0000_0000h

71.6.1.2 Management Page Control (MP_CSR)

Offset

Register	Offset
MP_CSR	0h

Function

The Management Page Control register defines the basic operating configuration of the DMA.

Arbitration uses a two-tier priority system; group and channel priority. The eDMA assigns each channel to a priority group. Group arbitration is fixed-priority and cannot be changed. Channel arbitration uses fixed priority and may be configured to use a selective round-robin scheme for specified channels within each priority group. For fixed-priority arbitration, eDMA selects for execution the highest priority channel requesting service in the highest priority arbitration group.

The channel priority registers assign the relative priorities within each arbitration group; see CHn_PRI. All channels with a non-zero CHn_PRI value use fixed-priority arbitration.

When you enable round-robin arbitration, all channels with channel priority set to zero do not have a priority and, of those channels requesting service, are cycled through (from high to low channel number) without regard to priority relative to each other within the same priority group. Any channel with a non-zero CHn_PRI value automatically has a higher priority over the round-robin channels. A channel's priority group is assigned in Channel Arbitration Group (CH0_GRPRI - CH15_GRPRI).

NOTE

For correct operation, changes to the MP_CSR[ERCA, GCLC, GMRC] fields must be performed when the DMA channels are inactive; that is, when the MP_CSR[ACTIVE] field is 0.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31 ACTIVE	DMA Active Status 0b - eDMA is idle 1b - eDMA is executing a channel

Table continues on the next page...

Table continued from the previous page...

Field	Function
30-28 —	Reserved
27-24 ACTIVE_ID	Active Channel ID This field identifies the channel number that is executing when the ACTIVE bit is 1.
23-16 —	Reserved
15-10 —	Reserved
9 CX	Cancel Transfer When set to 1, this field cancels the remaining data transfer, stops the executing channel, and forces the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. CX clears itself to 0 after the cancel has been honored. This cancel retires the channel normally as if the minor loop had been completed. 0b - Normal operation 1b - Cancel the remaining data transfer
8 ECX	Cancel Transfer With Error Cancellation of the remaining data transfer is similar to that of the CX field. Execution of the channel is stopped and the minor loop is forced to finish. The cancellation takes effect after the last write of the current read/write sequence. The ECX field clears itself to 0 after the cancel is honored. In addition to cancelling the transfer, ECX treats the cancel as an error condition, thus updating Management Page Error Status (MP_ES) and generating an optional error interrupt. 0b - Normal operation 1b - Cancel the remaining data transfer
7 GMRC	Global Initiator ID Replication Control **NOTE** If initiator ID replication is disabled, the nonsecure, privileged protection level for DMA transfers is used. 0b - Initiator ID replication disabled for all channels 1b - Initiator ID replication available and controlled by each channel's CHn_SBR[EMI] setting
6 GCLC	Global Channel Linking Control 0b - Channel linking disabled for all channels 1b - Channel linking available and controlled by each channel's link settings
5	Halt DMA Operations

Table continues on the next page...

Table continued from the previous page...

Field	Function
HALT	This field stalls the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this field is cleared to 0. 0b - Normal operation 1b - Stall the start of any new channels
4 HAE	Halt After Error When this field is set to 1, any error causes the HALT field to be set to 1. Then all service requests are ignored until the HALT field is cleared to 0. 0b - Normal operation 1b - Any error causes the HALT field to be set to 1
3 —	Reserved
2 ERCA	Enable Round Robin Channel Arbitration 0b - Round-robin channel arbitration disabled. Fixed priority arbitration used for channel selection 1b - Round-robin channel arbitration enabled. Round-robin arbitration used for channel selection
1 EDBG	Enable Debug When in debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. DMA resumes channel execution when the system exits debug mode or clears the EDBG field to 0. 0b - Debug mode disabled. When in debug mode, the DMA continues to operate 1b - Debug mode is enabled. When in debug mode, the DMA stalls the start of a new channel
0 —	Reserved

71.6.1.3 Management Page Error Status (MP_ES)

Offset

Register	Offset
MP_ES	4h

Function

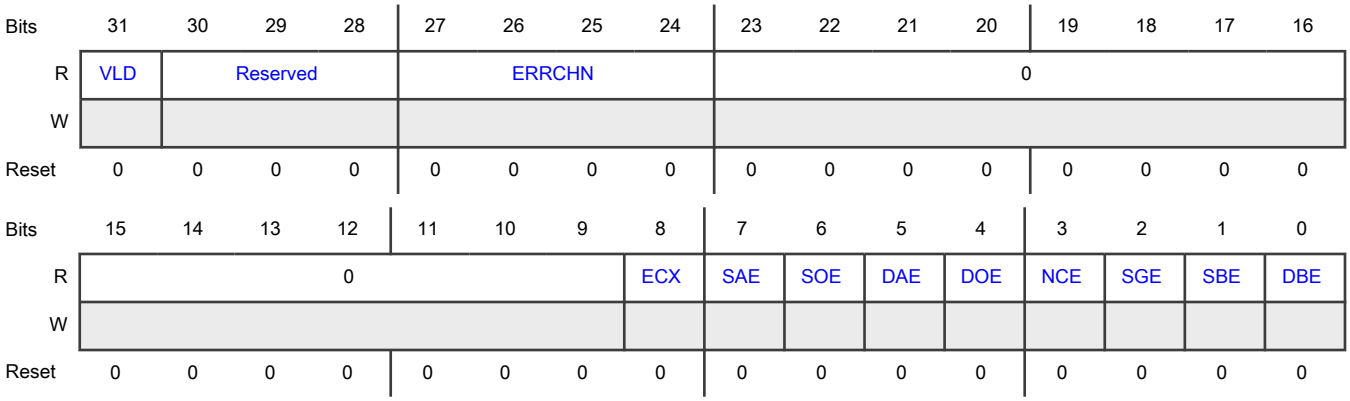
The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor
- An error termination to a bus initiator read or write cycle
- An uncorrectable error that occurred when the device was accessing the TCD SRAM

- A "cancel transfer with error" request was made via the corresponding cancel transfer field or input signal

Upon any error condition, the software must initialize the TCD of the channel that contains the error, as it is in an incomplete state after an error. See Fault reporting and handling for more details.

Diagram



Fields

Field	Function
31 VLD	Valid Logical OR of all CHn_ES[ERR] status fields. 0b - No CHn_ES[ERR] fields are set to 1 1b - At least one CHn_ES[ERR] field is set to 1, indicating a valid error exists that software has not cleared
30-28 —	Reserved
27-24 ERRCHN	Error Channel Number or Canceled Channel Number The channel number of the last recorded error or last recorded error-canceled transfer.
23-9 —	Reserved
8 ECX	Transfer Canceled The ECX operation is a management page function. When employed, the targeted channel's CHn_ES register reports an unspecified error; that is, only the CHn_ES[ERR] field is set to 1. The management page has full view of the error condition. 0b - No canceled transfers 1b - Last recorded entry was a canceled transfer by the error cancel transfer input
7 SAE	Source Address Error When this field is 1, it indicates that TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No source address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SADDR field
6 SOE	Source Offset Error When this field is 1, it indicates that TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SOFF field
5 DAE	Destination Address Error When this field is 1, it indicates that TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DADDR field
4 DOE	Destination Offset Error When this field is 1, it indicates that TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DOFF field
3 NCE	NBYTES/CITER Configuration Error This error indicates that one of the following has occurred: • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE] • TCDn_CITER[CITER] is equal to zero • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK] 0b - No NBYTES/CITER configuration error 1b - The last recorded error was NBYTES equal to zero or a CITER not equal to BITER error. Last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields
2 SGE	Scatter/Gather Configuration Error When this field is 1, it indicates that TCDn_DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG] is enabled. 0b - No scatter/gather configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DLAST_SGA field
1 SBE	Source Bus Error 0b - No source bus error 1b - Last recorded error was a bus error on a source read
0	Destination Bus Error

71.6.2.2 Management Page Control (MP_CSR)

Offset

Register	Offset
MP_CSR	0h

Function

The Management Page Control register defines the basic operating configuration of the DMA.

Arbitration uses a two-tier priority system; group and channel priority. The eDMA assigns each channel to a priority group. Group arbitration is fixed-priority and cannot be changed. Channel arbitration uses fixed priority and may be configured to use a selective round-robin scheme for specified channels within each priority group. For fixed-priority arbitration, eDMA selects for execution the highest priority channel requesting service in the highest priority arbitration group.

The channel priority registers assign the relative priorities within each arbitration group; see CHn_PRI. All channels with a non-zero CHn_PRI value use fixed-priority arbitration.

When you enable round-robin arbitration, all channels with channel priority set to zero do not have a priority and, of those channels requesting service, are cycled through (from high to low channel number) without regard to priority relative to each other within the same priority group. Any channel with a non-zero CHn_PRI value automatically has a higher priority over the round-robin channels. A channel's priority group is assigned in Channel Arbitration Group (CH0_GRPRI - CH15_GRPRI).

NOTE

For correct operation, changes to the MP_CSR[ERCA, GCLC, GMRC] fields must be performed when the DMA channels are inactive; that is, when the MP_CSR[ACTIVE] field is 0.

Diagram

Fields

Field	Function
31 ACTIVE	DMA Active Status 0b - eDMA is idle 1b - eDMA is executing a channel

Table continues on the next page...

Table continued from the previous page...

Field	Function
30-28 —	Reserved
27-24 ACTIVE_ID	Active Channel ID This field identifies the channel number that is executing when the ACTIVE bit is 1.
23-16 —	Reserved
15-10 —	Reserved
9 CX	Cancel Transfer When set to 1, this field cancels the remaining data transfer, stops the executing channel, and forces the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. CX clears itself to 0 after the cancel has been honored. This cancel retires the channel normally as if the minor loop had been completed. 0b - Normal operation 1b - Cancel the remaining data transfer
8 ECX	Cancel Transfer With Error Cancellation of the remaining data transfer is similar to that of the CX field. Execution of the channel is stopped and the minor loop is forced to finish. The cancellation takes effect after the last write of the current read/write sequence. The ECX field clears itself to 0 after the cancel is honored. In addition to cancelling the transfer, ECX treats the cancel as an error condition, thus updating Management Page Error Status (MP_ES) and generating an optional error interrupt. 0b - Normal operation 1b - Cancel the remaining data transfer
7 GMRC	Global Initiator ID Replication Control **NOTE** If initiator ID replication is disabled, the nonsecure, privileged protection level for DMA transfers is used. 0b - Initiator ID replication disabled for all channels 1b - Initiator ID replication available and controlled by each channel's CHn_SBR[EMI] setting
6 GCLC	Global Channel Linking Control 0b - Channel linking disabled for all channels 1b - Channel linking available and controlled by each channel's link settings
5	Halt DMA Operations

Table continues on the next page...

Table continued from the previous page...

Field	Function
HALT	This field stalls the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this field is cleared to 0. 0b - Normal operation 1b - Stall the start of any new channels
4 HAE	Halt After Error When this field is set to 1, any error causes the HALT field to be set to 1. Then all service requests are ignored until the HALT field is cleared to 0. 0b - Normal operation 1b - Any error causes the HALT field to be set to 1
3 —	Reserved
2 ERCA	Enable Round Robin Channel Arbitration 0b - Round-robin channel arbitration disabled. Fixed priority arbitration used for channel selection 1b - Round-robin channel arbitration enabled. Round-robin arbitration used for channel selection
1 EDBG	Enable Debug When in debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. DMA resumes channel execution when the system exits debug mode or clears the EDBG field to 0. 0b - Debug mode disabled. When in debug mode, the DMA continues to operate 1b - Debug mode is enabled. When in debug mode, the DMA stalls the start of a new channel
0 —	Reserved

71.6.2.3 Management Page Error Status (MP_ES)

Offset

Register	Offset
MP_ES	4h

Function

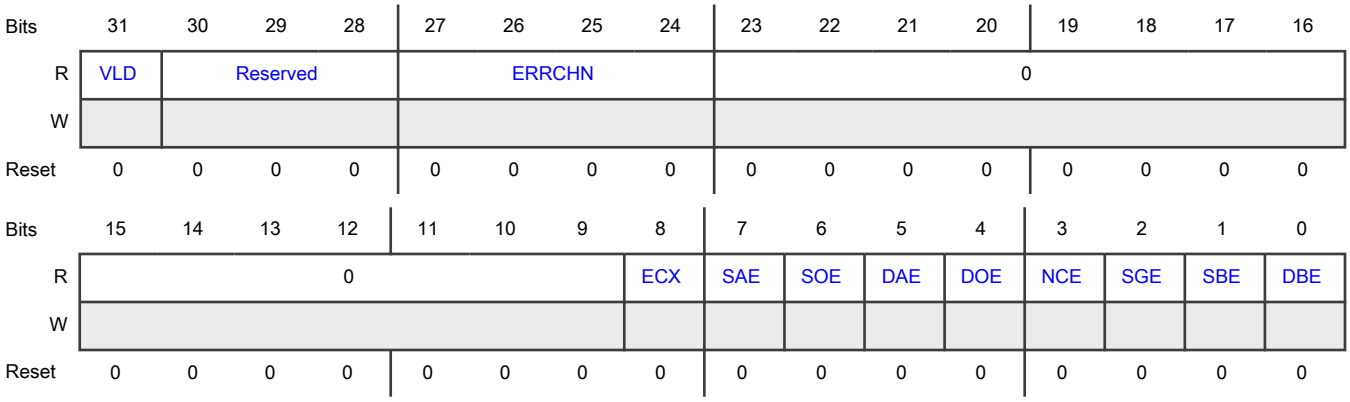
The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor
- An error termination to a bus initiator read or write cycle
- An uncorrectable error that occurred when the device was accessing the TCD SRAM

- A "cancel transfer with error" request was made via the corresponding cancel transfer field or input signal

Upon any error condition, the software must initialize the TCD of the channel that contains the error, as it is in an incomplete state after an error. See Fault reporting and handling for more details.

Diagram



Fields

Field	Function
31 VLD	Valid Logical OR of all CHn_ES[ERR] status fields. 0b - No CHn_ES[ERR] fields are set to 1 1b - At least one CHn_ES[ERR] field is set to 1, indicating a valid error exists that software has not cleared
30-28 —	Reserved
27-24 ERRCHN	Error Channel Number or Canceled Channel Number The channel number of the last recorded error or last recorded error-canceled transfer.
23-9 —	Reserved
8 ECX	Transfer Canceled The ECX operation is a management page function. When employed, the targeted channel's CHn_ES register reports an unspecified error; that is, only the CHn_ES[ERR] field is set to 1. The management page has full view of the error condition. 0b - No canceled transfers 1b - Last recorded entry was a canceled transfer by the error cancel transfer input
7 SAE	Source Address Error When this field is 1, it indicates that TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE].

71.6.3.2 Management Page Control (MP_CSR)

Offset

Register	Offset
MP_CSR	0h

Function

The Management Page Control register defines the basic operating configuration of the DMA.

Arbitration uses a two-tier priority system; group and channel priority. The eDMA assigns each channel to a priority group. Group arbitration is fixed-priority and cannot be changed. Channel arbitration uses fixed priority and may be configured to use a selective round-robin scheme for specified channels within each priority group. For fixed-priority arbitration, eDMA selects for execution the highest priority channel requesting service in the highest priority arbitration group.

The channel priority registers assign the relative priorities within each arbitration group; see CHn_PRI. All channels with a non-zero CHn_PRI value use fixed-priority arbitration.

When you enable round-robin arbitration, all channels with channel priority set to zero do not have a priority and, of those channels requesting service, are cycled through (from high to low channel number) without regard to priority relative to each other within the same priority group. Any channel with a non-zero CHn_PRI value automatically has a higher priority over the round-robin channels. A channel's priority group is assigned in Channel Arbitration Group (CH0_GRPRI - CH7_GRPRI).

NOTE

For correct operation, changes to the MP_CSR[ERCA, GCLC, GMRC] fields must be performed when the DMA channels are inactive; that is, when the MP_CSR[ACTIVE] field is 0.

71.6.4.2 Management Page Control (MP_CSR)

Offset

Register	Offset
MP_CSR	0h

Function

The Management Page Control register defines the basic operating configuration of the DMA.

Arbitration uses a two-tier priority system; group and channel priority. The eDMA assigns each channel to a priority group. Group arbitration is fixed-priority and cannot be changed. Channel arbitration uses fixed priority and may be configured to use a selective round-robin scheme for specified channels within each priority group. For fixed-priority arbitration, eDMA selects for execution the highest priority channel requesting service in the highest priority arbitration group.

The channel priority registers assign the relative priorities within each arbitration group; see CHn_PRI. All channels with a non-zero CHn_PRI value use fixed-priority arbitration.

When you enable round-robin arbitration, all channels with channel priority set to zero do not have a priority and, of those channels requesting service, are cycled through (from high to low channel number) without regard to priority relative to each other within the same priority group. Any channel with a non-zero CHn_PRI value automatically has a higher priority over the round-robin channels. A channel's priority group is assigned in Channel Arbitration Group (CH0_GRPRI - CH7_GRPRI).

NOTE

For correct operation, changes to the MP_CSR[ERCA, GCLC, GMRC] fields must be performed when the DMA channels are inactive; that is, when the MP_CSR[ACTIVE] field is 0.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 ACTIVE	DMA Active Status 0b - eDMA is idle 1b - eDMA is executing a channel

Table continues on the next page...

Table continued from the previous page...

Field	Function
30-27 —	Reserved
26-24 ACTIVE_ID	Active Channel ID This field identifies the channel number that is executing when the ACTIVE bit is 1.
23-16 —	Reserved
15-10 —	Reserved
9 CX	Cancel Transfer When set to 1, this field cancels the remaining data transfer, stops the executing channel, and forces the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. CX clears itself to 0 after the cancel has been honored. This cancel retires the channel normally as if the minor loop had been completed. 0b - Normal operation 1b - Cancel the remaining data transfer
8 ECX	Cancel Transfer With Error Cancellation of the remaining data transfer is similar to that of the CX field. Execution of the channel is stopped and the minor loop is forced to finish. The cancellation takes effect after the last write of the current read/write sequence. The ECX field clears itself to 0 after the cancel is honored. In addition to cancelling the transfer, ECX treats the cancel as an error condition, thus updating Management Page Error Status (MP_ES) and generating an optional error interrupt. 0b - Normal operation 1b - Cancel the remaining data transfer
7 GMRC	Global Initiator ID Replication Control **NOTE** If initiator ID replication is disabled, the nonsecure, privileged protection level for DMA transfers is used. 0b - Initiator ID replication disabled for all channels 1b - Initiator ID replication available and controlled by each channel's CHn_SBR[EMI] setting
6 GCLC	Global Channel Linking Control 0b - Channel linking disabled for all channels 1b - Channel linking available and controlled by each channel's link settings
5	Halt DMA Operations

Table continues on the next page...

Table continued from the previous page...

Field	Function
HALT	This field stalls the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this field is cleared to 0. 0b - Normal operation 1b - Stall the start of any new channels
4 HAE	Halt After Error When this field is set to 1, any error causes the HALT field to be set to 1. Then all service requests are ignored until the HALT field is cleared to 0. 0b - Normal operation 1b - Any error causes the HALT field to be set to 1
3 —	Reserved
2 ERCA	Enable Round Robin Channel Arbitration 0b - Round-robin channel arbitration disabled. Fixed priority arbitration used for channel selection 1b - Round-robin channel arbitration enabled. Round-robin arbitration used for channel selection
1 EDBG	Enable Debug When in debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. DMA resumes channel execution when the system exits debug mode or clears the EDBG field to 0. 0b - Debug mode disabled. When in debug mode, the DMA continues to operate 1b - Debug mode is enabled. When in debug mode, the DMA stalls the start of a new channel
0 —	Reserved

71.6.4.3 Management Page Error Status (MP_ES)

Offset

Register	Offset
MP_ES	4h

Function

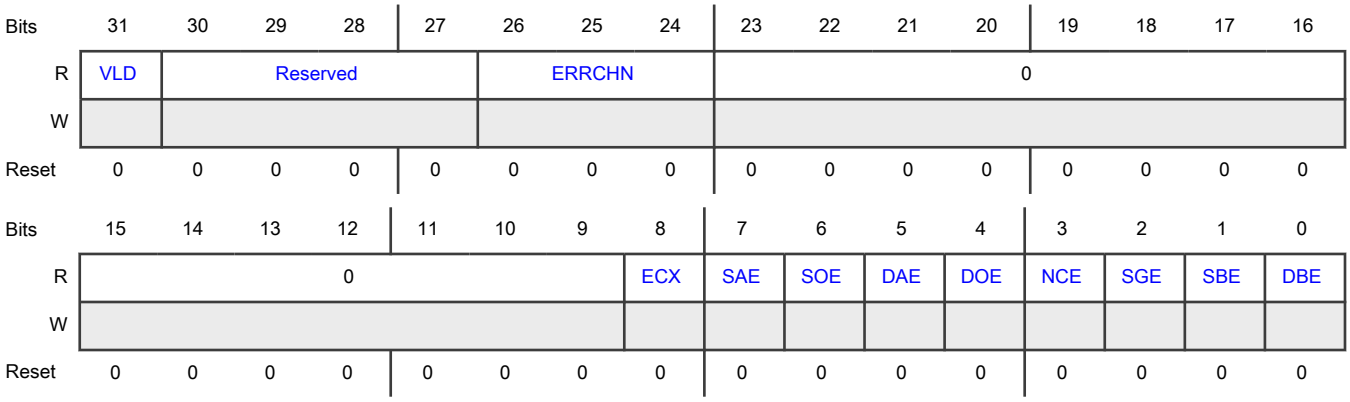
The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor
- An error termination to a bus initiator read or write cycle
- An uncorrectable error that occurred when the device was accessing the TCD SRAM

- A "cancel transfer with error" request was made via the corresponding cancel transfer field or input signal

Upon any error condition, the software must initialize the TCD of the channel that contains the error, as it is in an incomplete state after an error. See Fault reporting and handling for more details.

Diagram



Fields

Field	Function
31 VLD	Valid Logical OR of all CHn_ES[ERR] status fields. 0b - No CHn_ES[ERR] fields are set to 1 1b - At least one CHn_ES[ERR] field is set to 1, indicating a valid error exists that software has not cleared
30-27 —	Reserved
26-24 ERRCHN	Error Channel Number or Canceled Channel Number The channel number of the last recorded error or last recorded error-canceled transfer.
23-9 —	Reserved
8 ECX	Transfer Canceled The ECX operation is a management page function. When employed, the targeted channel's CHn_ES register reports an unspecified error; that is, only the CHn_ES[ERR] field is set to 1. The management page has full view of the error condition. 0b - No canceled transfers 1b - Last recorded entry was a canceled transfer by the error cancel transfer input
7 SAE	Source Address Error When this field is 1, it indicates that TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No source address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SADDR field
6 SOE	Source Offset Error When this field is 1, it indicates that TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SOFF field
5 DAE	Destination Address Error When this field is 1, it indicates that TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DADDR field
4 DOE	Destination Offset Error When this field is 1, it indicates that TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DOFF field
3 NCE	NBYTES/CITER Configuration Error This error indicates that one of the following has occurred: • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE] • TCDn_CITER[CITER] is equal to zero • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK] 0b - No NBYTES/CITER configuration error 1b - The last recorded error was NBYTES equal to zero or a CITER not equal to BITER error. Last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields
2 SGE	Scatter/Gather Configuration Error When this field is 1, it indicates that TCDn_DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG] is enabled. 0b - No scatter/gather configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DLAST_SGA field
1 SBE	Source Bus Error 0b - No source bus error 1b - Last recorded error was a bus error on a source read
0	Destination Bus Error

Table continues on the next page...

Table continued from the previous page...

Field	Function
DBE	0b - No destination bus error 1b - Last recorded error was a bus error on a destination write

71.6.4.4 Management Page Interrupt Request Status (MP_INT)

Offset

Register	Offset
MP_INT	8h

Function

This register shows the current state of the interrupt service requests for all eDMA channels.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-8 —	Reserved
7-0 INT	Interrupt Request Status The INT register presents the interrupt request status for each eDMA channel. Depending on the appropriate field setting in the transfer control descriptors, the eDMA engine generates an interrupt on data transfer completion. The eDMA routes channel interrupt requests to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate field in the channel’s interrupt request register, CHn_INT, thus negating the interrupt request. 0b - Interrupt request for corresponding channel not present 1b - Interrupt request for corresponding channel present

71.6.4.5 Management Page Hardware Request Status (MP_HRS)

Offset

Register	Offset
MP_HRS	Ch

Function

The hardware request status register (HRS) shows the current state of the hardware service request signaling as seen by eDMA's arbitration logic.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 HRS	Hardware Request Status The HRS bit for its respective channel remains asserted for the period when a hardware request is present on the channel. 0b - Hardware service request for corresponding channel is not present 1b - Hardware service request for corresponding channel is present

71.6.4.6 Channel Arbitration Group (CH0_GRPRI - CH7_GRPRI)

Offset

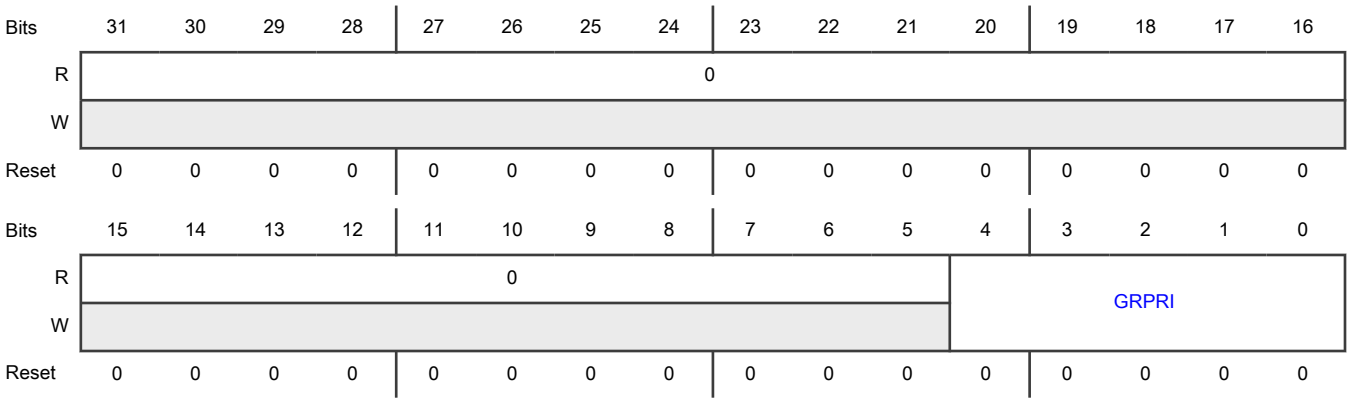
For n = 0 to 7:

Register	Offset
CHn_GRPRI	100h + (n × 4h)

Function

The contents of this register define the arbitration group associated with each channel. Using a fixed-priority group arbitration scheme, eDMA evaluates the arbitration group priorities by numeric value from highest group number to lowest; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. The range of the group priority values is limited to the values of 0 through 31. Within each arbitration group, the channel priority assignment CH*n*_PRI determines the highest-priority channel.

Diagram



Fields

Field	Function
31-5 —	Reserved

71.6.5.2 Channel Control and Status (CH0_CSR - CH15_CSR)

Offset

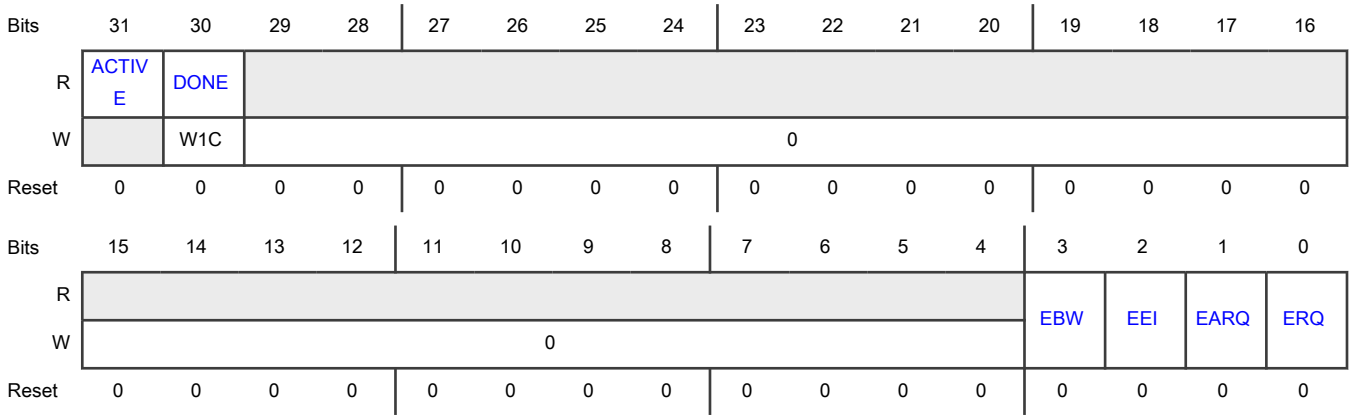
For n = 0 to 15:

Register	Offset
CHn_CSR	0h + (n × 1000h)

Function

This register contains several fields related to hardware and interrupt requests, configuration, and status for the given channel.

Diagram



Fields

Field	Function
31 ACTIVE	Channel Active The ACTIVE field indicates the channel was selected by arbitration and is executing the prescribed transfers. The eDMA sets it to 1 when channel service begins, and clears it to 0 as the minor loop completes or when any error condition is detected. Except for dynamic scatter/gather or dynamic channel linking, you must not modify the transfer control descriptor when a channel is active.
30 DONE	Channel Done The DONE field indicates the eDMA has completed the major loop. The eDMA engine sets this field as the CITER count reaches zero. If enabled, the eDMA generates an interrupt request corresponding to this completed channel. The software clears it, or the hardware clears it when the channel is activated. **NOTE** This field must be cleared to 0 before writing the MAJORELINK or ESG fields.
29-4 —	Reserved
3 EBW	Enable Buffered Writes When buffered writes are enabled, all writes except for the last write sequence of the minor loop are signaled by the eDMA as bufferable. 0b - Buffered writes on system bus disabled. Buffered writes on system bus disabled 1b - Buffered writes on system bus enabled. Bufferable write signal asserted on all system bus writes except during last write sequence
2 EEI	Enable Error Interrupt The EEI field enables the error interrupt signal for the channel. The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller. 0b - Error signal for corresponding channel does not generate error interrupt

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Assertion of error signal for corresponding channel generates error interrupt request
1 EARQ	Enable Asynchronous DMA Request The enable asynchronous DMA request field (EARQ) does not affect DMA operations. When set to 1, this field allows the hardware service request enable field (ERQ) to propagate out of the DMA to the power controller. When cleared to 0, this field masks the hardware service request enable field to the power controller. 0b - Disable asynchronous DMA request for the channel 1b - Enable asynchronous DMA request for the channel
0 ERQ	Enable DMA Request Disable a channel's hardware service request at the source before clearing the channel's ERQ field. The DMA hardware request input signal and the enable request field (ERQ) must be asserted before a channel's hardware service request is accepted. The state of the eDMA enable request field does not affect a channel service request made explicitly through software or channel linking. The state of the ERQ field does not affect the channel's START field. 0b - DMA hardware request signal for corresponding channel disabled 1b - DMA hardware request signal for corresponding channel enabled

71.6.5.3 Channel Error Status (CH0_ES - CH15_ES)

Offset

For n = 0 to 15:

Register	Offset
CHn_ES	4h + (n × 1000h)

Function

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor
- An error termination to a bus initiator read or write cycle

The ERR field signals the presence of an error for the channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate field in this register. The outputs of this register are enabled by the contents of the CHn_CSR[EEI] field, then logically summed across all channels to form an error interrupt request, which may be routed to the interrupt controller.

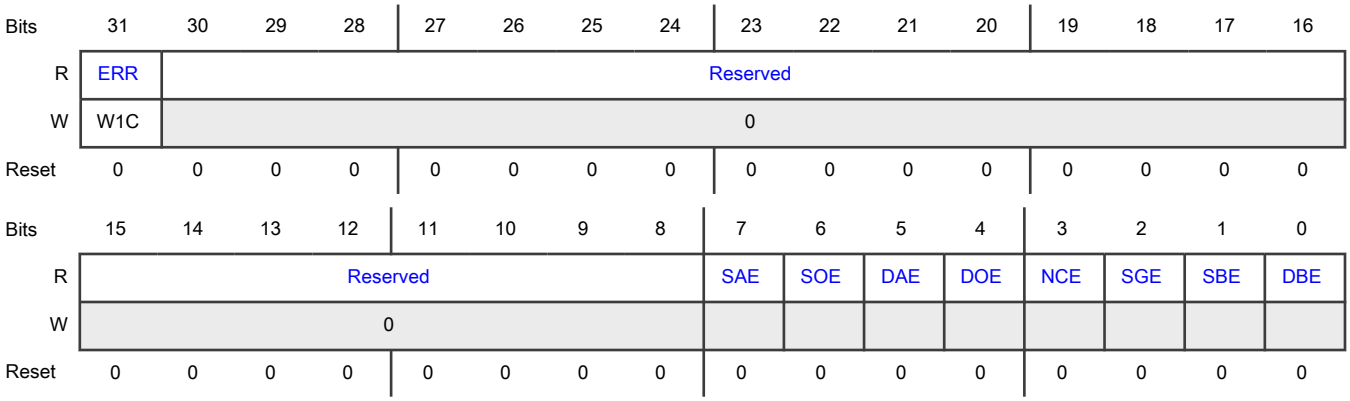
During the execution of the interrupt service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when eDMA detects an error. The contents of this ERR register field can also be polled because a non-zero value indicates the presence of a channel error, regardless of the state of the EEI mask.

The state of any given channel's error indicators is affected by writes to this register. Writing a 1 to the ERR field clears the channel's error status, and writing a 0 has no effect.

An unspecified error, where only the ERR field is set to 1, indicates that either a transfer was cancelled with an error. The Management Page Error Status register has full view of the error condition.

See Fault reporting and handling for more details.

Diagram



Fields

Field	Function
31 ERR	Error In Channel 0b - An error in this channel has not occurred 1b - An error in this channel has occurred
30-8 —	Reserved
7 SAE	Source Address Error TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SADDR field
6 SOE	Source Offset Error TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SOFF field
5 DAE	Destination Address Error TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DADDR field
4	Destination Offset Error TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE].

Table continues on the next page...

Table continued from the previous page...

Field	Function
DOE	0b - No destination offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DOFF field
3 NCE	NBYTES/CITER Configuration Error This error indicates that one of the following has occurred: • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE] • TCDn_CITER[CITER] is equal to zero • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK] 0b - No NBYTES/CITER configuration error 1b - Last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields
2 SGE	Scatter/Gather Configuration Error When this field is 1, it indicates that TCDn_DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG]is enabled. 0b - No scatter/gather configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DLAST_SGA field
1 SBE	Source Bus Error 0b - No source bus error 1b - Last recorded error was bus error on source read
0 DBE	Destination Bus Error 0b - No destination bus error 1b - Last recorded error was bus error on destination write

71.6.5.4 Channel Interrupt Status (CH0_INT - CH15_INT)

Offset

For n = 0 to 15:

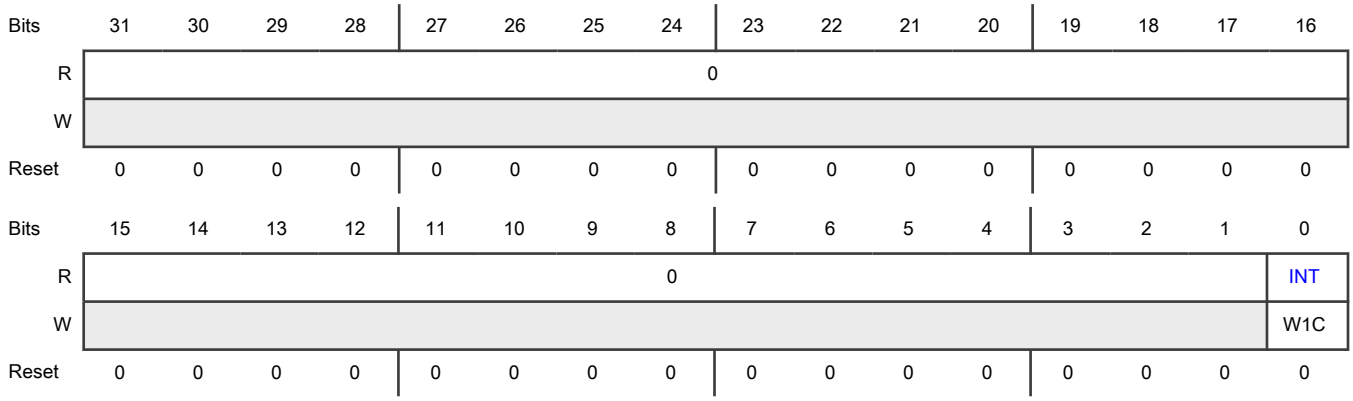
Register	Offset
CHn_INT	8h + (n × 1000h)

Function

The INT field signals the presence of an interrupt request for the channel. Depending on the appropriate bit setting in the transfer control descriptors, the eDMA engine generates an interrupt on data transfer completion.

The outputs of this register are directly routed to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. On writes to INT, a 1 clears the channel's interrupt request. A zero has no effect on the channel's current interrupt status.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 INT	Interrupt Request 0b - Interrupt request for corresponding channel cleared 1b - Interrupt request for corresponding channel active

71.6.5.5 Channel System Bus (CH0_SBR - CH15_SBR)

Offset

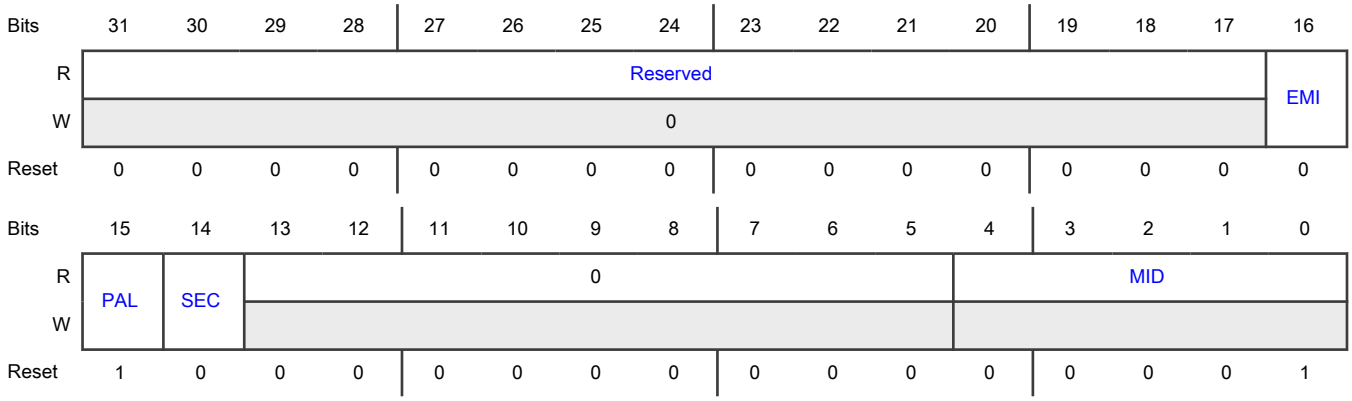
For n = 0 to 15:

Register	Offset
CHn_SBR	Ch + (n × 1000h)

Function

The Channel System Bus register places identification and attribute information on the system bus interface for the eDMA.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 EMI	Enable Initiator ID Replication The eDMA initiator ID replication field allows the eDMA to use the same protection level and system bus ID of the initiator programming the eDMA's TCD. When enabled, the eDMA uses the initiator ID and protection level stored in the CHn_SBR registers, instead of the eDMA's default values. When a initiator (for example a core) programs a TCD, its initiator ID is captured when the TCD*n*_CSR control attributes are written. A scatter/gather operation does not affect the CHn_SBR registers. You can write the EMI only if MP_CSR[GMRC] = 1, which means Global Initiator ID Replication Control is enabled; otherwise, the EMI is forced to zero. **NOTE** If initiator ID replication is disabled, the nonsecure, privileged protection level for DMA transfers is used. 0b - Initiator ID replication is disabled 1b - Initiator ID replication is enabled
15 PAL	Privileged Access Level This field controls DMA's protection level on the system bus when the channel is active. **NOTE** The value written into this register cannot exceed the security and privilege level of the core or other initiator writing the channel's system bus register; CH*n*_SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0b - User protection level for DMA transfers 1b - Privileged protection level for DMA transfers
14 SEC	Security Level DMA's security level on the system bus when the channel is active.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE The value written into this register cannot exceed the security and privilege level of the core or other initiator writing the channel's system bus register; CH*n*_SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0b - Nonsecure protection level for DMA transfers 1b - Secure protection level for DMA transfers
13-5 —	Reserved
4-0 MID	Initiator ID This field controls the DMA's initiator ID on the system bus when the channel is active. **NOTE** The ID captured in this register reflects the initiator ID of the core or other initiator writing the channel's security attributes, TCD*n*_SBR[SEC].

71.6.5.6 Channel Priority (CH0_PRI - CH15_PRI)

Offset

For n = 0 to 15:

Register	Offset
CHn_PRI	10h + (n × 1000h)

Function

The contents of these registers define unique priorities associated with each channel within the same channel group. Channel grouping is programmed via Channel Arbitration Group (CH0_GRPRI - CH15_GRPRI).

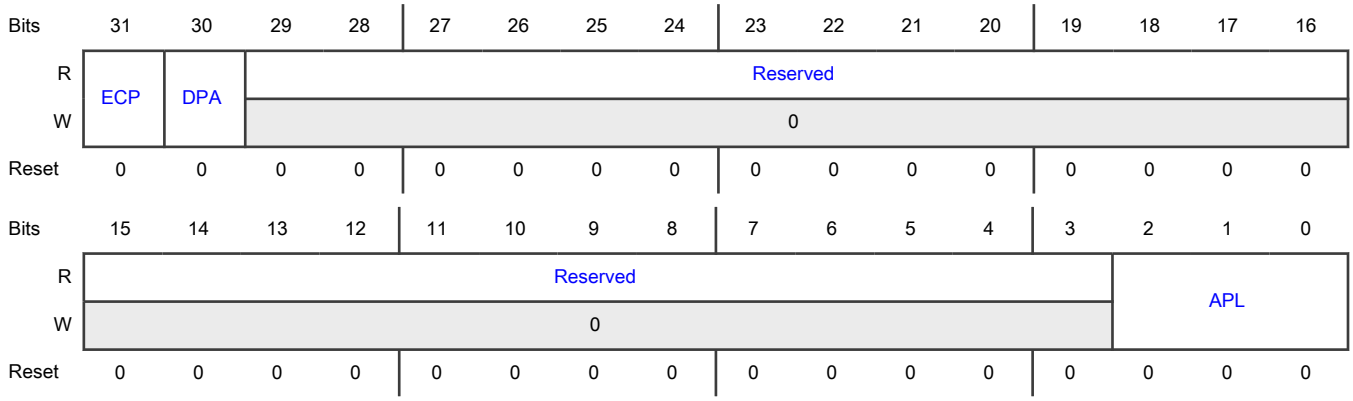
The channel priorities within a group are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Software must program the channel priorities with unique values; otherwise, channel numbers with the same, non-zero value, will be selected based on channel number with the higher channel number having higher priority.

If more than one channel in a group has an arbitration priority level value of zero, then the arbitration mode field MP_CSR[ERCA] is used to determine the arbitration scheme for all channels with APL=0 within a group.

When you enable round-robin channel arbitration (MP_CSR[ERCA] = 1), all channels with APL=0 within a group will use a round-robin arbitration scheme, which rotates among these channels requesting service without regard to priority. Round-robin provides a fairness mechanism within an arbitration group.

When you enable fixed-priority channel arbitration (MP_CSR[ERCA] = 0), eDMA selects channels with APL=0 based on channel number, with the higher channel number having higher priority.

Diagram



Fields

Field	Function
31 ECP	Enable Channel Preemption 0b - Channel cannot be suspended by a higher-priority channel's service request 1b - Channel can be temporarily suspended by a higher-priority channel's service request
30 DPA	Disable Preempt Ability 0b - Channel can suspend a lower-priority channel 1b - Channel cannot suspend any other channel, regardless of channel priority
29-3 —	Reserved
2-0 APL	Arbitration Priority Level Channel priority level for arbitration within the assigned arbitration group.

71.6.5.7 Channel Multiplexor Configuration (CH0_MUX - CH15_MUX)

Offset

For n = 0 to 15:

Register	Offset
CHn_MUX	14h + (n × 1000h)

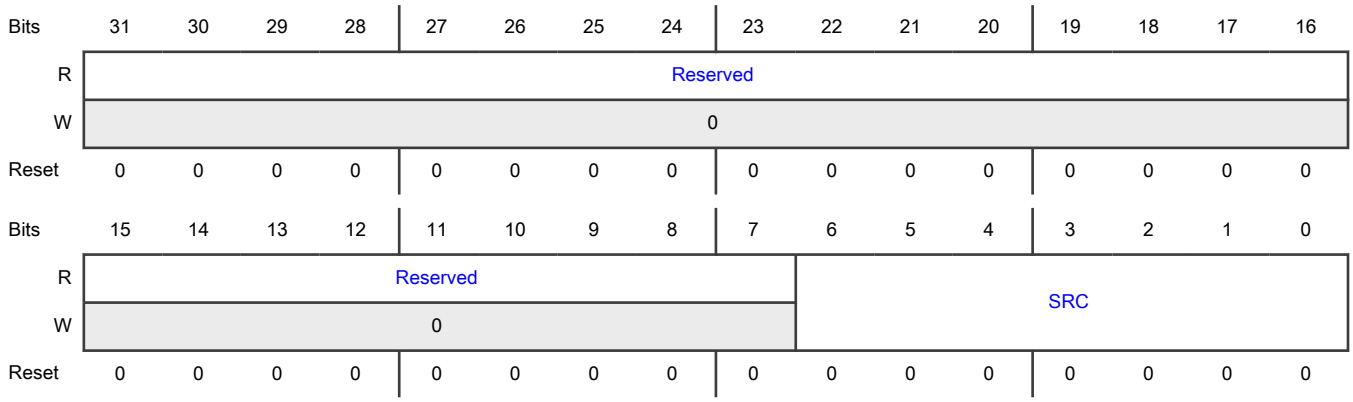
Function

Each of the DMA channels can be independently associated with various peripherals in the system. The Channel Multiplexor Configuration register selects the peripheral assigned to each channel. Service requests from the peripheral should be disabled when configuring a channel to a peripheral source.

Each channel must have a unique value when selecting a peripheral slot in the channel mux configuration. The only value that may overlap is source 0. If there is an attempt to write a mux configuration value that is already consumed by any channel, a mux configuration of 0 (SRC = 0) will be written.

All channels will default to source 0. When a particular peripheral is needed, the channel's mux configuration is set to that source number. When the peripheral is no longer needed, the mux configuration for that channel should be written to 0, thus releasing the resource.

Diagram



Fields

Field	Function
31-7 —	Reserved
6-0 SRC	Service Request Source Hardware service request source for the channel. **NOTE** With the exception of 0, attempts to write a value already in use will be forced to 0.

71.6.5.8 TCD Source Address (TCD0_SADDR - TCD15_SADDR)

Offset

For n = 0 to 15:

Register	Offset
TCDn_SADDR	20h + (n × 1000h)

Function

This register contains the address for the read transactions.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
15-0 SOFF	Source Address Signed Offset Sign-extended offset applied to the current source address to form the next-state value as each source read is completed.

71.6.5.10 TCD Transfer Attributes (TCD0_ATTR - TCD15_ATTR)

Offset

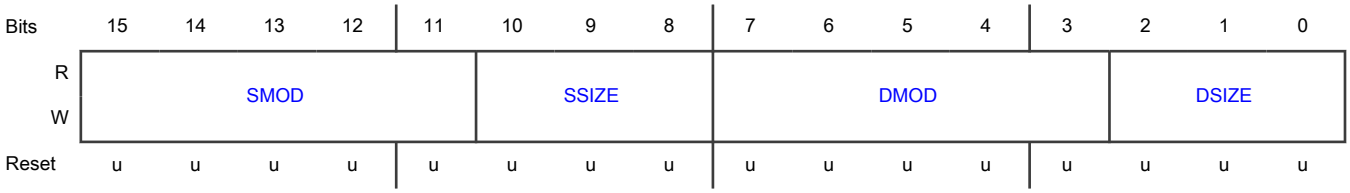
For n = 0 to 15:

Register	Offset
TCDn_ATTR	26h + (n × 1000h)

Function

This register contains size and option modulo addressing information for source and destination addresses.

Diagram



Fields

Field	Function
15-11 SMOD	Source Address Modulo This field defines a specific address range, which is the value after the SADDR + SOFF calculation is performed on the original register value. Setting this field makes it easy to implement a circular data queue. For data queues requiring power-of-2-sized bytes, the queue must start at a 0-modulo-size address and the SMOD field must be set to the appropriate value for the queue, freezing the required number of upper address bits. The value programmed into this field specifies the number of lower address bits that are allowed to change. For a circular queue application, you typically set TCDn_SOFF[SOFF] to the transfer size to implement post-increment addressing, with the SMOD function constraining the addresses to a 0-modulo-size range. 0_0000b - Source address modulo feature disabled
10-8 SSIZE	Source Data Transfer Size 000b - 8-bit 001b - 16-bit 010b - 32-bit 011b - 64-bit 100b - 16-byte 101b - 32-byte 110b - 64-byte 111b - Reserved

7-3 DMOD	Destination Address Modulo See the SMOD definition.
2-0 DSIZE	Destination Data Transfer Size See the SSIZE definition.

71.6.5.11 TCD Transfer Size Without Minor Loop Offsets (TCD0_NBYTES_MLOFFNO - TCD15_NBYTES_MLOFFNO)

Offset

For n = 0 to 15:

Register	Offset
TCDn_NBYTES_MLOFFNO	28h + (n × 1000h)

Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offsets are address offset values added to the final source address (TCDn_SADDR), or destination address (TCDn_DADDR), upon minor loop completion. Minor loop completion is when the channel has finished the service request and has transferred NBYTES. When minor loop offsets are enabled, the minor loop offset value (TCDn_NBYTES_MLOFFYES[MLOFF]) is added to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both, prior to the addresses being written back to the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When minor loop mapping is enabled (SMLOE or DMLOE is 1), TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is redefined. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is used to specify multiple fields:

- A source enable bit (SMLOE) to specify the minor loop offset must be applied to the source address (TCDn_SADDR) upon minor loop completion
- A destination enable bit (DMLOE) to specify the minor loop offset must be applied to the destination address (TCDn_DADDR) upon minor loop completion
- The sign extended minor loop offset value (MLOFF)

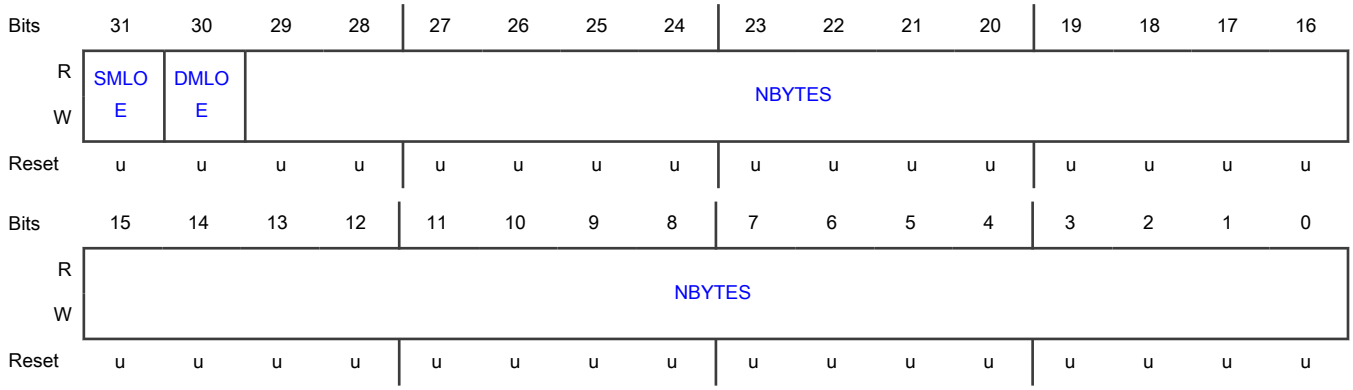
The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is defined as follows:

- If SMLOE = 0 and DMLOE = 0, then see the TCDn_NBYTES_MLOFFNO register description.
- If either SMLOE or DMLOE is 1, then see the TCDn_NBYTES_MLOFFYES register description.

Diagram



Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - Minor loop offset not applied to SADDR 1b - Minor loop offset applied to SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0b - Minor loop offset not applied to DADDR 1b - Minor loop offset applied to DADDR
29-0 NBYTES	Number of Bytes To Transfer Per Service Request Number of bytes to be transferred for each service request of the channel. When a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the byte transfer count has been reached. This process is normally an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the byte count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major loop iteration count (CITER) is decremented by one and written back to the TCD memory. If the major iteration count is complete, additional processing is performed.

71.6.5.12 TCD Transfer Size with Minor Loop Offsets (TCD0_NBYTES_MLOFFYES - TCD15_NBYTES_MLOFFYES)

Offset

For n = 0 to 15:

Register	Offset
TCDn_NBYTES_MLOFFYES	28h + (n × 1000h)

Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offset is an address offset value added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. Minor loop completion occurs when the channel has finished the service request and has transferred NBYTES. Minor loop offsets are enabled by setting either the source enable bit (SMLOE) or the destination enable bit (DMLOE).

The source enable bit (SMLOE) specifies the minor loop offset value (MLOFF) that is to be applied to the source address (TCDn_SADDR) upon minor loop completion. The destination enable bit (DMLOE) specifies the minor loop offset (MLOFF) that is to be applied to the destination address (TCDn_DADDR) upon minor loop completion.

If the major loop is complete, the minor loop offsets are ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

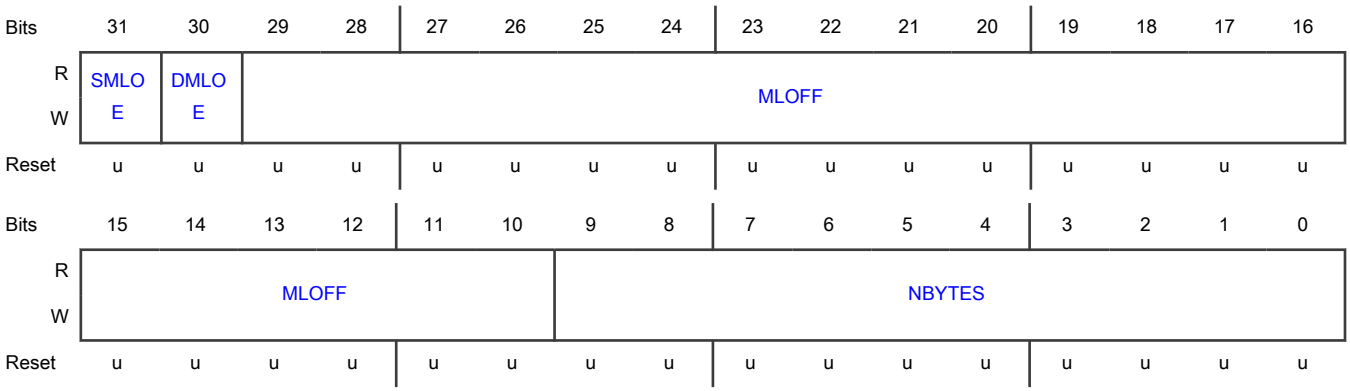
When you enable the minor loop offset overlay (either SMLOE or DMLOE is 1), eDMA redefines TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES specifies the sign-extended minor loop offset value (MLOFF). The same offset value (MLOFF) applies to both source and destination minor loop offsets. When the minor loop offset is enabled, you must align it to the transfer size of the source or destination it is associated with. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFNO) defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFYES is defined as follows:

- If either minor loop offset is enabled (SMLOE or DMLOE = 1), then see the TCDn_NBYTES_MLOFFYES register description.
- If SMLOE and DMLOE are both 0, then see the TCDn_NBYTES_MLOFFNO register description.

Diagram



Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - Minor loop offset not applied to SADDR 1b - Minor loop offset applied to SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0b - Minor loop offset not applied to DADDR 1b - Minor loop offset applied to DADDR
29-10 MLOFF	Minor Loop Offset If SMLOE or DMLOE is 1, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes.
9-0 NBYTES	Number of Bytes To Transfer Per Service Request The number of bytes to be transferred in each service request of the channel. As a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the minor byte transfer count has been reached. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major iteration count is decremented and restored to the TCD memory. If the major iteration count is complete, additional processing is performed.

71.6.5.13 TCD Last Source Address Adjustment / Store DADDR Address (TCD0_SLAST_SDA - TCD15_SLAST_SDA)

Offset

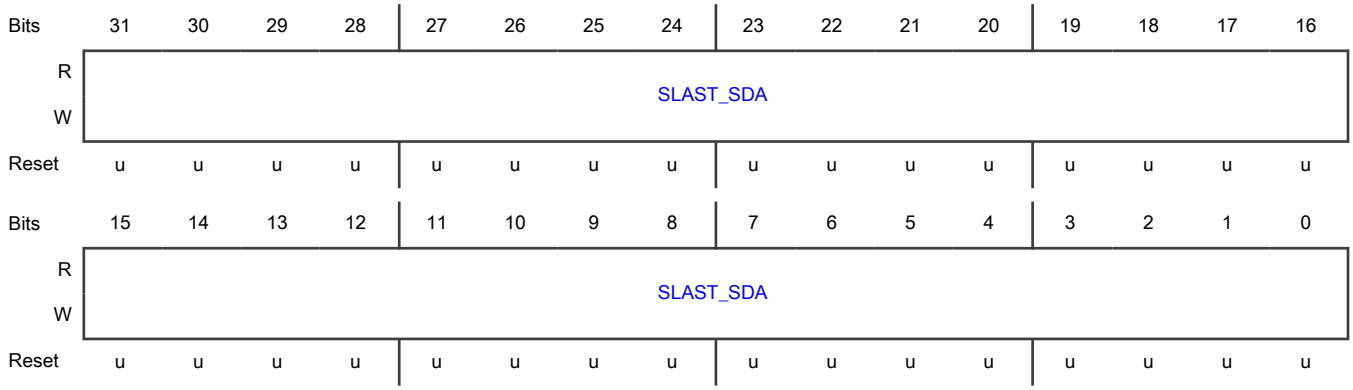
For n = 0 to 15:

Register	Offset
TCDn_SLAST_SDA	2Ch + (n × 1000h)

Function

This register contains the value added to the source address when the major loop is complete. When the store destination address option is enabled, this field provides a pointer to memory for storing the final destination address.

Diagram



Fields

Field	Function
31-0 SLAST_SDA	Last Source Address Adjustment / Store DADDR Address Source last address adjustment or the system memory address for destination address (DADDR) storage. If (TCDn_CSR[ESDA] = 0), then: • Adjustment value is added to the source address at the completion of the major iteration count. This value can be used to restore the source address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final source address adjustment. Otherwise: • This address points to the 32-bit-aligned memory location where the destination address (DADDR) is to be stored in system memory. By saving the final destination address in system memory via the ESDA feature, you are able to compute the size of a variable destination data buffer by simply subtracting the beginning DADDR from the final, saved DADDR. This feature is used together with the scatter/gather operation to prevent the loss of the final DADDR, which is overwritten during the scatter/gather operation. The "Store Destination Address" (SDA) value must be a 32-bit-aligned location because the eDMA forces the lower two address bits of the SLAST_SDA field to zero when ESDA is enabled. The module performs this write operation when the major loop is done; that is, when the major iteration count (CITER) decrements to zero.

71.6.5.14 TCD Destination Address (TCD0_DADDR - TCD15_DADDR)

Offset

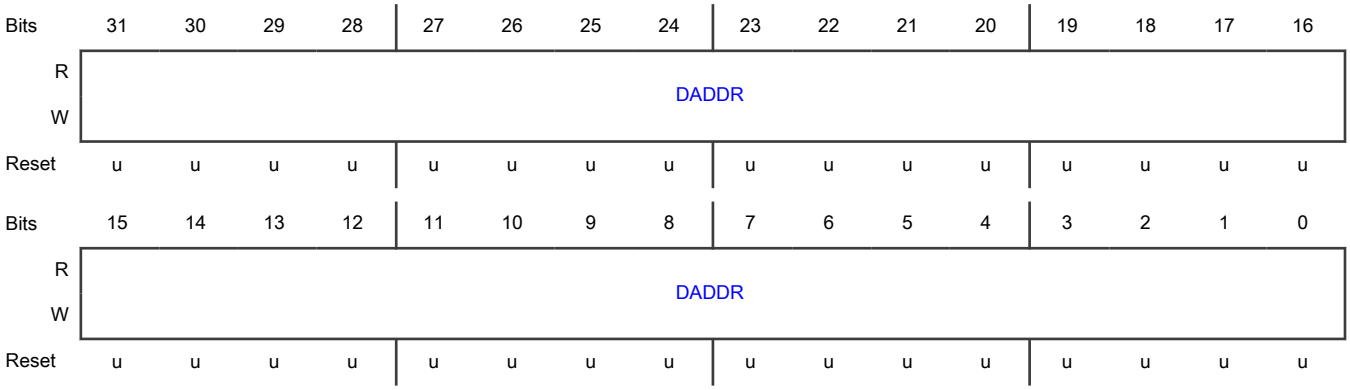
For n = 0 to 15:

Register	Offset
TCDn_DADDR	30h + (n × 1000h)

Function

This register contains the address for the write transactions.

Diagram



Fields

Field	Function
31-0 DADDR	Destination Address Memory address pointing to the destination data.

71.6.5.15 TCD Signed Destination Address Offset (TCD0_DOFF - TCD15_DOFF)

Offset

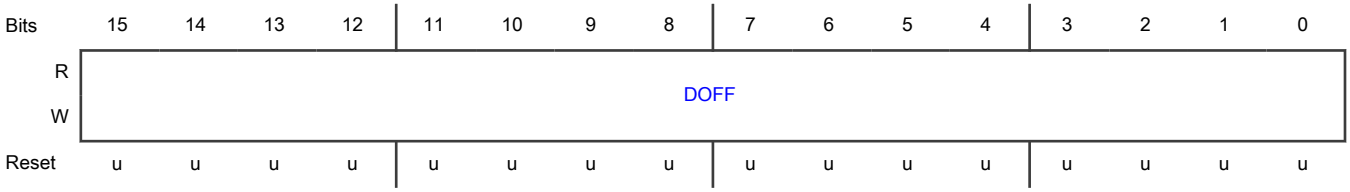
For n = 0 to 15:

Register	Offset
TCDn_DOFF	34h + (n × 1000h)

Function

This register contains the sign-extended value added to Destination Address register after each write transaction.

Diagram



Fields

Field	Function
15-0 DOFF	Destination Address Signed Offset Sign-extended offset that is applied to the current destination address to form the next-state value as each destination write is completed.

71.6.5.16 TCD Current Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_CITER_ELINKNO - TCD15_CITER_ELINKNO)

Offset

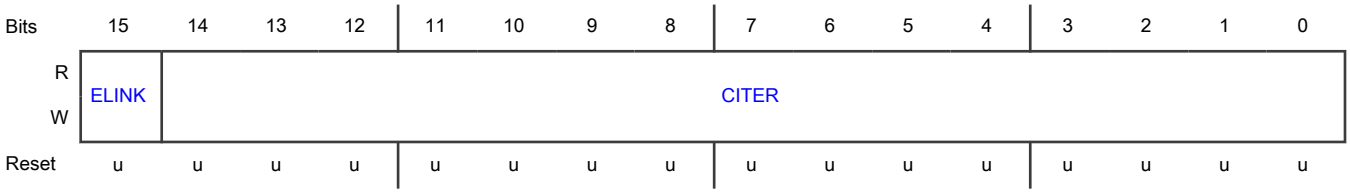
For n = 0 to 15:

Register	Offset
TCDn_CITER_ELINKNO	36h + (n × 1000h)

Function

If TCDn_CITER[ELINK] is 0, the TCDn_CITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel to 1. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking. **NOTE** This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

71.6.5.17 TCD Current Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_CITER_ELINKYES - TCD15_CITER_ELINKYES)

Offset

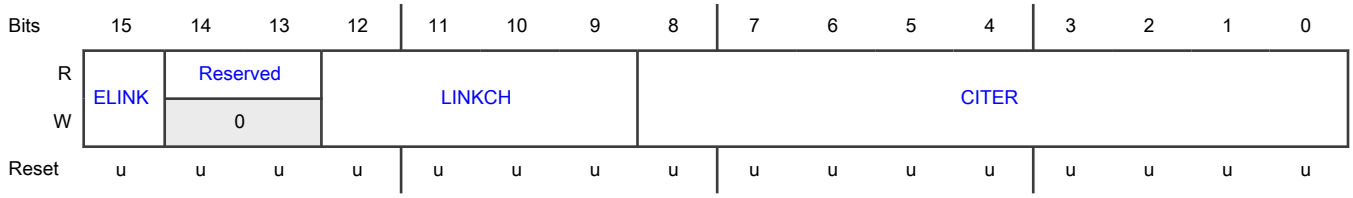
For n = 0 to 15:

Register	Offset
TCDn_CITER_ELINKYES	36h + (n × 1000h)

Function

If TCDn_CITER[ELINK] is 1, the TCDn_CITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. When enabled, an internal mechanism sets the TCDn_CSR[START] field of the specified channel (LINKCH) upon minor loop completion. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-13 —	Reserved
12-9 LINKCH	Minor Loop Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted the eDMA engine initiates a channel service request to the channel defined by this field by writing that channel's TCDn_CSR[START] field to 1.
8-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to the TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

71.6.5.18 TCD Last Destination Address Adjustment / Scatter Gather Address (TCD0_DLAST_SGA - TCD15_DLAST_SGA)

Offset

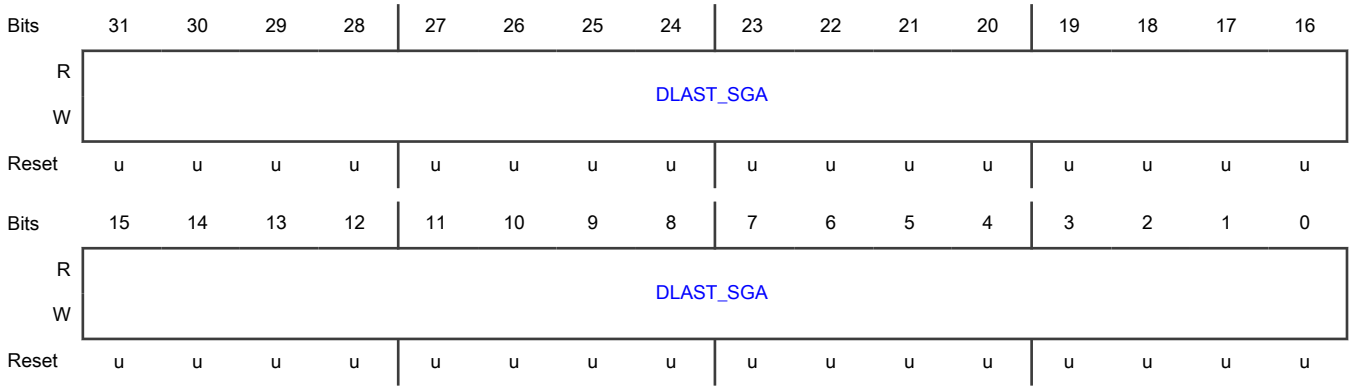
For n = 0 to 15:

Register	Offset
TCDn_DLAST_SGA	38h + (n × 1000h)

Function

This register contains the value added to the destination address when the major loop is complete. When the Scatter/Gather option is enabled, this field provides a pointer to memory for fetching a transfer control descriptor to reprogram the channel.

Diagram



Fields

Field	Function
31-0 DLAST_SGA	Last Destination Address Adjustment / Scatter Gather Address Adjustment of the last destination address or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather). If (TCDn_CSR[ESG] = 0) then: • Adjustment value is added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final destination address adjustment. Otherwise: • This address points to the beginning of a 0-modulo 32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo 32-byte, or else a configuration error is reported.

71.6.5.19 TCD Control and Status (TCD0_CSR - TCD15_CSR)

Offset

For n = 0 to 15:

Register	Offset
TCDn_CSR	3Ch + (n × 1000h)

Function

This register is used to enable optional features.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	BWC				MAJORLINKCH				ESDA	EEOP	MAJORELINK	ESG	DREQ	INTHALF	INTMAJOR	START
W			0													
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	0

Fields

Field	Function
15-14 BWC	Bandwidth Control Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces eDMA to stall after the completion of each read/write access, to control the bus request bandwidth seen by the system bus interconnect. **NOTE** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00b - No eDMA engine stalls 01b - Reserved 10b - eDMA engine stalls for 4 cycles after each R/W 11b - eDMA engine stalls for 8 cycles after each R/W
13-12 —	Reserved
11-8 MAJORLINKCH	Major Loop Link Channel Number If (MAJORELINK = 0) then: • No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted. Otherwise: • After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field to 1.
7 ESDA	Enable Store Destination Address As the channel completes the major loop by either the current iteration counter (CITER) decrementing to 0, or by receiving an enabled end-of-packet signal, this field enables writing the destination address (DADDR) to the address stored in the SLAST_SDA field. The value written to system memory is the next DADDR value prior to the DLAST_SGA offset being applied, or overwritten by an enabled scatter/gather operation. When the ESDA bit is 1, SLAST_SDA contains the write pointer instead of the final source address offset. Because this is a pointer and not a final offset, a last source address offset of zero is applied to SADDR instead of the SLAST_SGA value. 0b - Ability to store destination address to system memory disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Ability to store destination address to system memory enabled
6 EEOP	Enable End-Of-Packet Processing When enabled by the EEOP field, an end-of-packet hardware input signal directs eDMA to discontinue executing the active channel, and to treat the shutdown as the major-loop-completed event. If the EEOP field is 1, the end-of-packet signal from supported peripherals is accepted. If the EEOP field is 0, the end-of-packet input is ignored. With an end-of-packet retirement, the current TCD destination address (or ESDA-saved destination address), minus the software-saved initial address (DADDR), reflects the total amount of data transferred. 0b - End-of-packet operation disabled 1b - End-of-packet hardware input signal enabled
5 MAJORELINK	Enable Link When Major Loop Complete As the channel completes the major loop, this flag enables linking to another channel defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. **NOTE** To support the dynamic linking coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
4 ESG	Enable Scatter/Gather Processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses TCDn_DLAST_SGA as a memory pointer to a 0-modulo 32-bit address containing a 32-byte data structure, which is loaded as the transfer control descriptor into local memory. **NOTE** To support the dynamic scatter/gather coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0b - Current channel's TCD is normal format 1b - Current channel's TCD specifies scatter/gather format.
3 DREQ	Disable Request If this flag is 1, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches 0. 0b - No operation. Channel's ERQ field not affected 1b - Clear the ERQ field to 0 upon major loop completion, thus disabling hardware service requests. Channel's ERQ field cleared to 0 when major loop complete
2	Enable Interrupt If Major Counter Half-complete

Table continues on the next page...

Table continued from the previous page...

Field	Function
INTHALF	If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER = (BITER/2)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes, or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE** If BITER = 1, do not use INTHALF; use INTMAJOR instead. 0b - Halfway point interrupt disabled 1b - Halfway point interrupt enabled
1 INTMAJOR	Enable Interrupt If Major count complete If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count (CITER) reaches 0. 0b - End-of-major loop interrupt disabled 1b - End-of-major loop interrupt enabled
0 START	Channel Start If this flag is 1, the channel is requesting service. The eDMA hardware automatically clears this flag to 0 after the channel begins execution. 0b - Channel not explicitly started 1b - Channel explicitly started via a software-initiated service request

71.6.5.20 TCD Beginning Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_BITER_ELINKNO - TCD15_BITER_ELINKNO)

Offset

For n = 0 to 15:

Register	Offset
TCDn_BITER_ELINKNO	3Eh + (n × 1000h)

Function

If the TCDn_BITER[ELINK] field is 0, the TCDn_BITER register is defined as follows.

Diagram

Fields

Field	Function
15 ELINK	Enables Link As the channel completes the minor loop, this flag enables linking to another channel as defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. If channel linking is disabled, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-0 BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be set equal to the value in the CITER field. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0x0001.

71.6.5.21 TCD Beginning Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_BITER_ELINKYES - TCD15_BITER_ELINKYES)

Offset

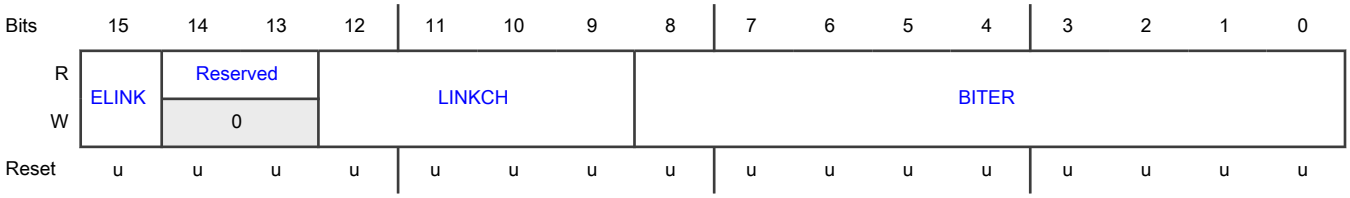
For n = 0 to 15:

Register	Offset
TCDn_BITER_ELINKYES	3Eh + (n × 1000h)

Function

If the TCDn_BITER[ELINK] field is set, the TCDn_BITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. If channel linking disables, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-13 —	Reserved
12-9 LINKCH	Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field.
8-0 BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be set equal to the value in the CITER field. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0x0001.

71.6.6.2 Channel Control and Status (CH0_CSR - CH15_CSR)

Offset

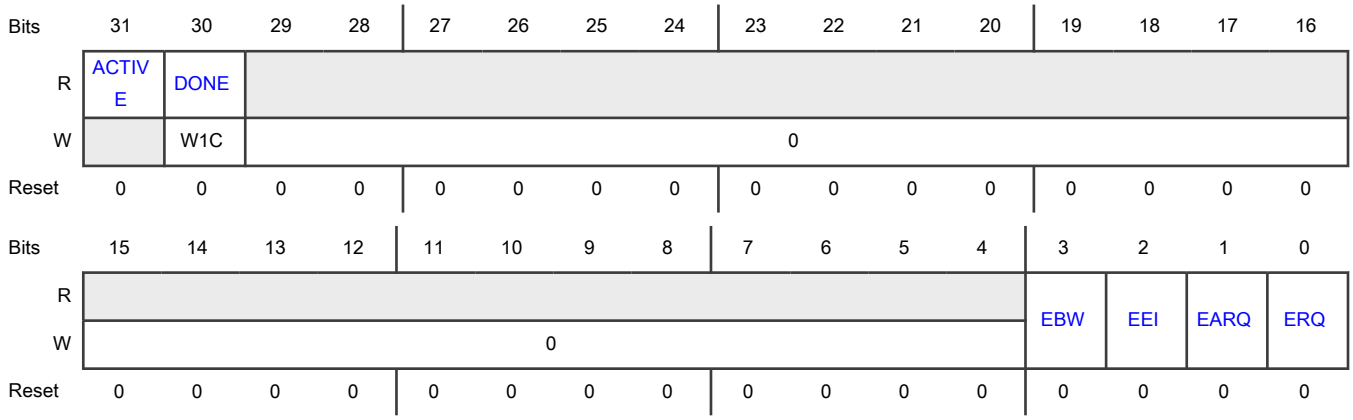
For n = 0 to 15:

Register	Offset
CHn_CSR	0h + (n × 1000h)

Function

This register contains several fields related to hardware and interrupt requests, configuration, and status for the given channel.

Diagram



Fields

Field	Function
31 ACTIVE	Channel Active The ACTIVE field indicates the channel was selected by arbitration and is executing the prescribed transfers. The eDMA sets it to 1 when channel service begins, and clears it to 0 as the minor loop completes or when any error condition is detected. Except for dynamic scatter/gather or dynamic channel linking, you must not modify the transfer control descriptor when a channel is active.
30 DONE	Channel Done The DONE field indicates the eDMA has completed the major loop. The eDMA engine sets this field as the CITER count reaches zero. If enabled, the eDMA generates an interrupt request corresponding to this completed channel. The software clears it, or the hardware clears it when the channel is activated. **NOTE** This field must be cleared to 0 before writing the MAJORELINK or ESG fields.
29-4 —	Reserved
3 EBW	Enable Buffered Writes When buffered writes are enabled, all writes except for the last write sequence of the minor loop are signaled by the eDMA as bufferable. 0b - Buffered writes on system bus disabled. Buffered writes on system bus disabled 1b - Buffered writes on system bus enabled. Bufferable write signal asserted on all system bus writes except during last write sequence
2 EEI	Enable Error Interrupt

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The EEI field enables the error interrupt signal for the channel. The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller. 0b - Error signal for corresponding channel does not generate error interrupt 1b - Assertion of error signal for corresponding channel generates error interrupt request
1 EARQ	Enable Asynchronous DMA Request The enable asynchronous DMA request field (EARQ) does not affect DMA operations. When set to 1, this field allows the hardware service request enable field (ERQ) to propagate out of the DMA to the power controller. When cleared to 0, this field masks the hardware service request enable field to the power controller. 0b - Disable asynchronous DMA request for the channel 1b - Enable asynchronous DMA request for the channel
0 ERQ	Enable DMA Request Disable a channel's hardware service request at the source before clearing the channel's ERQ field. The DMA hardware request input signal and the enable request field (ERQ) must be asserted before a channel's hardware service request is accepted. The state of the eDMA enable request field does not affect a channel service request made explicitly through software or channel linking. The state of the ERQ field does not affect the channel's START field. 0b - DMA hardware request signal for corresponding channel disabled 1b - DMA hardware request signal for corresponding channel enabled

71.6.6.3 Channel Error Status (CH0_ES - CH15_ES)

Offset

For n = 0 to 15:

Register	Offset
CHn_ES	4h + (n × 1000h)

Function

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor
- An error termination to a bus initiator read or write cycle

The ERR field signals the presence of an error for the channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate field in this register. The outputs of this register are enabled by the contents of the CHn_CSR[EEI] field, then logically summed across all channels to form an error interrupt request, which may be routed to the interrupt controller.

During the execution of the interrupt service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when eDMA detects an error. The

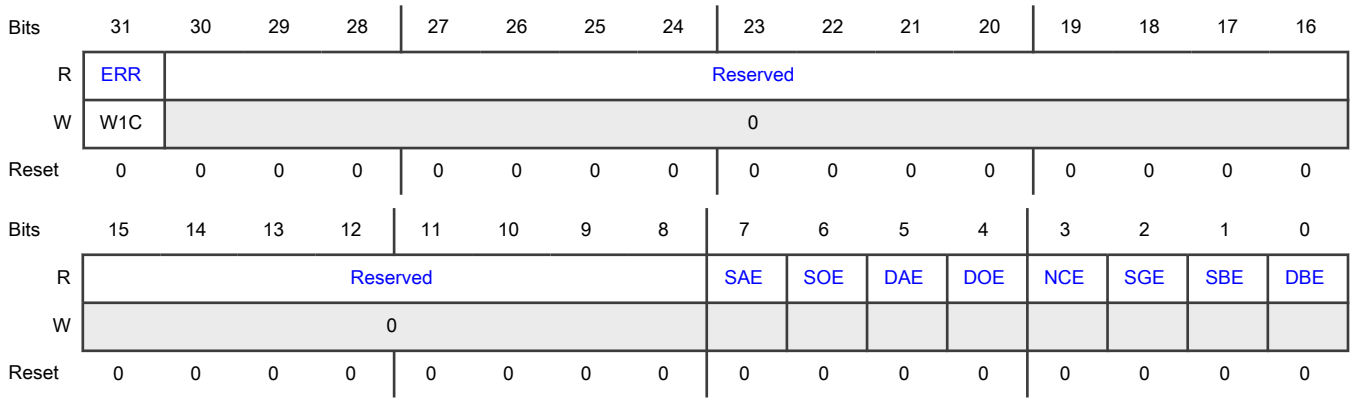
contents of this ERR register field can also be polled because a non-zero value indicates the presence of a channel error, regardless of the state of the EEI mask.

The state of any given channel's error indicators is affected by writes to this register. Writing a 1 to the ERR field clears the channel's error status, and writing a 0 has no effect.

An unspecified error, where only the ERR field is set to 1, indicates that either a transfer was cancelled with an error. The Management Page Error Status register has full view of the error condition.

See Fault reporting and handling for more details.

Diagram



Fields

Field	Function
31 ERR	Error In Channel 0b - An error in this channel has not occurred 1b - An error in this channel has occurred
30-8 —	Reserved
7 SAE	Source Address Error TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SADDR field
6 SOE	Source Offset Error TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SOFF field
5 DAE	Destination Address Error TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No destination address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DADDR field
4 DOE	Destination Offset Error TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DOFF field
3 NCE	NBYTES/CITER Configuration Error This error indicates that one of the following has occurred: • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE] • TCDn_CITER[CITER] is equal to zero • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK] 0b - No NBYTES/CITER configuration error 1b - Last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields
2 SGE	Scatter/Gather Configuration Error When this field is 1, it indicates that TCDn_DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG]is enabled. 0b - No scatter/gather configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DLAST_SGA field
1 SBE	Source Bus Error 0b - No source bus error 1b - Last recorded error was bus error on source read
0 DBE	Destination Bus Error 0b - No destination bus error 1b - Last recorded error was bus error on destination write

71.6.6.4 Channel Interrupt Status (CH0_INT - CH15_INT)

Offset

For n = 0 to 15:

Register	Offset
CHn_INT	8h + (n × 1000h)

Function

The INT field signals the presence of an interrupt request for the channel. Depending on the appropriate bit setting in the transfer control descriptors, the eDMA engine generates an interrupt on data transfer completion.

The outputs of this register are directly routed to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. On writes to INT, a 1 clears the channel's interrupt request. A zero has no effect on the channel's current interrupt status.

71.6.6.5 Channel System Bus (CH0_SBR - CH15_SBR)

Offset

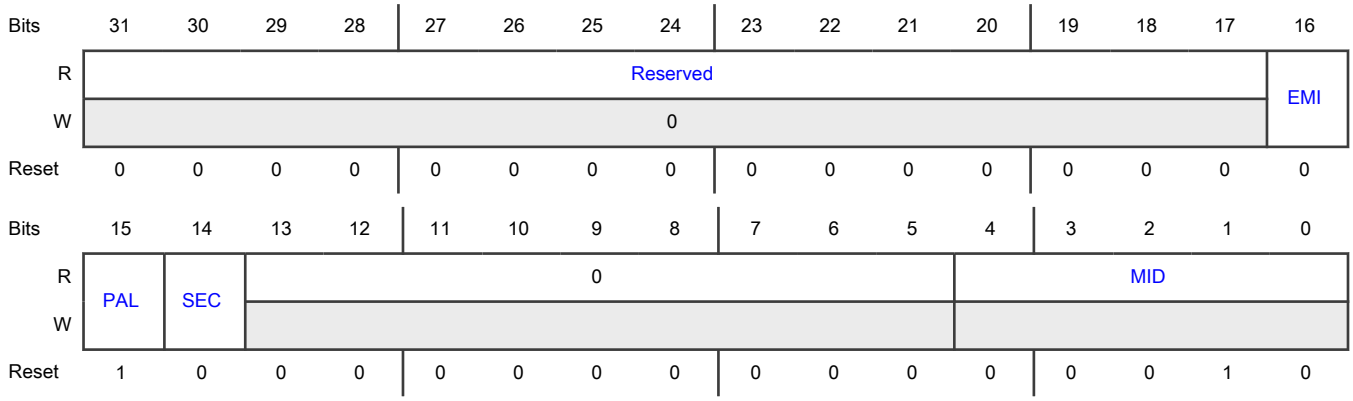
For n = 0 to 15:

Register	Offset
CHn_SBR	Ch + (n × 1000h)

Function

The Channel System Bus register places identification and attribute information on the system bus interface for the eDMA.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 EMI	Enable Initiator ID Replication The eDMA initiator ID replication field allows the eDMA to use the same protection level and system bus ID of the initiator programming the eDMA's TCD. When enabled, the eDMA uses the initiator ID and protection level stored in the CHn_SBR registers, instead of the eDMA's default values. When a initiator (for example a core) programs a TCD, its initiator ID is captured when the TCD*n*_CSR control attributes are written. A scatter/gather operation does not affect the CHn_SBR registers. You can write the EMI only if MP_CSR[GMRC] = 1, which means Global Initiator ID Replication Control is enabled; otherwise, the EMI is forced to zero. **NOTE** If initiator ID replication is disabled, the nonsecure, privileged protection level for DMA transfers is used. 0b - Initiator ID replication is disabled 1b - Initiator ID replication is enabled
15 PAL	Privileged Access Level This field controls DMA's protection level on the system bus when the channel is active. **NOTE** The value written into this register cannot exceed the security and privilege level of the core or other initiator writing the channel's system bus register; CH*n*_SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0b - User protection level for DMA transfers 1b - Privileged protection level for DMA transfers
14 SEC	Security Level DMA's security level on the system bus when the channel is active.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE The value written into this register cannot exceed the security and privilege level of the core or other initiator writing the channel's system bus register; CH*n*_SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0b - Nonsecure protection level for DMA transfers 1b - Secure protection level for DMA transfers
13-5 —	Reserved
4-0 MID	Initiator ID This field controls the DMA's initiator ID on the system bus when the channel is active. **NOTE** The ID captured in this register reflects the initiator ID of the core or other initiator writing the channel's security attributes, TCD*n*_SBR[SEC].

71.6.6.6 Channel Priority (CH0_PRI - CH15_PRI)

Offset

For n = 0 to 15:

Register	Offset
CHn_PRI	10h + (n × 1000h)

Function

The contents of these registers define unique priorities associated with each channel within the same channel group. Channel grouping is programmed via Channel Arbitration Group (CH0_GRPRI - CH15_GRPRI).

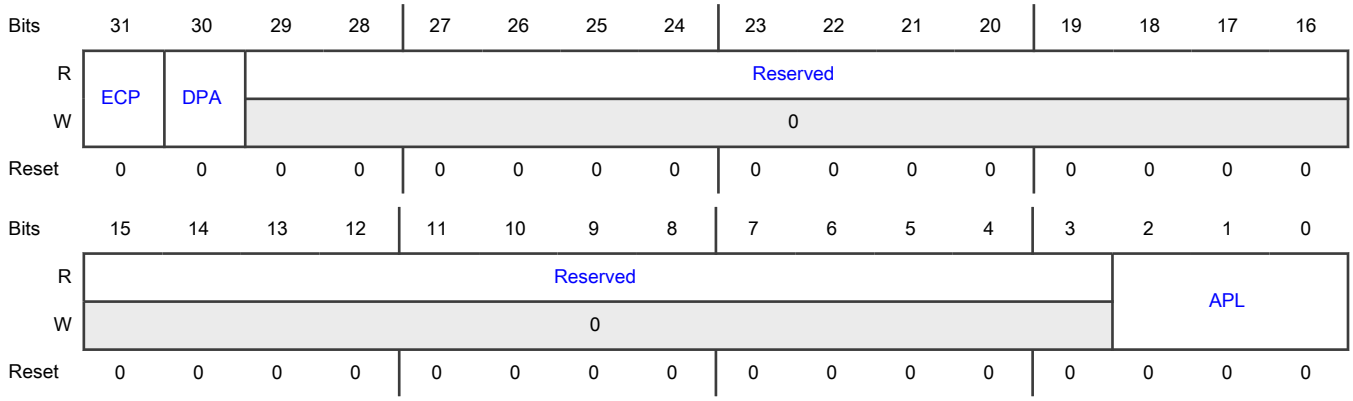
The channel priorities within a group are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Software must program the channel priorities with unique values; otherwise, channel numbers with the same, non-zero value, will be selected based on channel number with the higher channel number having higher priority.

If more than one channel in a group has an arbitration priority level value of zero, then the arbitration mode field MP_CSR[ERCA] is used to determine the arbitration scheme for all channels with APL=0 within a group.

When you enable round-robin channel arbitration (MP_CSR[ERCA] = 1), all channels with APL=0 within a group will use a round-robin arbitration scheme, which rotates among these channels requesting service without regard to priority. Round-robin provides a fairness mechanism within an arbitration group.

When you enable fixed-priority channel arbitration (MP_CSR[ERCA] = 0), eDMA selects channels with APL=0 based on channel number, with the higher channel number having higher priority.

Diagram



Fields

Field	Function
31 ECP	Enable Channel Preemption 0b - Channel cannot be suspended by a higher-priority channel's service request 1b - Channel can be temporarily suspended by a higher-priority channel's service request
30 DPA	Disable Preempt Ability 0b - Channel can suspend a lower-priority channel 1b - Channel cannot suspend any other channel, regardless of channel priority
29-3 —	Reserved
2-0 APL	Arbitration Priority Level Channel priority level for arbitration within the assigned arbitration group.

71.6.6.7 Channel Multiplexor Configuration (CH0_MUX - CH15_MUX)

Offset

For n = 0 to 15:

Register	Offset
CHn_MUX	14h + (n × 1000h)

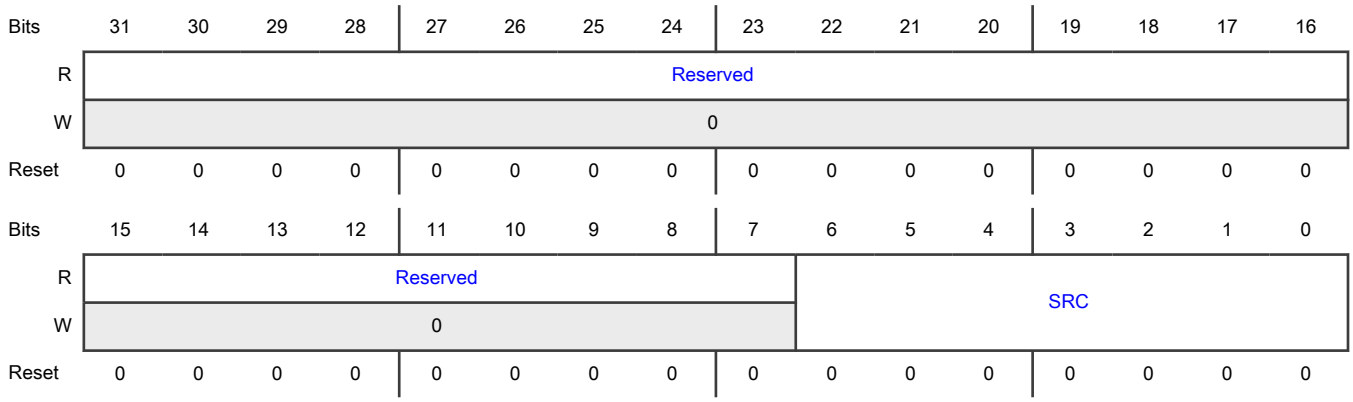
Function

Each of the DMA channels can be independently associated with various peripherals in the system. The Channel Multiplexor Configuration register selects the peripheral assigned to each channel. Service requests from the peripheral should be disabled when configuring a channel to a peripheral source.

Each channel must have a unique value when selecting a peripheral slot in the channel mux configuration. The only value that may overlap is source 0. If there is an attempt to write a mux configuration value that is already consumed by any channel, a mux configuration of 0 (SRC = 0) will be written.

All channels will default to source 0. When a particular peripheral is needed, the channel's mux configuration is set to that source number. When the peripheral is no longer needed, the mux configuration for that channel should be written to 0, thus releasing the resource.

Diagram



Fields

Field	Function
31-7 —	Reserved
6-0 SRC	Service Request Source Hardware service request source for the channel. **NOTE** With the exception of 0, attempts to write a value already in use will be forced to 0.

71.6.6.8 TCD Source Address (TCD0_SADDR - TCD15_SADDR)

Offset

For n = 0 to 15:

Register	Offset
TCDn_SADDR	20h + (n × 1000h)

Function

This register contains the address for the read transactions.

Diagram

Fields

Field	Function
15-0 SOFF	Source Address Signed Offset Sign-extended offset applied to the current source address to form the next-state value as each source read is completed.

71.6.6.10 TCD Transfer Attributes (TCD0_ATTR - TCD15_ATTR)

Offset

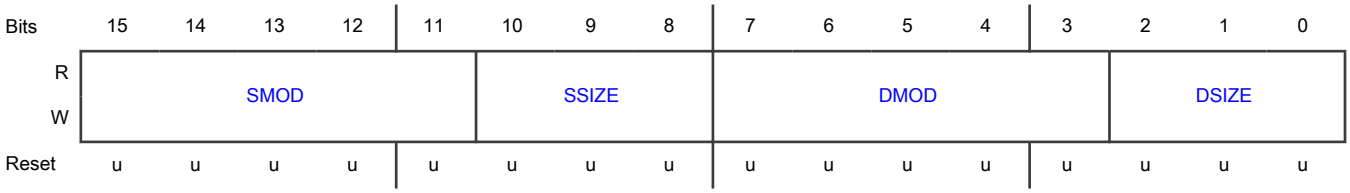
For n = 0 to 15:

Register	Offset
TCDn_ATTR	26h + (n × 1000h)

Function

This register contains size and option modulo addressing information for source and destination addresses.

Diagram



Fields

Field	Function
15-11 SMOD	Source Address Modulo This field defines a specific address range, which is the value after the SADDR + SOFF calculation is performed on the original register value. Setting this field makes it easy to implement a circular data queue. For data queues requiring power-of-2-sized bytes, the queue must start at a 0-modulo-size address and the SMOD field must be set to the appropriate value for the queue, freezing the required number of upper address bits. The value programmed into this field specifies the number of lower address bits that are allowed to change. For a circular queue application, you typically set TCDn_SOFF[SOFF] to the transfer size to implement post-increment addressing, with the SMOD function constraining the addresses to a 0-modulo-size range. 0_0000b - Source address modulo feature disabled
10-8 SSIZE	Source Data Transfer Size 000b - 8-bit 001b - 16-bit 010b - 32-bit 011b - 64-bit 100b - 16-byte 101b - 32-byte 110b - 64-byte 111b - Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-3 DMOD	Destination Address Modulo See the SMOD definition.
2-0 DSIZE	Destination Data Transfer Size See the SSIZE definition.

71.6.6.11 TCD Transfer Size Without Minor Loop Offsets (TCD0_NBYTES_MLOFFNO - TCD15_NBYTES_MLOFFNO)

Offset

For n = 0 to 15:

Register	Offset
TCDn_NBYTES_MLOFFNO	28h + (n × 1000h)

Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offsets are address offset values added to the final source address (TCDn_SADDR), or destination address (TCDn_DADDR), upon minor loop completion. Minor loop completion is when the channel has finished the service request and has transferred NBYTES. When minor loop offsets are enabled, the minor loop offset value (TCDn_NBYTES_MLOFFYES[MLOFF]) is added to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both, prior to the addresses being written back to the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When minor loop mapping is enabled (SMLOE or DMLOE is 1), TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is redefined. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is used to specify multiple fields:

- A source enable bit (SMLOE) to specify the minor loop offset must be applied to the source address (TCDn_SADDR) upon minor loop completion
- A destination enable bit (DMLOE) to specify the minor loop offset must be applied to the destination address (TCDn_DADDR) upon minor loop completion
- The sign extended minor loop offset value (MLOFF)

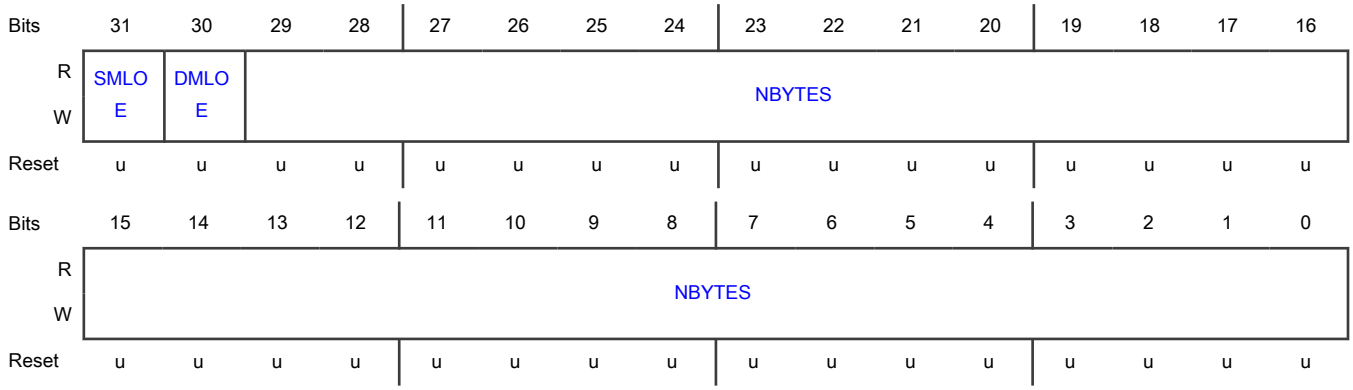
The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is defined as follows:

- If SMLOE = 0 and DMLOE = 0, then see the TCDn_NBYTES_MLOFFNO register description.
- If either SMLOE or DMLOE is 1, then see the TCDn_NBYTES_MLOFFYES register description.

Diagram



Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - Minor loop offset not applied to SADDR 1b - Minor loop offset applied to SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0b - Minor loop offset not applied to DADDR 1b - Minor loop offset applied to DADDR
29-0 NBYTES	Number of Bytes To Transfer Per Service Request Number of bytes to be transferred for each service request of the channel. When a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the byte transfer count has been reached. This process is normally an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the byte count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major loop iteration count (CITER) is decremented by one and written back to the TCD memory. If the major iteration count is complete, additional processing is performed.

71.6.6.12 TCD Transfer Size with Minor Loop Offsets (TCD0_NBYTES_MLOFFYES - TCD15_NBYTES_MLOFFYES)

Offset

For n = 0 to 15:

Register	Offset
TCDn_NBYTES_MLOFFYES	28h + (n × 1000h)

Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offset is an address offset value added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. Minor loop completion occurs when the channel has finished the service request and has transferred NBYTES. Minor loop offsets are enabled by setting either the source enable bit (SMLOE) or the destination enable bit (DMLOE).

The source enable bit (SMLOE) specifies the minor loop offset value (MLOFF) that is to be applied to the source address (TCDn_SADDR) upon minor loop completion. The destination enable bit (DMLOE) specifies the minor loop offset (MLOFF) that is to be applied to the destination address (TCDn_DADDR) upon minor loop completion.

If the major loop is complete, the minor loop offsets are ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

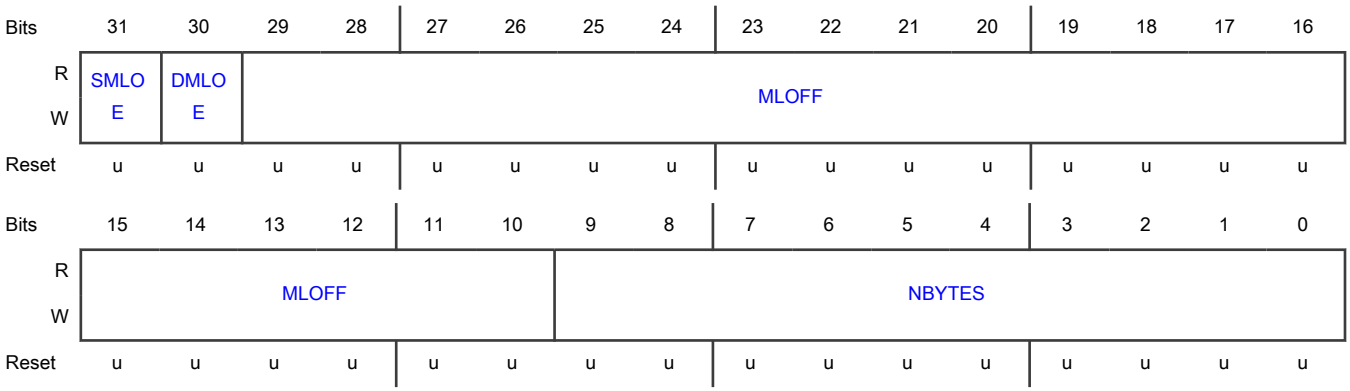
When you enable the minor loop offset overlay (either SMLOE or DMLOE is 1), eDMA redefines TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES specifies the sign-extended minor loop offset value (MLOFF). The same offset value (MLOFF) applies to both source and destination minor loop offsets. When the minor loop offset is enabled, you must align it to the transfer size of the source or destination it is associated with. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFNO) defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFYES is defined as follows:

- If either minor loop offset is enabled (SMLOE or DMLOE = 1), then see the TCDn_NBYTES_MLOFFYES register description.
- If SMLOE and DMLOE are both 0, then see the TCDn_NBYTES_MLOFFNO register description.

Diagram



Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - Minor loop offset not applied to SADDR 1b - Minor loop offset applied to SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0b - Minor loop offset not applied to DADDR 1b - Minor loop offset applied to DADDR
29-10 MLOFF	Minor Loop Offset If SMLOE or DMLOE is 1, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes.
9-0 NBYTES	Number of Bytes To Transfer Per Service Request The number of bytes to be transferred in each service request of the channel. As a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the minor byte transfer count has been reached. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major iteration count is decremented and restored to the TCD memory. If the major iteration count is complete, additional processing is performed.

71.6.6.13 TCD Last Source Address Adjustment / Store DADDR Address (TCD0_SLAST_SDA - TCD15_SLAST_SDA)

Offset

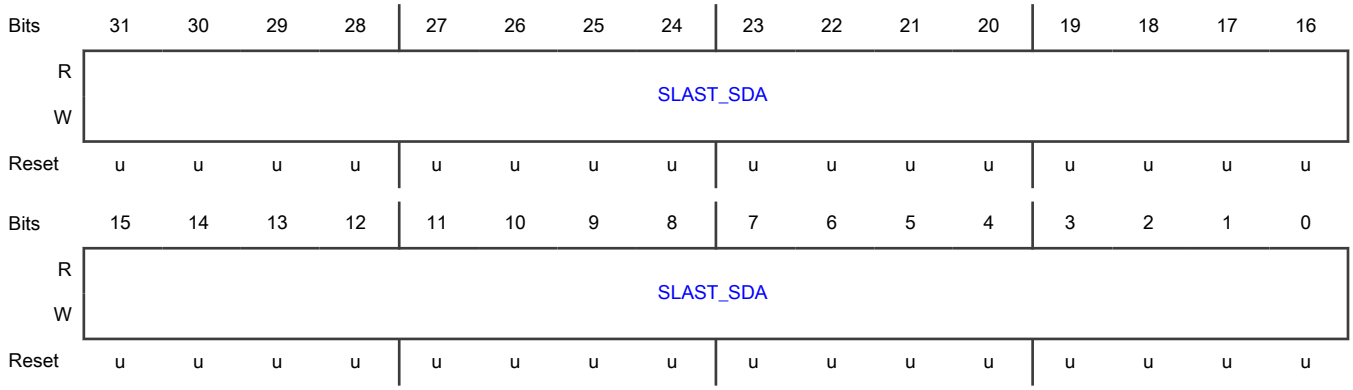
For n = 0 to 15:

Register	Offset
TCDn_SLAST_SDA	2Ch + (n × 1000h)

Function

This register contains the value added to the source address when the major loop is complete. When the store destination address option is enabled, this field provides a pointer to memory for storing the final destination address.

Diagram



Fields

Field	Function
31-0 SLAST_SDA	Last Source Address Adjustment / Store DADDR Address Source last address adjustment or the system memory address for destination address (DADDR) storage. If (TCDn_CSR[ESDA] = 0), then: • Adjustment value is added to the source address at the completion of the major iteration count. This value can be used to restore the source address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final source address adjustment. Otherwise: • This address points to the 32-bit-aligned memory location where the destination address (DADDR) is to be stored in system memory. By saving the final destination address in system memory via the ESDA feature, you are able to compute the size of a variable destination data buffer by simply subtracting the beginning DADDR from the final, saved DADDR. This feature is used together with the scatter/gather operation to prevent the loss of the final DADDR, which is overwritten during the scatter/gather operation. The "Store Destination Address" (SDA) value must be a 32-bit-aligned location because the eDMA forces the lower two address bits of the SLAST_SDA field to zero when ESDA is enabled. The module performs this write operation when the major loop is done; that is, when the major iteration count (CITER) decrements to zero.

71.6.6.14 TCD Destination Address (TCD0_DADDR - TCD15_DADDR)

Offset

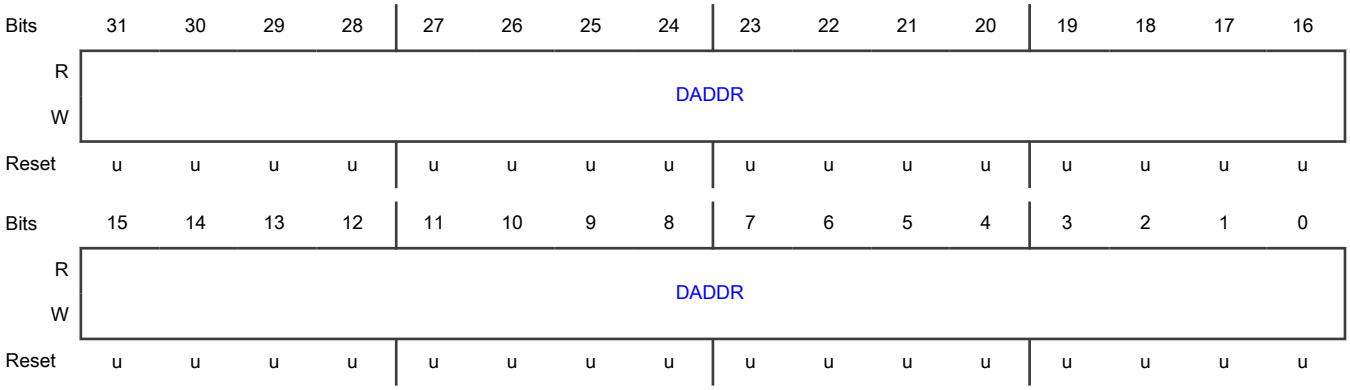
For n = 0 to 15:

Register	Offset
TCDn_DADDR	30h + (n × 1000h)

Function

This register contains the address for the write transactions.

Diagram



Fields

Field	Function
31-0 DADDR	Destination Address Memory address pointing to the destination data.

71.6.6.15 TCD Signed Destination Address Offset (TCD0_DOFF - TCD15_DOFF)

Offset

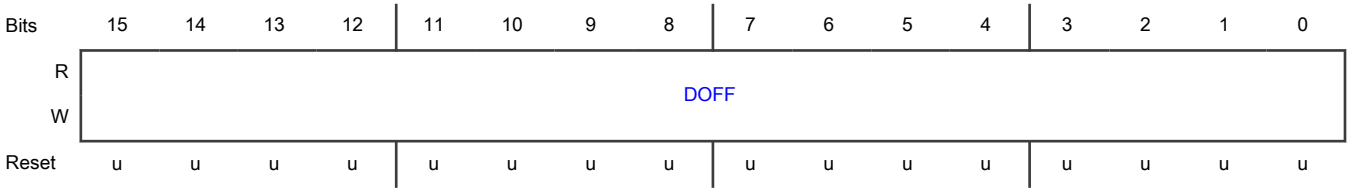
For n = 0 to 15:

Register	Offset
TCDn_DOFF	34h + (n × 1000h)

Function

This register contains the sign-extended value added to Destination Address register after each write transaction.

Diagram



Fields

Field	Function
15-0 DOFF	Destination Address Signed Offset Sign-extended offset that is applied to the current destination address to form the next-state value as each destination write is completed.

71.6.6.16 TCD Current Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_CITER_ELINKNO - TCD15_CITER_ELINKNO)

Offset

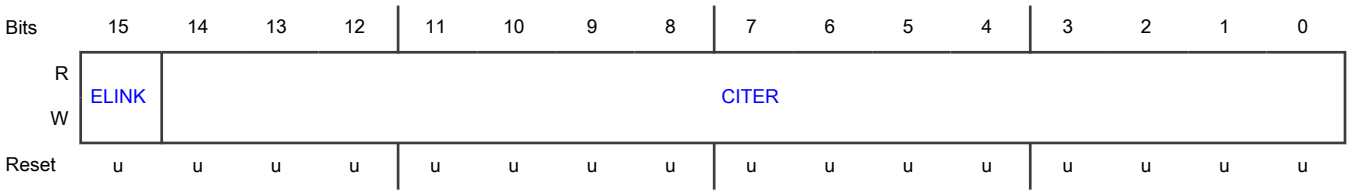
For n = 0 to 15:

Register	Offset
TCDn_CITER_ELINKNO	36h + (n × 1000h)

Function

If TCDn_CITER[ELINK] is 0, the TCDn_CITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel to 1. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking. **NOTE** This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

71.6.6.17 TCD Current Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_CITER_ELINKYES - TCD15_CITER_ELINKYES)

Offset

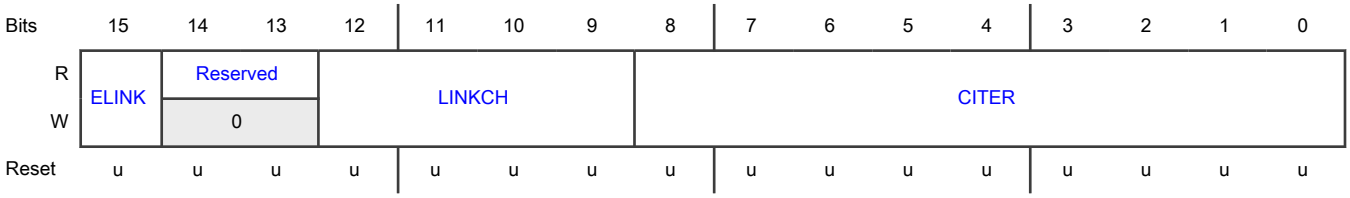
For n = 0 to 15:

Register	Offset
TCDn_CITER_ELINKYES	36h + (n × 1000h)

Function

If TCDn_CITER[ELINK] is 1, the TCDn_CITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. When enabled, an internal mechanism sets the TCDn_CSR[START] field of the specified channel (LINKCH) upon minor loop completion. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-13 —	Reserved
12-9 LINKCH	Minor Loop Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted the eDMA engine initiates a channel service request to the channel defined by this field by writing that channel's TCDn_CSR[START] field to 1.
8-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to the TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

71.6.6.18 TCD Last Destination Address Adjustment / Scatter Gather Address (TCD0_DLAST_SGA - TCD15_DLAST_SGA)

Offset

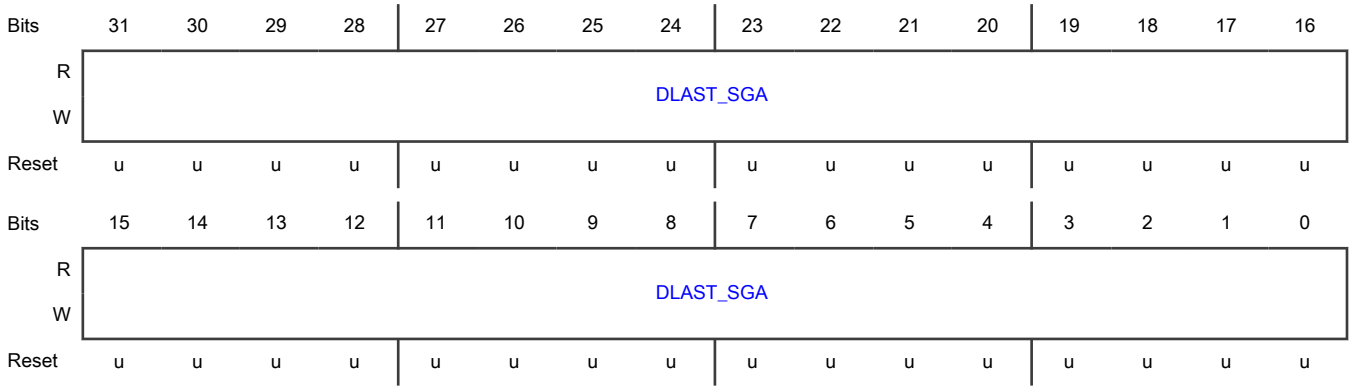
For n = 0 to 15:

Register	Offset
TCDn_DLAST_SGA	38h + (n × 1000h)

Function

This register contains the value added to the destination address when the major loop is complete. When the Scatter/Gather option is enabled, this field provides a pointer to memory for fetching a transfer control descriptor to reprogram the channel.

Diagram



Fields

Field	Function
31-0 DLAST_SGA	Last Destination Address Adjustment / Scatter Gather Address Adjustment of the last destination address or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather). If (TCDn_CSR[ESG] = 0) then: • Adjustment value is added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final destination address adjustment. Otherwise: • This address points to the beginning of a 0-modulo 32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo 32-byte, or else a configuration error is reported.

71.6.6.19 TCD Control and Status (TCD0_CSR - TCD15_CSR)

Offset

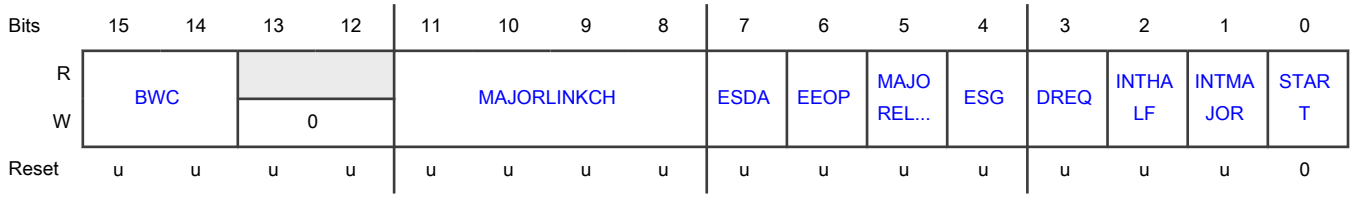
For n = 0 to 15:

Register	Offset
TCDn_CSR	3Ch + (n × 1000h)

Function

This register is used to enable optional features.

Diagram



Fields

Field	Function
15-14 BWC	Bandwidth Control Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces eDMA to stall after the completion of each read/write access, to control the bus request bandwidth seen by the system bus interconnect. **NOTE** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00b - No eDMA engine stalls 01b - Reserved 10b - eDMA engine stalls for 4 cycles after each R/W 11b - eDMA engine stalls for 8 cycles after each R/W
13-12 —	Reserved
11-8 MAJORLINKCH	Major Loop Link Channel Number If (MAJORELINK = 0) then: • No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted. Otherwise: • After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field to 1.
7 ESDA	Enable Store Destination Address As the channel completes the major loop by either the current iteration counter (CITER) decrementing to 0, or by receiving an enabled end-of-packet signal, this field enables writing the destination address (DADDR) to the address stored in the SLAST_SDA field. The value written to system memory is the next DADDR value prior to the DLAST_SGA offset being applied, or overwritten by an enabled scatter/gather operation. When the ESDA bit is 1, SLAST_SDA contains the write pointer instead of the final source address offset. Because this is a pointer and not a final offset, a last source address offset of zero is applied to SADDR instead of the SLAST_SGA value. 0b - Ability to store destination address to system memory disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Ability to store destination address to system memory enabled
6 EEOP	Enable End-Of-Packet Processing When enabled by the EEOP field, an end-of-packet hardware input signal directs eDMA to discontinue executing the active channel, and to treat the shutdown as the major-loop-completed event. If the EEOP field is 1, the end-of-packet signal from supported peripherals is accepted. If the EEOP field is 0, the end-of-packet input is ignored. With an end-of-packet retirement, the current TCD destination address (or ESDA-saved destination address), minus the software-saved initial address (DADDR), reflects the total amount of data transferred. 0b - End-of-packet operation disabled 1b - End-of-packet hardware input signal enabled
5 MAJORELINK	Enable Link When Major Loop Complete As the channel completes the major loop, this flag enables linking to another channel defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. **NOTE** To support the dynamic linking coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
4 ESG	Enable Scatter/Gather Processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses TCDn_DLAST_SGA as a memory pointer to a 0-modulo 32-bit address containing a 32-byte data structure, which is loaded as the transfer control descriptor into local memory. **NOTE** To support the dynamic scatter/gather coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0b - Current channel's TCD is normal format 1b - Current channel's TCD specifies scatter/gather format.
3 DREQ	Disable Request If this flag is 1, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches 0. 0b - No operation. Channel's ERQ field not affected 1b - Clear the ERQ field to 0 upon major loop completion, thus disabling hardware service requests. Channel's ERQ field cleared to 0 when major loop complete
2	Enable Interrupt If Major Counter Half-complete

Table continues on the next page...

Table continued from the previous page...

Field	Function
INTHALF	If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER = (BITER/2)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes, or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE** If BITER = 1, do not use INTHALF; use INTMAJOR instead. 0b - Halfway point interrupt disabled 1b - Halfway point interrupt enabled
1 INTMAJOR	Enable Interrupt If Major count complete If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count (CITER) reaches 0. 0b - End-of-major loop interrupt disabled 1b - End-of-major loop interrupt enabled
0 START	Channel Start If this flag is 1, the channel is requesting service. The eDMA hardware automatically clears this flag to 0 after the channel begins execution. 0b - Channel not explicitly started 1b - Channel explicitly started via a software-initiated service request

71.6.6.20 TCD Beginning Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_BITER_ELINKNO - TCD15_BITER_ELINKNO)

Offset

For n = 0 to 15:

Register	Offset
TCDn_BITER_ELINKNO	3Eh + (n × 1000h)

Function

If the TCDn_BITER[ELINK] field is 0, the TCDn_BITER register is defined as follows.

Diagram

Fields

Field	Function
15 ELINK	Enables Link As the channel completes the minor loop, this flag enables linking to another channel as defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. If channel linking is disabled, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-0 BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be set equal to the value in the CITER field. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0x0001.

71.6.6.21 TCD Beginning Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_BITER_ELINKYES - TCD15_BITER_ELINKYES)

Offset

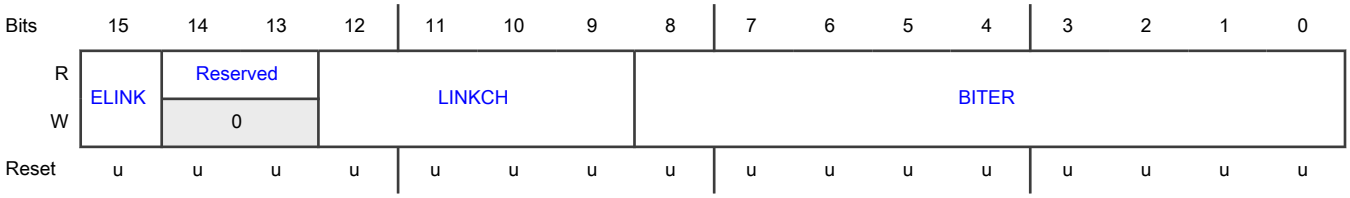
For n = 0 to 15:

Register	Offset
TCDn_BITER_ELINKYES	3Eh + (n × 1000h)

Function

If the TCDn_BITER[ELINK] field is set, the TCDn_BITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. If channel linking disables, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-13 —	Reserved
12-9 LINKCH	Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field.
8-0 BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be set equal to the value in the CITER field. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0x0001.

71.6.7.2 Channel Control and Status (CH0_CSR - CH7_CSR)

Offset

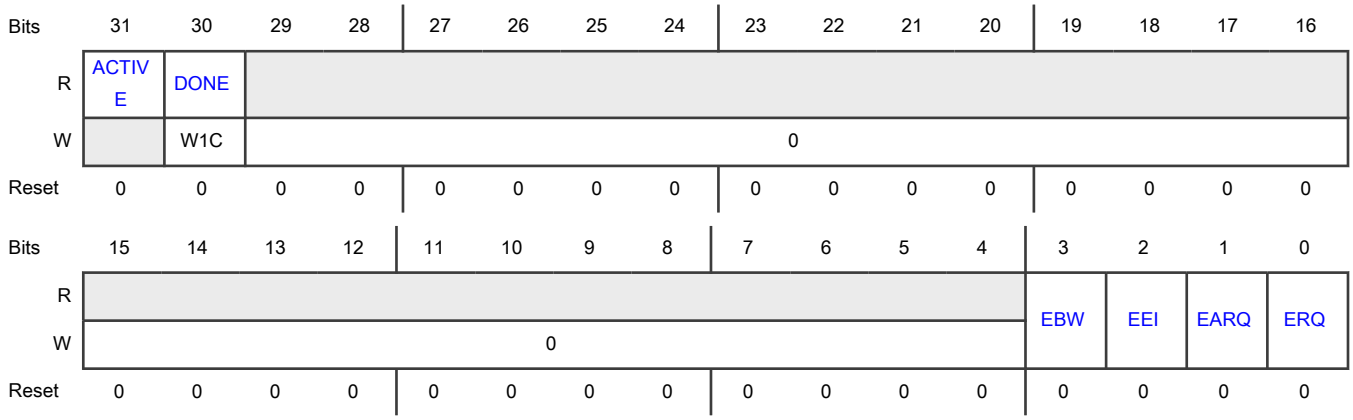
For n = 0 to 7:

Register	Offset
CHn_CSR	0h + (n × 1000h)

Function

This register contains several fields related to hardware and interrupt requests, configuration, and status for the given channel.

Diagram



Fields

Field	Function
31 ACTIVE	Channel Active The ACTIVE field indicates the channel was selected by arbitration and is executing the prescribed transfers. The eDMA sets it to 1 when channel service begins, and clears it to 0 as the minor loop completes or when any error condition is detected. Except for dynamic scatter/gather or dynamic channel linking, you must not modify the transfer control descriptor when a channel is active.
30 DONE	Channel Done The DONE field indicates the eDMA has completed the major loop. The eDMA engine sets this field as the CITER count reaches zero. If enabled, the eDMA generates an interrupt request corresponding to this completed channel. The software clears it, or the hardware clears it when the channel is activated. **NOTE** This field must be cleared to 0 before writing the MAJORELINK or ESG fields.
29-4 —	Reserved
3 EBW	Enable Buffered Writes When buffered writes are enabled, all writes except for the last write sequence of the minor loop are signaled by the eDMA as bufferable. 0b - Buffered writes on system bus disabled. Buffered writes on system bus disabled 1b - Buffered writes on system bus enabled. Bufferable write signal asserted on all system bus writes except during last write sequence
2 EEI	Enable Error Interrupt

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The EEI field enables the error interrupt signal for the channel. The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller. 0b - Error signal for corresponding channel does not generate error interrupt 1b - Assertion of error signal for corresponding channel generates error interrupt request
1 EARQ	Enable Asynchronous DMA Request The enable asynchronous DMA request field (EARQ) does not affect DMA operations. When set to 1, this field allows the hardware service request enable field (ERQ) to propagate out of the DMA to the power controller. When cleared to 0, this field masks the hardware service request enable field to the power controller. 0b - Disable asynchronous DMA request for the channel 1b - Enable asynchronous DMA request for the channel
0 ERQ	Enable DMA Request Disable a channel's hardware service request at the source before clearing the channel's ERQ field. The DMA hardware request input signal and the enable request field (ERQ) must be asserted before a channel's hardware service request is accepted. The state of the eDMA enable request field does not affect a channel service request made explicitly through software or channel linking. The state of the ERQ field does not affect the channel's START field. 0b - DMA hardware request signal for corresponding channel disabled 1b - DMA hardware request signal for corresponding channel enabled

71.6.7.3 Channel Error Status (CH0_ES - CH7_ES)

Offset

For n = 0 to 7:

Register	Offset
CHn_ES	4h + (n × 1000h)

Function

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor
- An error termination to a bus initiator read or write cycle

The ERR field signals the presence of an error for the channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate field in this register. The outputs of this register are enabled by the contents of the CHn_CSR[EEI] field, then logically summed across all channels to form an error interrupt request, which may be routed to the interrupt controller.

During the execution of the interrupt service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when eDMA detects an error. The

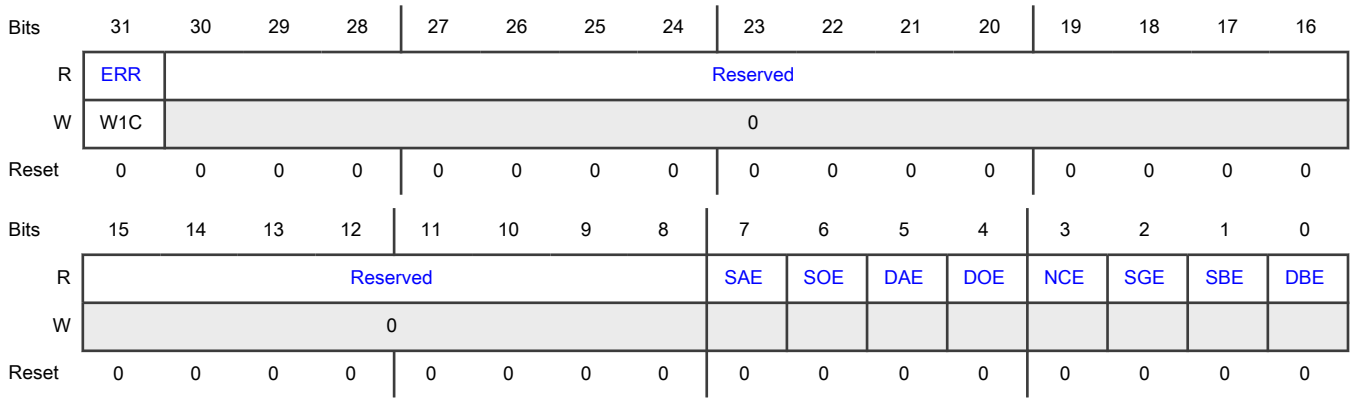
contents of this ERR register field can also be polled because a non-zero value indicates the presence of a channel error, regardless of the state of the EEI mask.

The state of any given channel's error indicators is affected by writes to this register. Writing a 1 to the ERR field clears the channel's error status, and writing a 0 has no effect.

An unspecified error, where only the ERR field is set to 1, indicates that either a transfer was cancelled with an error. The Management Page Error Status register has full view of the error condition.

See Fault reporting and handling for more details.

Diagram



Fields

Field	Function
31 ERR	Error In Channel 0b - An error in this channel has not occurred 1b - An error in this channel has occurred
30-8 —	Reserved
7 SAE	Source Address Error TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SADDR field
6 SOE	Source Offset Error TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SOFF field
5 DAE	Destination Address Error TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No destination address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DADDR field
4 DOE	Destination Offset Error TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DOFF field
3 NCE	NBYTES/CITER Configuration Error This error indicates that one of the following has occurred: • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE] • TCDn_CITER[CITER] is equal to zero • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK] 0b - No NBYTES/CITER configuration error 1b - Last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields
2 SGE	Scatter/Gather Configuration Error When this field is 1, it indicates that TCDn_DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG]is enabled. 0b - No scatter/gather configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DLAST_SGA field
1 SBE	Source Bus Error 0b - No source bus error 1b - Last recorded error was bus error on source read
0 DBE	Destination Bus Error 0b - No destination bus error 1b - Last recorded error was bus error on destination write

71.6.7.4 Channel Interrupt Status (CH0_INT - CH7_INT)

Offset

For n = 0 to 7:

Register	Offset
CHn_INT	8h + (n × 1000h)

Function

The INT field signals the presence of an interrupt request for the channel. Depending on the appropriate bit setting in the transfer control descriptors, the eDMA engine generates an interrupt on data transfer completion.

The outputs of this register are directly routed to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. On writes to INT, a 1 clears the channel's interrupt request. A zero has no effect on the channel's current interrupt status.

71.6.7.5 Channel System Bus (CH0_SBR - CH7_SBR)

Offset

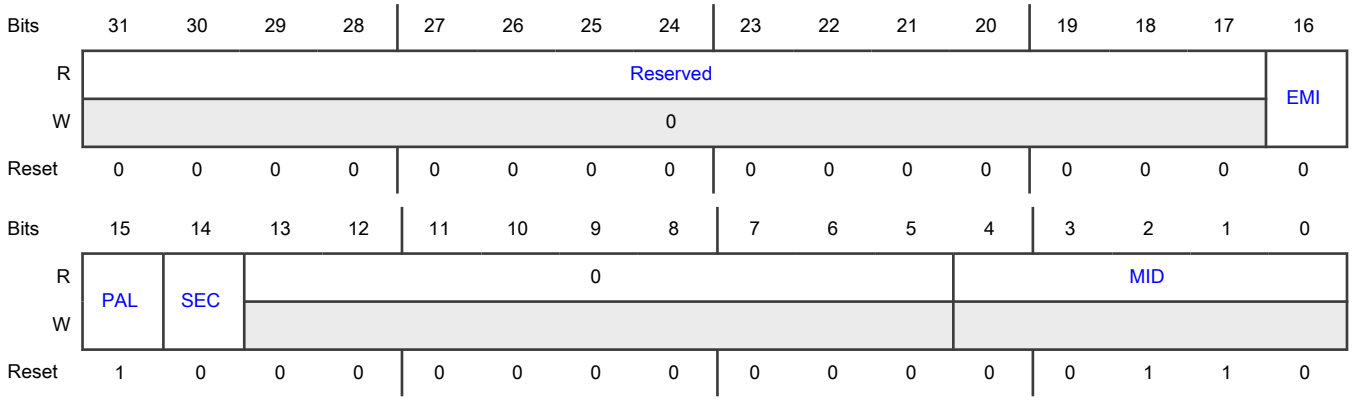
For n = 0 to 7:

Register	Offset
CHn_SBR	Ch + (n × 1000h)

Function

The Channel System Bus register places identification and attribute information on the system bus interface for the eDMA.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 EMI	Enable Initiator ID Replication The eDMA initiator ID replication field allows the eDMA to use the same protection level and system bus ID of the initiator programming the eDMA's TCD. When enabled, the eDMA uses the initiator ID and protection level stored in the CHn_SBR registers, instead of the eDMA's default values. When a initiator (for example a core) programs a TCD, its initiator ID is captured when the TCD*n*_CSR control attributes are written. A scatter/gather operation does not affect the CHn_SBR registers. You can write the EMI only if MP_CSR[GMRC] = 1, which means Global Initiator ID Replication Control is enabled; otherwise, the EMI is forced to zero. **NOTE** If initiator ID replication is disabled, the nonsecure, privileged protection level for DMA transfers is used. 0b - Initiator ID replication is disabled 1b - Initiator ID replication is enabled
15 PAL	Privileged Access Level This field controls DMA's protection level on the system bus when the channel is active. **NOTE** The value written into this register cannot exceed the security and privilege level of the core or other initiator writing the channel's system bus register; CH*n*_SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0b - User protection level for DMA transfers 1b - Privileged protection level for DMA transfers
14 SEC	Security Level DMA's security level on the system bus when the channel is active.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE The value written into this register cannot exceed the security and privilege level of the core or other initiator writing the channel's system bus register; CH*n*_SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0b - Nonsecure protection level for DMA transfers 1b - Secure protection level for DMA transfers
13-5 —	Reserved
4-0 MID	Initiator ID This field controls the DMA's initiator ID on the system bus when the channel is active. **NOTE** The ID captured in this register reflects the initiator ID of the core or other initiator writing the channel's security attributes, TCD*n*_SBR[SEC].

71.6.7.6 Channel Priority (CH0_PRI - CH7_PRI)

Offset

For n = 0 to 7:

Register	Offset
CHn_PRI	10h + (n × 1000h)

Function

The contents of these registers define unique priorities associated with each channel within the same channel group. Channel grouping is programmed via Channel Arbitration Group (CH0_GRPRI - CH15_GRPRI).

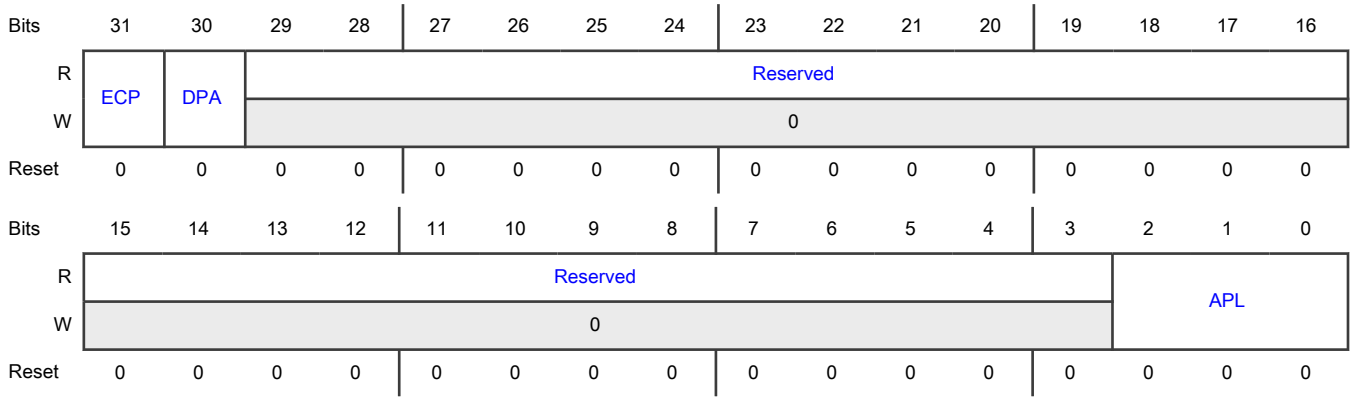
The channel priorities within a group are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Software must program the channel priorities with unique values; otherwise, channel numbers with the same, non-zero value, will be selected based on channel number with the higher channel number having higher priority.

If more than one channel in a group has an arbitration priority level value of zero, then the arbitration mode field MP_CSR[ERCA] is used to determine the arbitration scheme for all channels with APL=0 within a group.

When you enable round-robin channel arbitration (MP_CSR[ERCA] = 1), all channels with APL=0 within a group will use a round-robin arbitration scheme, which rotates among these channels requesting service without regard to priority. Round-robin provides a fairness mechanism within an arbitration group.

When you enable fixed-priority channel arbitration (MP_CSR[ERCA] = 0), eDMA selects channels with APL=0 based on channel number, with the higher channel number having higher priority.

Diagram



Fields

Field	Function
31 ECP	Enable Channel Preemption 0b - Channel cannot be suspended by a higher-priority channel's service request 1b - Channel can be temporarily suspended by a higher-priority channel's service request
30 DPA	Disable Preempt Ability 0b - Channel can suspend a lower-priority channel 1b - Channel cannot suspend any other channel, regardless of channel priority
29-3 —	Reserved
2-0 APL	Arbitration Priority Level Channel priority level for arbitration within the assigned arbitration group.

71.6.7.7 Channel Multiplexor Configuration (CH0_MUX - CH7_MUX)

Offset

For n = 0 to 7:

Register	Offset
CHn_MUX	14h + (n × 1000h)

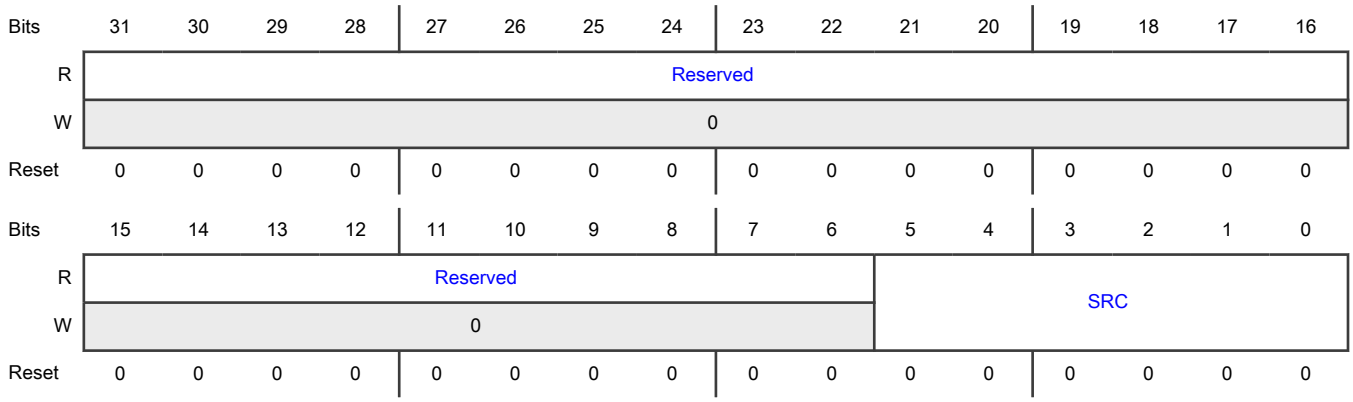
Function

Each of the DMA channels can be independently associated with various peripherals in the system. The Channel Multiplexor Configuration register selects the peripheral assigned to each channel. Service requests from the peripheral should be disabled when configuring a channel to a peripheral source.

Each channel must have a unique value when selecting a peripheral slot in the channel mux configuration. The only value that may overlap is source 0. If there is an attempt to write a mux configuration value that is already consumed by any channel, a mux configuration of 0 (SRC = 0) will be written.

All channels will default to source 0. When a particular peripheral is needed, the channel's mux configuration is set to that source number. When the peripheral is no longer needed, the mux configuration for that channel should be written to 0, thus releasing the resource.

Diagram



Fields

Field	Function
31-6 —	Reserved
5-0 SRC	Service Request Source Hardware service request source for the channel. **NOTE** With the exception of 0, attempts to write a value already in use will be forced to 0.

71.6.7.8 TCD Source Address (TCD0_SADDR - TCD7_SADDR)

Offset

For n = 0 to 7:

Register	Offset
TCDn_SADDR	20h + (n × 1000h)

Function

This register contains the address for the read transactions.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
15-0 SOFF	Source Address Signed Offset Sign-extended offset applied to the current source address to form the next-state value as each source read is completed.

71.6.7.10 TCD Transfer Attributes (TCD0_ATTR - TCD7_ATTR)

Offset

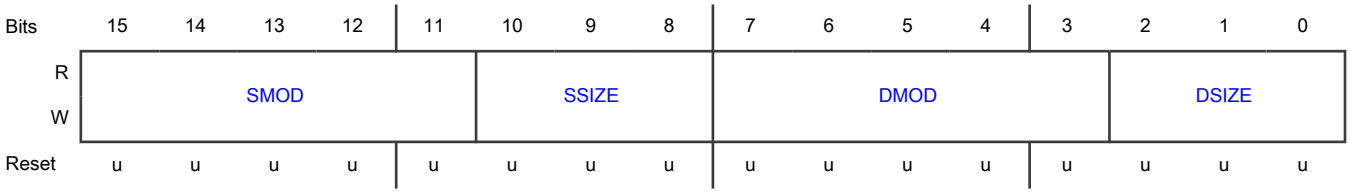
For n = 0 to 7:

Register	Offset
TCDn_ATTR	26h + (n × 1000h)

Function

This register contains size and option modulo addressing information for source and destination addresses.

Diagram



Fields

Field	Function
15-11 SMOD	Source Address Modulo This field defines a specific address range, which is the value after the SADDR + SOFF calculation is performed on the original register value. Setting this field makes it easy to implement a circular data queue. For data queues requiring power-of-2-sized bytes, the queue must start at a 0-modulo-size address and the SMOD field must be set to the appropriate value for the queue, freezing the required number of upper address bits. The value programmed into this field specifies the number of lower address bits that are allowed to change. For a circular queue application, you typically set TCDn_SOFF[SOFF] to the transfer size to implement post-increment addressing, with the SMOD function constraining the addresses to a 0-modulo-size range. 0_0000b - Source address modulo feature disabled
10-8 SSIZE	Source Data Transfer Size 000b - 8-bit 001b - 16-bit 010b - 32-bit 011b - 64-bit 100b - 16-byte 101b - 32-byte 110b - 64-byte 111b - Reserved

Table continued from the previous page...

Field	Function
7-3 DMOD	Destination Address Modulo See the SMOD definition.
2-0 DSIZE	Destination Data Transfer Size See the SSIZE definition.

71.6.7.11 TCD Transfer Size Without Minor Loop Offsets (TCD0_NBYTES_MLOFFNO - TCD7_NBYTES_MLOFFNO)

Offset

For n = 0 to 7:

Register	Offset
TCDn_NBYTES_MLOFFNO	28h + (n × 1000h)

Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offsets are address offset values added to the final source address (TCDn_SADDR), or destination address (TCDn_DADDR), upon minor loop completion. Minor loop completion is when the channel has finished the service request and has transferred NBYTES. When minor loop offsets are enabled, the minor loop offset value (TCDn_NBYTES_MLOFFYES[MLOFF]) is added to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both, prior to the addresses being written back to the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When minor loop mapping is enabled (SMLOE or DMLOE is 1), TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is redefined. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is used to specify multiple fields:

- A source enable bit (SMLOE) to specify the minor loop offset must be applied to the source address (TCDn_SADDR) upon minor loop completion
- A destination enable bit (DMLOE) to specify the minor loop offset must be applied to the destination address (TCDn_DADDR) upon minor loop completion
- The sign extended minor loop offset value (MLOFF)

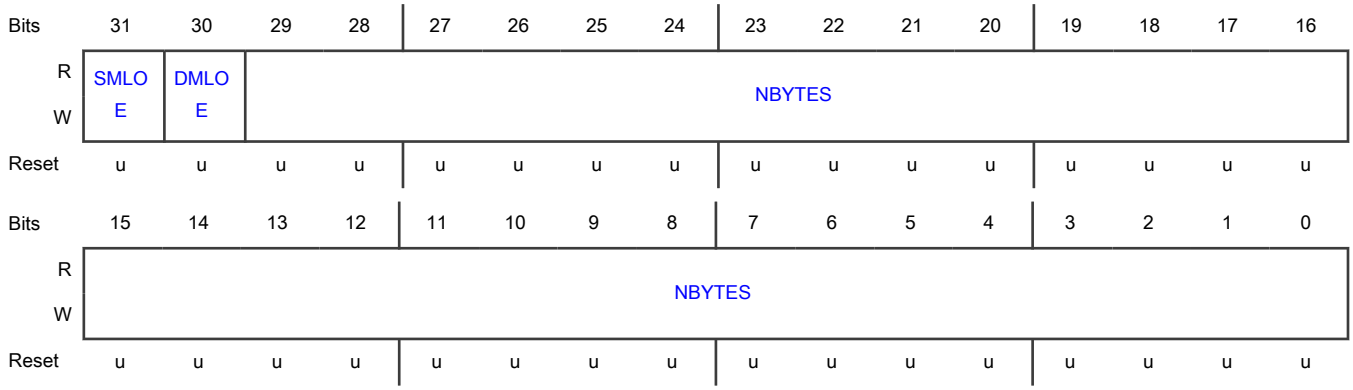
The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is defined as follows:

- If SMLOE = 0 and DMLOE = 0, then see the TCDn_NBYTES_MLOFFNO register description.
- If either SMLOE or DMLOE is 1, then see the TCDn_NBYTES_MLOFFYES register description.

Diagram



Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - Minor loop offset not applied to SADDR 1b - Minor loop offset applied to SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0b - Minor loop offset not applied to DADDR 1b - Minor loop offset applied to DADDR
29-0 NBYTES	Number of Bytes To Transfer Per Service Request Number of bytes to be transferred for each service request of the channel. When a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the byte transfer count has been reached. This process is normally an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the byte count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major loop iteration count (CITER) is decremented by one and written back to the TCD memory. If the major iteration count is complete, additional processing is performed.

71.6.7.12 TCD Transfer Size with Minor Loop Offsets (TCD0_NBYTES_MLOFFYES - TCD7_NBYTES_MLOFFYES)

Offset

For n = 0 to 7:

Register	Offset
TCDn_NBYTES_MLOFFYES	28h + (n × 1000h)

Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offset is an address offset value added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. Minor loop completion occurs when the channel has finished the service request and has transferred NBYTES. Minor loop offsets are enabled by setting either the source enable bit (SMLOE) or the destination enable bit (DMLOE).

The source enable bit (SMLOE) specifies the minor loop offset value (MLOFF) that is to be applied to the source address (TCDn_SADDR) upon minor loop completion. The destination enable bit (DMLOE) specifies the minor loop offset (MLOFF) that is to be applied to the destination address (TCDn_DADDR) upon minor loop completion.

If the major loop is complete, the minor loop offsets are ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

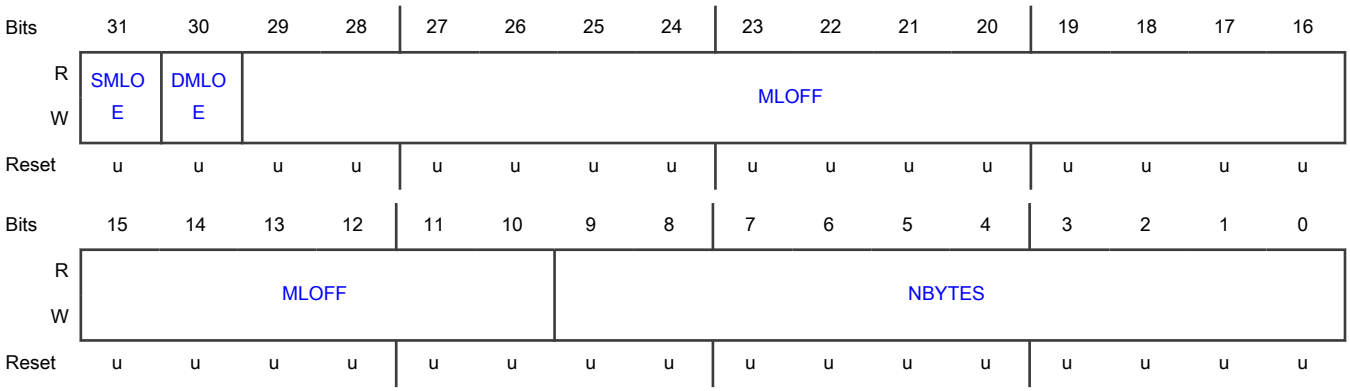
When you enable the minor loop offset overlay (either SMLOE or DMLOE is 1), eDMA redefines TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES specifies the sign-extended minor loop offset value (MLOFF). The same offset value (MLOFF) applies to both source and destination minor loop offsets. When the minor loop offset is enabled, you must align it to the transfer size of the source or destination it is associated with. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFNO) defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFYES is defined as follows:

- If either minor loop offset is enabled (SMLOE or DMLOE = 1), then see the TCDn_NBYTES_MLOFFYES register description.
- If SMLOE and DMLOE are both 0, then see the TCDn_NBYTES_MLOFFNO register description.

Diagram



Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - Minor loop offset not applied to SADDR 1b - Minor loop offset applied to SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0b - Minor loop offset not applied to DADDR 1b - Minor loop offset applied to DADDR
29-10 MLOFF	Minor Loop Offset If SMLOE or DMLOE is 1, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes.
9-0 NBYTES	Number of Bytes To Transfer Per Service Request The number of bytes to be transferred in each service request of the channel. As a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the minor byte transfer count has been reached. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major iteration count is decremented and restored to the TCD memory. If the major iteration count is complete, additional processing is performed.

71.6.7.13 TCD Last Source Address Adjustment / Store DADDR Address (TCD0_SLAST_SDA - TCD7_SLAST_SDA)

Offset

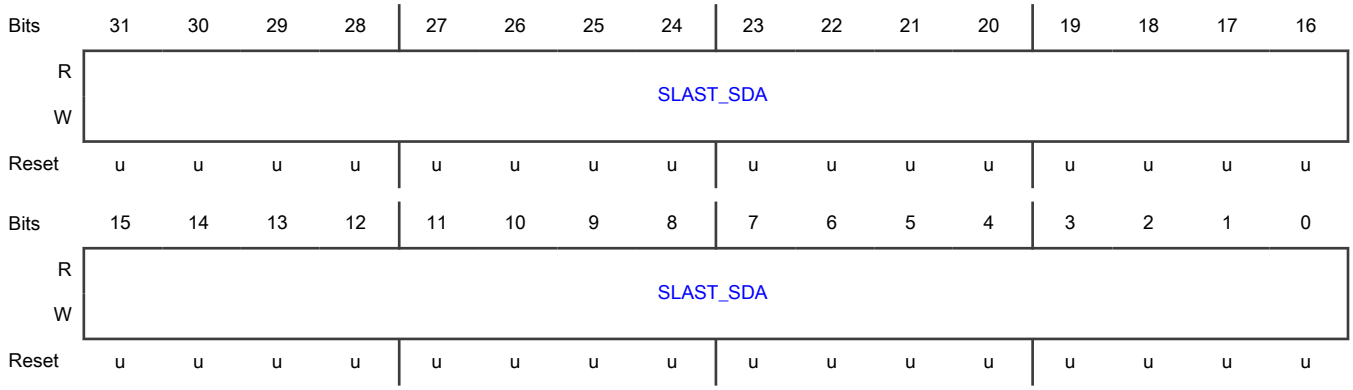
For n = 0 to 7:

Register	Offset
TCDn_SLAST_SDA	2Ch + (n × 1000h)

Function

This register contains the value added to the source address when the major loop is complete. When the store destination address option is enabled, this field provides a pointer to memory for storing the final destination address.

Diagram



Fields

Field	Function
31-0 SLAST_SDA	Last Source Address Adjustment / Store DADDR Address Source last address adjustment or the system memory address for destination address (DADDR) storage. If (TCDn_CSR[ESDA] = 0), then: • Adjustment value is added to the source address at the completion of the major iteration count. This value can be used to restore the source address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final source address adjustment. Otherwise: • This address points to the 32-bit-aligned memory location where the destination address (DADDR) is to be stored in system memory. By saving the final destination address in system memory via the ESDA feature, you are able to compute the size of a variable destination data buffer by simply subtracting the beginning DADDR from the final, saved DADDR. This feature is used together with the scatter/gather operation to prevent the loss of the final DADDR, which is overwritten during the scatter/gather operation. The "Store Destination Address" (SDA) value must be a 32-bit-aligned location because the eDMA forces the lower two address bits of the SLAST_SDA field to zero when ESDA is enabled. The module performs this write operation when the major loop is done; that is, when the major iteration count (CITER) decrements to zero.

71.6.7.14 TCD Destination Address (TCD0_DADDR - TCD7_DADDR)

Offset

For n = 0 to 7:

Register	Offset
TCDn_DADDR	30h + (n × 1000h)

Function

This register contains the address for the write transactions.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	DADDR

Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

Fields

Field	Function
31-0 DADDR	Destination Address Memory address pointing to the destination data.

71.6.7.15 TCD Signed Destination Address Offset (TCD0_DOFF - TCD7_DOFF)

Offset

For n = 0 to 7:

Register	Offset
TCDn_DOFF	34h + (n × 1000h)

Function

This register contains the sign-extended value added to Destination Address register after each write transaction.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DOFF															
Reset	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u	u

Fields

Field	Function
15-0 DOFF	Destination Address Signed Offset Sign-extended offset that is applied to the current destination address to form the next-state value as each destination write is completed.

71.6.7.16 TCD Current Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_CITER_ELINKNO - TCD7_CITER_ELINKNO)

Offset

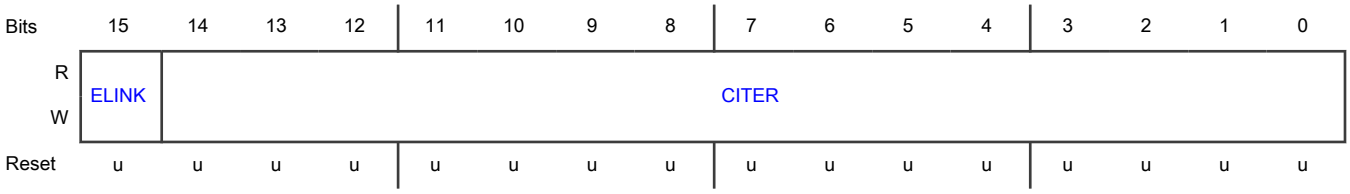
For n = 0 to 7:

Register	Offset
TCDn_CITER_ELINKNO	36h + (n × 1000h)

Function

If TCDn_CITER[ELINK] is 0, the TCDn_CITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel to 1. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking. **NOTE** This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

71.6.7.17 TCD Current Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_CITER_ELINKYES - TCD7_CITER_ELINKYES)

Offset

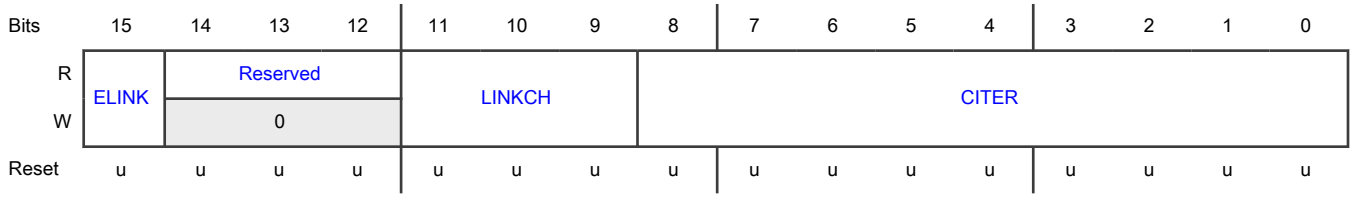
For n = 0 to 7:

Register	Offset
TCDn_CITER_ELINKYES	36h + (n × 1000h)

Function

If TCDn_CITER[ELINK] is 1, the TCDn_CITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. When enabled, an internal mechanism sets the TCDn_CSR[START] field of the specified channel (LINKCH) upon minor loop completion. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-12 —	Reserved
11-9 LINKCH	Minor Loop Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted the eDMA engine initiates a channel service request to the channel defined by this field by writing that channel's TCDn_CSR[START] field to 1.
8-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to the TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

71.6.7.18 TCD Last Destination Address Adjustment / Scatter Gather Address (TCD0_DLAST_SGA - TCD7_DLAST_SGA)

Offset

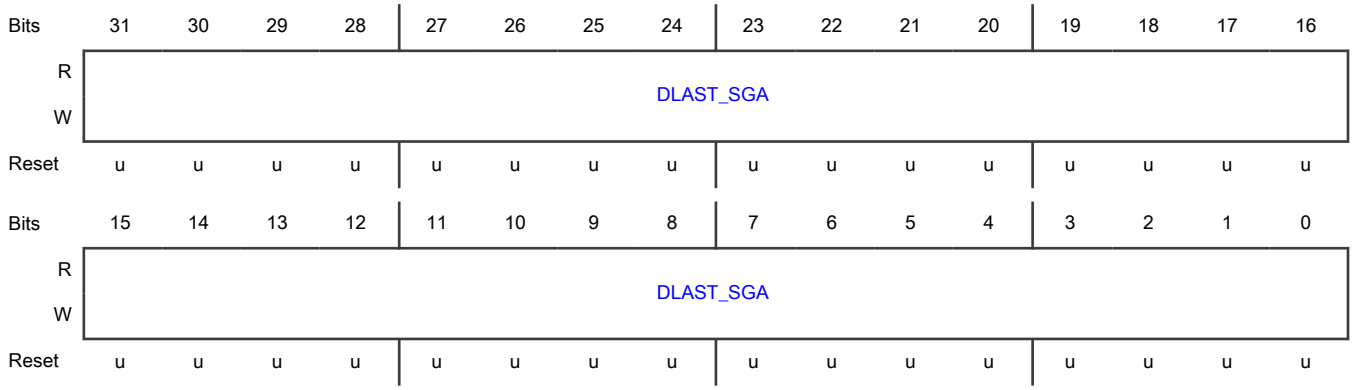
For n = 0 to 7:

Register	Offset
TCDn_DLAST_SGA	38h + (n × 1000h)

Function

This register contains the value added to the destination address when the major loop is complete. When the Scatter/Gather option is enabled, this field provides a pointer to memory for fetching a transfer control descriptor to reprogram the channel.

Diagram



Fields

Field	Function
31-0 DLAST_SGA	Last Destination Address Adjustment / Scatter Gather Address Adjustment of the last destination address or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather). If (TCDn_CSR[ESG] = 0) then: • Adjustment value is added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final destination address adjustment. Otherwise: • This address points to the beginning of a 0-modulo 32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo 32-byte, or else a configuration error is reported.

71.6.7.19 TCD Control and Status (TCD0_CSR - TCD7_CSR)

Offset

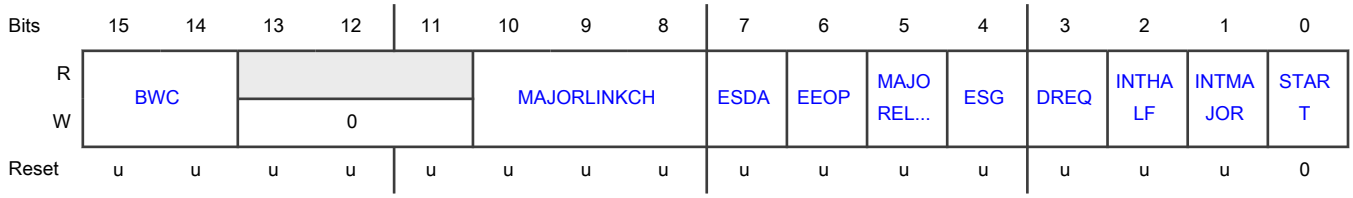
For n = 0 to 7:

Register	Offset
TCDn_CSR	3Ch + (n × 1000h)

Function

This register is used to enable optional features.

Diagram



Fields

Field	Function
15-14 BWC	Bandwidth Control Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces eDMA to stall after the completion of each read/write access, to control the bus request bandwidth seen by the system bus interconnect. **NOTE** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00b - No eDMA engine stalls 01b - Reserved 10b - eDMA engine stalls for 4 cycles after each R/W 11b - eDMA engine stalls for 8 cycles after each R/W
13-11 —	Reserved
10-8 MAJORLINKCH	Major Loop Link Channel Number If (MAJORELINK = 0) then: • No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted. Otherwise: • After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field to 1.
7 ESDA	Enable Store Destination Address As the channel completes the major loop by either the current iteration counter (CITER) decrementing to 0, or by receiving an enabled end-of-packet signal, this field enables writing the destination address (DADDR) to the address stored in the SLAST_SDA field. The value written to system memory is the next DADDR value prior to the DLAST_SGA offset being applied, or overwritten by an enabled scatter/gather operation. When the ESDA bit is 1, SLAST_SDA contains the write pointer instead of the final source address offset. Because this is a pointer and not a final offset, a last source address offset of zero is applied to SADDR instead of the SLAST_SGA value. 0b - Ability to store destination address to system memory disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Ability to store destination address to system memory enabled
6 EEOP	Enable End-Of-Packet Processing When enabled by the EEOP field, an end-of-packet hardware input signal directs eDMA to discontinue executing the active channel, and to treat the shutdown as the major-loop-completed event. If the EEOP field is 1, the end-of-packet signal from supported peripherals is accepted. If the EEOP field is 0, the end-of-packet input is ignored. With an end-of-packet retirement, the current TCD destination address (or ESDA-saved destination address), minus the software-saved initial address (DADDR), reflects the total amount of data transferred. 0b - End-of-packet operation disabled 1b - End-of-packet hardware input signal enabled
5 MAJORELINK	Enable Link When Major Loop Complete As the channel completes the major loop, this flag enables linking to another channel defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. **NOTE** To support the dynamic linking coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
4 ESG	Enable Scatter/Gather Processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses TCDn_DLAST_SGA as a memory pointer to a 0-modulo 32-bit address containing a 32-byte data structure, which is loaded as the transfer control descriptor into local memory. **NOTE** To support the dynamic scatter/gather coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0b - Current channel's TCD is normal format 1b - Current channel's TCD specifies scatter/gather format.
3 DREQ	Disable Request If this flag is 1, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches 0. 0b - No operation. Channel's ERQ field not affected 1b - Clear the ERQ field to 0 upon major loop completion, thus disabling hardware service requests. Channel's ERQ field cleared to 0 when major loop complete
2	Enable Interrupt If Major Counter Half-complete

Table continues on the next page...

Table continued from the previous page...

Field	Function
INTHALF	If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER = (BITER/2)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes, or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE** If BITER = 1, do not use INTHALF; use INTMAJOR instead. 0b - Halfway point interrupt disabled 1b - Halfway point interrupt enabled
1 INTMAJOR	Enable Interrupt If Major count complete If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count (CITER) reaches 0. 0b - End-of-major loop interrupt disabled 1b - End-of-major loop interrupt enabled
0 START	Channel Start If this flag is 1, the channel is requesting service. The eDMA hardware automatically clears this flag to 0 after the channel begins execution. 0b - Channel not explicitly started 1b - Channel explicitly started via a software-initiated service request

71.6.7.20 TCD Beginning Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_BITER_ELINKNO - TCD7_BITER_ELINKNO)

Offset

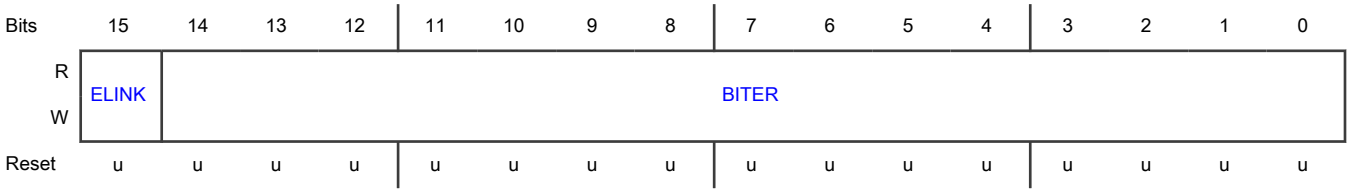
For n = 0 to 7:

Register	Offset
TCDn_BITER_ELINKNO	3Eh + (n × 1000h)

Function

If the TCDn_BITER[ELINK] field is 0, the TCDn_BITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enables Link As the channel completes the minor loop, this flag enables linking to another channel as defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. If channel linking is disabled, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-0 BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be set equal to the value in the CITER field. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0x0001.

71.6.7.21 TCD Beginning Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_BITER_ELINKYES - TCD7_BITER_ELINKYES)

Offset

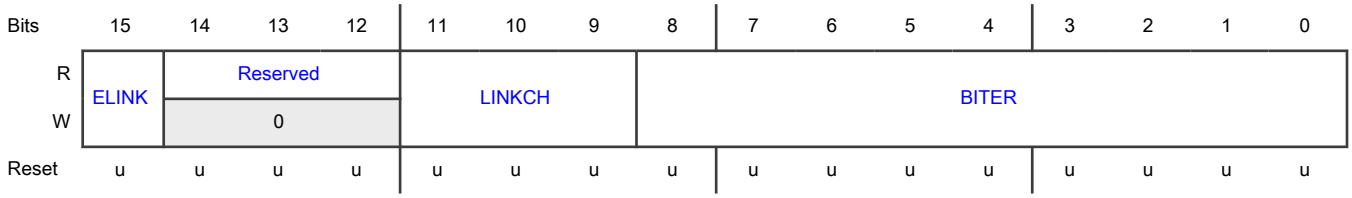
For n = 0 to 7:

Register	Offset
TCDn_BITER_ELINKYES	3Eh + (n × 1000h)

Function

If the TCDn_BITER[ELINK] field is set, the TCDn_BITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. If channel linking disables, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-12 —	Reserved
11-9 LINKCH	Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field.
8-0 BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be set equal to the value in the CITER field. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0x0001.

71.6.8.2 Channel Control and Status (CH0_CSR - CH7_CSR)

Offset

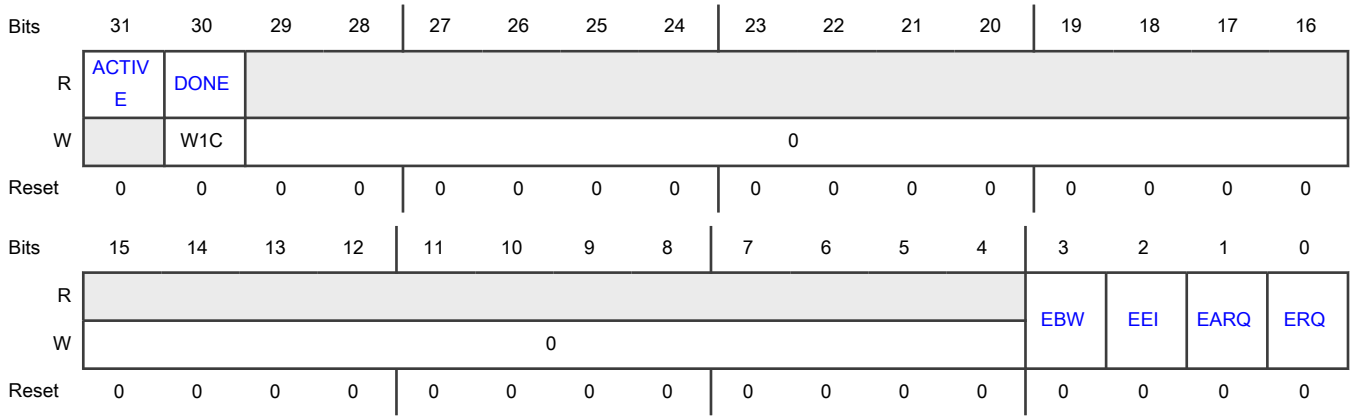
For n = 0 to 7:

Register	Offset
CHn_CSR	0h + (n × 1000h)

Function

This register contains several fields related to hardware and interrupt requests, configuration, and status for the given channel.

Diagram



Fields

Field	Function
31 ACTIVE	Channel Active The ACTIVE field indicates the channel was selected by arbitration and is executing the prescribed transfers. The eDMA sets it to 1 when channel service begins, and clears it to 0 as the minor loop completes or when any error condition is detected. Except for dynamic scatter/gather or dynamic channel linking, you must not modify the transfer control descriptor when a channel is active.
30 DONE	Channel Done The DONE field indicates the eDMA has completed the major loop. The eDMA engine sets this field as the CITER count reaches zero. If enabled, the eDMA generates an interrupt request corresponding to this completed channel. The software clears it, or the hardware clears it when the channel is activated. **NOTE** This field must be cleared to 0 before writing the MAJORELINK or ESG fields.
29-4 —	Reserved
3 EBW	Enable Buffered Writes When buffered writes are enabled, all writes except for the last write sequence of the minor loop are signaled by the eDMA as bufferable. 0b - Buffered writes on system bus disabled. Buffered writes on system bus disabled 1b - Buffered writes on system bus enabled. Bufferable write signal asserted on all system bus writes except during last write sequence
2 EEI	Enable Error Interrupt

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The EEI field enables the error interrupt signal for the channel. The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller. 0b - Error signal for corresponding channel does not generate error interrupt 1b - Assertion of error signal for corresponding channel generates error interrupt request
1 EARQ	Enable Asynchronous DMA Request The enable asynchronous DMA request field (EARQ) does not affect DMA operations. When set to 1, this field allows the hardware service request enable field (ERQ) to propagate out of the DMA to the power controller. When cleared to 0, this field masks the hardware service request enable field to the power controller. 0b - Disable asynchronous DMA request for the channel 1b - Enable asynchronous DMA request for the channel
0 ERQ	Enable DMA Request Disable a channel's hardware service request at the source before clearing the channel's ERQ field. The DMA hardware request input signal and the enable request field (ERQ) must be asserted before a channel's hardware service request is accepted. The state of the eDMA enable request field does not affect a channel service request made explicitly through software or channel linking. The state of the ERQ field does not affect the channel's START field. 0b - DMA hardware request signal for corresponding channel disabled 1b - DMA hardware request signal for corresponding channel enabled

71.6.8.3 Channel Error Status (CH0_ES - CH7_ES)

Offset

For n = 0 to 7:

Register	Offset
CHn_ES	4h + (n × 1000h)

Function

The ES provides information concerning the last recorded channel error. Channel errors can be caused by:

- An illegal setting in the transfer control descriptor
- An error termination to a bus initiator read or write cycle

The ERR field signals the presence of an error for the channel. The eDMA engine signals the occurrence of an error condition by setting the appropriate field in this register. The outputs of this register are enabled by the contents of the CHn_CSR[EEI] field, then logically summed across all channels to form an error interrupt request, which may be routed to the interrupt controller.

During the execution of the interrupt service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when eDMA detects an error. The

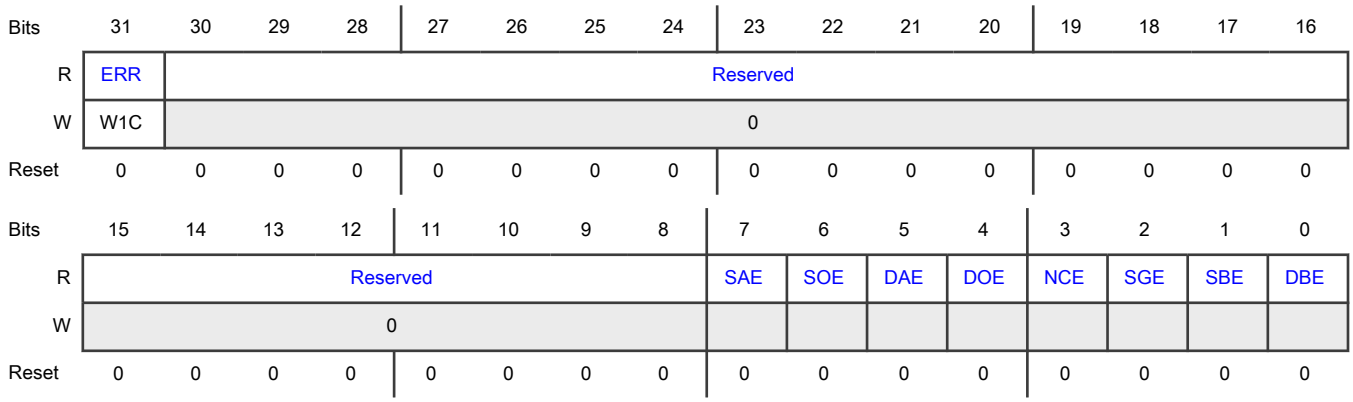
contents of this ERR register field can also be polled because a non-zero value indicates the presence of a channel error, regardless of the state of the EEI mask.

The state of any given channel's error indicators is affected by writes to this register. Writing a 1 to the ERR field clears the channel's error status, and writing a 0 has no effect.

An unspecified error, where only the ERR field is set to 1, indicates that either a transfer was cancelled with an error. The Management Page Error Status register has full view of the error condition.

See Fault reporting and handling for more details.

Diagram



Fields

Field	Function
31 ERR	Error In Channel 0b - An error in this channel has not occurred 1b - An error in this channel has occurred
30-8 —	Reserved
7 SAE	Source Address Error TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SADDR field
6 SOE	Source Offset Error TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE]. 0b - No source offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_SOFF field
5 DAE	Destination Address Error TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No destination address configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DADDR field
4 DOE	Destination Offset Error TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE]. 0b - No destination offset configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DOFF field
3 NCE	NBYTES/CITER Configuration Error This error indicates that one of the following has occurred: • TCDn_NBYTES is not a multiple of TCDn_ATTR[SSIZE] and TCDn_ATTR[DSIZE] • TCDn_CITER[CITER] is equal to zero • TCDn_CITER[ELINK] is not equal to TCDn_BITER[ELINK] 0b - No NBYTES/CITER configuration error 1b - Last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields
2 SGE	Scatter/Gather Configuration Error When this field is 1, it indicates that TCDn_DLAST_SGA is not on a 32-byte boundary. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG]is enabled. 0b - No scatter/gather configuration error 1b - Last recorded error was a configuration error detected in the TCDn_DLAST_SGA field
1 SBE	Source Bus Error 0b - No source bus error 1b - Last recorded error was bus error on source read
0 DBE	Destination Bus Error 0b - No destination bus error 1b - Last recorded error was bus error on destination write

71.6.8.4 Channel Interrupt Status (CH0_INT - CH7_INT)

Offset

For n = 0 to 7:

Register	Offset
CHn_INT	8h + (n × 1000h)

Function

The INT field signals the presence of an interrupt request for the channel. Depending on the appropriate bit setting in the transfer control descriptors, the eDMA engine generates an interrupt on data transfer completion.

The outputs of this register are directly routed to the interrupt controller. During the interrupt service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. On writes to INT, a 1 clears the channel's interrupt request. A zero has no effect on the channel's current interrupt status.

71.6.8.5 Channel System Bus (CH0_SBR - CH7_SBR)

Offset

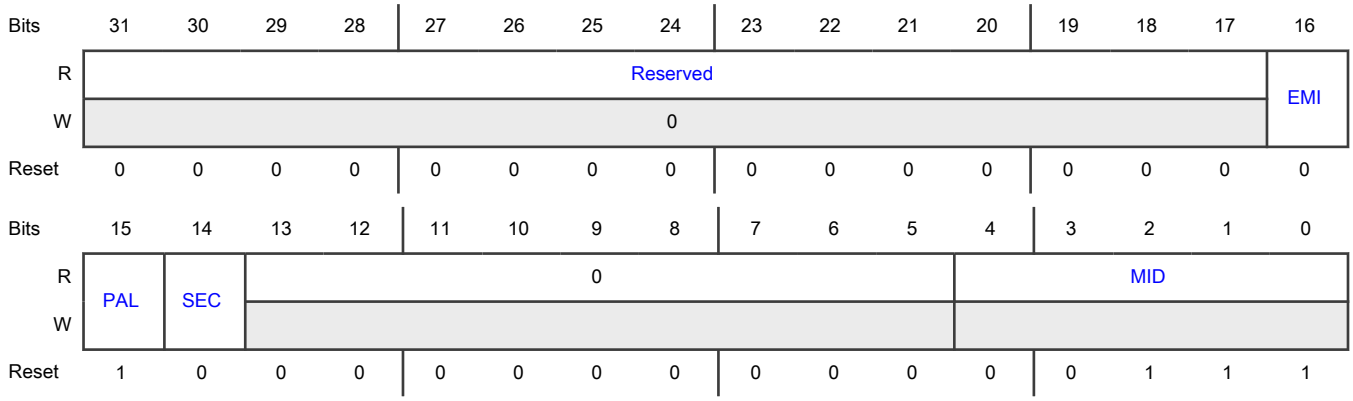
For n = 0 to 7:

Register	Offset
CHn_SBR	Ch + (n × 1000h)

Function

The Channel System Bus register places identification and attribute information on the system bus interface for the eDMA.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 EMI	Enable Initiator ID Replication The eDMA initiator ID replication field allows the eDMA to use the same protection level and system bus ID of the initiator programming the eDMA's TCD. When enabled, the eDMA uses the initiator ID and protection level stored in the CHn_SBR registers, instead of the eDMA's default values. When a initiator (for example a core) programs a TCD, its initiator ID is captured when the TCD*n*_CSR control attributes are written. A scatter/gather operation does not affect the CHn_SBR registers. You can write the EMI only if MP_CSR[GMRC] = 1, which means Global Initiator ID Replication Control is enabled; otherwise, the EMI is forced to zero. **NOTE** If initiator ID replication is disabled, the nonsecure, privileged protection level for DMA transfers is used. 0b - Initiator ID replication is disabled 1b - Initiator ID replication is enabled
15 PAL	Privileged Access Level This field controls DMA's protection level on the system bus when the channel is active. **NOTE** The value written into this register cannot exceed the security and privilege level of the core or other initiator writing the channel's system bus register; CH*n*_SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0b - User protection level for DMA transfers 1b - Privileged protection level for DMA transfers
14 SEC	Security Level DMA's security level on the system bus when the channel is active.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE The value written into this register cannot exceed the security and privilege level of the core or other initiator writing the channel's system bus register; CH*n*_SBR. The order of precedence is SecurePriv>SecureUser>NonsecurePriv>NonsecureUser 0b - Nonsecure protection level for DMA transfers 1b - Secure protection level for DMA transfers
13-5 —	Reserved
4-0 MID	Initiator ID This field controls the DMA's initiator ID on the system bus when the channel is active. **NOTE** The ID captured in this register reflects the initiator ID of the core or other initiator writing the channel's security attributes, TCD*n*_SBR[SEC].

71.6.8.6 Channel Priority (CH0_PRI - CH7_PRI)

Offset

For n = 0 to 7:

Register	Offset
CHn_PRI	10h + (n × 1000h)

Function

The contents of these registers define unique priorities associated with each channel within the same channel group. Channel grouping is programmed via Channel Arbitration Group (CH0_GRPRI - CH15_GRPRI).

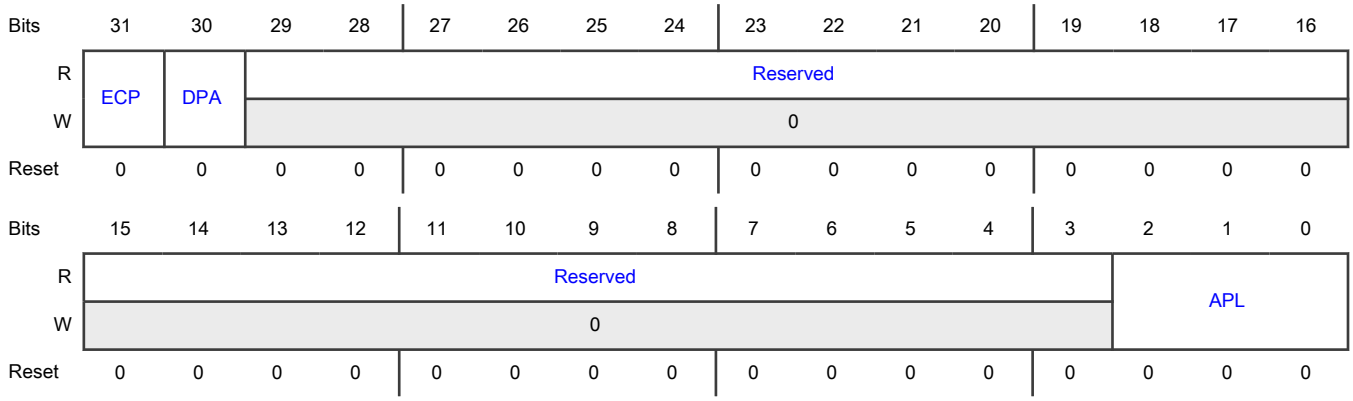
The channel priorities within a group are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Software must program the channel priorities with unique values; otherwise, channel numbers with the same, non-zero value, will be selected based on channel number with the higher channel number having higher priority.

If more than one channel in a group has an arbitration priority level value of zero, then the arbitration mode field MP_CSR[ERCA] is used to determine the arbitration scheme for all channels with APL=0 within a group.

When you enable round-robin channel arbitration (MP_CSR[ERCA] = 1), all channels with APL=0 within a group will use a round-robin arbitration scheme, which rotates among these channels requesting service without regard to priority. Round-robin provides a fairness mechanism within an arbitration group.

When you enable fixed-priority channel arbitration (MP_CSR[ERCA] = 0), eDMA selects channels with APL=0 based on channel number, with the higher channel number having higher priority.

Diagram



Fields

Field	Function
31 ECP	Enable Channel Preemption 0b - Channel cannot be suspended by a higher-priority channel's service request 1b - Channel can be temporarily suspended by a higher-priority channel's service request
30 DPA	Disable Preempt Ability 0b - Channel can suspend a lower-priority channel 1b - Channel cannot suspend any other channel, regardless of channel priority
29-3 —	Reserved
2-0 APL	Arbitration Priority Level Channel priority level for arbitration within the assigned arbitration group.

71.6.8.7 Channel Multiplexor Configuration (CH0_MUX - CH7_MUX)

Offset

For n = 0 to 7:

Register	Offset
CHn_MUX	14h + (n × 1000h)

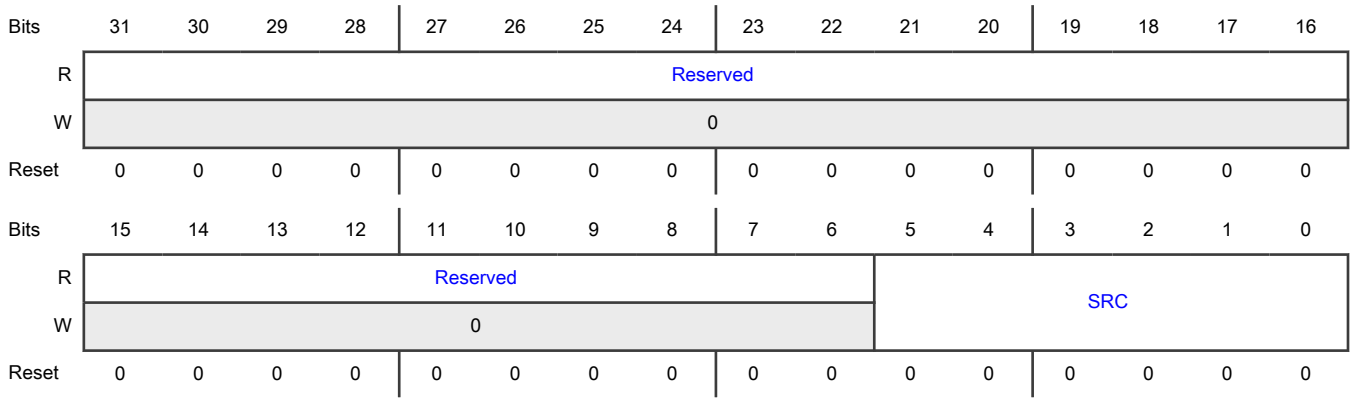
Function

Each of the DMA channels can be independently associated with various peripherals in the system. The Channel Multiplexor Configuration register selects the peripheral assigned to each channel. Service requests from the peripheral should be disabled when configuring a channel to a peripheral source.

Each channel must have a unique value when selecting a peripheral slot in the channel mux configuration. The only value that may overlap is source 0. If there is an attempt to write a mux configuration value that is already consumed by any channel, a mux configuration of 0 (SRC = 0) will be written.

All channels will default to source 0. When a particular peripheral is needed, the channel's mux configuration is set to that source number. When the peripheral is no longer needed, the mux configuration for that channel should be written to 0, thus releasing the resource.

Diagram



Fields

Field	Function
31-6 —	Reserved
5-0 SRC	Service Request Source Hardware service request source for the channel. **NOTE** With the exception of 0, attempts to write a value already in use will be forced to 0.

71.6.8.8 TCD Source Address (TCD0_SADDR - TCD7_SADDR)

Offset

For n = 0 to 7:

Register	Offset
TCDn_SADDR	20h + (n × 1000h)

Function

This register contains the address for the read transactions.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
15-0 SOFF	Source Address Signed Offset Sign-extended offset applied to the current source address to form the next-state value as each source read is completed.

71.6.8.10 TCD Transfer Attributes (TCD0_ATTR - TCD7_ATTR)

Offset

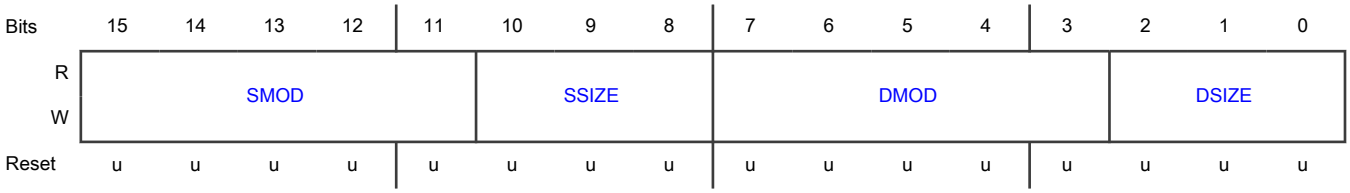
For n = 0 to 7:

Register	Offset
TCDn_ATTR	26h + (n × 1000h)

Function

This register contains size and option modulo addressing information for source and destination addresses.

Diagram



Fields

Field	Function
15-11 SMOD	Source Address Modulo This field defines a specific address range, which is the value after the SADDR + SOFF calculation is performed on the original register value. Setting this field makes it easy to implement a circular data queue. For data queues requiring power-of-2-sized bytes, the queue must start at a 0-modulo-size address and the SMOD field must be set to the appropriate value for the queue, freezing the required number of upper address bits. The value programmed into this field specifies the number of lower address bits that are allowed to change. For a circular queue application, you typically set TCDn_SOFF[SOFF] to the transfer size to implement post-increment addressing, with the SMOD function constraining the addresses to a 0-modulo-size range. 0_0000b - Source address modulo feature disabled
10-8 SSIZE	Source Data Transfer Size 000b - 8-bit 001b - 16-bit 010b - 32-bit 011b - 64-bit 100b - 16-byte 101b - 32-byte 110b - 64-byte 111b - Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-3 DMOD	Destination Address Modulo See the SMOD definition.
2-0 DSIZE	Destination Data Transfer Size See the SSIZE definition.

71.6.8.11 TCD Transfer Size Without Minor Loop Offsets (TCD0_NBYTES_MLOFFNO - TCD7_NBYTES_MLOFFNO)

Offset

For n = 0 to 7:

Register	Offset
TCDn_NBYTES_MLOFFNO	28h + (n × 1000h)

Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offsets are address offset values added to the final source address (TCDn_SADDR), or destination address (TCDn_DADDR), upon minor loop completion. Minor loop completion is when the channel has finished the service request and has transferred NBYTES. When minor loop offsets are enabled, the minor loop offset value (TCDn_NBYTES_MLOFFYES[MLOFF]) is added to the final source address (TCDn_SADDR), to the final destination address (TCDn_DADDR), or to both, prior to the addresses being written back to the TCD. If the major loop is complete, the minor loop offset is ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

When minor loop mapping is enabled (SMLOE or DMLOE is 1), TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is redefined. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is used to specify multiple fields:

- A source enable bit (SMLOE) to specify the minor loop offset must be applied to the source address (TCDn_SADDR) upon minor loop completion
- A destination enable bit (DMLOE) to specify the minor loop offset must be applied to the destination address (TCDn_DADDR) upon minor loop completion
- The sign extended minor loop offset value (MLOFF)

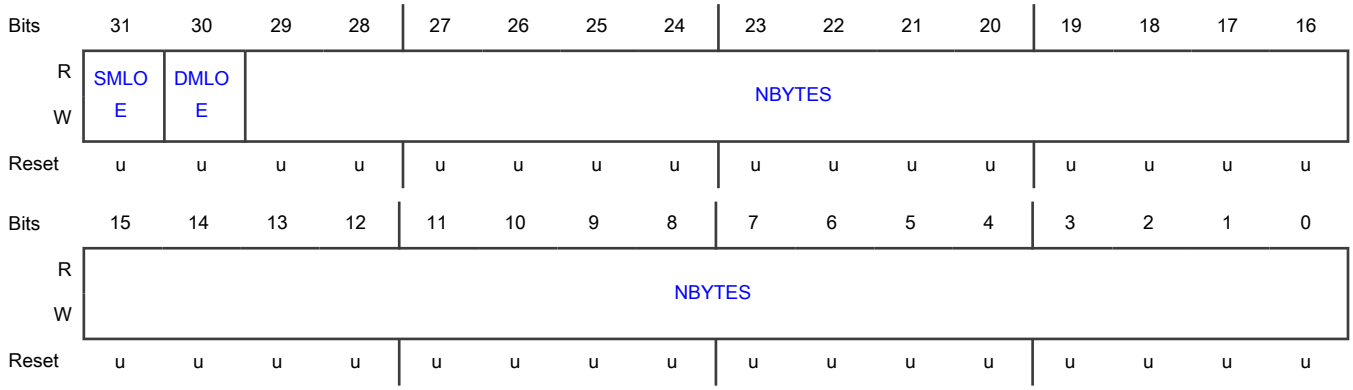
The same offset value (MLOFF) is used for both source and destination minor loop offsets. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFYES), defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES is defined as follows:

- If SMLOE = 0 and DMLOE = 0, then see the TCDn_NBYTES_MLOFFNO register description.
- If either SMLOE or DMLOE is 1, then see the TCDn_NBYTES_MLOFFYES register description.

Diagram



Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - Minor loop offset not applied to SADDR 1b - Minor loop offset applied to SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0b - Minor loop offset not applied to DADDR 1b - Minor loop offset applied to DADDR
29-0 NBYTES	Number of Bytes To Transfer Per Service Request Number of bytes to be transferred for each service request of the channel. When a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the byte transfer count has been reached. This process is normally an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the byte count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major loop iteration count (CITER) is decremented by one and written back to the TCD memory. If the major iteration count is complete, additional processing is performed.

71.6.8.12 TCD Transfer Size with Minor Loop Offsets (TCD0_NBYTES_MLOFFYES - TCD7_NBYTES_MLOFFYES)

Offset

For n = 0 to 7:

Register	Offset
TCDn_NBYTES_MLOFFYES	28h + (n × 1000h)

Function

The TCDn_NBYTES field defines the number of bytes to transfer per service request.

Minor loop offset is an address offset value added to the final source address (TCDn_SADDR) or destination address (TCDn_DADDR) upon minor loop completion. Minor loop completion occurs when the channel has finished the service request and has transferred NBYTES. Minor loop offsets are enabled by setting either the source enable bit (SMLOE) or the destination enable bit (DMLOE).

The source enable bit (SMLOE) specifies the minor loop offset value (MLOFF) that is to be applied to the source address (TCDn_SADDR) upon minor loop completion. The destination enable bit (DMLOE) specifies the minor loop offset (MLOFF) that is to be applied to the destination address (TCDn_DADDR) upon minor loop completion.

If the major loop is complete, the minor loop offsets are ignored and the major loop address offsets (TCDn_SLAST_SDA and TCDn_DLAST_SGA) are used to compute the next TCDn_SADDR and TCDn_DADDR values.

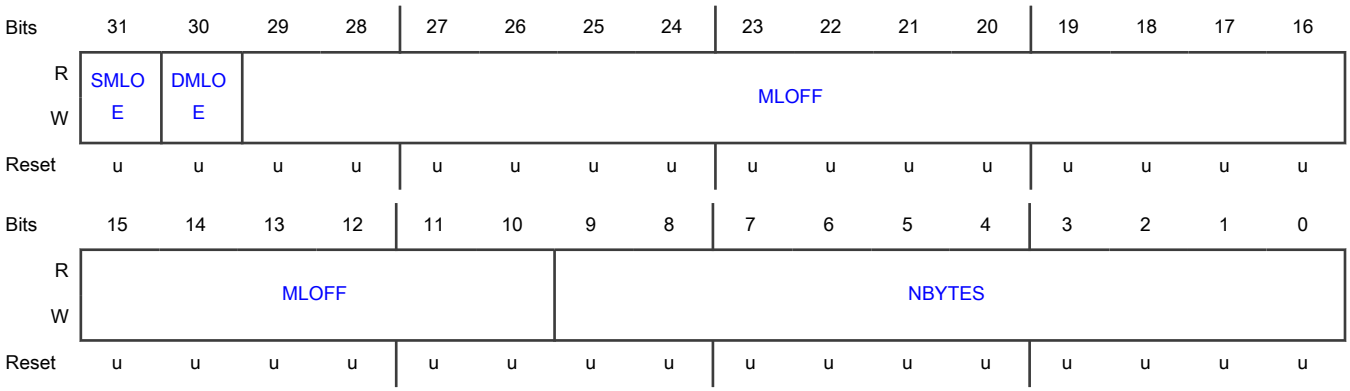
When you enable the minor loop offset overlay (either SMLOE or DMLOE is 1), eDMA redefines TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES. A portion of TCDn_NBYTES_MLOFFNO/TCDn_NBYTES_MLOFFYES specifies the sign-extended minor loop offset value (MLOFF). The same offset value (MLOFF) applies to both source and destination minor loop offsets. When the minor loop offset is enabled, you must align it to the transfer size of the source or destination it is associated with. When either minor loop offset is enabled (SMLOE set or DMLOE set), the NBYTES field is reduced to 10 bits. If both minor loop offsets are disabled (SMLOE cleared and DMLOE cleared), the NBYTES field is a 30-bit vector.

One of two register profiles (this register or TCDn_NBYTES_MLOFFNO) defines the number of bytes to transfer per request. Which register to use depends on whether source or destination minor loop mapping is enabled.

TCDn_NBYTES_MLOFFYES is defined as follows:

- If either minor loop offset is enabled (SMLOE or DMLOE = 1), then see the TCDn_NBYTES_MLOFFYES register description.
- If SMLOE and DMLOE are both 0, then see the TCDn_NBYTES_MLOFFNO register description.

Diagram



Fields

Field	Function
31 SMLOE	Source Minor Loop Offset Enable Selects whether the minor loop offset is applied to the source address upon minor loop completion. 0b - Minor loop offset not applied to SADDR 1b - Minor loop offset applied to SADDR
30 DMLOE	Destination Minor Loop Offset Enable Selects whether the minor loop offset is applied to the destination address upon minor loop completion. 0b - Minor loop offset not applied to DADDR 1b - Minor loop offset applied to DADDR
29-10 MLOFF	Minor Loop Offset If SMLOE or DMLOE is 1, this field represents a sign-extended offset applied to the source or destination address to form the next-state value after the minor loop completes.
9-0 NBYTES	Number of Bytes To Transfer Per Service Request The number of bytes to be transferred in each service request of the channel. As a channel activates, the module loads the appropriate TCD contents into the eDMA engine and performs the appropriate reads and writes until the minor byte transfer count has been reached. This is an indivisible operation and cannot be halted. It can, however, be stalled by using the bandwidth control field, or via preemption. After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, and the major iteration count is decremented and restored to the TCD memory. If the major iteration count is complete, additional processing is performed.

71.6.8.13 TCD Last Source Address Adjustment / Store DADDR Address (TCD0_SLAST_SDA - TCD7_SLAST_SDA)

Offset

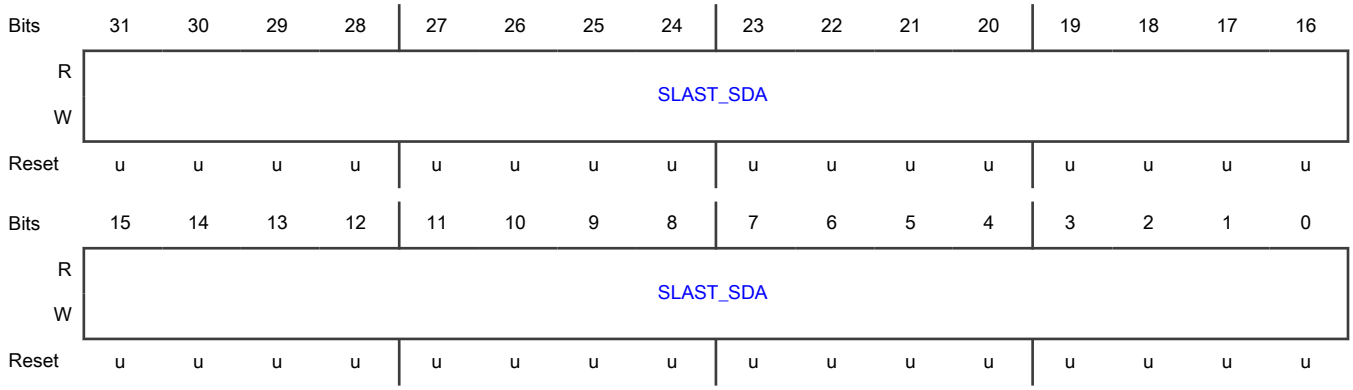
For n = 0 to 7:

Register	Offset
TCDn_SLAST_SDA	2Ch + (n × 1000h)

Function

This register contains the value added to the source address when the major loop is complete. When the store destination address option is enabled, this field provides a pointer to memory for storing the final destination address.

Diagram



Fields

Field	Function
31-0 SLAST_SDA	Last Source Address Adjustment / Store DADDR Address Source last address adjustment or the system memory address for destination address (DADDR) storage. If (TCDn_CSR[ESDA] = 0), then: • Adjustment value is added to the source address at the completion of the major iteration count. This value can be used to restore the source address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final source address adjustment. Otherwise: • This address points to the 32-bit-aligned memory location where the destination address (DADDR) is to be stored in system memory. By saving the final destination address in system memory via the ESDA feature, you are able to compute the size of a variable destination data buffer by simply subtracting the beginning DADDR from the final, saved DADDR. This feature is used together with the scatter/gather operation to prevent the loss of the final DADDR, which is overwritten during the scatter/gather operation. The "Store Destination Address" (SDA) value must be a 32-bit-aligned location because the eDMA forces the lower two address bits of the SLAST_SDA field to zero when ESDA is enabled. The module performs this write operation when the major loop is done; that is, when the major iteration count (CITER) decrements to zero.

71.6.8.14 TCD Destination Address (TCD0_DADDR - TCD7_DADDR)

Offset

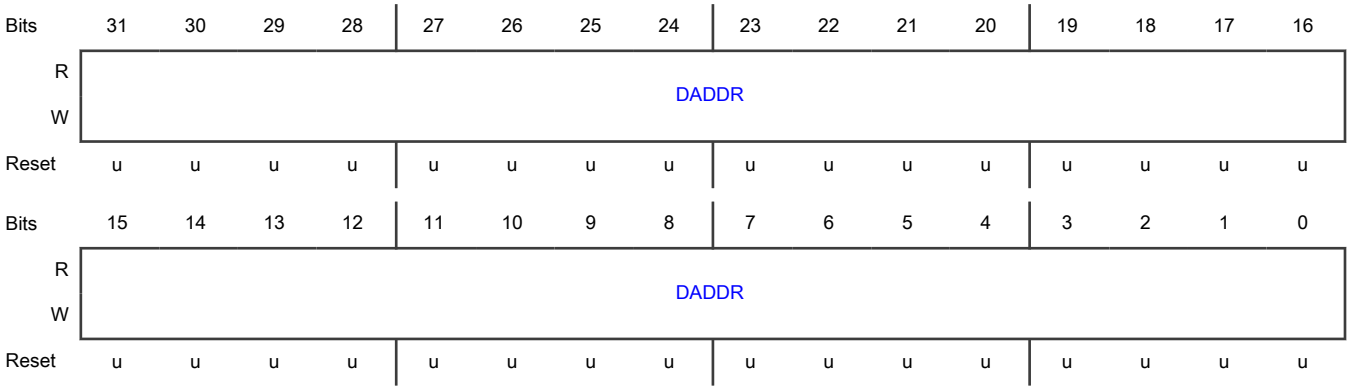
For n = 0 to 7:

Register	Offset
TCDn_DADDR	30h + (n × 1000h)

Function

This register contains the address for the write transactions.

Diagram



Fields

Field	Function
31-0 DADDR	Destination Address Memory address pointing to the destination data.

71.6.8.15 TCD Signed Destination Address Offset (TCD0_DOFF - TCD7_DOFF)

Offset

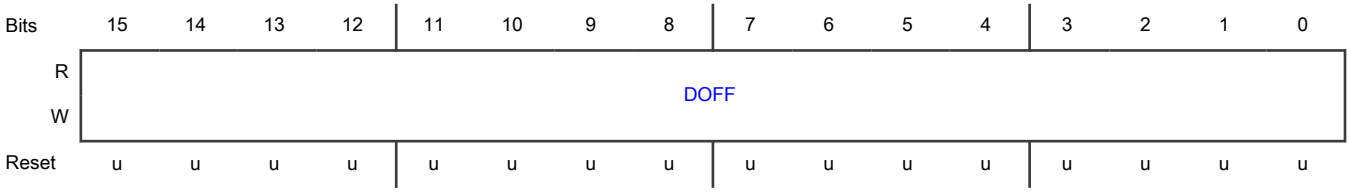
For n = 0 to 7:

Register	Offset
TCDn_DOFF	34h + (n × 1000h)

Function

This register contains the sign-extended value added to Destination Address register after each write transaction.

Diagram



Fields

Field	Function
15-0 DOFF	Destination Address Signed Offset Sign-extended offset that is applied to the current destination address to form the next-state value as each destination write is completed.

71.6.8.16 TCD Current Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_CITER_ELINKNO - TCD7_CITER_ELINKNO)

Offset

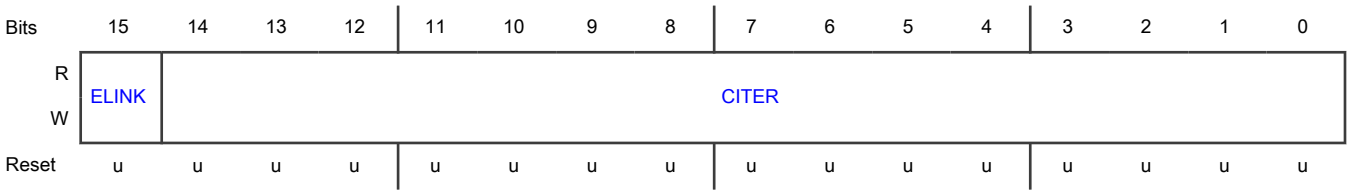
For n = 0 to 7:

Register	Offset
TCDn_CITER_ELINKNO	36h + (n × 1000h)

Function

If TCDn_CITER[ELINK] is 0, the TCDn_CITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel to 1. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking. **NOTE** This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

71.6.8.17 TCD Current Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_CITER_ELINKYES - TCD7_CITER_ELINKYES)

Offset

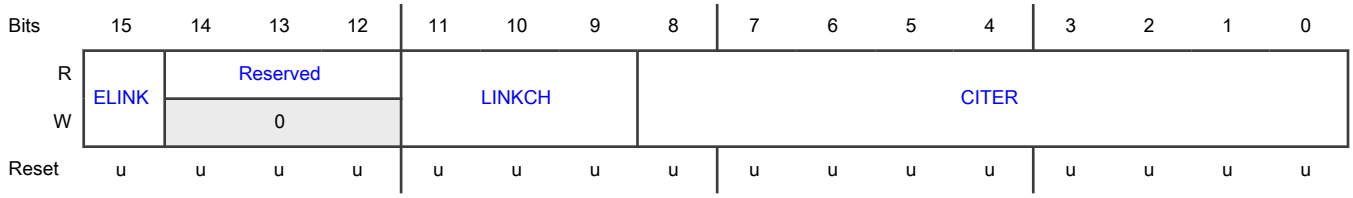
For n = 0 to 7:

Register	Offset
TCDn_CITER_ELINKYES	36h + (n × 1000h)

Function

If TCDn_CITER[ELINK] is 1, the TCDn_CITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by the relevant LINKCH field. When enabled, an internal mechanism sets the TCDn_CSR[START] field of the specified channel (LINKCH) upon minor loop completion. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of MAJORELINK channel linking.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field must be equal to the BITER[ELINK] field; otherwise, a configuration error is reported. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-12 —	Reserved
11-9 LINKCH	Minor Loop Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted the eDMA engine initiates a channel service request to the channel defined by this field by writing that channel's TCDn_CSR[START] field to 1.
8-0 CITER	Current Major Iteration Count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the channel finishes a service request and is written back to the TCD memory. After the major iteration count is exhausted, the channel performs a number of operations — for example, final source and destination address calculations — and optionally generates an interrupt to signal channel completion before reloading the CITER field from the Beginning Iteration Count (BITER) field. **NOTE** When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. **NOTE** If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.

71.6.8.18 TCD Last Destination Address Adjustment / Scatter Gather Address (TCD0_DLAST_SGA - TCD7_DLAST_SGA)

Offset

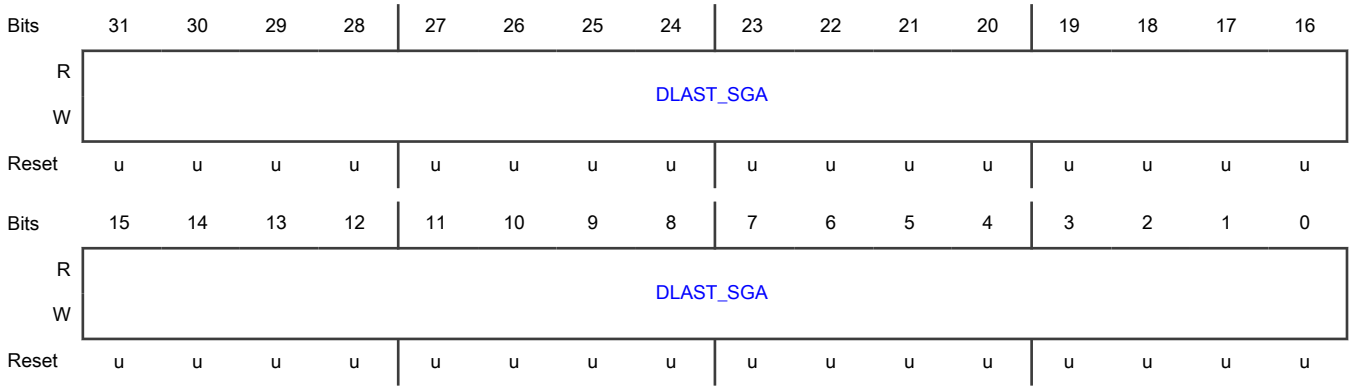
For n = 0 to 7:

Register	Offset
TCDn_DLAST_SGA	38h + (n × 1000h)

Function

This register contains the value added to the destination address when the major loop is complete. When the Scatter/Gather option is enabled, this field provides a pointer to memory for fetching a transfer control descriptor to reprogram the channel.

Diagram



Fields

Field	Function
31-0 DLAST_SGA	Last Destination Address Adjustment / Scatter Gather Address Adjustment of the last destination address or the memory address for the next transfer control descriptor to be loaded into this channel (scatter/gather). If (TCDn_CSR[ESG] = 0) then: • Adjustment value is added to the destination address at the completion of the major iteration count. This value can apply to restore the destination address to the initial value or adjust the address to reference the next data structure. • This field uses two's complement notation for the final destination address adjustment. Otherwise: • This address points to the beginning of a 0-modulo 32-byte region containing the next transfer control descriptor to be loaded into this channel. This channel reload is performed as the major iteration count completes. The scatter/gather address must be 0-modulo 32-byte, or else a configuration error is reported.

71.6.8.19 TCD Control and Status (TCD0_CSR - TCD7_CSR)

Offset

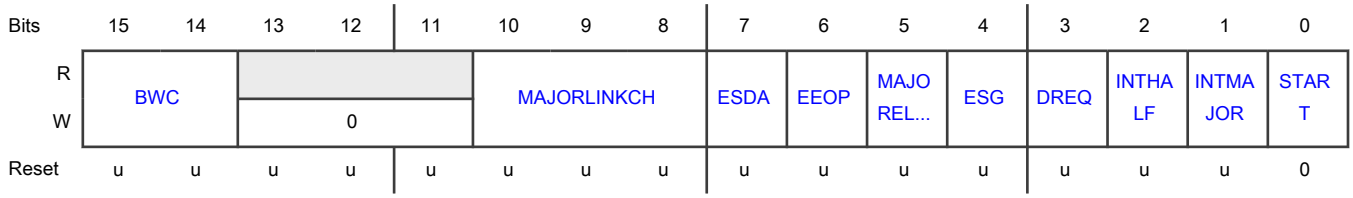
For n = 0 to 7:

Register	Offset
TCDn_CSR	3Ch + (n × 1000h)

Function

This register is used to enable optional features.

Diagram



Fields

Field	Function
15-14 BWC	Bandwidth Control Throttles the amount of bus bandwidth consumed by the eDMA. Generally, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces eDMA to stall after the completion of each read/write access, to control the bus request bandwidth seen by the system bus interconnect. **NOTE** If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency. 00b - No eDMA engine stalls 01b - Reserved 10b - eDMA engine stalls for 4 cycles after each R/W 11b - eDMA engine stalls for 8 cycles after each R/W
13-11 —	Reserved
10-8 MAJORLINKCH	Major Loop Link Channel Number If (MAJORELINK = 0) then: • No channel-to-channel linking, or chaining, is performed after the major loop counter is exhausted. Otherwise: • After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field to 1.
7 ESDA	Enable Store Destination Address As the channel completes the major loop by either the current iteration counter (CITER) decrementing to 0, or by receiving an enabled end-of-packet signal, this field enables writing the destination address (DADDR) to the address stored in the SLAST_SDA field. The value written to system memory is the next DADDR value prior to the DLAST_SGA offset being applied, or overwritten by an enabled scatter/gather operation. When the ESDA bit is 1, SLAST_SDA contains the write pointer instead of the final source address offset. Because this is a pointer and not a final offset, a last source address offset of zero is applied to SADDR instead of the SLAST_SGA value. 0b - Ability to store destination address to system memory disabled

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Ability to store destination address to system memory enabled
6 EEOP	Enable End-Of-Packet Processing When enabled by the EEOP field, an end-of-packet hardware input signal directs eDMA to discontinue executing the active channel, and to treat the shutdown as the major-loop-completed event. If the EEOP field is 1, the end-of-packet signal from supported peripherals is accepted. If the EEOP field is 0, the end-of-packet input is ignored. With an end-of-packet retirement, the current TCD destination address (or ESDA-saved destination address), minus the software-saved initial address (DADDR), reflects the total amount of data transferred. 0b - End-of-packet operation disabled 1b - End-of-packet hardware input signal enabled
5 MAJORELINK	Enable Link When Major Loop Complete As the channel completes the major loop, this flag enables linking to another channel defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. **NOTE** To support the dynamic linking coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
4 ESG	Enable Scatter/Gather Processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses TCDn_DLAST_SGA as a memory pointer to a 0-modulo 32-bit address containing a 32-byte data structure, which is loaded as the transfer control descriptor into local memory. **NOTE** To support the dynamic scatter/gather coherency model, this field is forced to 0 if written when TCDn_CSR[DONE] is 1. 0b - Current channel's TCD is normal format 1b - Current channel's TCD specifies scatter/gather format.
3 DREQ	Disable Request If this flag is 1, the eDMA hardware automatically clears the corresponding ERQ bit when the current major iteration count reaches 0. 0b - No operation. Channel's ERQ field not affected 1b - Clear the ERQ field to 0 upon major loop completion, thus disabling hardware service requests. Channel's ERQ field cleared to 0 when major loop complete
2	Enable Interrupt If Major Counter Half-complete

Table continues on the next page...

Table continued from the previous page...

Field	Function
INTHALF	If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER = (BITER/2)). This halfway point interrupt request is provided to support double-buffered, also known as ping-pong, schemes, or other types of data movement where the processor needs an early indication of the transfer's progress. **NOTE** If BITER = 1, do not use INTHALF; use INTMAJOR instead. 0b - Halfway point interrupt disabled 1b - Halfway point interrupt enabled
1 INTMAJOR	Enable Interrupt If Major count complete If this flag is 1, the channel generates an interrupt request by setting the appropriate field in the INT register to 1 when the current major iteration count (CITER) reaches 0. 0b - End-of-major loop interrupt disabled 1b - End-of-major loop interrupt enabled
0 START	Channel Start If this flag is 1, the channel is requesting service. The eDMA hardware automatically clears this flag to 0 after the channel begins execution. 0b - Channel not explicitly started 1b - Channel explicitly started via a software-initiated service request

71.6.8.20 TCD Beginning Major Loop Count (Minor Loop Channel Linking Disabled) (TCD0_BITER_ELINKNO - TCD7_BITER_ELINKNO)

Offset

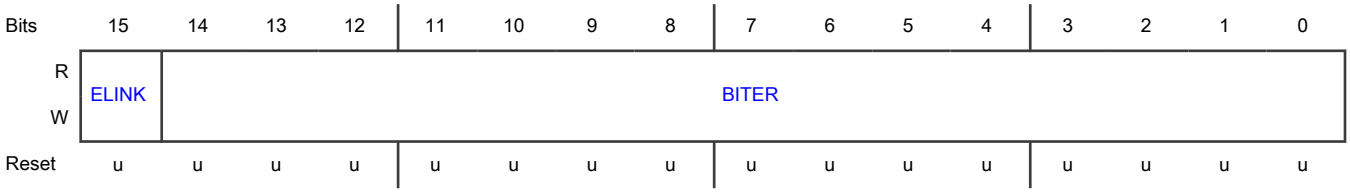
For n = 0 to 7:

Register	Offset
TCDn_BITER_ELINKNO	3Eh + (n × 1000h)

Function

If the TCDn_BITER[ELINK] field is 0, the TCDn_BITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enables Link As the channel completes the minor loop, this flag enables linking to another channel as defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. If channel linking is disabled, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-0 BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be set equal to the value in the CITER field. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0x0001.

71.6.8.21 TCD Beginning Major Loop Count (Minor Loop Channel Linking Enabled) (TCD0_BITER_ELINKYES - TCD7_BITER_ELINKYES)

Offset

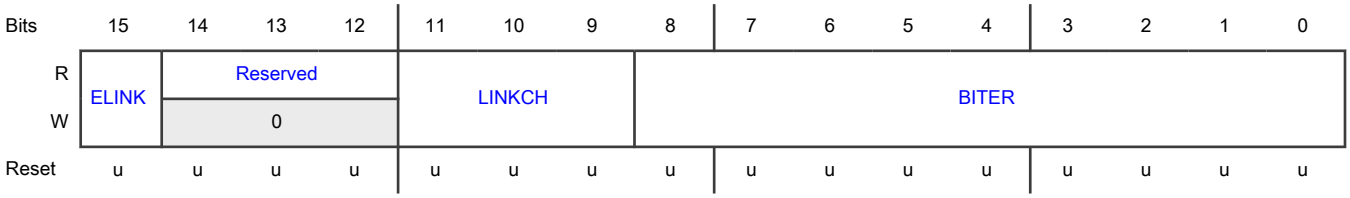
For n = 0 to 7:

Register	Offset
TCDn_BITER_ELINKYES	3Eh + (n × 1000h)

Function

If the TCDn_BITER[ELINK] field is set, the TCDn_BITER register is defined as follows.

Diagram



Fields

Field	Function
15 ELINK	Enable Link As the channel completes the minor loop, this flag enables linking to another channel as defined by BITER[LINKCH]. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] field of the specified channel. If channel linking disables, the BITER value extends to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. 0b - Channel-to-channel linking disabled 1b - Channel-to-channel linking enabled
14-12 —	Reserved
11-9 LINKCH	Link Channel Number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request at the channel defined by this field by setting that channel's TCDn_CSR[START] field. **NOTE** When the software loads the TCD, this field must be set equal to the corresponding CITER field; otherwise, a configuration error is reported. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field.
8-0 BITER	Starting Major Iteration Count As the transfer control descriptor is first loaded by software, this 9-bit (ELINK = 1) or 15-bit (ELINK = 0) field must be set equal to the value in the CITER field. As the major iteration count is exhausted, eDMA reloads the contents of this field into the CITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER must be 0x0001.

72.2 Overview

NIC is an Arm CoreLink network interconnect component that switches any initiator access to the target memory or peripheral. It has initiator interfaces (ASIB0 to ASIB9) and target interfaces (AMIB0 to AMIB12). It supports Arm CoreLink QoS-400 Network Interconnect Advanced Quality of Service (QoS) to arbitrate and regulate the transactions from various SoC initiators.

More details can be found in the following documentation on Arm website:

- ARM CoreLink QoS-400 Network Interconnect Advanced Quality of Service Supplement to ARM CoreLink NIC-400 Network Interconnect Technical Reference Manual

  (DSU0026F_corelink_qos400_network_interconnect_r1p0_trm)

72.2.1 Block diagram

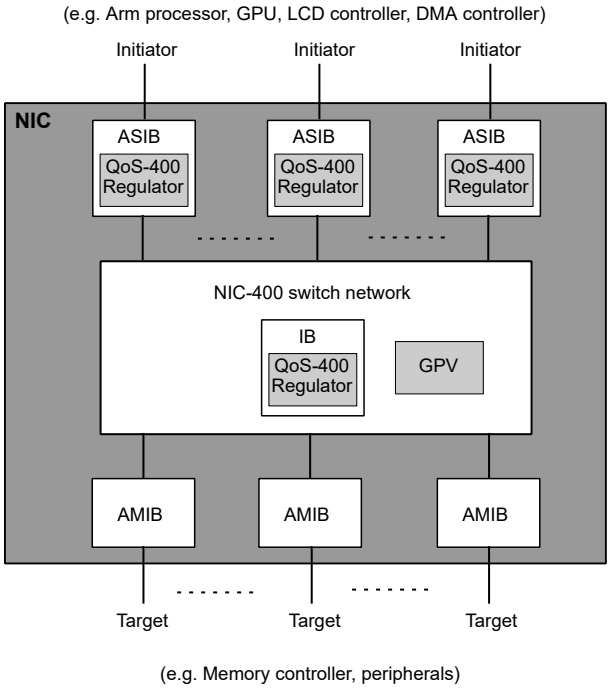

Figure 305. NIC block diagram

72.2.2 Features

- Programmable maximum for outstanding transactions as follows:
  - Separate maximum for read and write requests.
  - Combined maximum for all requests.
  - Fractional value to provide finer control.
- Regulation of read and write request issuing rates to meet programmed traffic specifications as follows:
  - Separate regulation for read and write requests.
  - Combined regulation for all requests.
- Regulation of read and write request QoS values to target a programmed transaction latency.
- Regulation of read and write request QoS values to target a programmed address request latency.

72.3 Functional description

72.3.1 QoS operations

72.3.1.1 Relationship with NIC

NIC includes a QoS value for each address, **awqos** for writes and **arqos** for reads.

Within the interconnect, the QoS values control arbitration. The QoS-400 supplies additional hardware that can both regulate the read and write requests and control the QoS value dynamically.

72.3.1.2 QoS regulators

NIC provides facilities to regulate transactions based on the following inter-related measures:

R_T	Issuing rate
L_T	Latency
N_T	Number of outstanding transactions

Assuming that the initiator is always trying to issue transaction requests, then R_T, L_T, and N_T are related by the following formula:

$$R_T = N_T \times 1/L_T$$

The formula is a variation on Little's Law, that relates queue length to arrival rate and time in the system. A three-dimensional surface plotted in a graph represents the relationship between the transaction issuing rate R_T, latency L_T, and the number of outstanding transactions N_T.

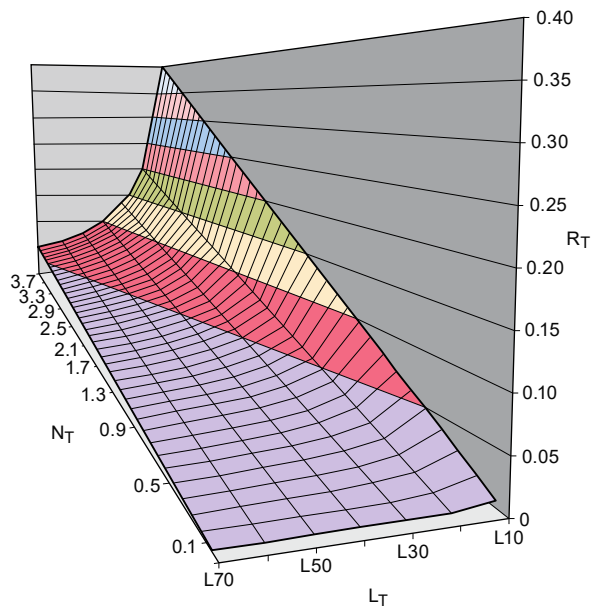

Figure 306. Relationship between R_T, L_T, and N_T

QoS-400 supports three regulation mechanisms based on the R_T, L_T, and N_T, measures. All three regulate the aggregate of the traffic through the ASIB or IB regardless of the eventual destination. This works best when the majority of the traffic is to a single shared resource, such as a DMC.

NOTE

A shared resource, such as a DMC, is often the most heavily loaded resource in a system.

The transaction rate regulators and the number of outstanding transactions set an upper bound on these measures. They prevent the measures from exceeding a limit that you program. They do this by holding back transaction requests whenever the limits are reached.

The transaction latency regulator adds a QoS value to the request, or modifies an existing one, and the interconnect uses that value as an arbitration priority. The latency regulator increases the QoS value when it observes an increase in latency.

Transaction latency specifies a target bandwidth in combination with a number of outstanding transactions using the formula from Little's Law. This might be easier to use where the number of outstanding transactions is limited.

Address request latency regulation directly sets a target period for address requests, that is equivalent to setting a target maximum bandwidth. The number of outstanding transactions can vary according to the transaction latency in accordance with Little's

Law. Consequently, as the transaction latency increases, the number of outstanding transactions also increases to maintain the bandwidth.

NIC QoS regulators provide mechanisms that control how NIC shares the resources of a target. You can use them either individually, or in combination, to control this sharing, and to prevent overloading the target.

One measure of resource loading is the number of requests in the queue waiting to be served. When most of the requests from a number of initiators all go to the same target, the sum of the number of outstanding transactions at each initiator corresponds to the number of requests waiting to be served at that target.

Regulating the number of outstanding transactions from each of the initiators therefore provides a direct means to distribute the resources of a target without overloading it. If the loading changes for any reason, for example when an initiator completes its task early, then:

- The load on the target is reduced.
- The queue length decreases.
- The average latency that the remaining initiators observe decreases.

Figure 306 shows that for a constant number of outstanding transactions, a decrease in latency corresponds to an increase in transaction issuing rate. In effect, some of the spare capacity has been distributed to the other initiators.

Another measure of the resource that a target provides is the rate at which it processes transactions. The transaction rate regulator enables you to limit the rate at which an initiator issues transactions, and therefore sets the proportion of the resource of the target that is requested. Figure 306 shows that for a constant issuing rate, an initiator can compensate for any increase in latency by increasing the number of outstanding transactions.

The third measure of latency is not under the direct control of an initiator because it depends on many factors in the interconnect and the target. The more heavily loaded a target is, the longer a transaction must wait for service, and the higher the latency. You can regulate the latency by adding a QoS value to transaction requests to indicate to the system and target when an initiator requires the latency to be reduced. The higher the value, the lower the latency required.

All three regulators can be active at the same time. For example, if the rate regulator is limiting an initiator to a particular rate, and the latency increases, then the number of outstanding transactions tends to increase to compensate. If you permit this to continue unchecked, then the initiator takes more than its share of the resource from the target. You can program the outstanding transaction regulator to prevent this. At the same time, the latency regulator increases the priority to decrease the latency, enabling the rate to recover, and the number of outstanding transactions to decrease.

ASIBn_QOS_CNTL permits you to enable or disable any combination of the three regulators in one programming step.

72.3.1.3 Transaction rate regulation

A variant of the standard internet Traffic SPECification (TSPEC) specifies transaction rate regulation using the following parameters:

p	Peak rate
b	Burstiness allowance
r	Average rate

You can independently program and enable the regulation of the read and write address channels with their own control bits. Alternatively, you can select combined regulation of the read and write address channels using another control bit.

The request arrival curve, that graph (A) TSPEC traffic upper bound shows, in Figure 307 represents the characteristics imposed on the request flow.

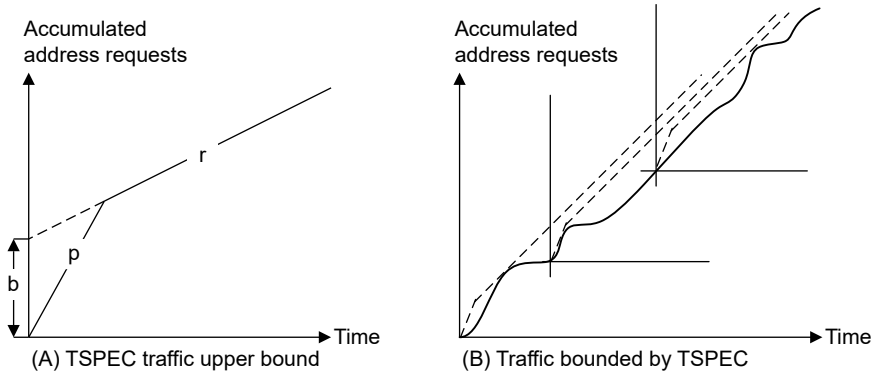

Figure 307. TSPEC traffic specification

The TSPEC parameters define an upper bound that applies over any time window.

(B) Traffic bounded by TSPEC in Figure 307 illustrates this, with the accumulated data curve bounded by the TSPEC curve from any point in the data sequence. You program the TSPEC parameter values for AW and AR request rates in separate sets of registers.

The regulators are disabled after reset. If you program the regulators while they are enabled, the new values take effect immediately. Alternatively, you can disable the regulators, update the values, and then re-enable the regulators.

Binary fractions in transfers per cycle provide the values for peak and average rates. For example:

- A value of 800h, that is, 0.5 in decimal, sets a rate of one transfer every two cycles.
- A value of 100h, that is, 0.0625 in decimal, sets a rate of one transfer every 16 cycles.
- A value of 000h sets a rate of one transfer per cycle, that is, no regulation. If you set either the burstiness to 0, or the average rate to 0, this disables the regulation of burstiness and average rate, (b,r).

In the same way, if you set the peak rate to 0, this disables the peak rate regulation. You can set:

- Peak rate only.
- Burstiness and average rate, without the peak rate.

72.3.1.3.1 Example: How to program the transaction rate regulator registers

This example describes a case where you set the following requirements:

- Transaction rate to use 4% of the available bandwidth.
- Each transaction to be a 16-beat burst.
- Peak rate, p.
- Burstiness allowance, b.
- Average rate registers, r.

It must be noted that the burstiness allowance is not related to the AXI burst length. It is a measure of traffic burstiness, in this case the burstiness of transfers on the AW or AR channels.

Transactions are regulated on AW and AR transfers, so you can use the burst length to calculate the AR or AW transfer rate from the required bandwidth as follows:

- The required data bandwidth is 4% that is equal to four data transfers in every 100 cycles.
- One transaction has 16 beats of data, so requires one transaction every 16/4 * 100 cycles.

  This gives one transaction every 400 cycles.

One transfer every 400 clock cycles is equivalent to 0.0025 transfers per cycle. You must convert this into a 12 bit binary fraction to give the value to program ASIBn_AW_R and ASIBn_AR_R with `0b000000001010`.

NOTE

To calculate the 12-bit binary from the decimal fraction use the following equation:

```
<12-bit binary fraction> = 12^12 * <decimal fraction> = 4096 *
<decimal fraction>
```

For example, converting the decimal fraction 0.0025, would give 4096 * 0.0025 or 10.24. Rounding this to the nearest whole number gives 10 or 0b0000 0000 1010 as a 12-bit binary number.

This value is an approximation limited in accuracy by the number of bits available in the average rate register. See ASIBn_AW_R and ASIBn_AR_R.

Example 1

In this example, the nearest approximation gives a rate of 1 transaction every 409.6 clock cycles or 16/409.6*100 = 3.9% of available bandwidth. If you do not set all three TSPEC values, you can set either the peak rate only, or the burstiness and average rate, without the peak rate.

The peak rate register, p is only 8 bits, not 12 bits as in the average rate register, r, so the previously calculated value does not fit. See ASIBn_AW_R and ASIBn_AR_R. Therefore, you can achieve hard regulation at one transaction in 409 clock cycles by setting the following:

- **p** `0b00000000`. See ASIBn_AW_P and ASIBn_AR_P.
- **r** `0b000000001010`. See ASIBn_AW_R and ASIBn_AR_R.
- **b** `0b0000000000000001`. See ASIBn_AW_B and ASIBn_AR_B.

Example 2

The burstiness allowance, combined with the peak rate and average rate, enables variance in the issuing rate from that initiator during different system loadings. For example, set the values as follows:

- **p** `0b00000001`, that is, 1 in 256. See ASIBn_AW_P and ASIBn_AR_P.
- **r** `0b000000001010`, that is, 1 in 409.6. See ASIBn_AW_R and ASIBn_AR_R.
- **b** `0b0000000000000101`. See ASIBn_AW_B and ASIBn_AR_B.

This permits a maximum issuing rate of one request every 256 clock cycles until the burstiness allowance, b, has been used up, and then, an average issuing rate, r, of one request every 409.6 clock cycles.

The regulator keeps track of the burstiness allowance to control whether the issuing rate is limited to the peak rate, p, or to the average rate, r. The maximum burstiness allowance is configured by ASIBn_AW_B and ASIBn_AR_B. When regulation is enabled it is decremented on every transfer and incremented at the average rate. While the burstiness allowance is non-zero the peak rate is allowed. In this example, the burstiness allowance starts at 5, so, at the peak issuing rate, the allowance reaches 0 after:

b * (p/(p-r)) = 5 * (0.0039/(0.0039 - 0.00244) = 13 transfers

When the allowance has reached zero the issuing rate is limited to the average rate. If the issuing rate from the initiator drops below the average rate, then the burstiness allowance increases until it reaches the programmed burstiness allowance, b.

72.3.1.3.2 Combined AW and AR transaction rate regulation

You can regulate the combined transaction rate from the AW and AR channels. When you select this mode, QoS ignores the AR channel registers and uses the AW channel values as the combined AW + AR transaction rates.

Because two channels support twice the rate of a single channel, QoS scales the parameters for combined regulation by a factor of two. For example, to specify a combined average rate of one transfer every eight cycles, set the value to 100h. This is equal to two transfers every 16 cycles. That is, the rate you program is half the required combined rate.

When the combined AW and AR channel traffic is so close to the transaction rate boundary that only one transfer is permitted, but both channels are requesting, then the regulator admits the AW channel and AR channel alternately.

72.3.1.4 Outstanding transaction regulation

The regulator enables you to program values for the number of AW and AR requests that it issues. You can enable this regulator by configuring ASIBn_QOS_CNTL[EN_AW_OT], ASIBn_QOS_CNTL[EN_AR_OT], and ASIBn_QOS_CNTL[EN_AWAR_OT].

72.3.1.4.1 Fractional outstanding transactions

You can characterize a sequence of transactions with periods when there are no outstanding transactions by using a fractional outstanding transaction number. For example, if requests occur every 100 cycles, but it only takes 50 cycles for the last response to arrive, then this would correspond to an average of 0.5 outstanding transactions. This generalizes to give an average value for any sequence of transactions where the number of outstanding transactions varies.

See ASIBn_MAX_OT registers for configuration details.

72.3.1.4.2 Combined AW and AR outstanding transaction regulation

You can program a maximum outstanding transaction capability for the combined AW and AR channels. This is in addition to the individual channel maximum, so that it is possible to set a combined limit that is lower than the sum of the individual channel limits. A combined value of zero, or greater than or equal to the sum of the individual configuration limits, has no effect.

For example, if the AW and AR configuration issuing capabilities are four and four, the default issuing capability is eight. Setting a combined value of six lowers the combined issuing capability, but leaves the individual channel configuration limits unaltered. Therefore, if there are four outstanding AW requests, then only two AR requests are permitted. Alternatively, if there are only two outstanding AW requests, then four AR requests can be made.

See ASIBn_MAX_COMB_OT registers for configuration details.

72.3.1.5 Transaction and address request latency regulation

72.3.1.5.1 Transaction latency regulation

axqos is either **arqos** or **awqos**. The transaction latency regulator modifies the **axqos** value of each transaction request. This overrides any **axqos** value that NIC might have specified. For example, if a transaction is given an **axqos** value that gives it a higher priority, then this tends to reduce the transaction latency of that transaction. In this way, a feedback loop is set up so that when the actual latency is higher than the target transaction latency, the **axqos** value is proportionately raised, and the larger the transaction latency discrepancy, the higher the priority.

NOTE

The regulator measures the time it takes for a transaction to complete.

Transaction latency regulation is useful for initiators that have performance that is directly dependent on transaction latency. For example, a processor might be stalled while it waits for data after a cache miss.

You program the target transaction latency separately for writes and reads. You enable transaction latency regulation by setting ASIBn_QOS_CNTL[MODE_AR_FC], ASIBn_QOS_CNTL[MODE_AW_FC], ASIBn_QOS_CNTL[EN_AR_FC], and ASIBn_QOS_CNTL[EN_AW_FC].

When you enable transaction latency regulation for reads or writes, the base product **axqos** values are not used. You set the range of **axqos** values used for transaction latency regulation by programming the minimum and maximum values for writes and reads in ASIBn_QOS_RANGE. You program a scaling factor to give control over how quickly the **axqos** values change. The smaller the scaling factor, the more slowly the **axqos** values change in response to changes in transaction latency. The scaling factor is specified in powers of two. See ASIBn_KI_FC.

72.3.1.5.2 Address request latency regulation

The address request latency regulator modifies the **axqos** value of each transaction request. This overrides any **axqos** value that the base product has specified. For example, if a transaction is given an **axqos** value that gives it a higher priority, then this reduces the latency between address requests. In this way, a feedback loop is set up so that when the actual latency is higher than the target latency, the **axqos** value is proportionately raised, and the larger the latency discrepancy, the higher the priority.

NOTE

- The regulator measures the time between address requests.
- **axqos** is either **arqos** or **awqos**.

Address request period regulation is useful for initiators that have minimum bandwidth requirements, for example, a GPU.

You program the target period separately for writes and reads. You enable address request period regulation by setting ASIBn_QOS_CNTL[MODE_AR_FC], ASIBn_QOS_CNTL[MODE_AW_FC], ASIBn_QOS_CNTL[EN_AR_FC], and ASIBn_QOS_CNTL[EN_AW_FC].

When you enable address request period regulation for reads or writes, the **axqos** values are not used. When you disable address request period regulation, the **axqos** values are passed through unmodified.

You set the range of **axqos** values used for address request period regulation by programming the minimum and maximum values for writes and reads in ASIBn_QOS_RANGE.

You program a scaling factor in ASIBn_KI_FC to give control over how quickly the **axqos** values change. The smaller the scaling factor, the more slowly the **axqos** values change in response to changes in latency. The scaling factor is specified in powers of two.

72.3.2 Clocking

NIC operations run off the bus clock that supports the peripherals within the same bus domain. See CLKCTL chapter for more information.

72.3.3 Reset

NIC reset is covered by the reset scheme for the chip and bus domain where it is implemented. See RSTCTL chapter for more information.

72.3.4 Interrupts

This module has no interrupts.

72.4 External signals

This module has no external signals.

72.5 Initialization

This module does not require initialization. Make sure that the associated bus clock and power are on, and follow programming considerations mentioned in QoS operations and Memory map and register definition.

72.6 Memory map and register definition

This section includes NIC memory map and detailed descriptions of all registers.

72.6.1 NIC register descriptions

Each target interface has one set of ASIB registers.

72.6.1.1 NIC memory map

NIC_MEDIA1 base address: 404C_0000h

Offset	Register	Width (In bits)	Access	Reset value
1_2100h - 1_B100h	Read Channel QoS Value (ASIB0_READ_QOS - ASIB9_READ_QOS)	32	RW	0000_0000h
1_2104h - 1_B104h	Write Channel QoS Value (ASIB0_WRITE_QOS - ASIB9_WRITE_QOS)	32	RW	0000_0000h
1_2108h - 1_B108h	Issuing Functionality Modification (ASIB0_FN_MOD - ASIB9_FN_MOD)	32	RW	0000_0000h
1_210Ch - 1_B10Ch	QoS Control (ASIB0_QOS_CNTL - ASIB9_QOS_CNTL)	32	RW	0000_0000h
1_2110h - 1_B110h	Maximum Number of Outstanding Transactions (ASIB0_MAX_OT - ASIB9_MAX_OT)	32	RW	0000_0000h
1_2114h - 1_B114h	Maximum Combined Outstanding Transactions (ASIB0_MAX_COMB_OT - ASIB9_MAX_COMB_OT)	32	RW	0000_0000h
1_2118h - 1_B118h	AW Channel Peak Rate (ASIB0_AW_P - ASIB9_AW_P)	32	RW	0000_0000h
1_211Ch - 1_B11Ch	AW Channel Burstiness Allowance (ASIB0_AW_B - ASIB9_AW_B)	32	RW	0000_0000h
1_2120h - 1_B120h	AW Channel Average Rate (ASIB0_AW_R - ASIB9_AW_R)	32	RW	0000_0000h
1_2124h - 1_B124h	AR Channel Peak Rate (ASIB0_AR_P - ASIB9_AR_P)	32	RW	0000_0000h
1_2128h - 1_B128h	AR Channel Burstiness Allowance (ASIB0_AR_B - ASIB9_AR_B)	32	RW	0000_0000h
1_212Ch - 1_B12Ch	AR Channel Average Rate (ASIB0_AR_R - ASIB9_AR_R)	32	RW	0000_0000h
1_2130h - 1_B130h	Feedback Controlled Target (ASIB0_TARGET_FC - ASIB9_TARGET_FC)	32	RW	0000_0000h
1_2134h - 1_B134h	Feedback Controlled Scale (ASIB0_KI_FC - ASIB9_KI_FC)	32	RW	0000_0000h
1_2138h - 1_B138h	QoS Range (ASIB0_QOS_RANGE - ASIB9_QOS_RANGE)	32	RW	0000_0000h

72.6.1.2 Read Channel QoS Value (ASIB0_READ_QOS - ASIB9_READ_QOS)

Offset

For n = 0 to 9:

Register	Offset
ASIBn_READ_QOS	1_2100h + (n × 1000h)

Function

Sets the priority of the initiator's read.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	Reserved												READ_QOS			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-4 —	Reserved
3-0 READ_QOS	Read Channel QoS Value The priority level is used when the initiator's read transaction is being arbitrated by the NIC. 0000b - The lowest priority 0001b-1110b - ... 1111b - The highest priority

72.6.1.3 Write Channel QoS Value (ASIB0_WRITE_QOS - ASIB9_WRITE_QOS)

Offset

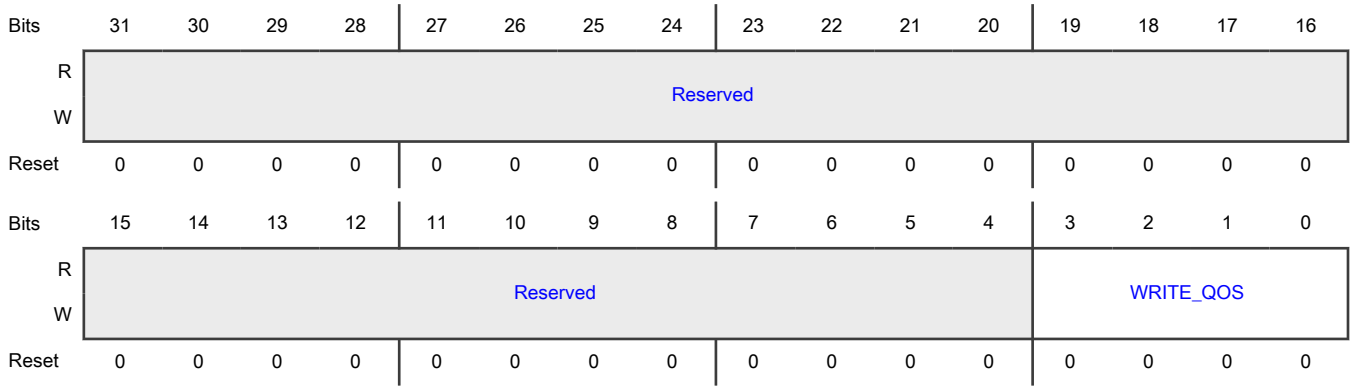
For n = 0 to 9:

Register	Offset
ASIBn_WRITE_QOS	1_2104h + (n × 1000h)

Function

Sets the priority of the initiator's write.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-0 WRITE_QOS	Write channel QoS value The priority level is used when the initiator's write transaction is being arbitrated by the NIC. 0000b - The lowest priority 0001b-1110b - ... 1111b - The highest priority

72.6.1.4 Issuing Functionality Modification (ASIB0_FN_MOD - ASIB9_FN_MOD)

Offset

For n = 0 to 9:

Register	Offset
ASIBn_FN_MOD	1_2108h + (n × 1000h)

Function

Issuing override. This register sets the block issuing capability to one outstanding transaction. The register bits are active high and have the following purpose:

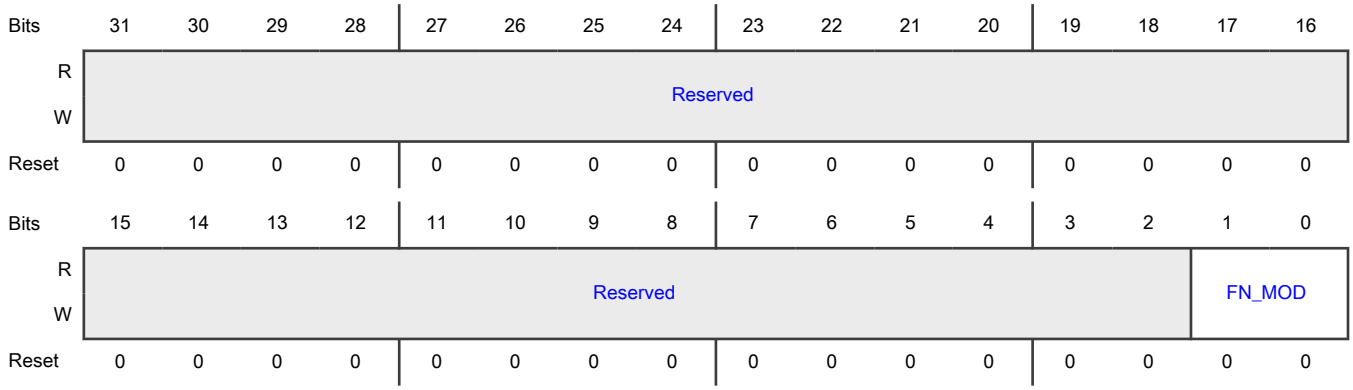
0 - Read issuing, READ_ISS_OVERRIDE.

1 - Write issuing, WRITE_ISS_OVERIDE.

NOTE

It is recommended to keep its reset value to obtain the best performance.

Diagram



Fields

Field	Function
31-2 —	Reserved
1-0 FN_MOD	Issuing Functionality Modification Sets block issuing capability to one outstanding transaction. 00b - Default issuing 01b - Read issuing 10b - Write issuing 11b - Read and write issuing

72.6.1.5 QoS Control (ASIB0_QOS_CNTL - ASIB9_QOS_CNTL)

Offset

For n = 0 to 9:

Register	Offset
ASIBn_QOS_CNTL	1_210Ch + (n × 1000h)

Function

Specifies the enable bits for all the regulators. By default, all of the bits are set to 0, and no regulation is enabled.

Regulation only takes place when both the enable bit is set, and its corresponding regulation value is non-zero. The QoS regulators are reset whenever they are re-enabled. The transaction and address latency regulator enables ASIB*n*_QOS_CNTL[EN_AR_FC] and ASIB*n*_QOS_CNTL[EN_AW_FC] can be used to provide a soft reset of these regulators.

Diagram

0 EN_AW_RATE	Enable AW Transaction Rate Regulation Enables AW channel transaction rate regulation. 0b - Disables 1b - Enables

72.6.1.6 Maximum Number of Outstanding Transactions (ASIB0_MAX_OT - ASIB9_MAX_OT)

Offset

For n = 0 to 9:

Register	Offset
ASIBn_MAX_OT	1_2110h + (n × 1000h)

Function

Configures the maximum number of address requests for the AR and AW channels. See Outstanding transaction regulation for more information. Register is ignored if outstanding transaction regulation is not enabled (ASIBn_QOS_CNTL[EN_AWAR_OT], [EN_AR_OT], and [EN_AW_OT] all equal 0).

NOTE

The outstanding transaction limits have an integer part and a fractional part. The AW and AR outstanding transaction limits are enabled when you set the corresponding ASIB*n*_QOS_CNTL[EN_AW_OT] or [EN_AR_OT] fields.

23-16 AR_MAX_OTF	Fractional Part of Maximum Outstanding AR Addresses Corresponds to the fractional part of the maximum outstanding AR addresses. A value of 0 for both the integer and fractional parts disables the programmable regulation so that the configuration limits apply. See the note about binary fraction representation in Example: How to program the transaction rate regulator registers for more information.
15-14 —	Reserved
13-8	Integer Part of Maximum Outstanding AW Addresses

Table continues on the next page...

Table continued from the previous page...

Field	Function
AW_MAX_OTI	Corresponds to the integer part of the maximum outstanding AW addresses. A value of 0 for both the integer and fractional parts disables the programmable regulation so that the configuration limits apply.
7-0 AW_MAX_OTF	Fractional Part of Maximum Outstanding AW Addresses Corresponds to the fractional part of the maximum outstanding AW addresses. A value of 0 for both the integer and fractional parts disables the programmable regulation so that the configuration limits apply. See the note about binary fraction representation in Example: How to program the transaction rate regulator registers for more information.

72.6.1.7 Maximum Combined Outstanding Transactions (ASIB0_MAX_COMB_OT - ASIB9_MAX_COMB_OT)

Offset

For n = 0 to 9:

Register	Offset
ASIBn_MAX_COMB_OT	1_2114h + (n × 1000h)

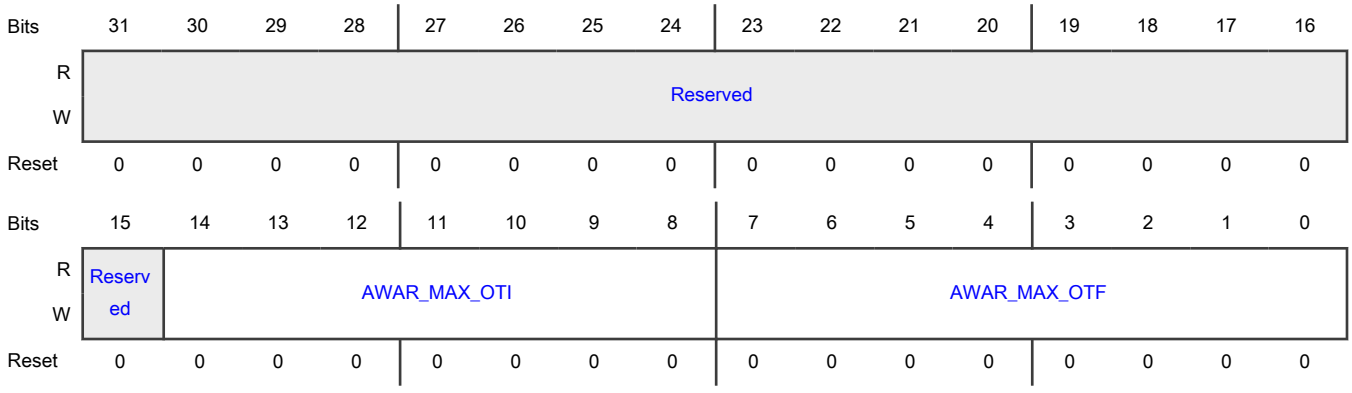
Function

Configures the maximum number of address requests for the AR and AW channels. The combined limit is applied after any individual channel limits. See Outstanding transaction regulation for more information. Register is ignored if outstanding transaction regulation is not enabled (ASIBn_QOS_CNTL[EN_AWAR_OT], [EN_AR_OT], and [EN_AW_OT] all equal 0).

NOTE

The outstanding transaction limits have an integer part and a fractional part. The regulation of the combined outstanding transaction limit also requires that you set ASIB*n*_QOS_CNTL[EN_AWAR_OT] field.

Diagram



Fields

72.6.1.16 QoS Range (ASIB0_QOS_RANGE - ASIB9_QOS_RANGE)

Offset

For n = 0 to 9:

Register	Offset
ASIBn_QOS_RANGE	1_2138h + (n × 1000h)

Function

Configures the minimum and maximum values for the arqos and awqos signals that the latency regulators generate. See Transaction latency regulation and Address request latency regulation for more information. If the values in this register are changed to make the range narrower than either the previous upper or lower bounds then, you must reset the regulator through a soft reset by disabling and re-enabling it. If the values in this register are changed to make the range wider than either the previous upper or lower bounds then, the regulator does not require a soft reset.

On-Chip OTP Controller (OCOTP_CTRL)

73.1 Chip-specific OCOTP_CTRL information

Table 701. Reference links to related information

Topic	Related module	Reference
Full description	OCOTP_CTRL	OCOTP_CTRL
Peripheral memory map		Memory map overview
Power management	PMC	Power overview PMC
Clocking		Clock overview Clock controller
Fusemap		Fusemap

73.1.1 Module instances

This device has one instance of the OCOTP_CTRL module.

Table 702. OCOTP_CTRL instance

Features	OCOTP_CTRL
Located in	VDD2_COM
Access	CPU0, HiFi4, EZH-V, eDMA0, eDMA1

73.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

73.2 Overview

This section contains information describing the On-Chip OTP controller (OCOTP_CTRL) along with details about the block functionality and implementation. In this document, the words "eFuse" and "OTP" are interchangeable. OCOTP refers to the hardware block itself.

73.2.1 Block Diagram

The system level block diagram for OCOTP is provided below.

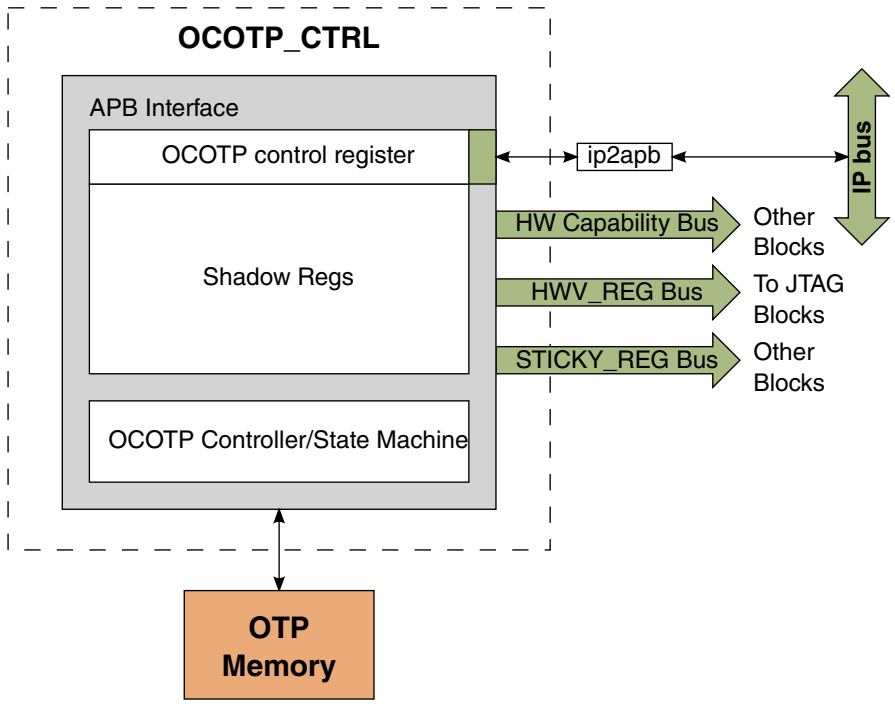

Figure 308. OCOTP System Level Block Diagram

73.2.2 Features

The OCOTP provides the following features :

- 32-bit word restricted program and read to
- Loading and housing of eFuse content into shadow registers
- Memory-mapped (restricted) access to shadow registers
- Generation of STICKY_REG which consists of sticky register bits
- Provides program-protect and read-protect of eFuse
- Provides read protection of shadow register
- Supports Error-Correcting Code (ECC) mode programming and reading for all of the user fuse words
- Supports redundancy mode programming and reading for all of the supplementary fuse words

73.3 Functional Description

73.3.1 Operations

The IP bus interface of the OCOTP has the following functions.

- Configure control registers for programming and reading all the fuse words
- Read shadow registers

OCOTP configuration for programs and reads is allocated on 32-bit word boundaries for software (SW) convenience. For writes, the 32-bit word reflects the "write-mask". OTP Memory bits not yet programmed are 0. Programmed bits are 1.

NOTE

For fuse words that use ECC, the fuse word can only be programmed one time, otherwise it will report single-bit error correction (SEC) / double-bit error detection (DED) issues in read or reload. Refer to the fusemap chapter to identifiy which fuse words use ECC for error correction.

NOTE

For fuse words that use redundant bits, the fuse word can be programmed more than one time (not the same fuse bit). Refer to the fusemap chapter to identifiy which fuse words use redundant bits for error correction.

73.3.1.1 Shadow Register Reload

All fuse words in efuse box are shadowed. This means that at reset, fuse values are read and then copied into memory-mapped shadow registers. If fuses are subsequently programmed, the shadow registers should be reloaded to keep them coherent with the fuse bank arrays.

The "reload shadows" feature allows the user to force a reload of all shadow registers without having to reset the device. To force a reload, complete the following steps:

1. Check that CTRL[BUSY] and CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write, read, or reload must be completed before a new access can be requested.
2. Set the CTRL[RELOAD_SHADOWS] bit. OCOTP will read all the fuses one by one and put it into the corresponding shadow register.
3. Wait for CTRL[BUSY] and CTRL[RELOAD_SHADOWS] to be cleared by the controller.
4. Check the values of OUT_STATUS[SEC_RELOAD] and OUT_STATUS[DED_RELOAD].
   - If OUT_STATUS[SEC_RELOAD] is set, it indicates at least one single bit correction happened when reloading.
   - If OUT_STATUS[DED_RELOAD] is set, it indicates at least one double-bit error happened when reloading. That is, one or more fuse words are not correct when reading from eFuse.

The controller will automatically clear the CTRL[RELOAD_SHADOWS] bit after the successful completion of the operation.

73.3.1.2 Fuse and Shadow Register Read

All shadow registers are always readable through the IPS bus except some secret key regions. When their corresponding fuse lock bits are set, the shadow registers also become read locked. After read locking, reading from these registers will return 0xBADABADA. In addition, CTRL[ERROR] will be set. CTRL[ERROR] must be cleared by software before any new write, read, or reload access can be issued. Subsequent reads to unlocked shadow registers will still work successfully.

To read fuse words directly from the fusebox instead of the shadow registers, complete the following steps:

1. Check that CTRL[BUSY] and CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write, read, or reload must be completed before a read access can be requested.
2. Write the requested fuse address to CTRL[ADDR].
3. Set READ_CTRL[READ_FUSE] to start the read operation.
4. Wait for the controller to clear CTRL[BUSY]. A read request to a protected or locked region will result in no OTP access and no setting of CTRL[BUSY]. In addition, CTRL[ERROR] will be set. CTRL[ERROR] must be cleared by software before any new access can be issued.
5. Read READ_FUSE_DATA to get fuse word value. READ_FUSE_DATA will be 0xBADABADA when CTRL[ERROR] is set.
6. After reading is completed, it is necessary to check OUT_STATUS[DED]. If it is 1, read fuse value is wrong, otherwise it is correct.

73.3.1.3 Fuse Writes

In order to avoid "rogue" code performing erroneous writes to OTP, a special unlocking sequence is required for writes to the fuse banks. To program fuse bank, complete the following steps:

1. Check that CTRL[BUSY] and CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write, read, or reload must be completed before a write access can be requested.
2. Write the requested address to CTRL[ADDR] and program the unlock code into CTRL[WR_UNLOCK]. The unlock code must be programmed for each write access. The unlock code is documented in the register description. Both the unlock code and address can be written in the same operation.
3. When programming a fuse word, OCOTP_CTRL will auto select ECC or redundancy mode to program the fuse word according to fuse map definition. In ECC mode, the 32 fuse bits in one word can only be written one time. In redundancy mode, the word can be written more than one time as long as they are different fuse bits. For the fuse word which needs be programmed with ECC mode, it is recommended to set CTRL[WORDLOCK] with unlock code and address in the same operation.
4. Write the data to the DATA register. This will automatically set CTRL[BUSY] and clear CTRL[WR_UNLOCK]. Bit fields with 1's will result in that OTP bit being programmed. Bit fields with 0's will be ignored. At the same time that the write is accepted, the controller makes an internal copy of CTRL[ADDR] which cannot be updated until the next write sequence is initiated. This copy guarantees that erroneous writes to CTRL[ADDR] will not affect an active write operation. During the write operation, DATA cannot be modified. If the requested fuse word is locked, the programming request will not be performed. Checking the appropriate LOCKEDn register before attempting to program is recommended
5. Wait for the controller to clear CTRL[BUSY]. A write request to a protected or locked region will result in no OTP access and no setting of CTRL[BUSY]. In addition CTRL[ERROR] will be set. CTRL[ERROR] must be cleared by software before any new write access can be issued.
6. Check the values of OUT_STATUS[PROGFAIL] and OUT_STATUS[LOCKED]. If either of these two bits is set, it indicates that programming has failed.

It should be noted that write latencies to OTP are multiples of 10 micro-seconds per word. The write latency is based on the number of "1" bits being written. For example, to program half the fuse bits in one 32-bt word requires approximately 10 µs x 16. The RT700 family device datasheet provides a guaranteed maximum programming time for per bit

73.3.1.4 Bank redundancy vs ECC

There are two mechanisms used by the fuse block to ensure that its values are correct. Each of these is performed on a word by word basis, however, the selected option is hardwired on a bank by bank basis.

Fuses can generally only be set from 0 to 1 and the most common failure is a 1 appearing as a 0. The simplest mechanism to verify these failures is redundancy. Bank redundancy is when two bits are OR'd together so that if either is set, then the output value is a 1.

In this case only 16 of the 32 bits are available (bits 15:0 are automatically copied to 31:16) and checked on read. The value here is that each pair of bits can be programmed at different times. This allows for multiple programming operations on a word, so bits can be configured at different times.

NOTE

In shadow registers, the inverted version of [15:0] will show in [31:16]. In the fuse array, [31:16] is the same as [15:0].

The more complex ECC mechanism is used when higher numbers of bits must be stored and configured at the same time in a group of 32. When written, the ECC must be calculated to allow an ECC correction. When read, any one bit of failure will be corrected, 2 bits will be detected (and an error flag asserted) by the controller.

NOTE

As the ECC is generated for the whole word, the whole word must be setup at one time and individual bits cannot be modified independently.

73.3.1.5 Error Conditions

The CTRL[ERROR] bit will be set under the following conditions:

- A read is performed to a shadow register which has been read locked.
- A program is performed to a non-existent fuse word
- A read is performed to a fuse word which has been read locked.
- Overlapping access - a read, write, or reload is attempted while a read, write, or reload is already in progress.
- A write request to a protected or locked region.

73.3.1.6 Write Postamble

Due to internal electrical characteristics of the OTP during writes, all OTP operations (direct reads, shadow reloads, or other writes) following a write must wait at least 2 µs after CTRL[BUSY] clears. The delay guarantees programming voltages on-chip reach a steady state when exiting a write sequence.

A recommended software sequence to meet the postamble requirements is as follows:

1. Issue the write and poll for CTRL[BUSY].
2. After CTRL[BUSY] is clear, wait 2 µs.
3. Perform the next OTP operation.

73.3.2 Fuse Shadow Memory Footprint

The OTP memory footprint is shown in the following figure. The registers are grouped by lock region. Their names correspond to the fusemap names.

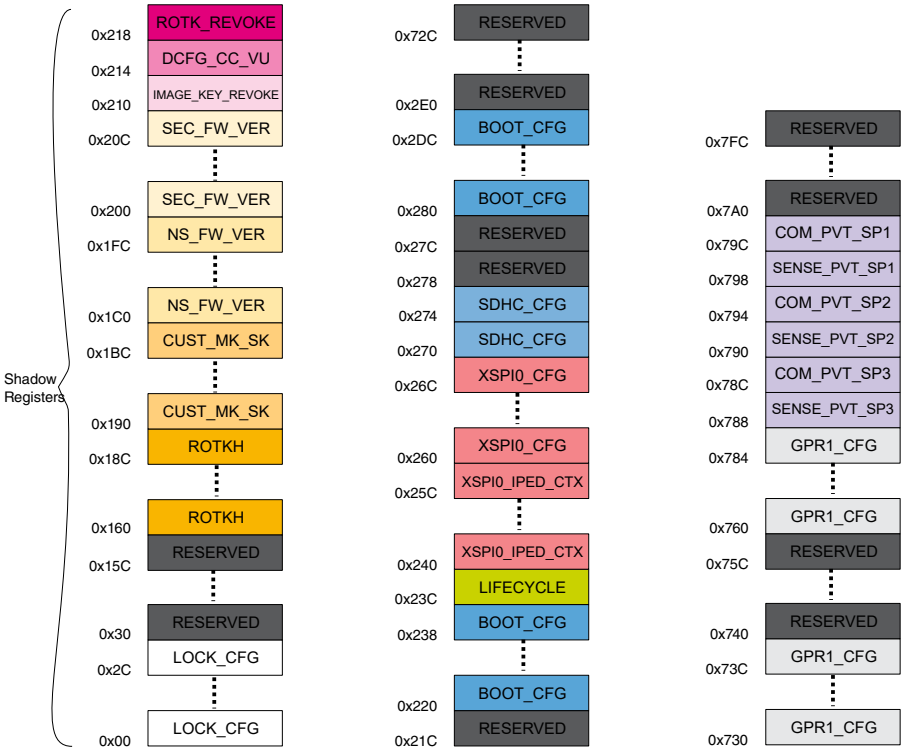

Figure 309. OTP Memory Footprint

73.3.3 Clocking

The table found here describes the clock sources for OCOTP. Please see the chip-specific clocking section for clock setting, configuration and gating information.

Table 703. OCOTP Clocks

Clock name	Description
ipg_clk	Peripheral clock to configure registers and function module.

73.3.4 Resets

The OCOTP is always active. The shadow registers automatically load the appropriate OTP contents after reset is deasserted. During this load-time CTRL[BUSY] is set.

73.4 External Signals

There are no external signals pinned out for OCOTP.

73.5 Fuse Map

See the Fusemap chapter of this reference manual for more information.

73.6 Memory Map/Register Definition

The OCOTP Memory Map/Register Definition can be found here.

NOTE

Writing or reading an unimplemented register address in the OCOTP Controller will not send a bus error and read data will be 0.

73.6.1 register descriptions

73.6.1.1 OCOTP memory map

OCOTP base address: 4001_8000h

R W	WORD LOCK	SUPP ADD	RED_MUX_SEL		RELO AD_...	SRAM _EN...	PRNG _OU...	ADDR								
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 WR_UNLOCK	Write 0x3E77 to enable OTP write accesses. NOTE: The write operation must be unlocked for each word by writing 0x3E77 to WR_UNLOCK field. Then writing to OTP_WRITE_DATA regsiter will automatically start the programming procedure.
15 WORDLOCK	Set to write-lock the fuse word when it's being programming.
14 SUPPADD	This bit should be set when programming pr reading the supplementary address space (aka test row).
13-12 RED_MUX_SEL	For fuse word with Redundancy mode, if set red_mux_sel to 0, low 16bit fuse OR high 16bit fuse value can be read, if set red_mux_sel to 1, low 16bit fuse value can be read, if set red_mux_sel to 2, high 16bit fuse value can be read. For fuse word with bit protect, if set red_mux_sel to 0, low 16bit fuse OR high 16bit fuse value can be read and low 16bit shadow OR high 16bit shadow can be read, if set red_mux_sel to 1, low 16bit fuse value can be read and low 16bit shadow can be read, if set red_mux_sel to 2, high 16bit fuse value can be read and high 16bit shadow value can be read.
11 RELOAD_SHADOWS	Set to force re-loading the shadow registers (HW/SW capability and LOCK). This operation will automatically set OTP_STATUS.BUSY. Once the shadow registers have been re-loaded, OTP_STATUS.BUSY and RELOAD_SHADOWS are automatically cleared by the controller.
10 SRAM_ENTROPY_DATA_EN	Default is 0: enable read value of sram entropy data, disable read when set to 1. This bit can only be cleared by POR.
9 PRNG_OUTPUT_DATA_EN	Default is 0: enable read value of prng out data, disable read when set to 1. This bit can only be cleared by POR.
8-0 ADDR	OTP word address for read/programming.

73.6.1.4 OTP Controller Write Data Register (HW_OCOTP_WRITE_DATA)

Offset

Register	Offset
HW_OCOTP_WRITE_DATA	808h

Fields

Field	Function
31-1 —	Reserved
0 READ	Writing 1 to start a fuse word read operation. It's cleared by hardware when the read operation is completed.

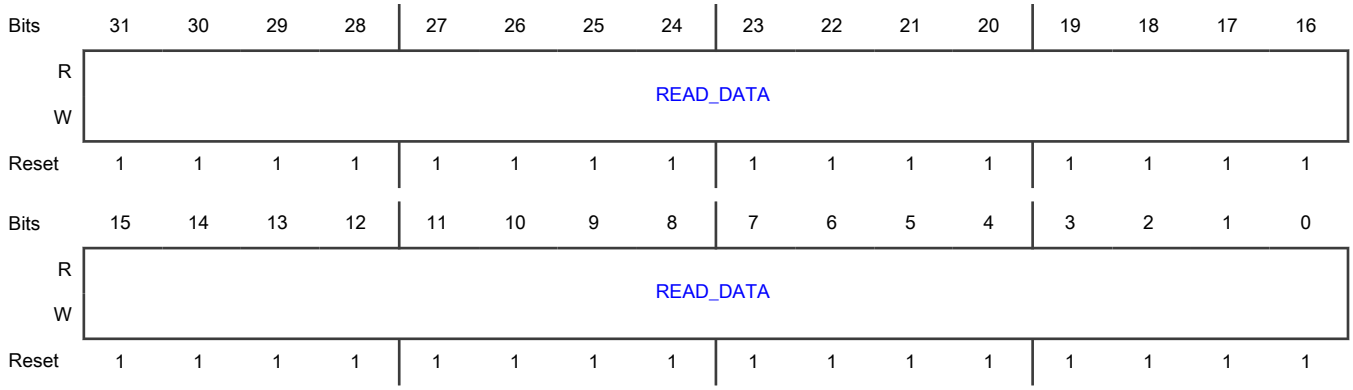
73.6.1.6 OTP Controller Read Data Register (HW_OCOTP_READ_DATA)

Offset

Register	Offset
HW_OCOTP_READ_DATA	810h

Function
OTP read data register.

Diagram



Fields

Field	Function
31-0 READ_DATA	Fuse word read data from read operation.When write any value to it, it will be clear to all 1.

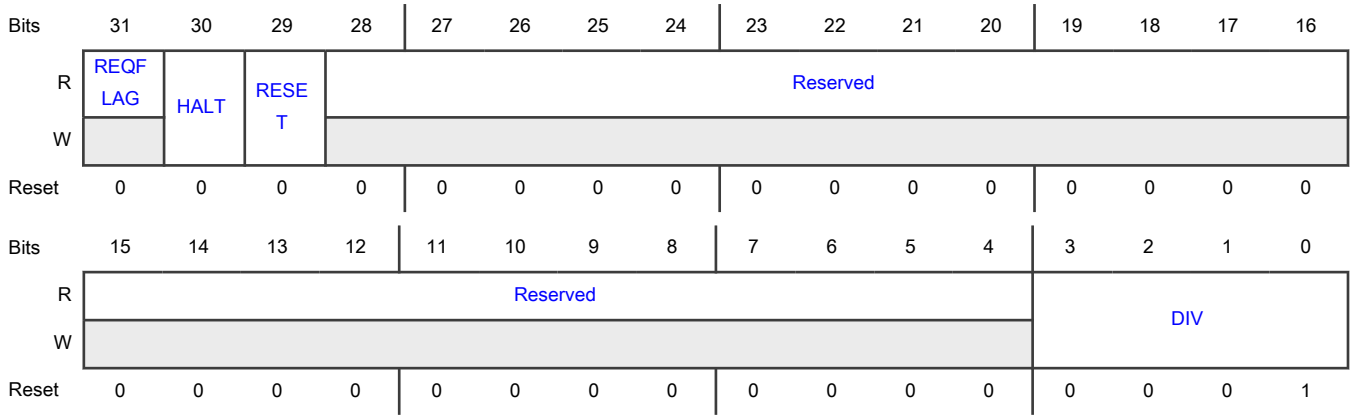
73.6.1.7 OTP Controller Clock Divider register (HW_OCOTP_CLK_DIV)

Offset

Register	Offset
HW_OCOTP_CLK_DIV	814h

Function
OTP clock divider register.

Diagram



Fields

Field	Function
31 REQFLAG	Divider status flag. Set when a change is made to the divider value, cleared when the change is complete.
30 HALT	Halts the divider counter. The intent is to allow the divider's clock source to be changed without the risk of a glitch at the output.
29 RESET	Resets the divider counter. Can be used to make sure a new divider value is used right away rather than completing the previous count.
28-4 —	Reserved
3-0 DIV	Clock divider value by 1 encoding. It's uesd to generate the clock to OTP memory (otp_clk) with apb_clk. The maximum otp_clk frequency is 120Mhz. 0 : Divide by 1 ... 15 : Divider by 16

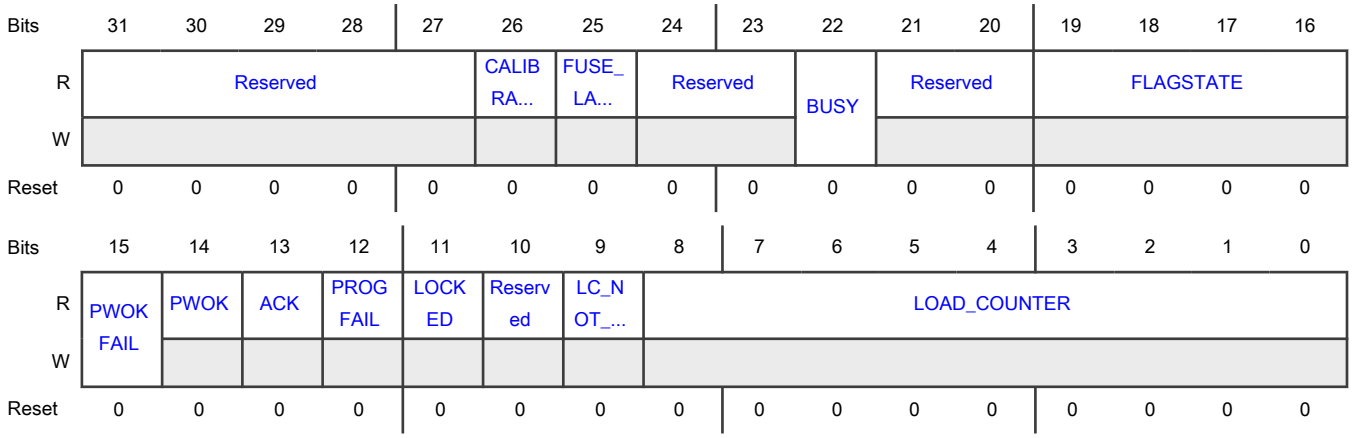
73.6.1.8 OTP Controller Status Register (HW_OCOTP_STATUS)

Offset

Register	Offset
HW_OCOTP_STATUS	820h

Function
Status register.

Diagram



Fields

Field	Function
31-27 —	Reserved
26 CALIBRATED	OTP CALIBRATED status.
25 FUSE_LATCHED	Indicate all shadows registers have been loaded with their corresponding fuse words when set by the controller after reset.
24-23 —	Reserved
22 BUSY	OTP controller status bit. When active, no new write or read access to OTP (including RELOAD_SHADOWS) can be performed. Cleared by the controller when the access completes. After reset (or after setting RELOAD_SHADOWS), this bit is set by the controller and cleared after all the shadow registers are successfully loaded.
21-20	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
19-16 FLAGSTATE	OTP FLAGSTATE[3:0] value.
15 PWOKFAIL	OTP PWOK fail indicate. When PWOK transitions from 1 to 0, PWOKFAIL will be high, and write 1 to clear.
14 PWOK	OTP PWOK value.
13 ACK	OTP ACK value.
12 PROGFAIL	OTP PROGFAIL status. Write 1 to clear.
11 LOCKED	OTP LOCKED status during read/write operation. Write 1 to clear.
10 —	Reserved
9 LC_NOT_BLANK_STICKY	indicate lc not blank has been blown.
8-0 LOAD_COUNTER	store load fuse number when load finished.

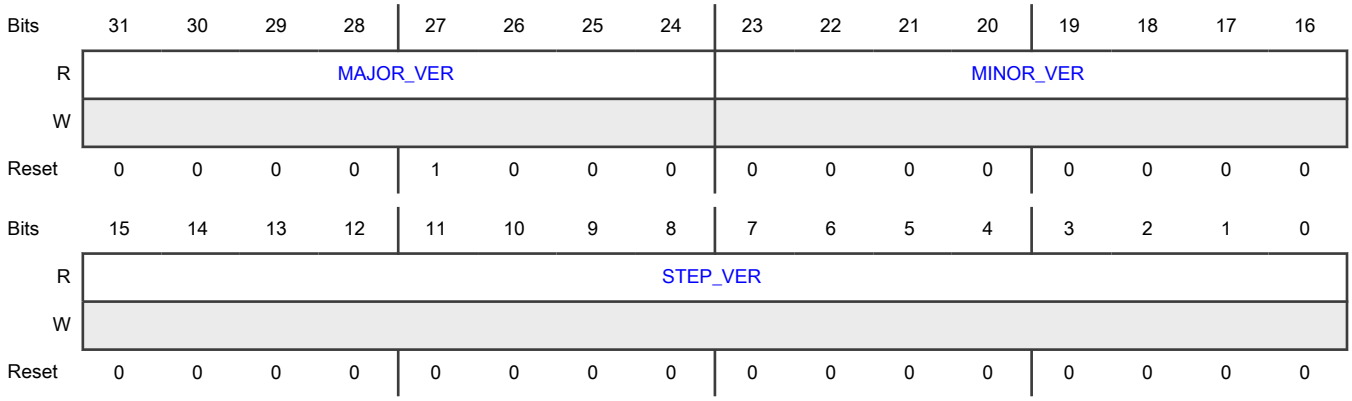
73.6.1.9 OTP Controller Version Register (HW_OCOTP_VERSION)

Offset

Register	Offset
HW_OCOTP_VERSION	828h

Function
VERSION ID register.

Diagram



Fields

Field	Function

74.1.1 Module instances

This device has one instance of the CRC module, CRC.

Table 705. CRC instance

	CRC
Located in	VDD2_COMP
Access	CPU0, HiFi4, EZH-V, eDMA0, eDMA1

74.2 Overview

CRC generates 16-bit or 32-bit CRC codes output for error detection. You can calculate these codes for up to 32 bits input data at a time.

CRC provides a programmable polynomial and other parameters to meet 16-bit or 32-bit CRC standards.

74.2.1 Block diagram

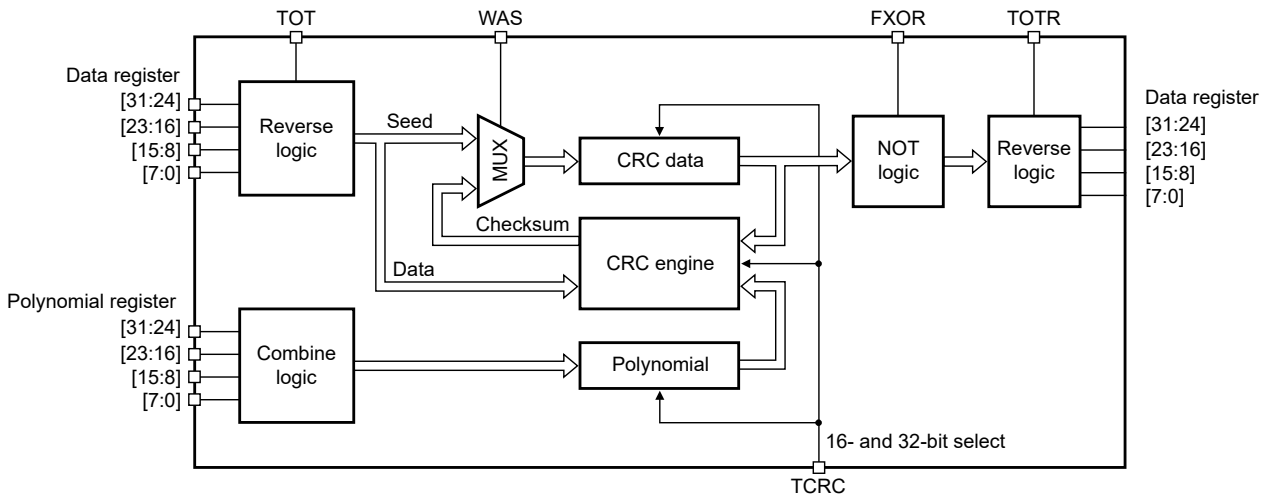

Figure 310. Block diagram

74.2.2 Features

CRC has the following features:

- Hardware CRC generator circuit using 16-bit or 32-bit programmable shift registers
- Programmable initial seed value and polynomial
- Transpose of input or output data (CRC result) in bitwise or bytewise (this option is required for certain CRC standards. You cannot perform a bytewise transpose operation when accessing DATA via 8-bit access.)
- Invert final CRC result
- 32-bit CPU register programming interface

74.3 Functional description

74.3.1 Modes of operation

The following sections describe various modes of operation that affect the functionality of CRC: Run mode and Low power mode.

74.3.1.1 Run mode

Run mode is the basic mode of operation.

74.3.1.2 Low-power modes

When the chip enters the low-power mode, the CRC module clock (ipg_clk and ipg_clk_s) is disabled and the in-progress CRC calculation stops. The calculation resumes after the CRC module clock is enabled or the chip exits low power mode via system reset.

NOTE

See the chip-specific power management chapter to know the specific low-power modes supported on your device.

74.3.2 CRC calculations

In 16-bit and 32-bit CRC modes, you can program data values as 8 bits, 16 bits, or 32 bits at a time, provided all bytes are contiguous. Noncontiguous bytes lead to an incorrect CRC calculation.

74.3.2.1 Calculating a 16-bit CRC

Perform these steps to calculate a 16-bit CRC:

1. Write 0 to CTRL[TCRC] to enable 16-bit CRC mode.
2. Program the transpose and complement options in Control (CTRL) as required for the CRC calculation.
3. Write a 16-bit polynomial to GPOLY[LOW].

   GPOLY[HIGH] is not usable in 16-bit CRC mode.
4. Write 1 to CTRL[WAS] to program the seed value.
5. Write a 16-bit seed to DATA[LU] and DATA[LL].

   DATA[HU] and DATA[HL] are not used.
6. Write 0 to CTRL[WAS] to start writing data values.
7. Write data values into DATA[LU], and DATA[LL]

   CRC is calculated on every data value write and the intermediate CRC result is stored back into DATA[LU] and DATA[LL]
8. After writing all the data values, read the final CRC result from DATA[LU] and DATA[LL].

CRC is calculated bytewise and two clocks are required to complete one CRC calculation.

The transpose and complement operations are performed on-the-fly when reading or writing values. See Transpose feature and Result complement for details.

74.3.2.2 Calculating a 32-bit CRC

Perform these steps to calculate a 32-bit CRC:

1. Write 1 to CTRL[TCRC] to enable 32-bit CRC mode.
2. Program the transpose and complement options in Control (CTRL) as required for CRC calculation. See Transpose feature and Result complement for details.
3. Write a 32-bit polynomial to GPOLY[HIGH] and GPOLY[LOW] .
4. Write 1 to CTRL[WAS] to program the seed value.
5. Write a 32-bit seed to DATA[HU], DATA[HL], DATA[LU], and DATA[LL].
6. Write 0 to CTRL[WAS] to start writing data values.
7. Write data values into DATA[HU], DATA[HL], DATA[LU], and DATA[LL]

   CRC is computed on every data value write and the intermediate CRC result is stored back into DATA .
8. After writing all the values, read the final CRC result from DATA[HU], DATA[HL], DATA[LU], and DATA[LL].

   CRC is calculated bytewise and two clocks are required to complete one CRC calculation.

The transpose and complement operations are performed on-the-fly when reading or writing values. See Transpose feature and Result complement for details.

74.3.3 Transpose feature

Transpose is not enabled by default. However, CRC requires input data and/or final checksum to be transposed. You have an option to configure each transpose operation separately to meet CRC standards. The data is transposed on-the-fly while being read or written.

Some protocols use the little-endian format for data stream to calculateCRC. In this case, transpose flips bits.

74.3.3.1 Types of transpose

CRC provides several types of transpose to flip bits and/or bytes for both writing input data and reading result separately using the CTRL[TOT] and CTRL[TOTR] according to the CRC calculation being used.

The following types of transpose are available for writing to and reading from DATA.

1. CTRL[TOT] or CTRL[TOTR] is 0.

   No transposition occurs.

2. CTRL[TOT] or CTRL[TOTR] is 1.

   Bits in a byte are transposed when bytes are not transposed.

   reg[31:0] becomes {reg[24:31], reg[16:23], reg[8:15], reg[0:7]}.

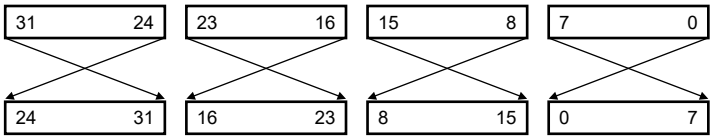

Figure 311. Transpose type 1b

3. CTRL[TOT] or CTRL[TOTR] is 10b.

   Both bits in bytes and bytes are transposed.

   reg[31:0] becomes {reg[0:7], reg[8:15], reg[16:23], reg[24:31]}.

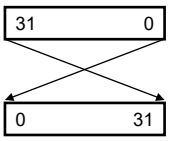

Figure 312. Transpose type 10b

4. CTRL[TOT] or CTRL[TOTR] is 11b.

   Bytes are transposed but bits are not transposed.

   reg[31:0] becomes {reg[7:0], reg[15:8], reg[23:16], reg[31:24]}.

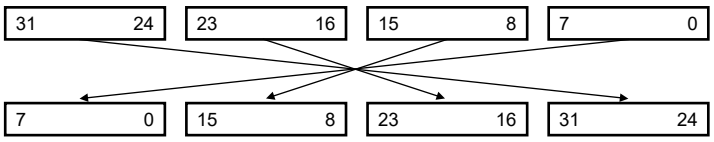

Figure 313. Transpose type 11b

NOTE

For 8-bit and 16-bit write accesses to Data (DATA), the data is transposed with 0s on the unused byte or bytes (taking 32 bits as a whole), but CRC is calculated on the valid byte(s) only. When reading the Data (DATA) for a 16-bit CRC result and using transpose options 10 and 11, the resulting value after transposition resides in DATA[HU] and DATA[HL]. You must account for this situation when reading the 16-bit CRC result, so reading 32 bits is preferred.

74.3.4 Result complement

When CTRL[FXOR] = 1, the checksum is complemented. The CRC result complement function outputs the complement of the checksum value stored in Data (DATA) every time Data (DATA) is read. When CTRL[FXOR] = 0,, reading Data (DATA) accesses the raw checksum value.

74.3.5 Clocking

Table 706. CRC clocks

Type of clock	Description
Bus clock (ipg_clk/ipg_clk_s)	ipg_clk_s controls the access to the CRC registers. ipg_clk and ipg_clk_s function the CRC module.

NOTE

See the chip-specific clocking chapter, to know the specific CRC clocks supported on your device.

74.3.6 Interrupts

This module has no interrupts.

74.4 External signals

There is no CRC signal that connects off chip.

74.5 Initialization

To enable CRC calculation, you must program:

- CTRL[WAS] .
- Polynomial (GPOLY).
- Parameters for transposition and CRC result inversion in the applicable registers.

Writing 1 to CTRL[WAS] enables you to program the seed value into CRC Data registers.

After writing all the data, you must wait for at least two clock cycles to read the data from CRC Data (DATA) register.

After a CRC calculation completes, you can reinitialize the module for a new CRC computation by again writing 1 to CTRL[WAS] and programming a new, or previously used, seed value. You must set all other parameters before programming the seed value and subsequent data values.

74.6 Use cases

The following tables use the little-endian format.

74.6.1 CTRL programming

The following table shows Control (CTRL) programming for 16-bit CRC.

Table 707. CTRL programming for 16-bit CRC

Algorithm	Polynomial	Seed	Ref in	Ref out	XOR out	CTRL[TOT]	CTRL[TOTR]	CTRL[FXOR]
CRC-16_CCITT_FALSE	1021h	FFFFh	0	0	0000h	0h	0h	0h

CRC-16_MCRF4XX	[31:16] = Valid data [15:0] = Unknown
CRC-16_RIELLO	[31:16] = Valid data [15:0] = Unknown
CRC-16_T10_DIF	[31:16] = Unknown [15:0] = Valid data
CRC-16_TELEDISK	[31:16] = Unknown [15:0] = Valid data
CRC-16_TMS37157	[31:16] = Valid data [15:0] = Unknown
CRC-16_USB	[31:16] = Valid data [15:0] = Unknown
CRC-16_A	[31:16] = Valid data [15:0] = Unknown
CRC-16_KERMIT	[31:16] = Valid data [15:0] = Unknown
CRC-16_MODBUS	[31:16] = Valid data [15:0] = Unknown
CRC-16_X_25	[31:16] = Valid data [15:0] = Unknown
CRC-16_XMODEM	[31:16] = Unknown [15:0] = Valid data

The following table shows the expected read data fields for 32-bit CRC.

Table 710. Expected read data fields for 32-bit CRC

Algorithm	Data (DATA)
CRC-32	[31:0] = Valid data
CRC-32_BZIP2	[31:0] = Valid data
CRC-32C	[31:0] = Valid data
CRC-32D	[31:0] = Valid data
CRC-32_MPEG-2	[31:0] = Valid data
CRC-32_POSIX	[31:0] = Valid data
CRC-32Q	[31:0] = Valid data
CRC-32_JAMCRC	[31:0] = Valid data
CRC-32_XFER	[31:0] = Valid data

74.7 Memory map and register descriptions

NOTE

You must reconfigure CRC engine in case an IPS transfer error occurs (ips_xfr_err).

The CRC module generates a transfer error in the following cases:

- Write accesses to the register addresses that are not mapped to the peripherals but included in the address spaces of the peripherals.

74.7.1 CRC register descriptions

74.7.1.1 CRC memory map

CRC base address: 4015_1000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Data (DATA)	32	RW	FFFF_FFFFh
4h	Polynomial (GPOLY)	32	RW	0000_1021h
8h	Control (CTRL)	32	RW	0000_0000h

74.7.1.2 Data (DATA)

Offset

Register	Offset
DATA	0h

Function

Configures the value of seed, data, and checksum. When CTRL[WAS] = 1, any write to this register is regarded as the seed value. When CTRL[WAS] becomes 0, any write to this register is regarded as data for general CRC calculation.

In 16-bit CRC mode, DATA[HU] and DATA[HL] are not used for programming the seed value, and reads of these fields return an indeterminate value. In 32-bit CRC mode, all fields are used for programming the seed value.

When programming data values, you can program to write 8 bits, 16 bits, or 32 bits in big endian order, provided all bytes are contiguous, with the MSB of data value written first.

After writing all data values, you can read the CRC result from DATA register. In 16-bit CRC mode, the CRC result is available in DATA[LU] and DATA[LL]. In 32-bit CRC mode, all fields contain the result. After writing all data, you must wait for at least two clock cycles to read the data from CRC data (DATA) register.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-24 HU	Upper Part of High Byte Generates CRC checksum in both 16-bit and 32-bit CRC modes if CTRL[WAS] = 0. • In 16-bit CRC mode (CTRL[TCRC] = 0), this field is not used for programming a seed value. • In 32-bit CRC mode (CTRL[TCRC] = 1), the values written to this field are part of the seed value when CTRL[WAS] = 1.
23-16 HL	Lower Part of High Byte Generates CRC checksum in both 16-bit and 32-bit CRC modes if CTRL[WAS] = 0. • In 16-bit CRC mode (CTRL[TCRC] = 0), this field is not used for programming a seed value. • In 32-bit CRC mode (CTRL[TCRC] = 1), the values written to this field are part of the seed value when CTRL[WAS] = 1.
15-8 LU	Upper Part of Low Byte Generates CRC checksum when CTRL[WAS] = 0. When CTRL[WAS] = 1,the values written to this field are part of the seed value.
7-0	Lower Part of Low Byte

Table continues on the next page...

Table continued from the previous page...

Field	Function
LL	Generates CRC checksum when CTRL[WAS] = 0. When CTRL[WAS] = 1, the values written to this field are part of the seed value.

74.7.1.3 Polynomial (GPOLY)

Offset

Register	Offset
GPOLY	4h

Function

Configures polynomial value for CRC calculation.

- Sets the upper 16 bits of polynomial that are used only in 32-bit CRC mode. Writes to this field are ignored in 16-bit CRC mode.
- Sets the lower 16 bits of polynomial that are used in both 16-bit and 32-bit CRC modes.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	HIGH

Fields

Field	Function
31-16 HIGH	High Half-Word Writable and readable in 32-bit CRC mode (CTRL[TCRC] = 1). You cannot write to this field in 16-bit CRC mode (CTRL[TCRC] = 0).
15-0 LOW	Low Half-Word Writable and readable in both 16-bit and 32-bit CRC modes.

74.7.1.4 Control (CTRL)

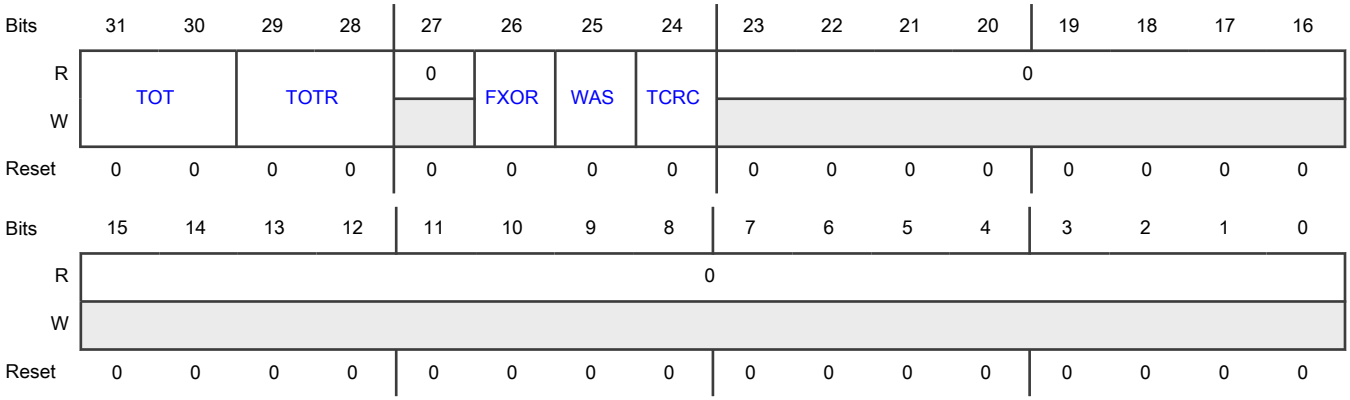
Offset

Register	Offset
CTRL	8h

Function

Sets control for CRC. You must write 1 to the appropriate fields of this register before starting a new CRC calculation, which you can initialize by writing 1 to CTRL[WAS] and then writing the seed into DATA.

Diagram



Fields

Field	Function
31-30 TOT	Transpose Type for Write Sets transpose type for the values written to DATA. See Transpose feature for the available transpose options. 00b - No transposition 01b - Bits in bytes are transposed, but bytes are not transposed. 10b - Both bits in bytes and bytes are transposed. 11b - Only bytes are transposed, no bits in a byte are transposed.
29-28 TOTR	Transpose Type for Read Sets transpose type for the values read from DATA . See Transpose feature for the available transpose options. 00b - No transposition 01b - Bits in bytes are transposed, but bytes are not transposed. 10b - Both bits in bytes and bytes are transposed. 11b - Only bytes are transposed, no bits in a byte are transposed.

Table continues on the next page...

Table continued from the previous page...

Field	Function
27 —	Reserved
26 FXOR	Complement Read of CRC Data Register Enables on-the-fly complementing of read data. Some CRC protocols require the final checksum to be XORed with FFFFFFFFh or FFFFh. 0b - Disables XOR on reading data. 1b - Inverts or complements the read value of the CRC Data.
25 WAS	Write as Seed Specifies whether writes to DATA are data values or seed values. When this field = 1, the value that you write to is considered as seed value. When this field = 0, the value that you write to is considered as data for CRC calculation. 0b - Data values 1b - Seed values
24 TCRC	TCRC Defines the width of CRC. 0b - 16 bits 1b - 32 bits
23-0 —	Reserved

No substantial content changes.

A.21 Pin Interrupt and Pattern Match (PINT)

A.21.1 Chip-specific PINT information changes

No substantial content changes.

A.21.2 PINT module changes

No substantial content changes.

A.22 General-Purpose Input/Output (GPIO)

A.22.1 Chip-specific GPIO information changes

No substantial content changes.

A.22.2 GPIO module changes

No substantial content changes.

A.23 Performance Monitor (CMX_PERFMON)

A.23.1 Chip-specific CMX_PERFMON information changes

No substantial content changes.

A.23.2 CMX_PERFMON changes

No substantial content changes.

A.24 Cache Memory Controller (XCACHE)

A.24.1 Chip-specific XCACHE information changes

No substantial content changes.

A.24.2 XCACHE module changes

No substantial content changes.

A.25 Semaphores2 (SEMA42)

A.25.1 Chip-specific SEMA42 information changes

No substantial content changes.

A.25.2 SEMA42 module changes

No substantial content changes.

A.26 Messaging Unit (MU)

A.26.1 Chip-specific MU information changes

No substantial content changes.

A.26.2 MU module changes

No substantial content changes.

A.27 Power Management Controller (PMC)

A.27.1 Chip-specific PMC information changes

No substantial content changes.

A.27.2 PMC module changes

No substantial content changes.

A.28 Clock Controller (CLKCTL)

A.28.1 Chip-specific CLKCTL information changes

No substantial content changes.

A.28.2 CLKCTL module changes

No substantial content changes.

A.29 System Controller (SYSCON)

A.29.1 Chip-specific SYSCON information changes

No substantial content changes.

A.29.2 SYSCON module changes

No substantial content changes.

A.30 Sleep Controller (SLEEPCON)

A.30.1 Chip-specific SLEEPCON information changes

No substantial content changes.

A.30.2 SLEEPCON module changes

No substantial content changes.

A.31 Reset Controller (RSTCTL)

A.31.1 Chip-specific RSTCTL information changes

No substantial content changes.

A.31.2 RSTCTL module changes

No substantial content changes.

A.32 FRO Clock Generator (FRO)

A.32.1 Chip-specific FRO information changes

No substantial content changes.

A.32.2 FRO module changes

No substantial content changes.

A.33 Frequency Measurement (FREQME)

A.33.1 Chip-specific FREQME information changes

No substantial content changes.

A.33.2 FREQME module changes

No substantial content changes.

A.34 Nano Power 32 kHz Oscillator (OSC32KNP)

A.34.1 Chip-specific OSC32KNP information changes

No substantial content changes.

A.34.2 OSC32KNP module changes

No substantial content changes.

A.35 Real Time Clock Subsystem (RTC_SS)

A.35.1 Chip-specific RTC_SS information changes

No substantial content changes.

A.35.2 RTC_SS module changes

No substantial content changes.

A.36 Real Time Clock (RTC)

A.36.1 Chip-specific RTC information changes

No substantial content changes.

A.36.2 RTC module changes

No substantial content changes.

A.37 Process, Voltage and Temperature Sensor (PVTS)

A.37.1 Chip-specific PVTS information changes

- Updated the functions of PVTS fuses with the word index of 486 and 487 in PVTS fuse programming.

A.37.2 PVTS module changes

No substantial content changes.

A.38 Analog-to-Digital Converter (ADC)

A.38.1 Chip-specific ADC information changes

No substantial content changes.

A.38.2 ADC module changes

No substantial content changes.

A.39 Comparator (ACMP)

A.39.1 Chip-specific ACMP information changes

No substantial content changes.

A.39.2 ACMP module changes

No substantial content changes.

A.40 Ultra Secured Digital Host Controller (uSDHC)

A.40.1 Chip-specific uSDHC information changes

No substantial content changes.

A.40.2 uSDHC module changes

No substantial content changes.

A.41 External Serial Peripheral Interface (XSPI)

A.41.1 Chip-specific XSPI information changes

No substantial content changes.

A.41.2 XSPI module changes

No substantial content changes.

A.42 Cache Controller (CACHE64_CTRL)

A.42.1 Chip-specific CACHE64_CTRL information changes

No substantial content changes.

A.42.2 CACHE64_CTRL module changes

• Updated Figure 162. • Changed Clocks to Clocking and Resets to Reset. • Added new topic Interrupts - "CACHE_CTRL has no interrupts".

Table continues on the next page...

• Added new topics Operations and #unique_3865. Moved the topics Cache configuration and Cache control under Operations. • Replaced "master/slave" with "controller/target" in Modes of operation and Features.
• Updated Figure 162.
• Changed Cache Control (CCR) bit 2 and 3 to read-write from read-only.
• Changed CACHE_CTRL to CACHE64_CTRL throughout the blockguide.
• Added CCR[FRCWT] and CCR[FRCNOALLC] instead of reserved.
• Changed "master" to "manager" and "slave" to "subordinate" in Cache configuration and Clocking.
• Revised the note given in Initialization.
• Deleted topic "Submodules". • Revised CLCR[LCIVB] to change "modified" bit to "valid" bit. • Revised description for CLCR[CACHEADDR].

A.43 CACHE64 Policy Select (CACHE64_POLSEL)

A.43.1 Chip-specific CACHE64_POLSEL module changes

No substantial content changes.

A.43.2 CACHE64_POLSEL module changes

No substantial content changes.

A.44 Memory Map Unit (MMU)

A.44.1 Chip-specific MMU information changes

No substantial content changes.

A.44.2 MMU module changes

No substantial content changes.

A.45 Neural Processing Unit (NPU)

A.45.1 Chip-specific NPU information changes

No substantial content changes.

A.45.2 eIQ Neutron N3-64 Neutron module changes

No substantial content changes.

A.46 EZ Handler RISC-V (EZH-V)

A.46.1 Chip-specific EZH-V information changes

No substantial content changes.

A.46.2 EZH-V module changes

No substantial content changes.

A.47 JPEG Decoder (JPEGDEC)

A.47.1 Chip-specific JPEGDEC information changes

No substantial content changes.

A.47.2 JPEGDEC module changes

No substantial content changes.

A.48 JPEG Decoder Wrapper (JPGDECWRP)

A.48.1 Chip-specific JPGDECWRP information changes

No substantial content changes.

A.48.2 JPGDECWRP module changes

No substantial content changes.

A.49 PNG Decoder (PNGDEC)

A.49.1 Chip-specific PNGDEC information changes

No substantial content changes.

A.49.2 PNGDEC module changes

No substantial content changes.

A.50 Vector Graphics Processing Unit (VGPU)

A.50.1 Chip-specific VGPU information changes

No substantial content changes.

A.50.2 VGPU module changes

No substantial content changes.

A.51 Universal Serial Bus Controller (USB)

A.51.1 Chip-specific USB information changes

No substantial content changes.

A.51.2 USB module changes

No substantial content changes.

A.52 Universal Serial Bus 2.0 PHY (USBPHY)

A.52.1 Chip-specific USBPHY information changes

No substantial content changes.

A.52.2 USBPHY module changes

No substantial content changes.

A.53 USB Device Charger Detection Module (USBDCD)

A.53.1 Chip-specific USBDCD information changes

No substantial content changes.

A.53.2 USBDCD module changes

No substantial content changes.

A.54 Mobile Industry Processor Interface and Display Serial Interface Controller (MIPI_DSI_HOST)

A.54.1 Chip-specific MIPI_DSI_HOST information changes

No substantial content changes.

A.54.2 MIPI_DSI_HOST module changes

No substantial content changes.

A.55 LCD Interface (LCDIF)

A.55.1 Chip-specific LCDIF information changes

No substantial content changes.

A.55.2 LCDIF module changes

No substantial content changes.

A.56 Sigma Delta Analog-to-Digital Converter (SDADC)

A.56.1 Chip-specific SDADC information changes

No substantial content changes.

A.56.2 SDADC module changes

No substantial content changes.

A.57 PDM Microphone Interface (MICFIL)

A.57.1 Chip-specific MICFIL information changes

No substantial content changes.

A.57.2 MICFIL module changes

No substantial content changes.

A.58 Synchronous Audio Interface (SAI)

A.58.1 Chip-specific SAI information changes

No substantial content changes.

A.58.2 SAI module changes

No substantial content changes.

A.59 HiFi 1 DSP Platform (HiFi1)

A.59.1 Chip-specific HiFi1 information changes

No substantial content changes.

A.59.2 HiFi1 module changes

No substantial content changes.

A.60 HiFi 4 DSP Platform (HiFi4)

A.60.1 Chip-specific HiFi4 information changes

No substantial content changes.

A.60.2 HiFi4 module changes

No substantial content changes.

A.61 Micro-Tick Timer (UTICK)

A.61.1 Chip-specific UTICK information changes

No substantial content changes.

A.61.2 UTICK module changes

No substantial content changes.

A.62 Standard Counter/Timers (CTIMER)

A.62.1 Chip-specific CTIMER information changes

No substantial content changes.

A.62.2 CTIMER module changes

No substantial content changes.

A.63 OS Event Timer (OSTIMER)

A.63.1 Chip-specific OSTIMER information changes

No substantial content changes.

A.63.2 OSTIMER module changes

No substantial content changes.

A.64 SCTimer (SCT)

A.64.1 Chip-specific SCT information changes

No substantial content changes.

A.64.2 SCT module changes

No substantial content changes.

A.65 Multi-Rate Timer (MRT)

A.65.1 Chip-specific MRT information changes

No substantial content changes.

A.65.2 MRT module changes

No substantial content changes.

A.66 Windowed Watchdog Timer (WWDT)

A.66.1 Chip-specific WWDT information changes

No substantial content changes.

A.66.2 WWDT module changes

No substantial content changes.

A.67 Flexible I/O (FLEXIO)

A.67.1 Chip-specific FLEXIO information changes

No substantial content changes.

A.67.2 FLEXIO module changes

No substantial content changes.

A.68 Low-Power Flexible Communications Interface (LP_FLEXCOMM)

A.68.1 Chip-specific LP_FLEXCOMM information changes

No substantial content changes.

A.68.2 LP_FLEXCOMM module changes

No substantial content changes.

A.68.3 LPI2C module changes

No substantial content changes.

A.68.4 LPSPI module changes

No substantial content changes.

A.68.5 LPUART module changes

No substantial content changes.

A.69 Improved Inter-Integrated Circuit (I3C)

A.69.1 Chip-specific I3C module changes

No substantial content changes.

A.69.2 I3C module changes

No substantial content changes.

A.70 Input Multiplexing (INPUTMUX)

A.70.1 Chip-specific INPUTMUX information changes

No substantial content changes.

A.70.2 INPUTMUX module changes

No substantial content changes.

A.71 Enhanced Direct Memory Access (eDMA)

A.71.1 Chip-specific eDMA information changes

No substantial content changes.

A.71.2 eDMA3 module changes

No substantial content changes.

A.72 Network Interconnect Component (NIC)

A.72.1 Chip-specific NIC information changes

No substantial content changes.

A.72.2 NIC module changes

No substantial content changes.

A.73 On-Chip OTP Controller (OCOTP_CTRL)

A.73.1 Chip-specific OCOTP_CTRL information changes

No substantial content changes.

A.73.2 OCOTP module changes

- Updated OTP_SHADOW registers.
- Added HW_OCOTP_CLK_DIV register.
- Updated Clocking.

A.74 Cyclic Redundancy Check (CRC)

A.74.1 Chip-specific CRC information changes

No substantial content changes.

A.74.2 CRC module changes

No substantial content changes.

Legal information

Definitions

Draft — A draft status on a document indicates that the content is still under internal review and subject to formal approval, which may result in modifications or additions. NXP Semiconductors does not give any representations or warranties as to the accuracy or completeness of information included in a draft version of a document and shall have no liability for the consequences of use of such information.

Disclaimers

Limited warranty and liability — Information in this document is believed to be accurate and reliable. However, NXP Semiconductors does not give any representations or warranties, expressed or implied, as to the accuracy or completeness of such information and shall have no liability for the consequences of use of such information. NXP Semiconductors takes no responsibility for the content in this document if provided by an information source outside of NXP Semiconductors.

In no event shall NXP Semiconductors be liable for any indirect, incidental, punitive, special or consequential damages (including - without limitation - lost profits, lost savings, business interruption, costs related to the removal or replacement of any products or rework charges) whether or not such damages are based on tort (including negligence), warranty, breach of contract or any other legal theory.

Notwithstanding any damages that customer might incur for any reason whatsoever, NXP Semiconductors' aggregate and cumulative liability towards customer for the products described herein shall be limited in accordance with the Terms and conditions of commercial sale of NXP Semiconductors.

Right to make changes — NXP Semiconductors reserves the right to make changes to information published in this document, including without limitation specifications and product descriptions, at any time and without notice. This document supersedes and replaces all information supplied prior to the publication hereof.

Suitability for use — NXP Semiconductors products are not designed, authorized or warranted to be suitable for use in life support, life-critical or safety-critical systems or equipment, nor in applications where failure or malfunction of an NXP Semiconductors product can reasonably be expected to result in personal injury, death or severe property or environmental damage. NXP Semiconductors and its suppliers accept no liability for inclusion and/or use of NXP Semiconductors products in such equipment or applications and therefore such inclusion and/or use is at the customer's own risk.

Applications — Applications that are described herein for any of these products are for illustrative purposes only. NXP Semiconductors makes no representation or warranty that such applications will be suitable for the specified use without further testing or modification.

Customers are responsible for the design and operation of their applications and products using NXP Semiconductors products, and NXP Semiconductors accepts no liability for any assistance with applications or customer product design. It is customer's sole responsibility to determine whether the NXP Semiconductors product is suitable and fit for the customer's applications and products planned, as well as for the planned application and use of customer's third party customer(s). Customers should provide appropriate design and operating safeguards to minimize the risks associated with their applications and products.

NXP Semiconductors does not accept any liability related to any default, damage, costs or problem which is based on any weakness or default in the customer's applications or products, or the application or use by customer's third party customer(s). Customer is responsible for doing all necessary testing for the customer's applications and products using NXP Semiconductors products in order to avoid a default of the applications and the products or of the application or use by customer's third party customer(s). NXP does not accept any liability in this respect.

Terms and conditions of commercial sale — NXP Semiconductors products are sold subject to the general terms and conditions of commercial sale, as published at https://www.nxp.com/profile/terms, unless otherwise agreed in a valid written individual agreement. In case an individual agreement is concluded only the terms and conditions of the respective agreement shall apply. NXP Semiconductors hereby expressly objects to applying the customer's general terms and conditions with regard to the purchase of NXP Semiconductors products by customer.

Export control — This document as well as the item(s) described herein may be subject to export control regulations. Export might require a prior authorization from competent authorities.

Suitability for use in non-automotive qualified products — Unless this document expressly states that this specific NXP Semiconductors product is automotive qualified, the product is not suitable for automotive use. It is neither qualified nor tested in accordance with automotive testing or application requirements. NXP Semiconductors accepts no liability for inclusion and/or use of non-automotive qualified products in automotive equipment or applications.

In the event that customer uses the product for design-in and use in automotive applications to automotive specifications and standards, customer (a) shall use the product without NXP Semiconductors' warranty of the product for such automotive applications, use and specifications, and (b) whenever customer uses the product for automotive applications beyond NXP Semiconductors' specifications such use shall be solely at customer's own risk, and (c) customer fully indemnifies NXP Semiconductors for any liability, damages or failed product claims resulting from customer design and use of the product for automotive applications beyond NXP Semiconductors' standard warranty and NXP Semiconductors' product specifications.

HTML publications — An HTML version, if available, of this document is provided as a courtesy. Definitive information is contained in the applicable document in PDF format. If there is a discrepancy between the HTML document and the PDF document, the PDF document has priority.

Translations — A non-English (translated) version of a document, including the legal information in that document, is for reference only. The English version shall prevail in case of any discrepancy between the translated and English versions.

Security — Customer understands that all NXP products may be subject to unidentified vulnerabilities or may support established security standards or specifications with known limitations. Customer is responsible for the design and operation of its applications and products throughout their lifecycles to reduce the effect of these vulnerabilities on customer's applications and products. Customer's responsibility also extends to other open and/or proprietary technologies supported by NXP products for use in customer's applications. NXP accepts no liability for any vulnerability. Customer should regularly check security updates from NXP and follow up appropriately.

Customer shall select products with security features that best meet rules, regulations, and standards of the intended application and make the ultimate design decisions regarding its products and is solely responsible for compliance with all legal, regulatory, and security related requirements concerning its products, regardless of any information or support that may be provided by NXP.

NXP has a Product Security Incident Response Team (PSIRT) (reachable at PSIRT@nxp.com) that manages the investigation, reporting, and solution release to security vulnerabilities of NXP products.

NXP B.V. — NXP B.V. is not an operating company and it does not distribute or sell products.
