Chapter 31
Reset Controller (RSTCTL)

31.1 Chip-specific RSTCTL information

Table 258. Reference links to related information

Topic	Related module	Reference
Full description	RSTCTL	RSTCTL
Peripheral memory map		Memory map overview
Power management	PMC	Power overview PMC
Clocking		Clock overview Clock controller

NOTE

The RSTCTL module includes some security functionality that is not described here. Refer to the i.MX RT700 Security Reference Manual for more details.

31.1.1 Module instances

This chip has five instances of the RSTCTL module.

Table 259. RSTCTL instances

	RSTCTL0	RSTCTL1	RSTCTL2	RSTCTL3	RSTCTL4
Located in	VDD2_COM	VDD1_SENSE	VDDN_COM	VDD1_SENSE	VDD2_MEDIA
Controls modules in	VDD2_COMP, VDD2_COM, VDD2_DSP	VDD1_SENSE (private region)	VDDN_COM	VDD1_SENSE (shared region)	VDD2_MEDIA, VDDN_MEDIA
Access	CPU0, HiFi4, EZH-V, eDMA0, eDMA1	CPU1, HiFi1, EZH-V, eDMA2, eDMA3	CPU0, CPU1, HiFi4, HiFi1, EZH-V, eDMA0, eDMA1, eDMA2, eDMA3	CPU0, CPU1, HiFi4, HiFi1, EZH-V, eDMA0, eDMA1, eDMA2, eDMA3	CPU0, CPU1, HiFi4, EZH-V, eDMA0, eDMA1, eDMA2, eDMA3

31.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

31.2 Overview

The RSTCTL module manages resets for the chip. It also provides registers for software to view the source of the latest reset event, and to reset individual peripheral modules. RSTCTL uses distributed structure to manage the reset function. The RSTCTL instances are illustrated and described in System diagram and Modules.

31.2.1 System diagram

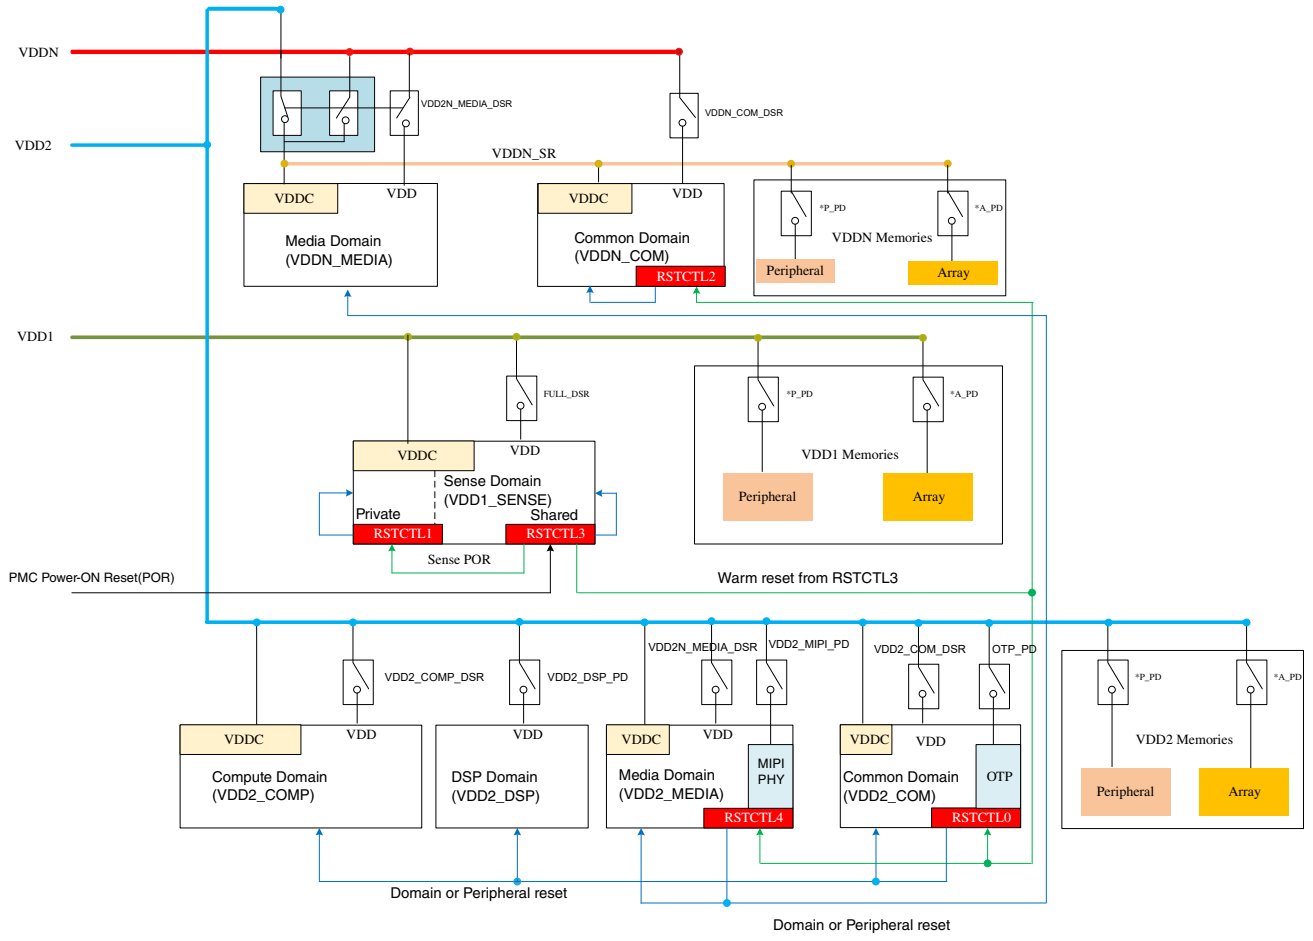

Figure 105. Reset controller system diagram

31.2.2 Features

The RSTCTL has the following key features:

- Cold Reset generation from PMC POR, triggered by POR, LVD, and HVD
- Warm Reset generation
  - RESETN
  - Software reset request (CPU0, CPU1)
  - Windowed Watchdog (WWDT0 - 3)
    - WWDT0 assigned to CPU0 (Compute Domain CM33 core), resets everything
    - WWDT1 assigned to HiFi4, resets everything
    - WWDT2 assigned to CPU1 (Sense Domain CM33 core), resets everything
    - WWDT3 assigned to HiFi1, resets DSP HiFi1 core
- Generate OCOTP reset and clock enable to trigger OCOTP FUSE reload after each Cold Reset.
- Generate domain power up reset, domain reset, peripheral reset, and domain clock enable to the Cold Reset, Warm Reset, and Deep Sleep Retention (DSR) mode.

- Reset individual peripheral modules based on software configuration.

31.2.3 Modules

The RSTCTL instances are described in Modules.

Table 260. Modules

Reset controller	Power Domain	Description
RSTCTL0	VDD2_COM	The RSTCTL0 is physically in the VDD2_COM power domain. It sends domain power-up reset, domain reset, and peripheral resets to VDD2_COMP, VDD2_DSP, and VDD2_COM power domains. RSTCTL0 and the domain peripherals can only be accessed by the Compute Domain CM33 (CPU0).
RSTCTL1	VDD1_SENSE (private)	The RSTCTL1 is physically in the VDD1_SENSE power domain. It sends peripheral resets to private peripherals in the VDD1_SENSE (private) power domain. RSTCTL1 and the domain peripherals can only be accessed by the Sense Domain CM33 (CPU1).
RSTCTL2	VDDN_COM	The RSTCTL2 is physically in the VDDN (Common) power domain. It sends domain power-up reset, domain reset, and peripheral resets to VDDN (Common) power domain. RSTCTL2 and the domain peripherals can be accessed by both CPUs.
RSTCTL3	VDD1_SENSE	The RSTCTL3 is physically in the VDD1_SENSE power domain. It sends power-up reset, domain reset, and peripheral resets to RSTCTL3 and shared peripherals in the VDD1_SENSE power domain. RSTCTL3 and the domain shared peripherals can be accessed by both CPUs.
RSTCTL4	VDD2_MEDIA	The RSTCTL4 is physically in the VDD2_MEDIA power domain. It sends domain power-up reset, domain reset, and peripheral resets to the VDD2_MEDIA and VDDN_MEDIA power domains. RSTCTL4 and the domain peripherals can be accessed by both CPUs. **NOTE** The VDD2_MEDIA and VDDN_MEDIA power domains will always power ON and OFF at the same time, although they are on different power rails (VDD2, VDDN).

31.3 Functional description

This section describes the key functionalities of RSTCTL.

31.3.1 Operation

After initial power up, the sequential order of reset is noted below:

1. Cold Reset is released.
2. Domain power-up reset.
3. Warm Reset is released.
4. OCOTP reload.
5. RESETN is released.
6. Domain reset, bus clock, and default peripheral clock are released.

NOTE

After initial power-up, VDD2_MEDIA and VDDN_MEDIA power domains are powered off by default, and VDDN_COM, VDD2_COM, VDD2_COMP, and VDD1_SENSE power domains are powered on by default.

You can configure software reset for modules in the RSTCTL registers. Write 1 to assert reset or write 0 to de-assert reset in the RSTCTL registers. You can also set and clear RSTCTL registers. This means each reset bit in RSTCL registers can also be controlled by the set and clear registers, which are at 2 different addresses. After initial power-up reset, most modules will be in reset state until software clears the corresponding bits in RSTCTL registers.

NOTE

Do not access the module instance whose related PRSTCTL register field is configured as 1b (sets reset) because the module instance under reset may not response.

In Deep Sleep Retention (DSR) mode, if a domain's power is off, its power-up reset, domain reset, and peripheral reset will be asserted for non-retention logic, and will not be asserted for retention logic. After wakeup from DSR mode, the peripheral's reset value will come from previous values in RSTCTL registers, before entering into DSR mode. This value may not be the hardware value if software changed it before entering into DSR mode.

31.3.2 Reset Controller 0 (RSTCTL0) in VDD2_COM Domain

RSTCTL0 has functions as below:

- Get Cold Reset and power switch to generate the domain power-up reset for VDD2_COMP, VDD2_DSP, and VDD2_COM power domains.
- Get Warm Reset and this domain's power-up reset to generate the domain reset for VDD2_COMP, VDD2_DSP, and VDD2_COM power domains.
- Generate the domain power-up reset and the domain reset for non-retention logic in VDD2_COMP, VDD2_DSP, and VDD2_COM power domains. Meanwhile keep domain power up and domain reset deasserted for retention logic in DSR mode.
- Configure individual peripheral resets by software.
- Only Compute Domain CM33 (CPU0) can access RSTCTL0 registers.

RSTCTL0 is in the VDD2_COM Domain, powered by the VDD2 power rail. It should be the last to power off amongst the other domains connected to VDD2, so VDD2 can supply power-up reset and domain reset to the domains when it is powered on.

31.3.3 Reset controller 1 (RSTCTL1) in VDD1_SENSE Domain (private)

RSTCTL1 has functions as below:

- Use RSTCTL3's domain power-up reset and domain reset to generate reset for Sense Domain CM33 (CPU1) private peripherals.
- Configure individual peripheral resets by software.

- Only Sense Domain CM33 (CPU1) can access RSTCTL1 registers.

RSTCTL1 is the reset controller for the CPU1 private peripherals. Its domain power up reset and domain reset come from RSTCTL3.

31.3.4 Reset controller 2 (RSTCTL2) in VDDN (Common) Domain

RSTCTL2 has functions as below:

- Enable Cold Reset and power switch to generate the domain power-up reset for VDDN_COM power domain's peripherals.
- Enable Warm Reset and this domain power-up reset to generate the domain reset for VDDN_COM power domain's peripherals.
- Configure individual peripheral resets by software.
- CPU0 and CPU1 can access RSTCTL2 registers.

RSTCTL2 is the reset controller for VDDN_COM domain's peripherals.

31.3.5 Reset controller 3 (RSTCTL3) in VDD1_SENSE Domain

RSTCTL3 has functions as below:

- Use PMC power-up reset to generate the Cold Reset for RSTCTL0, RSTCTL2 and RSTCTL4.
- Collect Warm Reset sources to generate the Warm Reset for RSTCTL0, RSTCTL2 and RSTCTL4.
- Generate the domain power-up reset for RSTCTL1 and RSTCTL3.
- Generate the domain reset for RSTCTL1 and RSTCTL3.
- Generate the domain power-up reset and the domain reset for VDD1_SENSE power domain while in DSR mode.
- Configure individual peripheral resets by software.
- CPU0 and CPU1 can access RSTCTL3 registers.

If PMC's power-up reset releases, RSTCTL3 starts to work. It is also the main reset controller for RSTCTL1. RSTCTL1 uses RSTCTL3's domain power-up reset and domain reset as its reset input.

Because VDD1_SENSE power domain should be the last one to power-off compared with other domains on the VDD1, VDD2 and VDDN power rails, VDD1_SENSE power domain can continue work as long as it is powered on.

The Warm Reset is released after all of Warm Reset sources are de-asserted.

31.3.6 Reset controller 4 (RSTCTL4) in VDD2_MEDIA Domain

RSTCTL4 has functions as below:

- Enable Cold Reset and power switch to generate the domain power-up reset for the RSTCTL4's peripherals.
- Enable Warm Reset and this domain power-up reset to generate the domain reset for the RSTCTL4's peripherals.
- Configure individual peripheral resets by software.
- CPU0 and CPU1 can access RSTCTL4 registers.

RSTCTL4 is a target reset controller for the VDD2_MEDIA and VDDN_MEDIA power domains.

31.3.7 Clocking

Each RSTCTL has its own always running clock shown in Table 261.

Table 261. Clocking

Clock	Description
1m_lposc	The clock source for RSTCTL is generated by CLKCTL. All synchronizers use this clock as sync clock.

31.3.8 Reset

31.3.8.1 Cold Reset

The Cold Reset will be triggered by any of the Cold Reset source assertion.

Table 262. Main cold reset source

Cold reset source	Description
PMC power-on reset (POR)	PMC power-on reset will only be released when all power rails (VDD1, VDD2 and VDDN) are ready.
PMC Low Voltage Detect (LVD) reset	PMC will assert this reset when any LVD happens in any power rails (VDD1, VDD2 or VDDN).
PMC High Voltage Detect (HVD) reset	PMC will assert this reset when any HVD happens in any power rails (VDD1, VDD2 or VDDN).

The Cold Reset will trigger the following:

- Resets all logic in VDD1_SENSE, VDD2_COM, VDD2_MEDIA, and VDDN_COM domains.
- Triggers Warm Reset.
- Resets debug and trace relative components.
- OCOTP FUSE reloads.
- Wakes up from low power mode without recovery to old state before entering into low power mode. After wakeup, the chip follows power up sequence.

31.3.8.2 Warm Reset

The Warm Reset will be triggered by the following:

- Cold Reset
- Any Warm Reset source assertion

Warm Reset will trigger the following:

- Resets all modules in the VDD1_SENSE, VDD2_COM, VDD2_MEDIA, and VDDN_COM domains except for debug and trace modules.
- Resets all individual peripheral reset bits in RSTCTL0 - 4.
- After reset releases, individual peripheral reset status will come from the default values of RSTCTL0 - 4. Software configurable reset bits default value is asserted, and software un-configurable reset bit value is deasserted by default.
- If device was in a low power mode and reset source was not a cold reset, then wakes up PMC from low power mode. Power switch and LDO status will be recovered to the previous state before entering into the new low-power mode.

NOTE

This may be different with power up state depending on how software configures PDRUNCFG.

The Warm Reset sources are listed below.

- RESETN
- Software reset request from CPU0
- Software reset request from CPU1
- WWDT0 (assigned to CPU0)
- WWDT1 (assigned to DSP HiFi4 Core)
- WWDT2 (assigned to CPU1)
- WWDT3 (assigned to DSP HiFi1 Core)

31.3.8.3 Peripheral reset

Individual peripheral reset will be triggered by the following:

- Writes 1 to the bit fields in reset controller registers.

NOTE

Software needs to write 0 to release the module reset.

- The peripheral modules' power domain is OFF. After peripheral modules' power domain is powered up, its reset state comes from the current value of its reset controller.

31.3.8.4 Special reset case(s)

WWDT3 resets HiFi1. In case of system reset or WWDT3 timeout, HiFi1 is held in reset until released by a software command issued by the CM33 Processor. Nothing else in the system should be directly impacted by WWDT3. Once WWDT3 is enabled, you can enable or disable WWDT3 reset and generate an interrupt to the Sense CM33 Processor, depending on the configuration of WWDT3. See Windowed Watchdog Timer (WWDT) section for configuration details of WWDT3.

31.3.9 Interrupts (RESETN)

RESET PAD (RESETN) is a warm reset source, and is in the AON 1.8V power domain. RESETN can wakeup the chip from any low-power mode, even if VDD1, VDD2, VDDN and PMC are OFF. After wakeup, RESETN will trigger a Warm Reset.

31.3.10 Low-power modes

If Cold Reset happens when the chip is in low-power mode, it wakes up from low-power mode and triggers a Cold Reset.

When VDD1 is ON, Warm Reset can wakeup the chip from low-power mode. PMC will wake up the DSR domain and trigger a Warm Reset. Only power switch restores to the old value before entering low power mode. Other configuration will go to reset default state.

NOTE

This may be different with power up state depending on how SW configure PDRUNCFG.

31.3.11 Debug mode

- Cold Reset and Domain POR can reset debug and trace components.
- Warm Reset, Domain Reset, and software cannot reset debug and trace components.

31.4 External signals

The module signals are shown as below:

Signal	I/O	Description
RESET_PAD (RESETN) **NOTE** RESETN only connects to RSTCTL3.	I/O	Bi-directional PAD. A LOW on this signal will trigger a main warm reset, cause I/O ports and peripherals to take on their default states, and execute boot code without FUSE reload. If the chip is in any low power mode, a LOW on this PAD wakes up the chip from the low power mode, and triggers a main warm reset at the same time. When RESETN is driven low externally, the device will stay in reset the entire time. When the external RESETN source releases, the chip will driver RESETN low through the main warm reset process to indicate the chip is still in the reset state internally. RESETN will be released (HiZ) when the warm reset process completes internally.

31.5 RSTCTL register descriptions

This section includes the RSTCTL module memory map and detailed descriptions of all registers.

31.5.1 RSTCTL0 register descriptions

This section includes the memory map and detailed descriptions of registers for RSTCTL0. This reset controller controls peripherals in the VDD2_COMP, VDD2_DSP, and VDD2_COM power domains on the VDD2 power rail.

31.5.1.1 RSTCTL0 memory map

RSTCTL0 base address: 4000_0000h

Offset	Register	Width (In bits)	Access	Reset value
4h	Domain Reset Status (DOMRSTSTAT)	32	R	0000_000Bh

31.5.2 RSTCTL1 register descriptions

This section includes the memory map and detailed descriptions of registers for Reset Controllers 1. This reset controller controls private peripherals in the VDD1_SENSE power domain on the VDD1 power rail.

31.5.2.1 RSTCTL1 memory map

RSTCTL1 base address: 4004_0000h

Offset	Register	Width (In bits)	Access	Reset value
10h	Sense Domain Private Peripheral Reset Control 0 (PRSTCTL0)	32	RW	133F_FFF7h
40h	Sense Domain Private Peripheral Reset Control 0 SET (PRSTCTL0_SET)	32	W	0000_0000h
70h	Sense Domain Private Peripheral Reset Control 0 CLR (PRSTCTL0_CLR)	32	W	0000_0000h

31.5.2.2 Sense Domain Private Peripheral Reset Control 0 (PRSTCTL0)

Offset

Register	Offset
PRSTCTL0	10h

Function

Allows software to reset individual peripherals. Writing zero to any assigned bit in this register clears the reset and allows the specified peripheral to operate. Writing one asserts the reset. This register will be reset by main cold reset and main warm reset. Because the reset controller module is in the DSR list, the values in this register are retained, even the reset controller module is waken up from the DSR mode, except for wakeup by RESET PAD.

31.5.3 RSTCTL2 register descriptions

This section includes the memory map and detailed descriptions of registers for Reset Controllers 2. This reset controller controls peripherals in the VDDN_COM power domain on the VDDN power rail.

31.5.3.1 RSTCTL2 memory map

RSTCTL2 base address: 4006_7000h

Offset	Register	Width (In bits)	Access	Reset value
10h	VDDN Domain Peripheral Reset Control 0 (PRSTCTL0)	32	RW	0000_0002h
40h	VDDN Domain Peripheral Reset Control 0 SET (PRSTCTL0_SET)	32	W	0000_0000h
70h	VDDN Domain Peripheral Reset Control 0 CLR (PRSTCTL0_CLR)	32	W	0000_0000h

31.5.3.2 VDDN Domain Peripheral Reset Control 0 (PRSTCTL0)

Offset

Register	Offset
PRSTCTL0	10h

Function

Allows software to reset specific peripherals. Writing zero to any assigned bit in this register clears the reset and allows the specified peripheral to operate. Writing one asserts the reset. This register will be reset by main cold reset and main warm reset. Because the reset controller module is in the DSR list, the values in this register are retained, even the reset controller module is waken up from the DSR mode, except for wakeup by RESET PAD.

31.5.4 RSTCTL3 register descriptions

This section includes the memory map and detailed descriptions of registers for Reset Controllers 3. This controller controls shared peripherals in the VDD1_SENSE power domain on the VDD1 power rail.

31.5.4.1 RSTCTL3 memory map

RSTCTL3 base address: 4006_0000h

Offset	Register	Width (In bits)	Access	Reset value
0h	System Reset Status (SYSRSTSTAT)	32	RW	0000_0001h
4h	Domain Reset Status (DOMRSTSTAT)	32	R	0000_000Bh

Table continues on the next page...

Table continued from the previous page...

Offset	Register	Width (In bits)	Access	Reset value
10h	Sense Domain Peripheral Reset Control 0 (PRSTCTL0)	32	RW	8000_0001h
14h	Sense Domain Peripheral Reset Control 1 (PRSTCTL1)	32	RW	0004_43EEh

70h	Sense Domain Peripheral Reset Control 0 CLR (PRSTCTL0_CLR)	32	W	0000_0000h
74h	Sense Peripheral Reset Control 1 CLR (PRSTCTL1_CLR)	32	W	0000_0000h

31.5.4.2 System Reset Status (SYSRSTSTAT)

Offset

Register	Offset
SYSRSTSTAT	0h

Function

Shows the status of the latest reset event. The bits are cleared by writing one to any of the bits in this register. The POR event clears all other bits in this register. If another reset signal, for example the external RESET pin, remains asserted after the POR signal is negated, the reset events are set to be detected.

Sleep Controller	SLEEPCON	SLEEPCON

32.1.1 Module instances

This device contains three instances of the FRO module, FRO0, FRO1, and FRO2.

Table 264. FRO instances

	FRO0	FRO1	FRO2
Located	VDD2_COM	VDD2_COM	VDD1_SENSE
Access	CPU0, HiFi4, EZH-V, eDMA0, eDMA1	CPU0, HiFi4, EZH-V, eDMA0, eDMA1	CPU0, CPU1, HiFi4, HiFi1, EZH-V, eDMA0, eDMA1, eDMA2, eDMA3
FRO_CLK should be configured (MHz)	150-325	192	150-325

32.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

32.1.3 FRO_PD

FRO_PD signal is from SLEEPCON. It works together with CSR[FROEN] to control the power on (enable) and power down (disable) of the FRO module.

You can power down (disable) the FRO module by:

- Configure FRO_PD as power down in SLEEPCON
- and configure CSR[FROEN] as disable in FRO

You can power on the FRO module by:

- Configure FRO_PD as power on in SLEEPCON

- or configure CSR[FROEN] as enable in FRO

The following table shows the register fields in SLEEPCON to control the FRO_PD.

Table 265. FRO instances

	FRO_PD control field in SLEEPCON
FRO0	• SLEEPCON0_SLEEPCFG[FRO0_PD] • SLEEPCON0_RUNCFG[FRO0_PD] • SLEEPCON0_RUNCFG_SET[FRO0_PD] • SLEEPCON0_RUNCFG_CLR[FRO0_PD]

FRO2	• SLEEPCON0_SLEEPCFG[FRO2_PD] • SLEEPCON0_RUNCFG[FRO2_PD] • SLEEPCON0_RUNCFG_SET[FRO2_PD] • SLEEPCON0_RUNCFG_CLR[FRO2_PD] • SLEEPCON1_SLEEPCFG[FRO2_PD] • SLEEPCON1_RUNCFG[FRO2_PD] • SLEEPCON1_RUNCFG_SET[FRO2_PD] • SLEEPCON1_RUNCFG_CLR[FRO2_PD]

32.2 Overview

FRO provides a trimmable system clock, which consists of an internal free-running oscillator (FRO_INT) and an autotuner (FRO_TUNER).

32.2.1 Block diagram

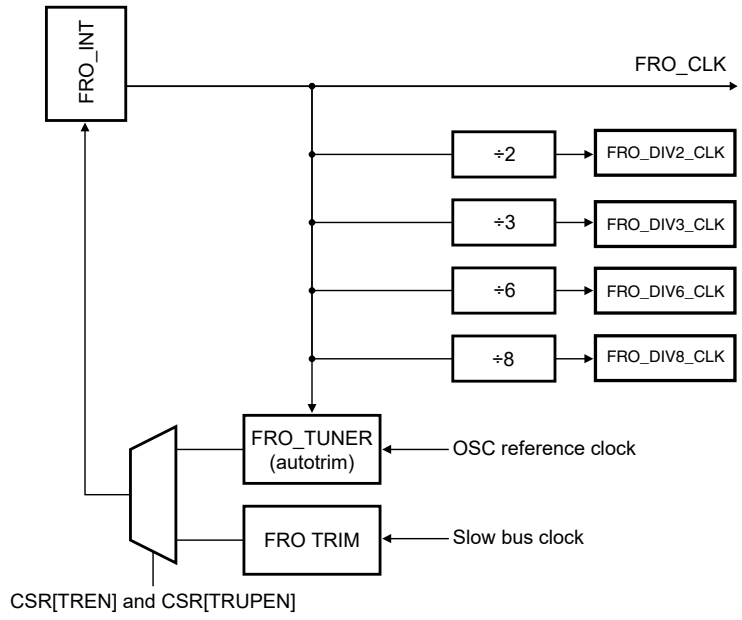

Figure 106. Block diagram

32.2.2 Features

- Trimmable FRO output
- Programmable FRO post divider
- Several interrupt requests
- Provides tune-in logic
- Fast startup option

32.3 Functional description

FRO generates system clock outputs that are based on a trimmable FRO clock source. It operates in the following modes:

- Open Loop (default): In this mode, the trim value (configured either via metal-option or a programmable trim value written to FRO Trim (FROTRIM)) specifies the FRO output clock frequency. See Modes for settings related to this mode.
- Closed Loop: In this mode, FRO_TUNER provides the option for a built-in hardware to adjust the FRO output clock automatically until the output clock locks to a target frequency that you configure in FRO Expected Trim Count (TEXPCNT). FRO_TUNER enters this mode when both CSR[TREN] and CSR[TRUPEN] are 1. See Modes for settings related to this mode.

  The autotuner provides CSR[TRIM_LOCK] to indicate whether the target frequency has been achieved. It continues to monitor the FRO clock source to detect a loss of the target lock frequency when the FRO output clock source deviates from the allowable range specified that TEXPCNT[TEXPCNT_RANGE] specifies. To accomplish this autotuning process, FRO_TUNER uses an external OSC clock source or reference clock to generate an FRO sample window that CNFG1[RFCLKCNT] controls. FRO_TUNER also provides a reference clock divider to support the external reference clocks of multiple chips. The output of this divider is what FRO_TUNER uses to sample the FRO output clock source. You program the correct value in CNFG1[REFDIV] to specify the divide ratio.

32.3.1 Modes

Table 266. Mode settings

Mode	Entry	Exit	Description
Off	POR disabled	POR exit and disabled deassertion	FRO is off and disabled.
Open Loop (on)	CSR[TREN] = 0 CSR[TRUPEN] = 0	CSR[TREN] = 1 CSR[TRUPEN] = 1	FRO runs in Open Loop mode. FRO Trim (FROTRIM) controls the FRO output frequency.
Closed Loop (on)	CSR[TREN] = 1 CSR[TRUPEN] = 1	CSR[TREN] = 0 CSR[TRUPEN] = 0 Warm reset POR	FRO runs in Closed Loop mode. The FRO output frequency is automatically trimmed to the target frequency that you configure by using FRO Expected Trim Count (TEXPCNT) with the use of an accurate clock source.

32.3.2 Interrupts

FRO includes several sources for interrupt requests. The following table summarizes these sources.

Each of these sources includes a mask control field (such as CNFG1[LOL_ERR_IE], CNFG1[TUNE_ERR_IE], and CNFG1[TRUPREQ_IE]).

Table 267. Interrupts

Flag	Functionality	Can generate interrupt?
CSR[LOL_ERR]	Indicates whether FRO is running in Closed Loop mode and the target frequency has deviated more than the expected frequency range after a lock condition is detected.	Yes, if CNFG1[LOL_ERR_IE] = 1
CSR[TUNE_ERR]	Indicates whether FRO is running in Closed Loop mode and has saturated FROTRIM[COARSE_TRIM] and FROTRIM[FINE_TRIM] without achieving the target frequency that you configure in FRO Expected Trim Count (TEXPCNT).	Yes, if CNFG1[TUNE_ERR_IE] = 1
CSR[TRUPREQ]	When configured with CSR[TREN] = 1 and CSR[TRUPEN] = 0, this flag asserts when FRO runs outside the expected frequency range that you configure in TEXPCNT.	Yes, if CNFG1[TRUPREQ_IE] = 1

32.3.3 Clocking

Table 268. Clocking

Clock	Type	Description
Slow bus clock	Input	FRO R/W clock source
OSC reference clock	Input	Used to autotune FRO to the target frequency in Closed Loop mode
FRO_CLK	Output	Undivided FRO trimmed clock (see the chip-specific FRO information for the maximum trim frequency)
FRO_DIV2_CLK	Output	FRO_DIV2_CLK = FRO_CLK ÷ 2

Table continues on the next page...

Table 268. Clocking (continued)

Clock	Type	Description
FRO_DIV3_CLK	Output	FRO_DIV3_CLK = FRO_CLK ÷ 3
FRO_DIV6_CLK	Output	FRO_DIV6_CLK = FRO_CLK ÷ 6
FRO_DIV8_CLK	Output	FRO_DIV8_CLK = FRO_CLK ÷ 8

32.4 External signals

Table 269. External Signals

Signal	Description	Direction
FRO_PD	Signal to power down FRO. This signal can be used to control whether FRO is on or off by default. FRO_PD works together with CSR[FROEN] to determine whether FRO is enabled or disabled. Either FRO_PD or CSR[FROEN] can enable FRO. However, FRO will only be powered down when both FRO_PD and CSR[FROEN] are configured to disable FRO. **NOTE** See the chip-specific information for more details about this signal.	Input

32.5 Initialization

FRO is enabled either externally or by writing 1 to CSR[FROEN]. It supports:

- Open Loop mode (default mode of operation): In this mode, you can adjust the FRO output by writing to FROTRIM[COARSE_TRIM] and FROTRIM[FINE_TRIM].
- Closed Loop mode: In this mode, FRO automatically adjusts the FRO frequency using an external reference clock source.

32.5.1 Open Loop mode

FOPT trim bits initially configure the FRO output frequency, which can be adjusted after exiting chip reset via writes to FROTRIM[COARSE_TRIM] and FROTRIM[FINE_TRIM]. To configure FRO in Open Loop mode:

1. Write 0 to CSR[TREN] (default setting).
2. Write 0 to CSR[TRUPEN].
3. Configure FROTRIM[COARSE_TRIM] and FROTRIM[FINE_TRIM] to the desired frequency setting.

   NOTE

   See FRO Trim (FROTRIM) for more information about how to determine the FRO trim values.

4. Write 1 to CSR[FROEN] to enable FRO (when FRO is not on or enabled by default).

32.5.2 Closed Loop (Autotuner) mode

In Closed Loop mode (CSR[TREN] and CSR[TRUPEN]), FRO automatically adjusts the FRO output frequency by sampling the FRO output clock using an external reference clock, which can be further divided using CNFG1[REFDIV]. The divided reference clock is used to determine how long the FRO clock is sampled. You can configure the sample window using CNFG1[RFCLKCNT]. At the end of the FRO sampled window, a captured FRO clock cycle is compared to the expected count

stored in TEXPCNT[TEXPCNT]. Based on the output comparison result, the FRO autotuner adjusts FRO trim values and feeds them back to FRO to adjust the output frequency up or down.

Initially, the FRO autotuner starts with the trim values stored in FROTRIM[COARSE_TRIM] and FROTRIM[FINE_TRIM]. If CSR[COARSEN] = 1, the FRO autotuner first adjusts the COARSE_TRIM bits, followed by the FINE_TRIM bits. This produces the fastest lock settling but generates maximum frequency disturbance, hence it is not recommended for most applications. If CSR[COARSEN] = 0, the autotuner starts by adjusting the FINE_TRIM bits and only adjusts the COARSE_TRIM bits if saturation of FINE_TRIM is detected. This gives the least disturbance and is the generally recommended configuration to use.

CSR[TRIM_LOCK] sets when the FRO autotuner detects the FRO output frequency to be within TEXPCNT[TEXPCNT] ± TEXPCNT[TEXPCNT_RANGE]. When the autotuner is in locked state (CSR[TRIM_LOCK] = 1), it continues to monitor and adjust the FRO output frequency, and CSR[LOL_ERR] will set if the FRO output frequency drifts outside the TEXPCNT[TEXPCNT] ± TEXPCNT[TEXPCNT_RANGE] range. If the autotuner saturates all trim value options without reaching a locking state condition, then CSR[TUNE_ERR] will set. You can configure both CSR[LOL_ERR] and CSR[TUNE_ERR] to generate an output interrupt request by writing 1 to CNFG1[LOL_ERR_IE] and CNFG1[TUNE_ERR_IE], respectively.

To configure FRO in Closed Loop mode:

1. Write 0 to CSR[TREN] and CSR[TRUPEN].
2. Configure the FRO trim values (FROTRIM[COARSE_TRIM] and FROTRIM[FINE_TRIM]) to correct the start frequency, if applicable.

   NOTE

   Gating off output clocks is recommended when changing the FRO frequency. You can do this by disabling each of the clock gates in CSR[CLKGATE]. Writing 0 to CSR[CLKGATE] disables the output clock.

3. Configure CNFG1[REFDIV] to generate the desired FRO reference frequency.
4. Configure CNFG1[RFCLKCNT] to be large enough to sample the FRO for a minimum of 4000 FRO clock cycles.
5. Configure TEXPCNT[TEXPCNT] to the expected FRO count based on the FRO sample size configured in 4.
6. Configure TEXPCNT[TEXPCNT_RANGE] to the desired lock setting tolerance.
7. Configure TRIM*n*_DELAY (see CNFG2[TRIM1_DELAY] and CNFG2[TRIM2_DELAY]) to insert the minimum delay that is decided based on the divided reference clock.
8. Write 1 to the desired FRO monitor interrupt options, including CNFG1[LOL_ERR_IE] and CNFG1[TUNE_ERR_IE].
9. To enable FRO autotuner:
   a. Write 1 to CSR[FROEN] to enable FRO if it is not already enabled.
   b. Write 1 to CSR[COARSEN] if autotuning of the coarse trim is required.

      NOTE

      This could generate a faster settling to the final target frequency but generates coarser frequency adjustments.

   c. Write 1 to CSR[TREN] and CSR[TRUPEN].

32.6.2 Control Status (CSR)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
CSR	200h	Control Status
CSR_SET	204h	Writing 1 to a bit in this register ensures that the corresponding bit in CSR is 1
CSR_CLR	208h	Writing 1 to a bit in this register ensures that the corresponding bit in CSR is 0
CSR_TOG	20Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in CSR

Function

Configures FRO in Closed Loop mode or Open Loop mode and also controls individual clock gating.

Diagram

Fields

Field	Function
31-27 —	Reserved
26 —	Reserved
25 TUNEONCE_DONE	FRO Tune Once Done Flag Indicates when the FRO tune once is complete and ready to trigger another tune once sequence. When this flag is cleared, it triggers another tune once sequence. **NOTE** You can only clear this flag by writing 1 to the corresponding bit in CSR_CLR. 0b - Not complete 1b - Complete

Table continues on the next page...

Table continued from the previous page...

Field	Function
24 TRIM_LOCK	FRO Trim Lock Flag Indicates when autotrimming is complete and locked to the target trimmed frequency that you configure by using FRO Expected Trim Count (TEXPCNT), if FRO is configured in Closed Loop mode (TREN = 1 and TRUPEN = 1). **NOTE** • If the trimmed frequency drifts outside the expected range determined by TEXPCNT[TEXPCNT_RANGE], this flag is cleared automatically. Under this scenario, LOL_ERR sets to indicate an unexpected loss-of-lock condition. • If either TREN or TRUPEN is cleared, this flag also clears automatically, and LOL_ERR is not set. 0b - Not locked 1b - Locked
23-19 —	Reserved
18 TRUPREQ	Trim Update Request Flag Indicates whether a trim update request is detected and FRO is running outside the expected frequency range that you configure by using FRO Expected Trim Count (TEXPCNT). **NOTE** • This flag is set only when you configure FRO with TREN = 1 and TRUPEN = 0. • An interrupt is generated when this field is 1 and TRUPREQ_IE is 1. **NOTE** You can only clear this flag by writing 1 to the corresponding bit in CSR_CLR. 0b - Not detected 1b - Detected
17 TUNE_ERR	Tune Error Flag Indicates whether an autotune error is detected and FRO has saturated high- and low-byte trim bits without reaching the target frequency in Closed Loop mode (TREN = 1 and TRUPEN = 1). **NOTE** You can only clear this flag by writing 1 to the corresponding bit in CSR_CLR. 0b - Not detected 1b - Detected
16 LOL_ERR	Loss-of-Lock Error Flag Indicates whether FRO has detected a loss-of-trimmed-lock condition when running in Closed Loop mode (TREN = 1 and TRUPEN = 1).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE You can only clear this flag by writing 1 to the corresponding bit in CSR_CLR. 0b - Not detected 1b - Detected
15-14 —	Reserved
13 —	Reserved
12-8 CLKGATE	FRO Clock Enable Enables the FRO clocks. This field controls the FRO output clocks and allows the option to gate them off. 0_xxxxb - Disables FRO divider 8 clock 1_xxxxb - Enables FRO divider 8 clock x_0xxxb - Disables FRO divider 6 clock x_1xxxb - Enables FRO divider 6 clock x_x0xxb - Disables FRO divider 3 clock x_x1xxb - Enables FRO divider 3 clock x_xx0xb - Disables FRO divider 2 clock x_xx1xb - Enables FRO divider 2 clock x_xxx0b - Disables FRO divider 1 clock x_xxx1b - Enables FRO divider 1 clock
7 TUNEONCE	Tune Once Control When running in Closed Loop mode (TREN = 1 and TRUPEN = 1) with this field set, the FRO frequency autotuner will pause after tuning once. The autotuner waits until the TUNEONCE_DONE flag is cleared before it tunes again. When using least disturbance (COARSEN = 0), the autotuner can only move one low-byte trim and may not achieve the tuning goal. The tune once feature can also be used with TREN = 1 and TRUPEN = 0. In this configuration, the behavior is almost identical to when running in Closed Loop mode, except the FRO trim will always be controlled by FRO Trim (FROTRIM) (instead of the FRO Auto Tune Trim (AUTOTRIM) calculated by the autotuner). This means the application is responsible for programming FRO Trim (FROTRIM) to the next desired trim value based on the FRO Trim Count (TRIMCNT) result. To avoid disturbing the FRO frequency during tuning, the FRO Trim (FROTRIM) should only be changed after TUNEONCE_DONE is set and before clearing TUNEONCE_DONE to trigger the next tune once sequence. **NOTE** This field must be configured before enabling TREN.

Table continues on the next page...

Table continued from the previous page...

Field	Function
6 COARSEN	Coarse Trim Enable Enables autotrimming of the FRO high-byte trim bits, which have a coarse frequency adjustment when FRO is programmed in Closed Loop mode (TREN = 1 and TRUPEN = 1). Writing 1 to this field allows autotrimming of the FRO high-byte trim bits. When this field is 0, only the low-bytes or fine trim bits are adjusted automatically. **NOTE** When autotrim updating is enabled (TRUPEN = 1), it is recommended to keep this field as 0 to minimize frequency disturbance and risk of overshoot. 0b - Disable 1b - Enable
5 TRUPEN	FRO Autotrim Update Enable Enables FRO to run in Closed Loop mode when TREN = 1, trimming the FRO to an external clock source. If this field is 0, FRO is configured in Open Loop mode. Configure the FRO frequency by using FRO Trim (FROTRIM). If this field is 1, FRO autotrimming is enabled. Configure the target frequency by using FRO Expected Trim Count (TEXPCNT). **NOTE** You must write 1 to TREN before enabling this field. 0b - Disable 1b - Enable
4 TREN	FRO Trim Enable Enables the FRO frequency to be compared with an expected count that you configure in FRO Trim Count (TRIMCNT) by using an external reference clock. If this field is 0, FRO is configured in Open Loop mode. Configure the FRO frequency by using FRO Trim (FROTRIM). If this field is 1, FRO autotrimming is enabled. FRO is trimmed to an external reference clock. Configure the target frequency by using FRO Expected Trim Count (TEXPCNT). TRUPREQ is set when the FRO frequency is outside TEXPCNT[TEXPCNT_RANGE] and TRUPEN is disabled. **NOTE** • Writing 1 to this field and writing 0 to TRUPEN allows the FRO frequency to be compared to the expected frequency that you configure in FRO Trim Count (TRIMCNT), but keeps FRO running in Open Loop mode, where its output frequency is based on FRO Trim (FROTRIM) configurations. • To configure FRO in Closed Loop mode and automatically adjust the FRO output clock based on the target frequency that you configure by using FRO Trim Count (TRIMCNT), you must enable this field and TRUPEN.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
3 —	Reserved
2 —	Reserved
1 —	Reserved
0 FROEN	FRO Enable Enables FRO. **NOTE** Depending on the chip's configuration, FRO can be on by default. When FRO is off by default, writing 1 to this field enables FRO. FRO will only be powered down when both FRO_PD and this field are configured to disable FRO. See External signals. 0b - Disable 1b - Enable

32.6.3 Trim Configuration 1 (CNFG1)

Offset

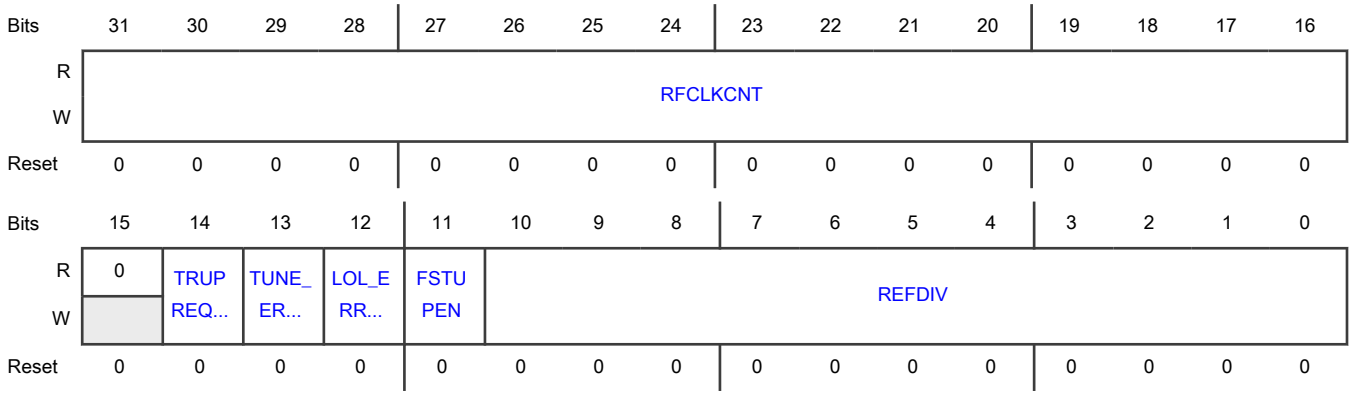
This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
CNFG1	210h	Trim Configuration 1
CNFG1_SET	214h	Writing 1 to a bit in this register ensures that the corresponding bit in CNFG1 is 1
CNFG1_CLR	218h	Writing 1 to a bit in this register ensures that the corresponding bit in CNFG1 is 0
CNFG1_TOG	21Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in CNFG1

Function

Controls the FRO fast startup enable, FRO reference clock divider, FRO sample window when running in Autotuner or Closed Loop mode, and FRO interrupt enable.

Diagram



Fields

Field	Function
31-16 RFCLKCNT	Reference Clock Counter Specifies the number of reference clocks where FRO is sampled when running in Closed Loop mode (CSR[TREN] = 1). This window should be large enough to sample the FRO for a minimum of 4000 FRO clock cycles. Use the following formula to calculate the minimum RFCLKCNT to use: RFCLKCNT ≥ 4000 × divided reference frequency ÷ FRO target frequency **NOTE** Count value of 0 is invalid and not supported.
15 —	Reserved
14 TRUPREQ_IE	Trim Update Request Interrupt Enable Enables the trim update request to generate an interrupt when FRO is running in Closed Loop mode (CSR[TREN] = 1 and CSR[TRUPEN] = 1) and CSR[TUNE_ERR] is set. 0b - Disable 1b - Enable
13 TUNE_ERR_IE	Tune Error Interrupt Enable Enables the tune error to generate an interrupt when FRO is running in Closed Loop mode (CSR[TREN] = 1 and CSR[TRUPEN] = 1) and CSR[TUNE_ERR] is set. 0b - Disable 1b - Enable
12 LOL_ERR_IE	Loss-of-Lock Error Interrupt Enable Enables a loss-of-lock error to generate an interrupt when FRO is running in Closed Loop mode (CSR[TREN] = 1 and CSR[TRUPEN] = 1) and CSR[LOL_ERR] = 1. 0b - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enable
11 FSTUPEN	FRO Fast Startup Enable Enables FRO fast startup. During the fast startup period, the FRO will output a divide-by-2 clock until the frequency is within 5% of the target. Then the FRO will automatically switch to the undivided clock output. The amplitude and duty cycle are stable while the frequency ramps to its final value. 0b - Disable 1b - Enable
10-0 REFDIV	OSC Reference Clock Divider Specifies the divide ratio to divide the OSC reference clock for FRO trimming. **NOTE** This field is an N-divider supporting a divide ratio of 1 (REFDIV = 0h) to a divide ratio of 2048 (REFDIV = 7FFh).

32.6.4 Trim Configuration 2 (CNFG2)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
CNFG2	220h	Trim Configuration 2
CNFG2_SET	224h	Writing 1 to a bit in this register ensures that the corresponding bit in CNFG2 is 1
CNFG2_CLR	228h	Writing 1 to a bit in this register ensures that the corresponding bit in CNFG2 is 0
CNFG2_TOG	22Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in CNFG2

Function

Controls the delay before FRO is sampled after adjusting the FRO trim values in Autotuner mode.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-28 —	Reserved
27-16 TRIM1_DELAY	Trim 1 Delay Register Specifies the number of divided reference clocks to wait for the FRO frequency to settle after trim values are updated by 1 decimal unit. This delay is applied only when the FRO is running in Closed Loop mode (CSR[TREN] = 1 and CSR[TRUPEN] = 1) and coarse trimming is disabled (CSR[COARSEN] = 0). **NOTE** • A count value of 0 is invalid and not supported. • A minimum trim delay of 5 µs should be used.
15-12 —	Reserved
11-0 TRIM2_DELAY	Trim 2 Delay Register Specifies the number of divided reference clocks to wait for the FRO frequency to settle after trim values are updated by 16 decimal unit steps (when CSR[COARSEN] = 0) or 128 decimal unit steps (when CSR[COARSEN] = 1). This delay is applied only when the FRO is running in Closed Loop mode (CSR[TREN] = 1 and CSR[TRUPEN] = 1). **NOTE** • A count value of 0 is invalid and not supported. • If CSR[COARSEN] = 0, a minimum trim delay of 30 µs should be used. • If CSR[COARSEN] = 1, a minimum trim delay of 150 µs should be used.

32.6.5 FRO Trim (FROTRIM)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
FROTRIM	240h	FRO Trim
FROTRIM_SET	244h	Writing 1 to a bit in this register ensures that the corresponding bit in FROTRIM is 1
FROTRIM_CLR	248h	Writing 1 to a bit in this register ensures that the corresponding bit in FROTRIM is 0
FROTRIM_TOG	24Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in FROTRIM

Function

Configures the FRO trim values when FRO is configured in Open Loop mode.

NOTE

- This register is reset only on POR.
- A larger [COARSE_TRIM:FINE_TRIM] trim value corresponds to a higher FRO output frequency.
- The desired trim can be found by observing the FRO Auto Tune Trim (AUTOTRIM) value after the FRO is locked in Closed Loop Mode OR by using some other frequency measurement method supported on the chip.

Diagram

Fields

Field	Function
31-22 —	Reserved
21-16 TRIMTEMP	Trim Temperature Specifies the temperature trim.
15-12 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
11-7 COARSE_TRIM	Coarse Trim Adjusts the frequency with a resolution of 2%.
6-0 FINE_TRIM	Fine Trim Adjusts the frequency with a resolution of 0.1%.

32.6.6 FRO Expected Trim Count (TEXPCNT)

Offset

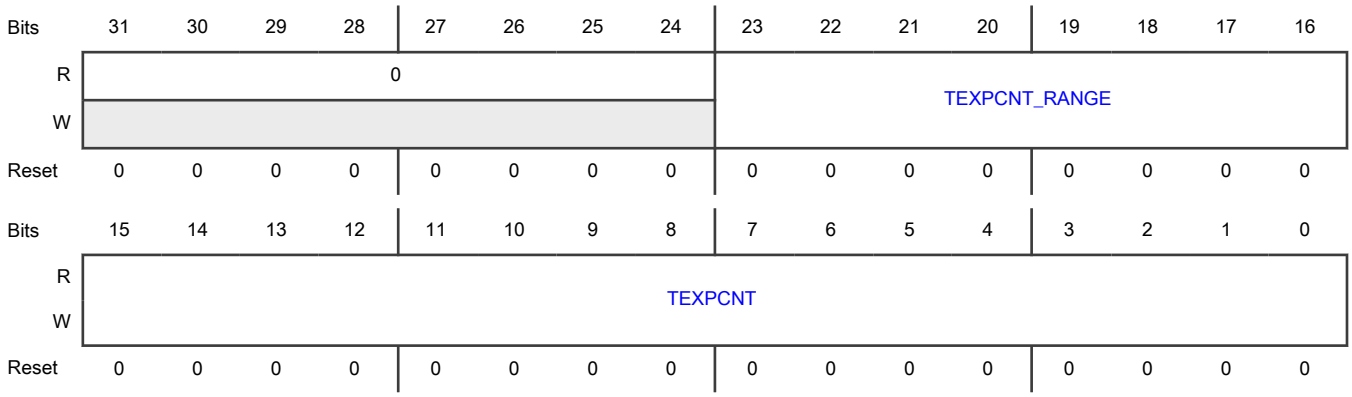
This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
TEXPCNT	250h	FRO Expected Trim Count
TEXPCNT_SET	254h	Writing 1 to a bit in this register ensures that the corresponding bit in TEXPCNT is 1
TEXPCNT_CLR	258h	Writing 1 to a bit in this register ensures that the corresponding bit in TEXPCNT is 0
TEXPCNT_TOG	25Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in TEXPCNT

Function

Configures the target trim FRO frequency count based on the configured CNFG1[RFCLKCNT] value and a known reference clock.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 TEXPCNT_RANGE	Trim Expected Count Range Specifies the + or – counts that the FRO frequency can be off from TEXPCNT to be considered locked. A smaller count corresponds to a lower tolerance for deviation from the target frequency. The percentage of frequency deviation is roughly equal to the ratio of TEXPCNT_RANGE / TEXPCNT.
15-0 TEXPCNT	Trim Expected Count Specifies the expected trim frequency target count when CSR[TREN] = 1. Use the following equation to determine the TEXPCNT for a specific target frequency: TEXPCNT = RFCLKCNT × (FRO target frequency ÷ divided reference frequency)

32.6.7 FRO Auto Tune Trim (AUTOTRIM)

Offset

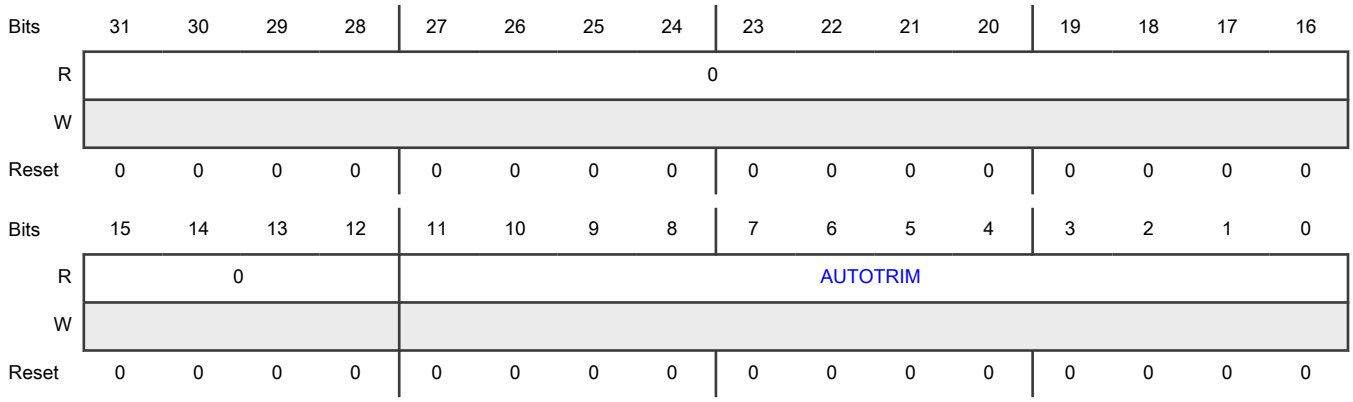
This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
AUTOTRIM	260h	FRO Auto Tune Trim
AUTOTRIM_SET	264h	Writing 1 to a bit in this register ensures that the corresponding bit in AUTOTRIM is 1
AUTOTRIM_CLR	268h	Writing 1 to a bit in this register ensures that the corresponding bit in AUTOTRIM is 0
AUTOTRIM_TOG	26Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in AUTOTRIM

Function

Returns the autotune trim value.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-0 AUTOTRIM	Auto Tune Trim Value Stores the autotrim value when FRO is running in Closed Loop mode.

32.6.8 FRO Trim Count (TRIMCNT)

Offset

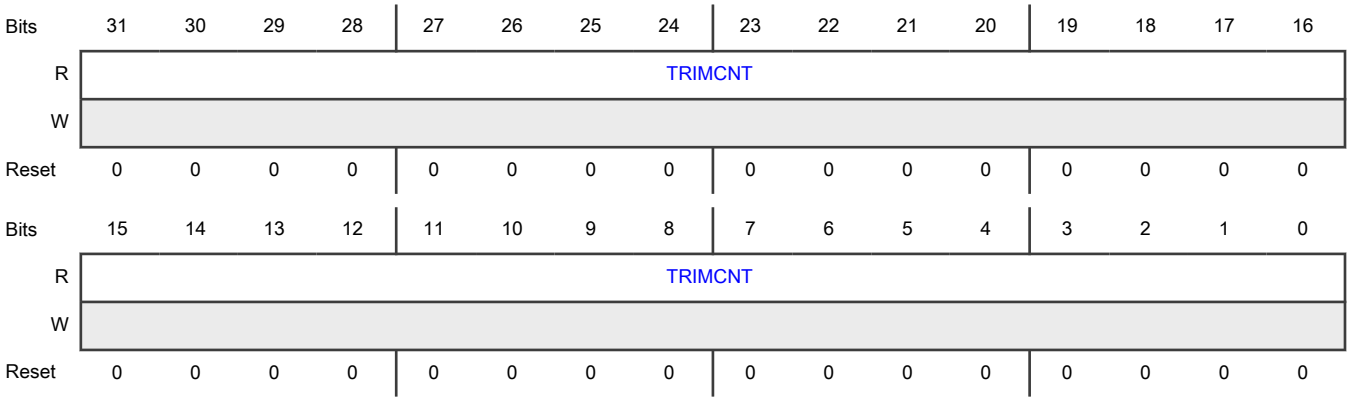
This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
TRIMCNT	270h	FRO Trim Count
TRIMCNT_SET	274h	Writing 1 to a bit in this register ensures that the corresponding bit in TRIMCNT is 1
TRIMCNT_CLR	278h	Writing 1 to a bit in this register ensures that the corresponding bit in TRIMCNT is 0
TRIMCNT_TOG	27Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in TRIMCNT

Function

Stores the count value that FRO last sampled.

Diagram



Fields

Field	Function
31-0 TRIMCNT	Trim Count Stores the last FRO sampled count value. **NOTE** The FRO frequency can be derived from the formula below. Frequency = TRIMCNT × (divided ref clock frequency) ÷ CNFG1[REFCLKCNT]

Chapter 33
Frequency Measurement (FREQME)

33.1.1 Module instances

This device has one instance of the FREQME module.

Table 271. FREQME instance

Features	FREQME
Located in	VDD2_COMP
Access	CPU0, HiFi4, EZH-V, eDMA0, eDMA1

33.1.2 Reference clock and target clock

FREQME reference clock and target clock are configured by INPUTMUX0 registers.

Table 272. Reference clock and target clock configuration

Clock	Configured by
Reference clock	INPUTMUX0_FREQME_TRIG0[TRIGIN]
Target clock	INPUTMUX0_FREQME_TRIG1[TRIGIN]

33.2 Overview

FREQME accurately measures the frequency of an on- or off-chip target clock signal using a selectable on-chip reference clock. For example, it can accurately determine the frequency of a low-power oscillator that varies depending on process and temperature.

33.2.1 Block diagram

Figure 107. Block diagram

See the chip-specific FREQME information for the target and reference clock selection options.

33.2.2 Features

- High-accuracy Frequency Measurement mode for on- and off-chip clocks
- Pulse Width Measurement (PWM) mode
- Reference and target clock inputs selectable from among various chip-specific options
- Optional measurement complete interrupt
- Result out-of-range detection with optional interrupt

33.3 Functional description

The following sections describe FREQME functional details.

33.3.1 Frequency Measurement mode

In Frequency Measurement mode (CTL_W[PULSE_MODE] = 0), FREQME counts the number of target clock cycles that occur during a specified number of cycles from a reference clock that has a known frequency. You can then calculate the target clock frequency based on the frequency of the reference clock, the number of reference clock cycles, and the number of target clock cycles (see Equation 1).

The frequency measurement circuit is based on two 31-bit counters—one clocked by the selected reference clock and one by the selected target clock. You can only read the target clock counter. FREQME synchronizes the clocks at the start and end of each count sequence during preparation for the next count sequence. A count sequence consists of incrementing the target clock counter for each target clock pulse that occurs during the time defined by $2^{CTRL_W[REF_SCALE]}$ periods of the reference clock.

After selecting reference and target clocks, you initiate a measurement cycle by writing 1 to CTRL_W[MEASURE_IN_PROGRESS]. You can then poll this same field, which automatically transitions to 0 when the measurement operation completes. Alternatively, the completion of the measurement operation can generate an interrupt.

The measurement cycle terminates when the reference counter equals the value $2^{CTRLSTAT[REFSCALE]}$. If CTRLSTAT[REFSCALE] = 0, the reference counter counts to one and stops. You can use this feature to measure the frequency of a fast target clock using a slow reference clock such as the 32 kHz clock without taking much time for the measurement to complete. The penalty is reduced accuracy in the measurement.

When the counting operation completes, the state of the target counter is loaded into CTRL_R[RESULT], and the CTRL_W[MEASURE_IN_PROGRESS] field is 0. You can then read the value and calculate the target frequency as follows, with the frequencies given in MHz.

$$F_{target} = (CTRL_R[RESULT] - 2) \times F_{reference} \div 2^{CTRLSTAT[REFSCALE]}$$

Equation 1. Calculating the target clock frequency

33.3.1.1 Accuracy

The Frequency Measurement mode can measure the frequency of any on-chip (or off-chip) clock (referred to as the target clock) with a high degree of accuracy by using an on-chip clock of known frequency as a reference clock.

Uncertainty in the reference clock (for example a ±1 % accuracy of the clock) adds to the measurement error of the target clock. In general, though, this additional error is less than the uncertainty of the reference clock.

33.3.2 Pulse Measurement mode

When you write 1 to CTRL_W[PULSE_MODE] and write 1 to CTRL_W[MEASURE_IN_PROGRESS] to start a measurement cycle, FREQME counts target clock pulses while the reference clock is in a specific state (high or low), selected by writing to CTRL_W[PULSE_POL]. See the description of these fields for more details.

33.3.3 Clocking

The clock inputs are as follows:

- Reference clock (REF_CLK_IN). This clock has a known frequency.
- Target clock (TARGET_CLK_IN). This clock frequency can be calculated based on the reference clock.
- Peripheral clock used for register access (PCLK). This clock is used to write and read memory-mapped registers of this module.

NOTE

These clocks can be all synchronous.

See the chip-specific FREQME information for the target and reference clock selection options.

33.3.4 Interrupts

The following interrupts can optionally be generated at the completion of a frequency measurement cycle.

Table 273. Interrupts

Condition	Interrupt enable field	Interrupt status field
Result is ready to read	CTRL_W[RESULT_READY_INT_EN]	CTRLSTAT[RESULT_READY_INT_EN]
Result is greater than MAX[MAX_VALUE]	CTRL_W[GT_MAX_INT_EN]	CTRLSTAT[GT_MAX_INT_EN]
Result is less than MIN[MIN_VALUE]	CTRL_W[LT_MIN_INT_EN]	CTRLSTAT[LT_MIN_INT_EN]

33.4 External signals

Table 274. External signals

Signal	Description	Direction
REF_CLK_IN	Reference clock. On-chip clock with known frequency chosen as reference.	Input
TARGET_CLK_IN	Target clock. On- or off-chip clock to be measured by FREQME.	Input

33.5 Initialization

Initialize FREQME by performing the following steps:

1. Enable the clock that drives FREQME in the chip-level clock control register. This step enables the register interface and the peripheral function clock.
2. Clear the FREQME peripheral reset in the chip-level reset control register.

3. If measuring an external clock, use the Input/Output pin configuration registers to connect the FREQME target clock input (TARGET_CLK_IN) to an external pin.
4. Ensure that the reference and target clocks are enabled.
5. Select the reference and target clocks.

33.6 Memory map and register definition

This section includes the FREQME memory map and detailed descriptions of all registers.

33.6.1 FREQME register descriptions

33.6.1.1 FREQME memory map

FREQME base address: 4002_3000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Control (in Read mode) (CTRL_R)	32	R	0000_0000h
0h	Control (in Write mode) (CTRL_W)	32	W	0000_0000h
4h	Control Status (CTRLSTAT)	32	RW	0000_0000h
8h	Minimum (MIN)	32	RW	0000_0000h
Ch	Maximum (MAX)	32	RW	7FFF_FFFFh

33.6.1.2 Control (in Read mode) (CTRL_R)

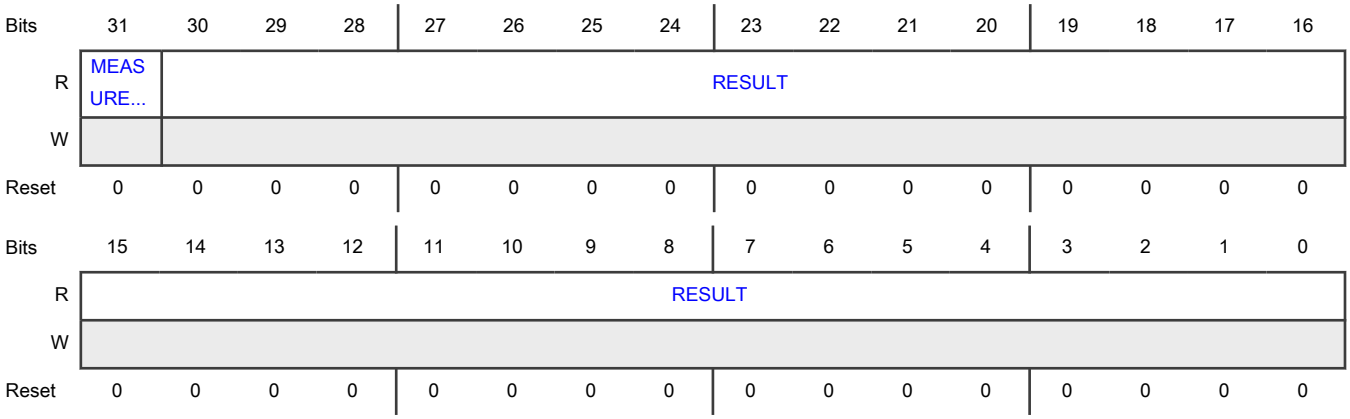
Offset

Register	Offset
CTRL_R	0h

Function

Contains different fields depending on whether you are performing a read or a write. Reading this register provides the measurement results and the status of the measurement cycle.

Diagram



Fields

Field	Function
31 MEASURE_IN_PROGRESS	Measurement In Progress Indicates whether measurement is in progress or complete. If complete, you can read the result from RESULT. 0b - Complete 1b - In progress
30-0 RESULT	Indicates the measurement result—either the target clock counter value (for Frequency Measurement mode) or pulse width measurement (for Pulse Width Measurement mode). This field is valid only when MEASURE_IN_PROGRESS = 0, In Continuous mode (CTRL_W[CONTINUOUS_MODE_EN] = 1), the value is the result from the most-recently completed measurement.

33.6.1.3 Control (in Write mode) (CTRL_W)

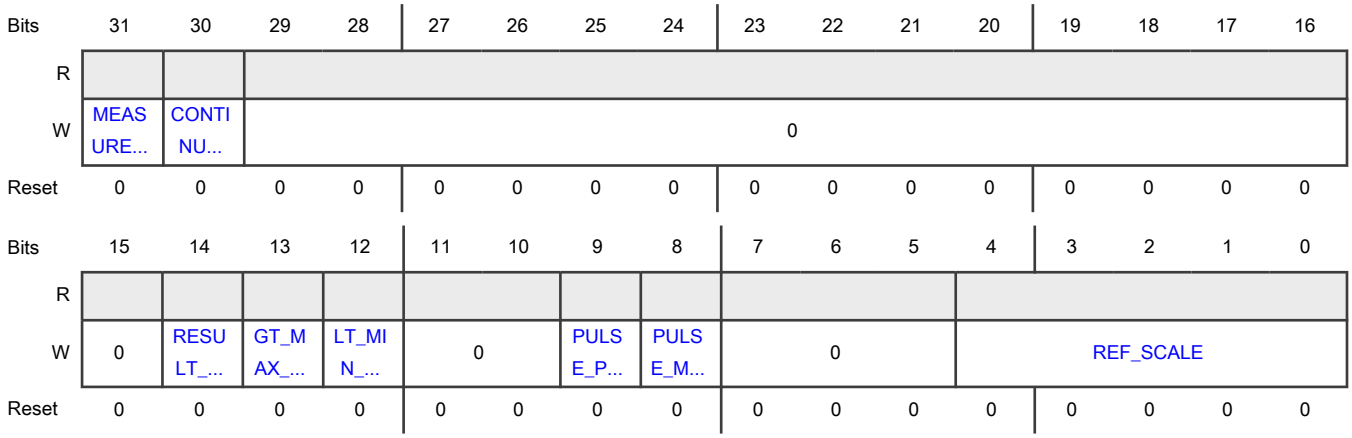
Offset

Register	Offset
CTRL_W	0h

Function

Writes to this register control and configure the measurement cycle.

Diagram



Fields

Field	Function
31 MEASURE_IN_PROGRESS	Measurement In Progress Initiates a frequency measurement cycle or terminates a measurement cycle that is in progress. Writing 1 to this field initiates a frequency or pulse width measurement process. Hardware automatically writes 0 to the MEASURE_IN_PROGRESS field when the measurement cycle completes. If there is an active measurement in progress, a new measurement starts. Writing 0 to this field forces the termination of any measurement cycle currently in progress and resets CTRL_R[RESULT] or just resets CTRL_R[RESULT] if idle. 0b - Terminates measurement 1b - Initiates measurement
30 CONTINUOUS_MODE_EN	Continuous Mode Enable When you write 1 to both MEASURE_IN_PROGRESS and this field, measurement is performed continuously. The result for the most-recently completed measurement is available in CTRL_R[RESULT]. When the result is out of range (that is, CTRLSTAT[GT_MAX_STAT] = 1 or CTRLSTAT[LT_MIN_STAT] = 1), this field automatically transitions to 0 and the continuous measurement is suspended. After clearing both status bits, you must write 1 to both MEASURE_IN_PROGRESS and this field restart measurement in continuous mode. 0b - Disable 1b - Enable
29-15 —	Reserved
14 RESULT_READY_INT_EN	Result Ready Interrupt Enable Generates interrupt when a measurement completes and the result is ready (CTRLSTAT[RESULT_READY_STAT] = 1).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
13 GT_MAX_INT_EN	Greater Than Maximum Interrupt Enable Generates an interrupt when the result is greater than MAX[MAX_VALUE] (CTRLSTAT[GT_MAX_STAT] = 1). 0b - Disable 1b - Enable
12 LT_MIN_INT_EN	Less Than Minimum Interrupt Enable Generates an interrupt when the result is less than MIN[MIN_VALUE] (CTRLSTAT[LT_MIN_STAT] = 1). 0b - Disable 1b - Enable
11-10 —	Reserved
9 PULSE_POL	Pulse Polarity Specifies whether a pulse width (high period or low period) of the reference clock is measured in the Pulse Width Measurement mode. **NOTE** PULSE_POL is valid only in the Pulse Width Measurement mode. • A high period measurement is triggered by the rising edge on the reference clock input. • A low period measurement is triggered by the falling edge on the reference clock input. 0b - High period 1b - Low period
8 PULSE_MODE	Pulse Width Measurement Mode Select Selects the measurement mode—either Frequency Measurement mode or Pulse Width Measurement mode. In Frequency Measurement mode, measurement begins at the rising edge of the selected reference clock and continues until a count of 2^{REF_SCALE} reference clock pulses is reached. In Pulse Width Measurement mode, the counter starts incrementing when the selected trigger edge (rising edge for high period measurement or falling edge for low period) occurs, and stops at the next edge (falling edge for a high period measurement or rising edge for a low period measurement). Select high or low period measurement by writing the desired value to PULSE_POL. 0b - Frequency Measurement mode 1b - Pulse Width Measurement mode
7-5	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
4-0 REF_SCALE	Reference Clock Scaling Factor Specifies the reference clock scaling factor in Frequency Measurement mode. The reference count cycle is 2^{REF_SCALE}. A higher number provides better accuracy but consumes more processing time. This field is valid only in Frequency Measurement mode.

33.6.1.4 Control Status (CTRLSTAT)

Offset

Register	Offset
CTRLSTAT	4h

Function
Contains the current CTRL_W register configuration fields.

34.1.1 Module instances

This chip contains one instance of the OSC32KNP module.

Table 276. OSC32KNP instance

Features	OSC32KNP
Located in	VDD1V8_AON
Access	CPU0, CPU1, HiFi4, HiFi1, EZH-V, eDMA0, eDMA1, eDMA2, eDMA3

34.1.2 Disable/enable OSC32KNP

You can enable or disable the OSC32KNP module via RTC_SS0_WAKE_TIMER_CTRL[SHUTOFF_OSC32].

34.2 Overview

OSC32KNP contains the following parts:

- An analog module that provides a 32.768 kHz clock to the chip with an external crystal oscillator
- A digital module used to configure the analog part and controls the monitoring of clock stability

34.2.1 Block diagram

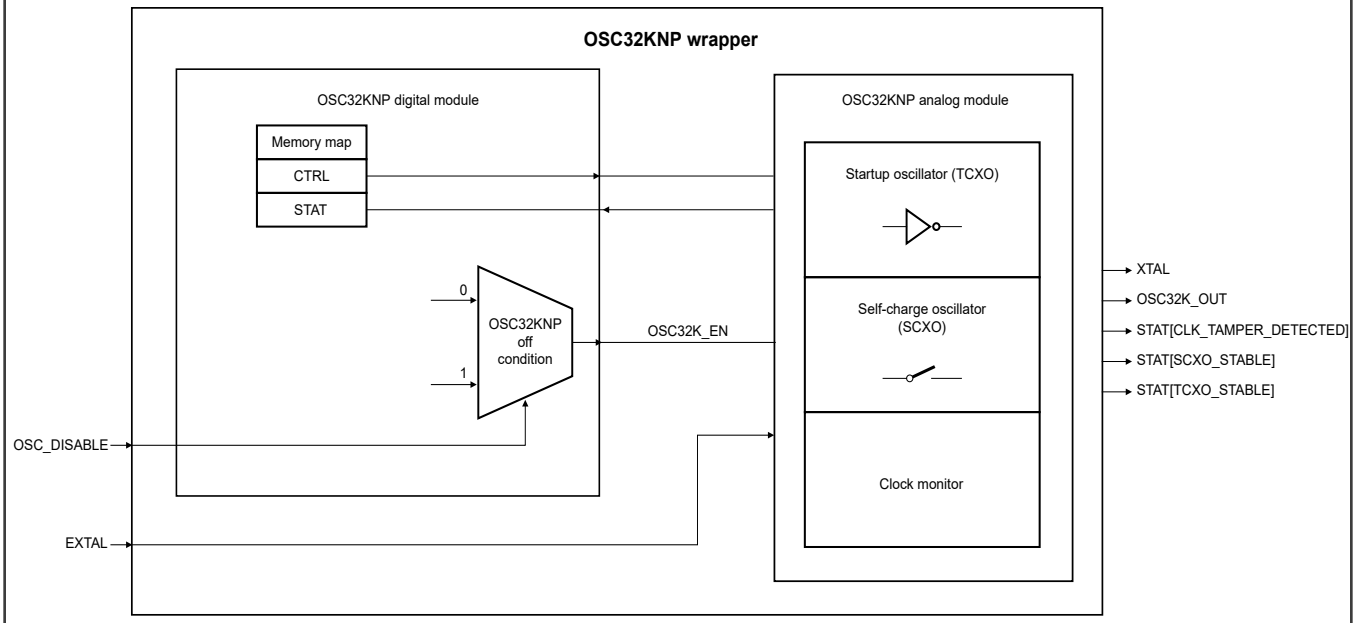

Figure 108. Block diagram

34.2.2 Features

- Provides a 32.768 kHz clock to the chip
- Provides a configurable clock accuracy
- Supports the clock in High-Power and Low-Power (Nano-Power) modes
- Detects clock tamper events across all operational power modes
- Supports current and switch cap resistor clock tracking
- Supports scan channel to turn off analog signals
- Supports disabling of OSC32KNP via OSC_DISABLE input signal

34.3 Functional description

34.3.1 Modes

34.3.1.1 Low-Power mode

The Low-Power mode uses the self-charge oscillator (SCXO) to ensure a ultra-low power consumption in battery application. This mode is also known as Nano-Power mode. OSC32KNP is fully functional in this mode.

34.3.1.2 High-Power mode

The High-Power mode uses the startup oscillator (TCXO) which enables the module to work with a higher ESR (equivalent series resistance) resonator up to 120 kΩ with high immunity performance to the external noise. OSC32KNP is fully functional in High-Power mode.

34.3.1.3 Clock Monitor mode

The clock tamper event test occurs in this mode. This test allows you to monitor the clock in a given system for loss-of-clock errors or out-of-range errors.

34.3.1.4 Bypass mode

In this mode, OSC32KNP recognizes an external 32.768 kHz input clock, and passes the clock directly to the output port.

34.3.2 Disabling OSC32KNP

If this module is not used, especially when there's no external crystal oscillator, OSC32KNP can be disabled.

NOTE

See chip-specific information on how to disable this module for your specific SoC.

After disabling, attempts to access OSC32KNP registers might cause a bus hang.

34.3.3 Clocking

The OSC32KNP registers and logic use the internally generated 32 kHz clock synchronized with the bus clock.

34.3.4 Reset

The bus reset resets the OSC32KNP registers and logic.

34.3.5 Interrupts

This module has no interrupts.

34.4 External signals

35.2 Overview

RTS_SS provides wake timers and miscellaneous functions for RTC modules.

35.2.1 Block diagram

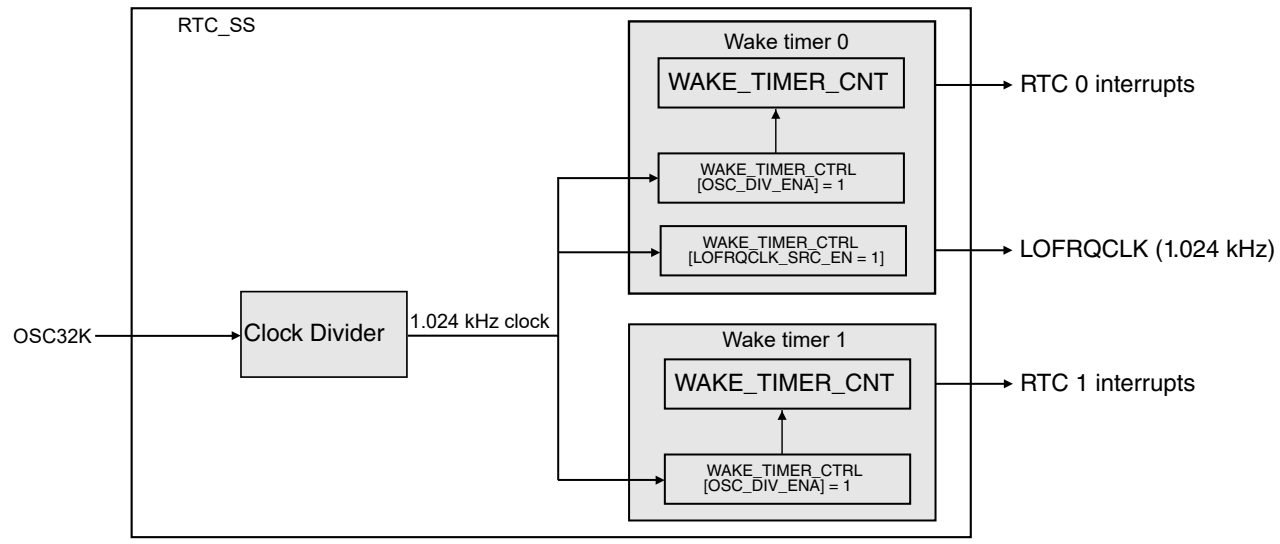

Figure 109. Block diagram

35.2.2 Features

- 32-bit wake-up timer counter in AON domain to wake up the chip.
- 1.024 kHz clock source shut-off control.
- OSC32KNP module shut-off control.

35.3 Functional description

RTC_SS is logically split into 2 parts, RTC_SS0 and RTC_SS1. RTC_SS0 contains a wake timer (Wake Timer 0) and miscellaneous control bits. RTC_SS1 contains a wake timer (Wake Timer 1).

CPU0 and HiFi4 have exclusive access to RTC_SS0 while CPU1 and HiFi1 have exclusive access to RTC_SS1.

35.3.1 Wake timer

Wake timer is a 32-bit down counter clocked at 1.024 kHz when enabled. Writing any non-zero value to the timer's counter register enables the counter and launches a countdown sequence, the counter register decreases by 1 on each 1.024 kHz clock cycle.

Upon timeout (counter value reaches zero), wake timer generates a flag which is also an interrupt source, and then turns itself off until relaunched by writing a non-zero value to the counter register.

When the counter is used as a wake-up interrupt source, the countdown sequence must be launched prior to entering a low-power mode.

35.3.2 Clocking

Signal	Description	Direction
OSC32K	32.768 kHz oscillator clock from OSC32KNP module	Input
LOFRQCLK	1.024 kHz clock source for low-frequency peripherals	Output

35.3.3 Interrupts

RTC_SS has two wake timer interrupt sources. Interrupt 0 (from Wake Timer 0) is routed to CPU0 and interrupt 1 (from Wake Timer 1) is routed to CPU1.

For each wake timer, write 1 to WAKE_TIMER_CTRL[INTR_EN] to enable the interrupt. The interrupt is asserted when the wake timer times out (read value of WAKE_TIMER_CTRL[WAKE_FLAG]=1). The wake timer's status flag bit and interrupt are cleared by writing 1 to WAKE_TIMER_CTRL[WAKE_FLAG]. The status flag is also cleared on module reset.

35.4 External signals

This module has no external signals.

35.5 Initialization

This module has no initialization considerations.

35.6 Memory map and register description

This section includes the RTC_SS memory map and detailed descriptions of all registers.

NOTE

CPU0 and HiFi4 cannot access RTC_SS1 registers. CPU1 and HiFi1 cannot access RTC_SS0 registers.

512 Hz clock	Not connected	Not connected

NOTE

The "Not connected" signals in the above table are not connected to out of the module. Ignore the related information and register fields in this chapter.

36.1.3 VBAT domain

For this chip, VBAT domain refers to the VDD1V8_AON domain. Only the VDD1V8_AO supplies power to the RTC logic in this domain.

In stop mode, VDD1V8_AO keeps supplying power to the RTC logic in VDD1V8_AON domain and the VDD1 to the rest of the RTC logic will be removed.

36.1.4 RTC shared counter

RTC1 shares the data and time counters of RTC0.

36.1.5 Register access after waking up from DSR

When RTC is waking up from DSR, you need to wait for one 32 kHz clock cycle before accessing its registers.

36.2 Overview

Real Time Clock (RTC) is a low-power module that provides time keeping and calendaring functions, protection against spurious memory/register updates. It can also compensate the 1 Hz clock against variations in 32 kHz clock in oscillator due to crystal or temperature.

36.2.1 Block diagram

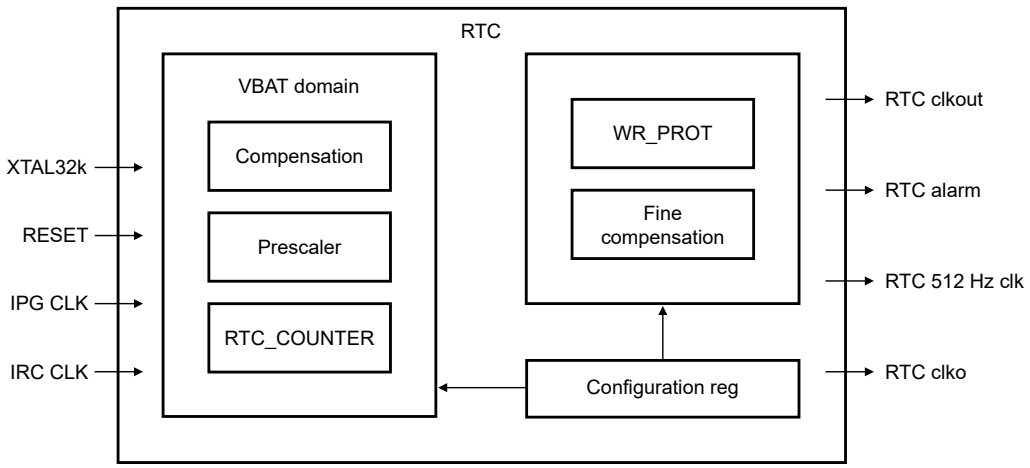

Figure 110. RTC block diagram

36.2.2 Features

RTC includes the following features:

- Designed for low power
  - Time and date counters are interleaved to prevent simultaneous toggling
- Basic clock functions
  - Separate counters for days, hour, minutes, and seconds
  - Calendaring support—Separate counters for year, month, and day of the week
    - Automatic adjustment for daylight saving with user-defined parameters
    - Automatic adjustment for month and leap year
  - External clock support to run the counters if you choose to provide an externally-compensated 1Hz clock
- Time zone offset—RTC uses local time which implicitly contains the time zone offset
- Programmable alarm with interrupt—Alarm is output from RTC in case the MCU uses it as a wake up event
- Periodic interrupts (sampling timer interrupts)
- Hardware compensation—Compensates 1 Hz clock (to the counters) against frequency variations in oscillator clock due to temperature changes or crystal characteristics. Programmable correction factor calculated by firmware.
- 16-bit CPU register programming interface with protection against runaway code
- Option to output the buffered 32.768 kHz clock or the compensated 1 Hz clock.
- The target RTC uses the controller RTC counters.

36.3 Functional description

36.3.1 Modes of Operation

This section describes the RTC modes of operation.

36.3.1.1 Wait mode/Power Down mode

RTC is fully operational in Wait mode (called Wait mode or Power Down mode depending on the device series). RTC runs off a 32.768 kHz clock that is not gated in Wait mode. This means the timekeeping functions (and other functions) that depend on the 32.768 kHz clock continue to operate independent of the CPU. Only the register block's clock is gated and no register contents are lost.

36.3.1.2 Stop mode/Deep Power Down mode

In Stop mode (called Stop mode or Deep Power Down mode depending on the device series), RTC is fully operational and behaves in the same way as it does when in Wait mode. If CPU power (VDD) is removed in Stop mode, RTC switches its power supply source to battery supply (VBAT) and isolates itself from the powered off domains.

NOTE

If the system bus clock is off in Stop mode, no read happens on RTC registers. When the system bus clock is switched on again, synchronization takes time. During the synchronization time, no write is allowed and any read to the RTC register returns FFFEh as the code to indicate the clock domains are synchronizing.

36.3.1.3 VBAT mode

Because it runs off a 32.768 kHz clock, RTC is fully operational in VBAT mode. The 32.768 kHz clock is not gated in VBAT mode and RTC's timekeeping functions (and other functions) that depend on the clock continue to operate independent of the CPU. Only the register block's clock is gated and no register contents are lost. After coming out of VBAT mode, the register content is not accessible for two osc_clk cycles due to synchronization.

36.3.2 Design overview

RTC provides basic timekeeping functions through counters for seconds, minutes, and hours, and calendaring functions via date, day-of-week, month, and year counters, including automatic adjustments for leap years and daylight saving time. Reading these counters indicates the current date and time and writing to these registers sets the date and time as provided by the user.

The alarm is set for a specific hour, minute, and second. If the alarm interrupt is enabled, an interrupt to CPU is generated when the time counters match the configured alarm hour, minute, and second settings. The target RTC uses the controller RTC counters. The alarm can also be configured to match a specific day, month, and year to generate an interrupt. The alarm signal is output to an MCU pin to allow wake up or control of external devices on board.

RTC also provides sampling timer interrupts. Both RTC controller and RTC target have independent alarm functions.

A frequency compensation module is integrated into the RTC to correct any error in the 1 Hz clock due to variations in the 32.768 kHz clock which could be caused by crystal inaccuracy, board variations, or change in temperature. The combined compensation value for both crystal and temperature variation is determined by software and the correction is done in hardware. The target RTC does not need compensation, because in addition to the main counters the target RTC uses the subcounters from the controller RTC.

The registers in RTC are configured via the CPU register programming interface. A protection mechanism is built into RTC to protect its registers against unintended writes by any runaway code. Both the controller RTC and target RTC have the protection mechanism.The protection mechanism requires the CPU to write a specific sequence of codes to the STATUS[7:6] bits to allow write access to the registers. After updating the registers, the CPU can write 10 to STATUS[7:6] bits to enable the write protection. After unlocking the registers, the CPU has a window of two seconds in which to update the register space. Following power-on reset, a window of 15 seconds is allowed for the CPU to configure the RTC, after which the registers are locked. Any updates beyond the unlock window require the CPU to unlock the registers, again.

For detailed description on the complete functionality of RTC, see Time and calendaring functions.

36.3.3 Clocking

The 32.768 kHz clock input from the oscillator is divided to generate a 512 Hz and a 1 Hz clock in RTC.

Table 282. Clocking

Signal name	Description	Direction
rtc_clk_out	1 Hz or 32.768 kHz clock output. Option for selecting compensated 1 Hz clock or buffered 32.768 kHz clock is available in Control (CTRL).	Output
rtc_clko_s	Gated 32.768 kHz clock output to other peripherals. Controlled by CTRL[CLKO_DIS].	Output
rtc_osc_32k_in_clk_hp	32.768 kHz clock input from oscillator, used in HP domain.	Input
rtc_osc_32k_in_clk_lp	32.768 kHz clock input from oscillator, used in LP domain.	Input
ipg_clk_hp_s	Gated system bus clock used for register read or write for high power or the CPU domain.	Input
ipg_clk_lp_s	Gated system bus clock used for register read or write for low power or the battery domain.	Input
ipg_clk_hp	System bus clock used to synchronize the oscillator 32.768 kHz clock to the ipg_clk domain (free running clock), used in HP domain.	Input
ipg_clk_lp	System bus clock used to synchronize the oscillator 32.768 kHz clock to the ipg_clk domain (free running clock), used in LP domain.	Input
rtc_irc_clk	Mhz clock used to fine compensate the oscillator clock.	Input

RTC has a 32.768 kHz clock input from the oscillator. The clock becomes the output to the peripherals and divided to generate a 512 Hz clock and a 1 Hz clock. The 512 Hz clock becomes the output to peripherals and the 1 Hz clock is the input of the counter.

The 1 Hz clock is subject to variations in speed due to temperature changes or crystal irregularities. The input clock rtc_irc_clk runs in cycles of MHz and compensates for these variations by making precise adjustments to the 1 Hz clock.

RTC has one system bus clock used to synchronize the oscillator 32.768 kHz clock to the ipg_clk domain.

Writing to CTRL[CLKOUT] configures either the clock input (32.768 kHz) or the 1 Hz clock as the output from the SOC for use outside RTC. Writing to CTRL[CLKO_DIS] determines if the selected clock outputs to other peripherals.

36.3.4 Interrupts

Write one to IER[ALM_IE] to enable the alarm interrupt. The alarm interrupt is asserted when the programmed alarm value matches the counter values and the ISR[ALM_IS] bit is set. The status bit and interrupt are cleared by writing one. The status register is also cleared on software reset. The counters matched for the alarm interrupt are selected based on the alarm type set in CTRL[ALM_MATCH].

There are eight periodic, sampling timer interrupts. When the clock generation counter counts to the programmed value, the corresponding bit in the status register is set. The status bits are cleared either by writing one or by software reset.

36.3.5 Time and calendaring functions

The controller RTC performs and controls all the chronological functions listed below.

The target RTC shares the controller RTC counters for these functions.

- Implements all counters for date and time and the related control logic
- Calculates leap year and adjusts the day count accordingly
- Increments or decrements counters to adjust for leap seconds
- Tracks the number of days in a month
- Automatically adjusts for daylight saving time

- Generates alarm with selectable matching of different counters. Both controller and target RTC have independent alarm functions.

Dynamic modifications to the date counters are done based on leap year, month, and daylight saving. Additionally, the user software can add or subtract a second to adjust for leap seconds. All changes are controlled by hardware and triggered by software. Used on controller RTC counters only.

A leap year is defined as a year in which the year value is divisible by 4 and 400 and has an extra day in February. Daylight saving is implemented in different regions of the world to shift the local time according to the summer or winter seasons. Time is shifted at a pre-defined time decided by the regional conditions and programmed by the user software. RTC automatically adjusts the time using hardware alarms for daylight saving. The day counter is also adjusted for months which have 28, 29, 30, or 31 days. Used on controller RTC counters only.

Alarm generation is done by the RTC block. Matching the counters is controlled by CTRL[ALM_MATCH] to give various alarm options for daily, monthly, yearly, or one-time alarms.

NOTE

Setting an hour alarm value that coincides with the daylight saving start hour value will not generate an alarm because the hour counter is incremented by two (instead of one) when daylight saving comes into effect. For example, setting ALM_HOURMIN to 0x1500 (hour alarm value = 15 or 3 PM) when DST_HOUR = 0x1411 (DST start hour value = 14 or 2 PM) will cause the hour counter to go from 14 to 16. The hour counter will not equal 15 and therefore the alarm which was set for 15 (or 3 PM) will not trigger. User software must take daylight saving changes into account when setting alarm values.

NOTE

User software must program an alarm time equal to the daylight saving end time (fallback time). The user software must write 0 to CTRL[DST_EN] when the alarm interrupt occurs, otherwise the correct operation might not take place.

36.3.6 RTC compensation logic

The compensation logic supports temperature and frequency compensation and provides an accurate and wide range of compensation suitable for many crystals. It can correct a wide range of crystal offsets from as low as 0.119 PPM.

NOTE

The target RTC does not need compensation logic because it uses compensation logic from the controller RTC.

There are two important components in the compensation logic: coarse compensation and fine compensation. The coarse compensation provides an accurate clock to RTC's internal time and date counters, and fine compensation generates an accurate 1 Hz clock output (via MCU pin) with high resolution clock edge placement (up to 0.88 ppm) and near 50 percent duty cycle.

Enabling the required compensation logic

Coarse compensation is enabled by writing to CTRL[COMP_EN] and fine compensation is enabled by writing to CTRL[FINEEN]. However, when FINEEN = 1, COMP_EN must be equal to 1. Setting both bits to 0 disables all compensation. This is the default state out of reset.

Compensation parameters need to be provided to allow required compensation logic to run. The parameters are provided by writing to the COMPEN register.

NOTE

If CTRL[FINEEN] = 0, then compensation must be disabled using CTRL[COMP_EN] before changing COMPEN for the first time. Successive changes can be done without disabling compensation.

If FINEEN = 1, then there are two options:

- Either clear previously accumulated fractional compensation value by disabling compensation from the CTRL register, program new values, and re-enable compensation and start a fresh
- Or, overwrite the current values leading to the addition of previously accumulated fractional compensation value to programmed fractional compensation value.

The integer part is always overwritten

Compensation parameters

Compensation logic requires the user software to provide compensation parameters in the COMPEN register in order to generate an accurate 1 Hz clock. These parameters are defined depending on the type of compensation enabled.

The compensation parameters (when FINEEN = 0) are defined as:

- **Compensation correction value:** Compensation correction value is a two's complement value by which the 1 Hz Clock is modified (during its generation) by either adding or removing RTC oscillator clock cycles.
- **Compensation interval:** Compensation interval is the duration in seconds over which the correction is applied. This is the time in which the addition or removal of 32.768 kHz clock cycles is done, thereby ensuring that the compensation interval is close to the interval obtained with an ideal 1 Hz clock.

The compensation parameters (when FINEEN = 1) are defined as:

- **Integral compensation value:** This is a two's complement value of the integer part of correction or compensation value that has to be adjusted in every 1 second period. This value is expressed in terms of the number of clock cycles of the RTC oscillator clock.
- **Fraction compensation value:** This is the fractional part of the correction or compensation value that has to be adjusted. This value is expressed as the number of clock cycles of a fixed 4.194304 MHz clock that have to be added. This value is always a positive number.

NOTE

When FINEEN = 1, the compensation interval is by default set to 1, indicating that the compensation will be done at every second.

Coarse compensation logic

Coarse compensation logic provides the accurate 1 Hz clock pulses to the time and date counters and the coarse 1 Hz clock to the fine compensation logic.

When FINEEN = 0: RTC compensates the clock over the provided compensation interval. The addition or removal of clocks is done in a single 1 Hz period, leaving the other 1 Hz periods of the compensation interval the same. This addition or removal of RTC oscillator clock cycles adjusts the 1 Hz clock in a way that keeps the overall compensation interval time close to the same interval being measured with an ideal clock.

When FINEN = 1: The integer part of the compensation (or correction) value is added or removed every 1 Hz period and the fraction part is accumulated and adjusted when the accumulated value equals 1 RTC oscillator clock cycle period.

To perform crystal offset compensation, the user software computes the compensation parameters external to RTC and, using details about the crystal characteristics (aging, drift, and so on), computes the correction factor. The user software then programs it in the two's complement format in the compensation register (COMPEN). Based on the values written in the COMPEN register, the compensation is performed.

To perform temperature compensation, the user software can maintain a lookup table in its memory which lists the change in frequency of 32.768 kHz crystal clock for each degree change in temperature. The CPU wakes up periodically to measure the external temperature via a temperature sensor connected to an A/D converter. The user software uses the lookup table to

determine the compensation factor and writes the value to be compensated (in terms of number of 32.768 kHz clock cycles in two's complement format) in the compensation register (COMPEN). Based on the new values written, the compensation logic adjusts the clock from the next compensation interval.

The user software must compute a common compensation factor if it detects a variation in 32.768 kHz clock due to both temperature and crystal characteristics.

Vital statistics

- Range of compensation interval: 1 second to 255 seconds. If FINEEN = 0, writing a 0 disables compensation. If FINEEN = 1, this interval is always 1 second.
- Range of compensation: -128 to +127 (number of 32.768 kHz clock cycles)
- Selection criteria: Compensation is done only when enabled by user software. User software can disable compensation by writing a 0 compensation interval or setting CTRL[COMPEN] = 0.

Fine compensation logic

The fine compensation logic takes the coarse 1 Hz clock (from coarse compensation block) and generates accurate 1 Hz clock output with accurate clock edge placement and near 50 percent duty cycle.

The fine compensation runs when FINEEN = 1 and uses the MCU's IRC clock to adjust the fractional part of the compensation value every 1 Hz period. This provides an accurate edge placement on the 1 Hz clock.

The fine compensation module automatically adjusts the fractional compensation value for any variation in the IRC clock.

NOTE

Because the IRC clock is generated on MCU, this clock will be disabled when MCU power is OFF or in certain low power modes. In this case, the coarse 1 Hz clock is output from the MCU. The coarse 1 Hz clock is not a 50 percent duty cycle clock.

36.3.7 Write protection mechanism

The write protection mechanism protects the RTC registers from any unexpected updates that can happen from a runaway code. This logic monitors the values written to STATUS[WE]. By default, unconditional write access is allowed to these bits only. For writing the locking and unlocking sequence, 8-bit access should be configured in STATUS[7:0].

To enable write protection, write 10 to these bits. To disable write protection, write the following sequence to those bits: 00, 01, 11, 10.

After a power-on reset, the write protection mechanism is disabled, allowing the user software to configure the RTC block. After configuration is complete, the user code can enable the write protection mode. If this is not done by the user software, the registers are put into write protect mode 15 seconds after power-on. If the write protection mode is unlocked to update registers and not locked again by the user software, the write protection mode is automatically enabled after two seconds.

Any write access made to the registers when write protection is enabled (that is, registers are locked) will cause the transfer error signal to be asserted. Reads are allowed at all times.

NOTE

1. Always check STATUS[WRITE_PROT_EN] after running unlocking and locking sequences and re-run the sequence if STATUS[WRITE_ PROT_EN] is not in the required state.
2. Two consecutive unlocking sequences will lock the registers. After they are unlocked, running an unlock sequence before the timeout will lock RTC registers.

36.4 External Signals

Table 283. External signals

Signal	Description	Direction
RTC_CLKOUT	Output clock to external devices on the board.	Output

36.5 Memory map and registers

36.5.1 RTC register descriptions

The register address is the sum of the base address and the address offset. The base address is defined at the chip level. The address offset is defined at the module level.

NOTE

A 32.768 kHz clock is needed to initialize the RTC. This clock can later be gated when programming the RTC registers.

NOTE

Use valid dates to configure registers. For example, do not configure a value like February 30, 2024, because there is no 30th in February 2024.

36.5.1.1 RTC memory map

RTC0 base address: 4006_8000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Year and Month Counters (YEARMON)	16	RW	0001h
2h	Days and Day-of-Week Counters (DAYS)	16	RW	0001h
4h	Hours and Minutes Counters (HOURMIN)	16	RW	0000h
6h	Seconds Counters (SECONDS)	16	RW	0000h
8h	Year and Months Alarm (ALM_YEARMON)	16	RW	0000h
Ah	Days Alarm (ALM_DAYS)	16	RW	0000h
Ch	Hours and Minutes Alarm (ALM_HOURMIN)	16	RW	0000h
Eh	Seconds Alarm (ALM_SECONDS)	16	RW	0000h
10h	Control (CTRL)	16	RW	0200h
12h	Status (STATUS)	16	RW	0000h

24h	Daylight Saving Month (DST_MONTH)	16	RW	0000h

Table continues on the next page...

Table continued from the previous page...

Offset	Register	Width (In bits)	Access	Reset value
26h	Daylight Saving Day (DST_DAY)	16	RW	0000h
28h	Compensation (COMPEN)	16	RW	0000h

36.5.1.2 Year and Month Counters (YEARMON)

Offset

Register	Offset
YEARMON	0h

Function

Stores the value of the month and year counters. The year field stores the offset in years from a hardcoded base year (2112), not the actual year value. This is a signed value that ranges from -128 to +127. The actual year value can be calculated by adding the base year (2112) and the offset in the YEARMON[15:8] register, meaning the range of years supported is 1984 (2112 - 128) to 2239 (2112 + 127). For example, if the current year is 2007, then it will be represented in this register as 105 or 0x97. Software should program the offset from the base year into this register.

For year calculation:

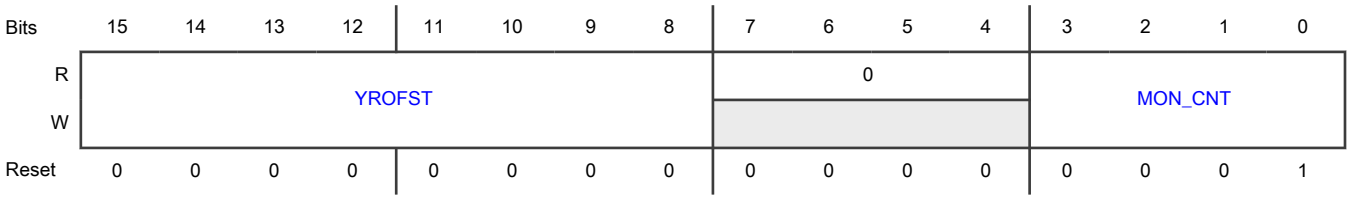
Actual Year = Base Year (for example, 2112) + Offset Year

The month field stores the count value of the months register. Writing to this register loads the months counter with this new value. The valid values are shown in table below.

User software should first determine the state of STATUS[INVAL_BIT] to determine if the counters are stable before a value can be read or changed. The assertion of STATUS[INVAL_BIT] ensures that no operation is done at the boundary of a second when counters change value.

Both month and year are unaffected by software reset.

Diagram



Fields

Field	Function
15-8 YROFST	Year Offset Count Value

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates the offset in years from the base year (hard coded as 2112) and does not show the actual year value. This is a signed value. Valid values are -128 to 127. The base year is 2112 and if the value of YEAR field is 0x10, the actual year is 2112 + 16 = 2128.
7-4 —	Reserved
3-0 MON_CNT	Month Counter Provides the value of the Months Counter. Valid Values are: 0000b,1101b,1110b,1111b - Illegal Value 0001b - January 0010b - February 0011b - March 0100b - April 0101b - May 0110b - June 0111b - July 1000b - August 1001b - September 1010b - October 1011b - November 1100b - December

36.5.1.3 Days and Day-of-Week Counters (DAYS)

Offset

Register	Offset
DAYS	2h

Function

Shows the current value of the day-of-week counter and the days counter. Reading this register returns the latest value of the counters. Writing to this register loads the value to the day-of-week and days counters, and the counters continue to count from this new value. The day-of-week is not calculated automatically and should be written by CPU. This register is unaffected by software reset.

User software should first determine the state of STATUS[INVAL_BIT] to determine if the counters are stable before their value can be read or changed. The assertion of STATUS[INVAL_BIT] ensures that no operation is done at the boundary of a second when counters change value.

Diagram

4-0 DAY_CNT	Days Counter Value Valid values are 1 to 31.

36.5.1.4 Hours and Minutes Counters (HOURMIN)

Offset

Register	Offset
HOURMIN	4h

Function

Used to program the hours and minutes counter. The register can be read anytime to get the current value of the counters. The hours counter can be set to anything between 0 and 23. The minutes counter can be set to anything between 0 and 59. This register is unaffected by software reset. Only power-on reset can reset this register.

User software should first determine the state of the STATUS[INVAL_BIT] to determine if the counters are stable before their value can be read or changed. The assertion of STATUS[INVAL_BIT] ensures that no operation is done at the boundary of a second when counters change value.

36.5.1.6 Year and Months Alarm (ALM_YEARMON)

Offset

Register	Offset
ALM_YEARMON	8h

Function

Used to configure the months and year setting of the alarm. The alarm setting can be read or written anytime. Alarm interrupt bit is set when all values of alarm seconds, minutes, hours, days, month, and year match their respective counter values. This register is reset to its default state on software reset.

User software can configure the alarm type by using the CTRL[ALM_MATCH].

36.5.1.9 Seconds Alarm (ALM_SECONDS)

Offset

Register	Offset
ALM_SECONDS	Eh

Function

Used to configure the seconds setting of the alarm. The alarm setting can be read or written anytime. This register is reset to default value on software reset.

User software has the option of using bits 9:8 to perform a correction on the seconds counter to compensate for leap seconds. Writing to these bits adds or subtracts 1 from the seconds counter and read returns zeros.

User software should first determine the state of STATUS[INVAL_BIT] to determine if the counters are stable before they can be incremented or decremented. The assertion of STATUS[INVAL_BIT] ensures that no operation is done at the boundary of a second when counters change value.

User software can configure alarm type using CTRL[ALM_MATCH].

3-2 ALM_MATCH	Alarm Match Defines the type of alarm function. Selects which time and calendar counters are used for matching and will generate an alarm. 00b - Only seconds, minutes, and hours matched. 01b - Only seconds, minutes, hours, and days matched. 10b - Only seconds, minutes, hours, days, and months matched. 11b - Only seconds, minutes, hours, days, months, and year (offset) matched.
1 COMP_EN	Compensation Enable **NOTE** Hardware will not allow user software to write 1 to COMP_EN if both the FINEEN and COMP_EN bits are set to 1'b1. 0b - Coarse compensation is disabled. 1b - Coarse compensation is enabled.
0 FINEEN	Fine Compensation Enable 0b - Fine compensation is disabled 1b - Fine compensation is enabled.

36.5.1.11 Status (STATUS)

Offset

Register	Offset
STATUS	12h

Function

Indicates the status of various processes occurring inside the RTC. Also helps the user software to read time or date register when the values are stable and not changing. Compensation Done bit and Bus Error bit are cleared by writing 1. Software reset resets the whole register to its default state.

All memory mapped registers are protected against spurious updates by the write protect mechanism. To unlock the registers, a specific pattern (as mentioned in the table above) has to be written in the write enable bits (WE[1:0]) to enable or disable write protection. The WE[1:0] bits are the only bits that are freely writeable by user software. The write enable bits are self-clearing bits that always return zeros on read.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0				CMP_DONE	0	0	BUS_ERR	0		CMP_INT	0	0		WRITE_P...	INVAL_B...
W					W1C			W1C	WE							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-12 —	Reserved
11 CMP_DONE	Compensation Done Indicates that the current compensation cycle is complete. This field is cleared by writing 1. This bit is asserted seven 32.768 kHz clock cycles before the actual compensation interval completes so that back-to-back compensation can be enabled. 0b - Compensation busy or not enabled 1b - Compensation completed
10 —	Reserved
9 —	Reserved
8 BUS_ERR	Bus Error Indicates that a read or write cycle was initiated by software when the STATUS[INVAL_BIT] = 1. Write access to time or date registers is nullified (terminate normally) and no register value is changed. Reading when STATUS[INVAL_BIT] is asserted returns 0xFFFF. No transfer error is asserted. This bit is cleared by writing 1. 0b - Read and write accesses are normal. 1b - Read or write accesses occurred when STATUS[INVAL_BIT] was asserted.
7-6 WE	Write Enable Controls entry into and exit from the write protection mode. Both registers are protected by the write protection mechanism. These are self-clearing bits. Reads will return zeros. Disable write protection by writing this sequence: 00b, 01b, 11b, 10b. See Write protection mechanism for more information. **NOTE** When the registers are unlocked, they remain in this unlocked state for a time of 2 seconds, after which they are locked automatically. After power-on reset, the registers are unlocked and then are locked automatically after 15 seconds.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - Enable Write Protection - Registers are locked.
5 CMP_INT	Compensation Interval Asserted for a time equal to compensation interval seconds as configured by the user. Used by the MCU to calculate the interrupts serviced during this interval and performs corrections in case of deviations (calibration). This bit toggles on at the start of every new compensation interval and is either 0 or 1 during the entire duration. This bit will not toggle if compensation logic has been disabled by MCU.
4 —	Reserved
3-2 —	Reserved
1 WRITE_PROT_EN	Write Protect Enable Status Indicates that registers are in locked mode and writing to them is disabled. Any write access made to the register space when write protection is enabled (that is, when they are in locked mode) will cause the transfer error signal to be asserted. 0b - Registers are unlocked and can be accessed. 1b - Registers are locked and in read-only mode.
0 INVAL_BIT	Invalidate CPU Read/Write Access Indicates the time and date counters are invalid or changing and therefore should not be read or written to. This bit is asserted for one oscillator clock cycle before and after the 1 Hz (seconds clock) boundary edge. Write access to time and date registers is nullified (terminate normally) and no register value is changed. Reading when STATUS[INVAL_BIT] is asserted returns 0xFFFF. No transfer error is asserted. 0b - Time and date counters can be read or written. Time and date is valid. 1b - Time and date counter values are changing or time and date is invalid and cannot be read or written.

36.5.1.12 Interrupt Status (ISR)

Offset

Register	Offset
ISR	14h

Function

NOTE

For the sampling timer interrupt status bits [14:6], see the chip configuration chapter for the applicable sampling timer frequencies.

Indicates the status of the various real-time clock interrupts. When an event of the types included in this register occurs, the bit will be set in this register regardless of the status of its corresponding interrupt enable bit. The status bits and interrupts are cleared by writing a value of 1. Interrupts may occur when the system clock is idle or in Standby mode. When the system enters the active power mode, an interrupt is indicated to the CPU. The first event of the Sampling Timer interrupts after power-on reset should not be used to qualify any periodic interval. However, the correct periodic interval (that is, 512 Hz or 256 Hz, and so on) should be determined using two sampling timer interrupts. The time between two interrupts should always be the correct time period.

This register is cleared on software reset.

NOTE

Sampling interrupts from 512 Hz to 2 Hz are generated using uncompensated clock. Only 1 Hz is compensated.

36.5.1.13 Interrupt Enable (IER)

Offset

Register	Offset
IER	16h

Function

NOTE

For the sampling timer interrupt enable bits [14:6], see the chip configuration chapter for the applicable sampling timer frequencies.

Enables and disables the various real-time clock interrupts. De-asserting an interrupt enable bit has no effect on the assertion of its corresponding status bit.

Alarm interrupt is asserted on counters matching the alarm setting done in the memory map. The counters matched for the alarm interrupt are selected based on the alarm type set in CTRL[3:2]. The various types of alarms available are shown in the following table. Only one alarm type can be used at a time.

Table 284. Alarm Match Table

ALM_MATCH[1:0] (CTRL[3:2])	Counters Matched	Alarm Type
00	Seconds, Minutes, and Hours	Daily
01	Seconds, Minutes, Hours, and Days	Monthly
10	Seconds, Minutes, Hours, Days, and Months	Yearly
11	Seconds, Minutes, Hours, Days, Months, and Year	One Time

RTC generates a common interrupt. The user software should read the status register in the interrupt service routine to determine which interrupt has occurred.

36.5.1.14 Sub Second Counter (RTC_TEST2)

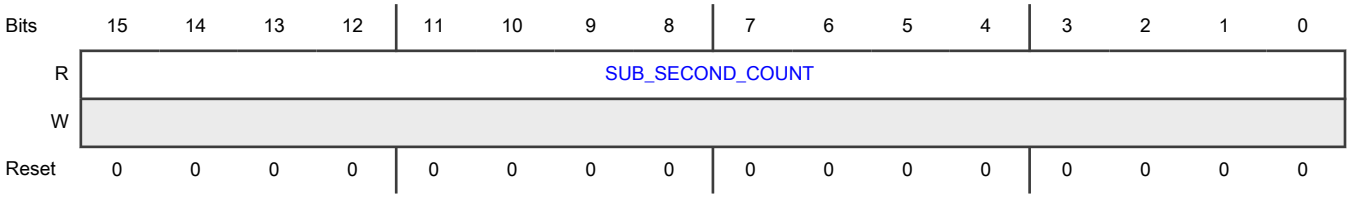
Offset

Register	Offset
RTC_TEST2	1Ch

Function

The RTC_TEST2 counter is used as a subsecond counter.

Diagram



Fields

Field	Function
15-0	Sub Second Counter Value

Table continues on the next page...

Field	Function
SUB_SECOND_COUNT	This counter is used as a sub second counter. Actually it counts the 32 kHZ clk cycles and auto clear every second.

36.5.1.15 Daylight Saving Hour (DST_HOUR)

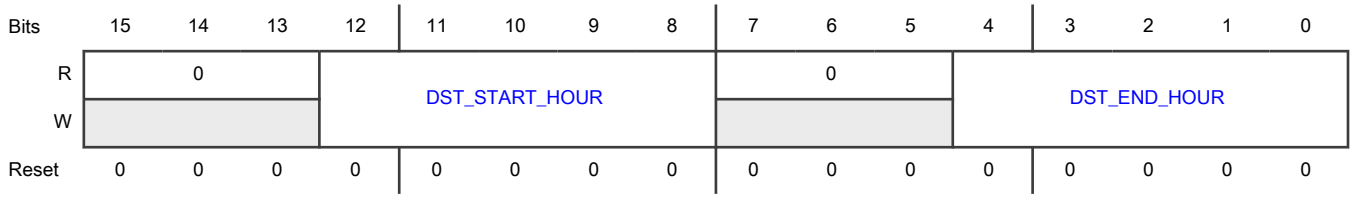
Offset

Register	Offset
DST_HOUR	22h

Function

Stores the time in hours when daylight saving has to be applied or reversed. This register is programmable when CTRL[DST_EN] = 0. When CTRL[DST_EN] = 1, the contents of this register cannot be changed. The user software should program the correct hour value (0-23) per the regional settings. For example, if daylight saving starts at 2:00 AM on March 25 and ends at 2:00 AM on October 28 in 2007 then the time at which the RTC advances or falls back is actually 1:59 AM. Therefore, the user software should program one, not two, for the hour count value (that is, write 0x0101) in this register. A 59-minute count is automatically checked inside RTC and not required to be programmed. This register has no effect on software reset.

Diagram



Fields

Field	Function
15-13 —	Reserved
12-8 DST_START_HOUR	Daylight Saving Time (DST) Hours Start Value The hour value for the time when DST comes into effect. Same as hours counter value in the Hours and Minutes Counters (HOURMIN).
7-5 —	Reserved
4-0 DST_END_HOUR	Daylight Saving Time (DST) Hours End Value The hour value for the time when DST is reversed. Same as hours counter value in the Hours and Minutes Counters (HOURMIN).

36.5.1.16 Daylight Saving Month (DST_MONTH)

Offset

Register	Offset
DST_MONTH	24h

Function

Stores the month when the daylight saving needs to be applied or reversed. This register is programmable when CTRL[DST_EN] = 0. When CTRL[DST_EN] = 1, the contents of this register cannot be changed. The CPU should program the correct month value (1-12) per the regional settings. For example, if daylight saving starts on March 25 and ends on October 28 in 2007, then CPU should write 0x030A in this register. This register has no effect on software reset.

Diagram

Fields

Field	Function
15-12 —	Reserved
11-8 DST_START_MONTH	Daylight Saving Time (DST) Month Start Value The month value for the time when DST comes into effect. See Year and Month Counters (YEARMON).
7-4 —	Reserved
3-0 DST_END_MONTH	Daylight Saving Time (DST) Month End Value The month value for the time when DST is reversed. See Year and Month Counters (YEARMON).

36.5.1.17 Daylight Saving Day (DST_DAY)

Offset

Register	Offset
DST_DAY	26h

Function

Stores the day when the daylight saving needs to be applied or reversed. This register is programmable when CTRL[DST_EN] = 0. When CTRL[DST_EN] = 1, the contents of this register cannot be changed. The CPU should program the correct day value (1-31) per the regional settings. For example, if the Daylight Saving starts at March 25 and ends at October 28 in 2007, then the CPU should write 0x191C in this register. This register is unaffected by software reset.

Diagram

36.5.1.18 Compensation (COMPEN)

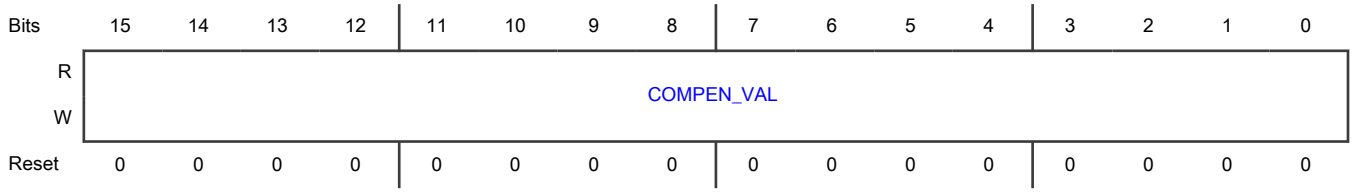
Offset

Register	Offset
COMPEN	28h

Function

Stores the compensation value to be used by the compensation block to correct the 1 Hz clock.

Diagram



Fields

Field	Function
15-0 COMPEN_VAL	Compensation Value Stores the compensation parameters. The definition of this field is dependent on the setting of CTRL[FINEEN]. If CTRL[FINEEN] = 0: • Compensation or Correction Value (COMPEN[7:0]) — Compensation or correction value is a two's complement value that modifies the 1 Hz clock (during its generation) by either adding or removing RTC oscillator clock cycles. • Compensation Interval (COMPEN[15:8]) — Compensation interval is the duration in seconds over which the correction is applied. This is the time in which the addition or removal of 32.768 kHz clock cycles occurs, thereby ensuring that the compensation interval is close to the interval obtained with an ideal 1 Hz clock. If CTRL[FINEEN] = 1 • Integral Compensation Value (COMPEN[15:12]) — This is a two's complement value of the integer part of correction or compensation value that has to be adjusted in every 1 second period. This value is expressed in terms of number of clock cycles of the RTC oscillator clock. • COMPEN[11:7] — Should be zero • Fraction Compensation Value (COMPEN[6:0]) — This is the fractional part of the correction or compensation value that has to be adjusted. This value is expressed as number of clock cycles of a fixed IRC_CLK. This value is always a positive number.

36.5.2 RTC register descriptions

These registers are read only in the target RTC and read the values from the controller RTC registers: YEARMON, DAYS, HOURMIN, SECONDS, DST_HOUR, DST_MONTH, DST_DAY, and COMPEN.

NOTE

Use valid dates to configure registers. For example, do not configure a value like February 30, 2024, because there is no 30th in February 2024.

36.5.2.1 RTC memory map

RTC1 base address: 4006_9000h

36.5.2.2 Year and Month Counters (YEARMON)

Offset

Register	Offset
YEARMON	0h

Function

The function of YEARMON on the target RTC is the same as on the controller RTC YEARMON register, from where the value of this register is directly read.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	YROFST								0				MON_CNT			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Fields

Field	Function
15-8 YROFST	Year Offset Count Value Indicates the offset in years from the base year (hard coded as 2112) and does not show the actual year value. This is a signed value. Valid values are -128 to 127. The base year is 2112 and if the value of YEAR field is 0x10, the actual year is 2112 + 16 = 2128.
7-4 —	Reserved
3-0 MON_CNT	Month Counter Provides the value of the Months Counter. Valid Values are: 0000b,1101b,1110b,1111b - Illegal Value 0001b - January 0010b - February 0011b - March 0100b - April 0101b - May 0110b - June 0111b - July 1000b - August 1001b - September 1010b - October 1011b - November 1100b - December

36.5.2.3 Days and Day-of-Week Counters (DAYS)

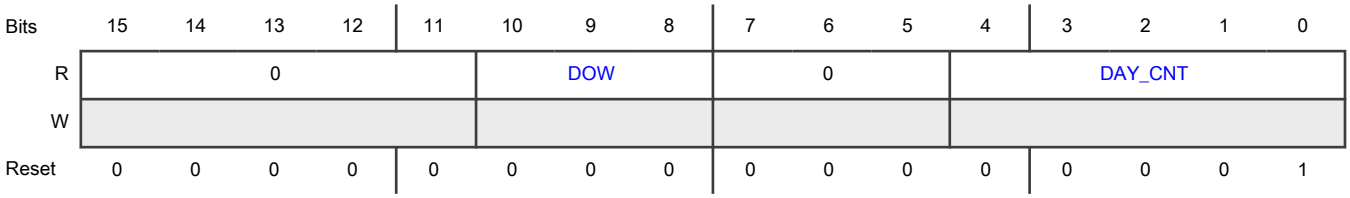
Offset

Register	Offset
DAYS	2h

Function

The function of DAYS on the target RTC is the same as on the controller DAYS register, from where the value of this register is directly read.

Diagram



Fields

Field	Function
15-11 —	Reserved
10-8 DOW	Day of Week Counter Value 000b - Sunday 001b - Monday 010b - Tuesday 011b - Wednesday 100b - Thursday 101b - Friday 110b - Saturday 111b - Reserved
7-5 —	Reserved
4-0 DAY_CNT	Days Counter Value Valid values are 1 to 31.

36.5.2.4 Hours and Minutes Counters (HOURMIN)

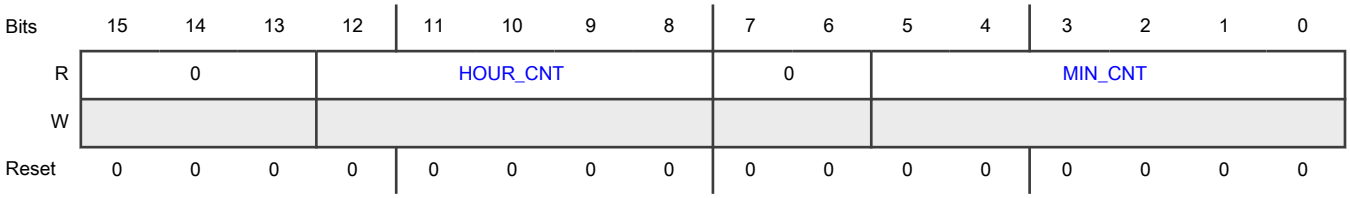
Offset

Register	Offset
HOURMIN	4h

Function

The function of HOURMIN on the target RTC is the same as on the controller RTC HOURMIN register, from where the value of this register is directly read.

Diagram



Fields

Field	Function
15-13 —	Reserved
12-8 HOUR_CNT	Hours Counter Value Valid count values are 0 to 23.
7-6 —	Reserved

36.5.2.5 Seconds Counters (SECONDS)

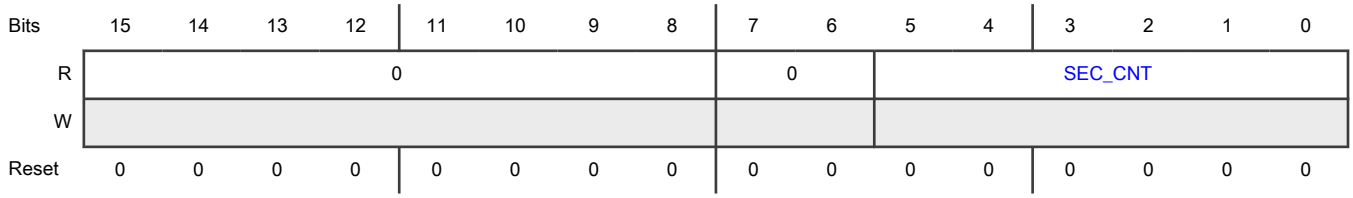
Offset

Register	Offset
SECONDS	6h

Function

The function of SECONDS on the target RTC is the same as on the controller RTC SECONDS register, from where the value of this register is directly read.

Diagram



Fields

Field	Function
15-8 —	Reserved
7-6 —	Reserved
5-0 SEC_CNT	Seconds Counter Value Valid count values are 0 to 59.

36.5.2.6 Year and Months Alarm (ALM_YEARMON)

Offset

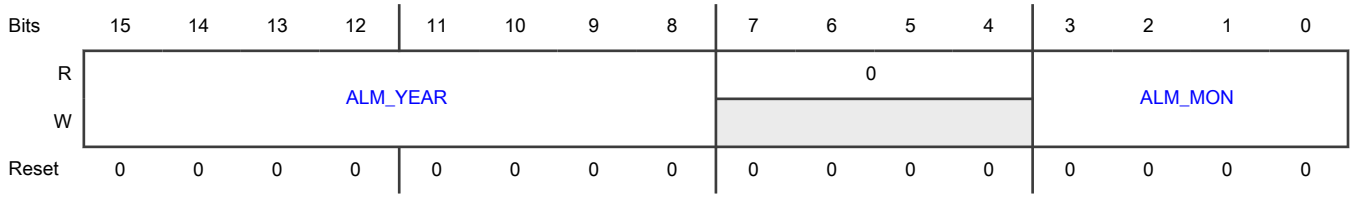
Register	Offset
ALM_YEARMON	8h

Function

Used to configure the months and year setting of the alarm. The alarm setting can be read or written anytime. Alarm interrupt bit is set when all values of alarm seconds, minutes, hours, days, month, and year match their respective counter values. This register is reset to its default state on software reset.

User software can configure the alarm type by using the CTRL[ALM_MATCH].

Diagram



Fields

Field	Function
15-8 ALM_YEAR	Year Value for Alarm Same as years offset value in Year and Month Counters (YEARMON) .
7-4 —	Reserved
3-0 ALM_MON	Months Value for Alarm Same as months counter value in Year and Month Counters (YEARMON).

36.5.2.7 Days Alarm (ALM_DAYS)

Offset

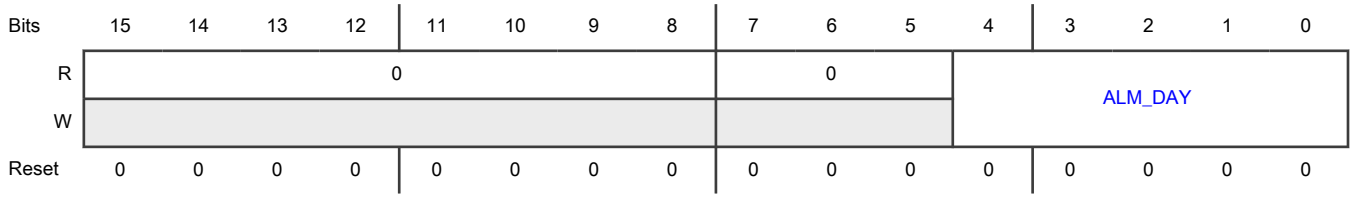
Register	Offset
ALM_DAYS	Ah

Function

Used to configure the day setting of the alarm. The alarm setting can be read or written anytime. Alarm interrupt bit is set when all values of alarm seconds, minutes, hours, days, month, and year match their respective counter values. This register is reset to its default state on software reset.

User software can configure the alarm type using CTRL[ALM_MATCH].

Diagram



Fields

12-8 ALM_HOUR	Hours Value for Alarm Same as hours counter value in Hours and Minutes Counters (HOURMIN) .
7-6 —	Reserved
5-0 ALM_MIN	Minutes Value for Alarm Same as minutes counter value in Hours and Minutes Counters (HOURMIN) .

36.5.2.9 Seconds Alarm (ALM_SECONDS)

Offset

Register	Offset
ALM_SECONDS	Eh

Function

Used to configure the seconds setting of the alarm. The alarm setting can be read or written anytime. This register is reset to default value on software reset.

User software has the option of using bits 9:8 to perform a correction on the seconds counter to compensate for leap seconds. Writing to these bits adds or subtracts 1 from the seconds counter and read returns zeros.

User software should first determine the state of STATUS[INVAL_BIT] to determine if the counters are stable before they can be incremented or decremented. The assertion of STATUS[INVAL_BIT] ensures that no operation is done at the boundary of a second when counters change value.

User software can configure alarm type using CTRL[ALM_MATCH].

14-13	RTC Clock Output Selection Selects which clock to output from SoC for use outside RTC.

Table continues on the next page...

Table continued from the previous page...

Field	Function
CLKOUT	00b - No output clock 01b - Fine 1 Hz clock with both precise edges 10b - 32.768 kHz clock 11b - Coarse 1 Hz clock with both precise edges
12-11 —	Reserved
10 CLKO_DIS	Clock Output Disable Determines whether the selected clock is output to other peripherals. 0b - The selected clock is output to other peripherals. 1b - The selected clock is not output to other peripherals.
9 —	Reserved
8 SWR	Software Reset Self clearing bit. Asserting this field clears the contents of alarm, interrupt (status and enable) registers, STATUS[CMP_DONE], and STATUS[BUS_ERR], and has no effect on DST, calendaring, time registers. 0b - Software Reset cleared 1b - Software Reset asserted
7 —	Reserved
6 —	Value must be zero.
5 —	Reserved
4 —	Reserved
3-2 ALM_MATCH	Alarm Match Defines the type of alarm function. Selects which time and calendar counters are used for matching and will generate an alarm. 00b - Only seconds, minutes, and hours matched. 01b - Only seconds, minutes, hours, and days matched. 10b - Only seconds, minutes, hours, days, and months matched.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	11b - Only seconds, minutes, hours, days, months, and year (offset) matched.
1 —	Value must be zero.
0 —	Value must be zero.

36.5.2.11 Status (STATUS)

Offset

Register	Offset
STATUS	12h

Function

Indicates the status of various processes occurring inside the RTC. Also helps the user software to read time or date register when the values are stable and not changing. Compensation Done bit and Bus Error bit are cleared by writing 1. Software reset resets the whole register to its default state.

All memory mapped registers are protected against spurious updates by the write protect mechanism. To unlock the registers, a specific pattern (as mentioned in the table above) has to be written in the write enable bits (WE[1:0]) to enable or disable write protection. The WE[1:0] bits are the only bits that are freely writeable by user software. The write enable bits are self-clearing bits that always return zeros on read.

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0					0	0	BUS_ERR	0			0	0		WRITE_P...	INVAL_B...
W					0			W1C	WE		0					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
15-12 —	Reserved
11 —	Value must be zero.

Table continues on the next page...

Table continued from the previous page...

Field	Function
10 —	Reserved
9 —	Reserved
8 BUS_ERR	Bus Error Indicates that a read or write cycle was initiated by software when the STATUS[INVAL_BIT] = 1. Write access to time or date registers is nullified (terminate normally) and no register value is changed. Reading when STATUS[INVAL_BIT] is asserted returns 0xFFFF. No transfer error is asserted. This bit is cleared by writing 1. 0b - Read and write accesses are normal. 1b - Read or write accesses occurred when STATUS[INVAL_BIT] was asserted.
7-6 WE	Write Enable Controls entry into and exit from the write protection mode. Both registers are protected by the write protection mechanism. These are self-clearing bits. Reads will return zeros. Disable write protection by writing this sequence: 00b, 01b, 11b, 10b. See Write protection mechanism for more information. **NOTE** When the registers are unlocked, they remain in this unlocked state for a time of 2 seconds, after which they are locked automatically. After power-on reset, the registers are unlocked and then are locked automatically after 15 seconds. 10b - Enable Write Protection - Registers are locked.
5 —	Value must be zero.
4 —	Reserved
3-2 —	Reserved
1 WRITE_PROT_EN	Write Protect Enable Status Indicates that registers are in locked mode and writing to them is disabled. Any write access made to the register space when write protection is enabled (that is, when they are in locked mode) will cause the transfer error signal to be asserted. 0b - Registers are unlocked and can be accessed. 1b - Registers are locked and in read-only mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 INVAL_BIT	Invalidate CPU Read/Write Access Indicates the time and date counters are invalid or changing and therefore should not be read or written to. This bit is asserted for one oscillator clock cycle before and after the 1 Hz (seconds clock) boundary edge. Write access to time and date registers is nullified (terminate normally) and no register value is changed. Reading when STATUS[INVAL_BIT] is asserted returns 0xFFFF. No transfer error is asserted. 0b - Time and date counters can be read or written. Time and date is valid. 1b - Time and date counter values are changing or time and date is invalid and cannot be read or written.

36.5.2.12 Interrupt Status (ISR)

Offset

Register	Offset
ISR	14h

Function

NOTE

For the sampling timer interrupt status bits [14:6], see the chip configuration chapter for the applicable sampling timer frequencies.

Indicates the status of the various real-time clock interrupts. When an event of the types included in this register occurs, the bit will be set in this register regardless of the status of its corresponding interrupt enable bit. The status bits and interrupts are cleared by writing a value of 1. Interrupts may occur when the system clock is idle or in Standby mode. When the system enters the active power mode, an interrupt is indicated to the CPU. The first event of the Sampling Timer interrupts after power-on reset should not be used to qualify any periodic interval. However, the correct periodic interval (that is, 512 Hz or 256 Hz, and so on) should be determined using two sampling timer interrupts. The time between two interrupts should always be the correct time period.

This register is cleared on software reset.

NOTE

Sampling interrupts from 512 Hz to 2 Hz are generated using uncompensated clock. Only 1 Hz is compensated.

1 —	Reserved
0 —	Reserved

36.5.2.13 Interrupt Enable (IER)

Offset

Register	Offset
IER	16h

Function

NOTE

For the sampling timer interrupt enable bits [14:6], see the chip configuration chapter for the applicable sampling timer frequencies.

Enables and disables the various real-time clock interrupts. De-asserting an interrupt enable bit has no effect on the assertion of its corresponding status bit.

Alarm interrupt is asserted on counters matching the alarm setting done in the memory map. The counters matched for the alarm interrupt are selected based on the alarm type set in CTRL[3:2]. The various types of alarms available are shown in the following table. Only one alarm type can be used at a time.

Table 285. Alarm Match Table

ALM_MATCH[1:0] (CTRL[3:2])	Counters Matched	Alarm Type
00	Seconds, Minutes, and Hours	Daily
01	Seconds, Minutes, Hours, and Days	Monthly
10	Seconds, Minutes, Hours, Days, and Months	Yearly
11	Seconds, Minutes, Hours, Days, Months, and Year	One Time

RTC generates a common interrupt. The user software should read the status register in the interrupt service routine to determine which interrupt has occurred.

37.1.2 PVTS fuse programming

The appropriate PVTS delay values to use for a given device are programmed to fuses during chip manufacturing. The appropriate fuse value corresponding to the selected system configuration should be read from fuses and is then used to write the appropriate DEL_CTRLn register.

Table 288. PVTS fuses for RT700

Fuse word index	Fuse word name	Functions
482	SENSE_PVT_SP3	250 MHz PVTS delay values, HiFi1[15:8], CPU1[7:0]
483	COM_PVT_SP3	325 MHz PVTS delay values, HiFi4[15:8], CPU0[7:0]
484	SENSE_PVT_SP2	160 MHz PVTS delay values, HiFi1[15:8], CPU1[7:0]
485	COM_PVT_SP2	192 MHz PVTS delay values, HiFi4[15:8], CPU0[7:0]
486	SENSE_PVT_SP1	100 MHz PVTS delay values, HiFi1[15:8], CPU1[7:0]
487	COM_PVT_SP1	110 MHz PVTS delay values, HiFi4[15:8], CPU0[7:0]

37.1.3 Optimizing PVTS delay with temperature

The PVTS delay value retrieved from fuses is a safe value that works for the whole temperature range. To achieve greater power savings at warmer temperatures between 30 °C and 85 °C, you can subtract the PVTS temperature deviation shown in the table below from the delay value in the fuses before programming it to the PVTS sensor.

Table 289. PVTS temperature deviation

Domain	Typical voltage (V)	Frequency (MHz)	PVTS temperature deviation	
			-30 °C - 30 °C	30 °C - 85 °C
Compute (CPU0, HiFi4)	1.1	325	0	1
	0.9	192	0	1
	0.8	60	0	1
Sense (CPU1, HiFi1)	1.1	250	0	0
	0.9	160	0	0
	0.8	60	0	1

Updating the PVTS delay with this additional optimization requires that the application monitors the temperature. Some applications may find that monitoring the temperature and changing the PVTS delay is not worth doing. Those applications can use the fixed PVTS delay value with no optimization.

37.2 Overview

The PVTS is a peripheral that monitors the timing margin of one or more main_clk signals within a given power domain at runtime. Refer to the chip-specific section for details on which clocks are monitored. While using the PVTS, the minimum voltage for the domain can potentially be decreased below the normal datasheet specification. PVTS triggers an interrupt when this timing margin is not met, which indicates the power rail voltage for the domain must be increased to meet the required timing.

The PVTS helps reduce voltage and power in active modes, including the Sleep mode. The PVTS is not intended for use in low power modes.

37.2.1 Block diagram

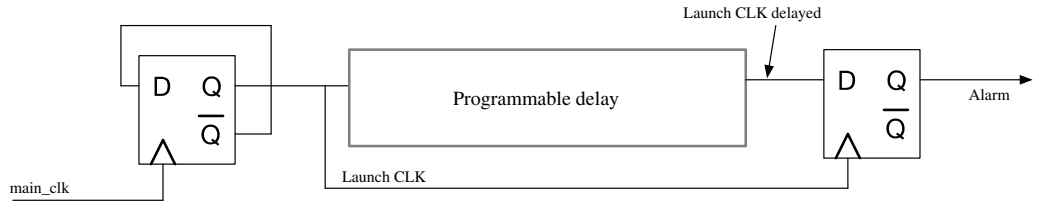

Figure 111. Block diagram

37.2.2 Features

PVTS features:

- Provides 2 sets of sensors to monitor 2 CPUs in the same power domain.
- Each sensor supports up to 62 delay cycles.

37.3 Functional description

37.3.1 PVTS theory of operation

The internal timing of a semiconductor is dependent on the process, voltage, and temperature (PVT) variation. The datasheet specifies the minimum voltage requirements for given operating conditions; however, the datasheet minimum voltage is set to guarantee operation of all devices with a wide range of PVT variations and cover worst case conditions. Most devices and conditions are actually capable of running below the specified minimum voltage.

The PVTS module allows for monitoring unique device frequency behavior taking frequency changes into account to find the actual ideal minimum voltage. This allows for running the device below the specified minimum voltage for given operating conditions and thereby optimizing the power consumption.

37.3.2 Monitor timing margin

The PVTS monitors the timing margin of main_clk using a delay line, see Figure 111. main_clk is divided by 2 and generates the Launch CLK. The Launch CLK is compared to a delayed version of itself. This delay is programmable and must be set to a value that correlates to the speed of that unique device based on process corners for the N-channel and P-channel MOSFETs. There are three primary corners: typical, fast, and slow. With this naming convention each device is described as typical-typical (TT), fast-fast (FF), slow-slow (SS). The timing comparison is done through a flip-flop that uses Launch CLK to clock the delayed version of itself. If the added delay is too long, the flip-flop output is high, indicating a timing issue and triggering an alarm.

For the PVTS to properly monitor the main_clk timing, the delay line must be programmed with a delay that matches the worst-case timing path of the logic clocked by main_clk. See chip-specific section for information on finding the value to program the correct delay value. Once programmed with this delay, the PVTS emulates this worst-case timing path in the domain logic. This delay tracks the actual timing required by this unique device across temperature and voltage variations. As the voltage decreases or as the temperature gets colder, the delayed Launch CLK has a longer delay. When the alarm signal triggers, the application increases the domain voltage, which increases the performance of the logic, which decreases the delay on Launch CLK.

Figure 112 shows the timing of the PVT Delay Line. The status of delayed Launch CLK is sampled on every rising edge of Launch CLK. When operating above the minimum voltage needed for that device and current temperature, the delay is short and the delayed Launch CLK is low at rising edge of Launch CLK, so the alarm output remains low. However, when the domain voltage is too low for current conditions, the delay is long enough that the delayed Launch CLK is still high at the rising edge of Launch CLK. The alarm output is high, triggering an interrupt to indicate that higher domain voltage is needed to reduce the timing delay.

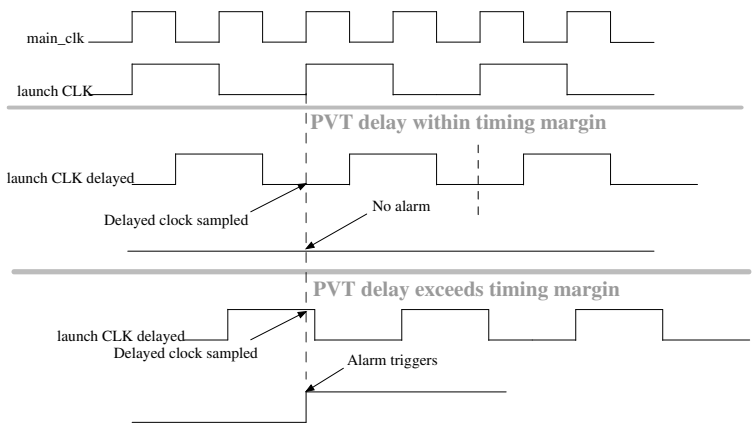

Figure 112. PVT delay line timing with alarm trigger

37.3.3 PVTS considerations with low-power modes

Because PVTS cannot monitor the timing in modes where the main_clk is not running, care must be taken when using PVTS in combination with low-power modes.

Consider a situation where the device is using PVTS and is running at a reduced voltage and then enters a low power mode that disables PVTS. If the device is in the low-power mode for an extended time the temperature could decrease. Now, when the device wakes up, the PVTS reduced voltage might be too low for operation at the new temperature. The PVTS will trigger the alarm after the wakeup, but at the lower voltage the device might not be running properly or capable of requesting the higher voltage.

To avoid conditions like those described above, the recommendation is to ensure that on low-power wakeup the system will always return to the normal minimum voltage specified in data sheet. Depending on the specifics of the power system, this might require raising the voltage before entering the low-power mode. After the device wakes up at the safe voltage, the PVTS can resume monitoring and the voltage can be reduced to the optimal level again.

NOTE

Low-power modes that wake through a reset should return the device to reset/start-up voltage conditions. This should already be accounted for in the system power design/configuration, and therefore special consideration of PVTS before entering these modes is not typically required.

37.3.4 Requirements for using PVTS

Proper usage of the PVTS allows an application to operate the voltage below the data sheet minimum specification. It can lead to issues or faults in the application if the following requirements are not met:

- The minimum voltage required is not always limited by the frequency of the main_clk. The data sheet may also have restrictions on voltage for specific peripherals, features, or use-cases of the MCU. The PVT Sensor is not designed to monitor voltage for other data sheet restrictions. Refer to the device datasheet for other requirements.

  If there are multiple minimum voltage requirements in the datasheet that apply, the highest minimum must be used, regardless of what the PVTS reports. For example, reading OTP fuses might have a minimum voltage specification that should be used. This is important to keep in mind when reading the PVTS delay values from fuses (refer to chip-specific section for details on fuses that store PVTS delay values).

- There are also requirements for interrupts in an application using PVTS. When a higher voltage is required, the PVTS triggers an alarm interrupt, but it is the application that must request the higher voltage from the PMIC. Therefore, best practices must be used to manage interrupts. The PVTS IRQ must be serviced quickly without much latency, and it must not be blocked for long.

- The settling time for the voltage power rail must also be taken into account. Any time the application is using PVTS and reduces the voltage, it must wait long enough for the PMIC to change the voltage, and the supply rail to settle to the new voltage. The exact delay can depend on the board design, like the PMIC/regulator driving the voltage and the capacitance on

this supply rail. If the application drops the voltage too quickly before it has settled, PVTS may not be able to detect a timing issue before the voltage is dropped again, which can lead to a fault occurring.

37.3.5 Clocking

Table 290. PVTS clocks

Clock	Description
peripheral_clk	Used to write and read registers of this module.
main_clk0 main_clk1	CPU clocks the PVTS monitors.

See chip-specific section for more information.

37.3.6 Interrupts

PVTS can trigger the following interrupts, see chip-specific information for more details:

- PVTS interrupt 0
- PVTS interrupt 1

NOTE

These interrupts are always enabled.

37.4 Application information

When the application enables the PVTS, the first goal is to find the lowest voltage for the current conditions. The PVTS alarm indicates when higher voltage is required, but PVTS does not give any indication of when voltage can be further reduced. The application can test lower voltages using this procedure. See Figure 113 for an example of this reduction method.

1. Reduce the voltage by one voltage step
2. Wait for the voltage to settle
3. If no PVTS interrupt is triggered, go back to #1.
4. If PVTS interrupt is triggered, then increase the voltage by one voltage step. This is the optimal/lowest voltage for the current configuration and conditions.

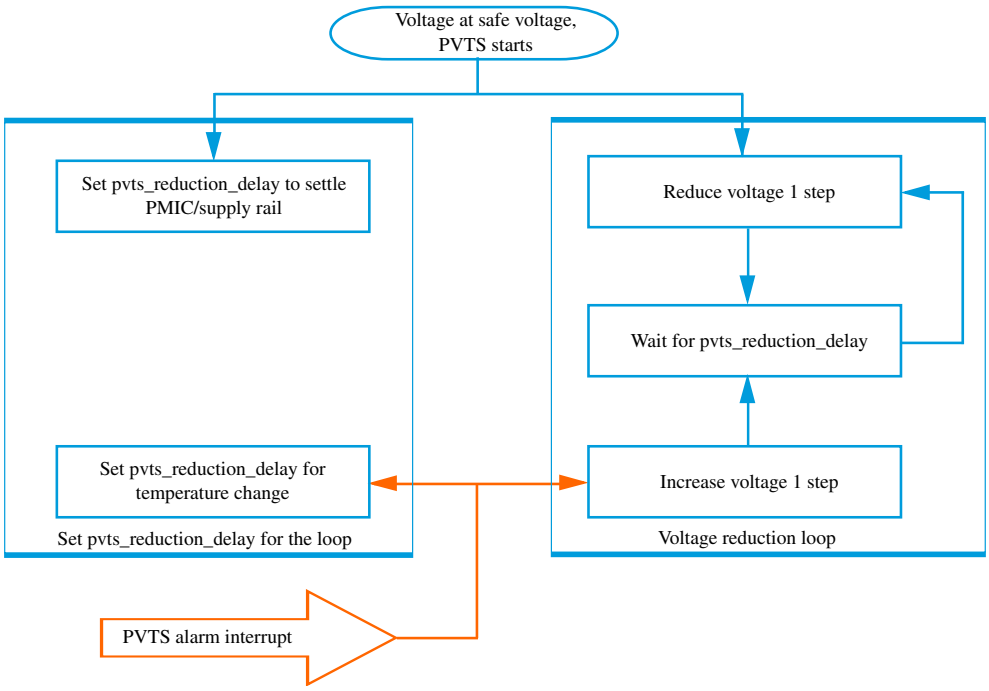

Figure 113. Voltage reduction flowchart with PVTS

NOTE

There may be additional voltage constraints that prevent decreasing the voltage to the point where the PVTS interrupt is triggered. See Requirements for using PVTS.

NOTE

The total wait time for steps one and two should take into account the total time needed to request the voltage decrease, and then for the voltage to settle at the requested value. If an external PMIC is used, then time to control the PMIC should be taken into account.

The next stage for the application is to wait for PVTS alarms indicating the voltage needs to be increased, and also check if the temperature has changed enough that a lower voltage is now acceptable. This can be done by periodically reducing the voltage.

Figure 114 shows an example of voltage dynamically changing as temperature changes. This chart is an example where the minimum voltage specification in the datasheet for the frequency used is 900 mV. This graph starts where the voltage has already been reduced to 850 mV using the procedure for finding the lowest voltage described above and is operating at 25 ℃. In this example, the voltage source has a 25 mV voltage step. While the temperature drops, the PVTS Delay Line gets slower, and at some point the PVTS alarm triggers. The application requests the voltage to increase one step to 875 mV. The temperature continues to drop, so another PVTS alarm triggers, and the voltage is increased to 900 mV. The application tests periodically (for example, every 10 seconds) if a reduced voltage is acceptable, by reducing the voltage one step. Typically, reducing the voltage one step immediately triggers the PVTS interrupt, and the voltage is increased one step back to the previous level. As the temperature warms, at some point the reduced voltage test does not trigger an alarm, and PVTS allows the voltage to reduce one step to 875 mV. As the temperature continues to warm, this example eventually drops down to 800 mV. Then as the temperature then cools back to 25 ℃, PVTS triggers its alarm that voltage must be increased, the voltage is returned to 850 mV.

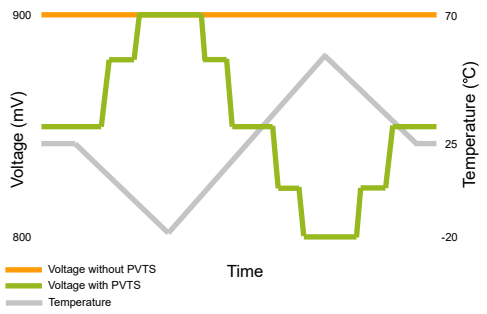

Figure 114. Dynamic voltage at runtime

37.5 Memory map and registers

37.5.1 PVTS register descriptions

37.5.1.1 PVTS memory map

PVTS0 base address: 4000_5000h

PVTS1 base address: 4004_3000h

38.1.3 ADC voltage reference options

The ADC voltage reference options:

- CFG[REFSEL]=00b, VREFH reference pin. If an external reference voltage is not available, the on chip VREF_OUT can be used instead
- CFG[REFSEL]=01b or 10b, VDDA_ADC_1P8 supply pin
- CFG[REFSEL]=11b, reserved

38.1.4 ADC trigger inputs

ADC trigger sources get routed through the Input Multiplexing (INPUTMUX). See ADC0_TRIG0 - ADC0_TRIG1 of INPUTMUX1 in INPUTMUX chapter for available trigger sources.

38.1.5 ADC supply and ground connections

V_{SSA} and V_{REFL} is tied to common ground VSSA_0 in package.

38.2 Overview

The 16-bit ADC is a dual successive approximation converter designed for operation within an integrated microcontroller chip.

NOTE

For the chip-specific modes of operation, see the power management information of the chip.

38.2.1 Block diagram

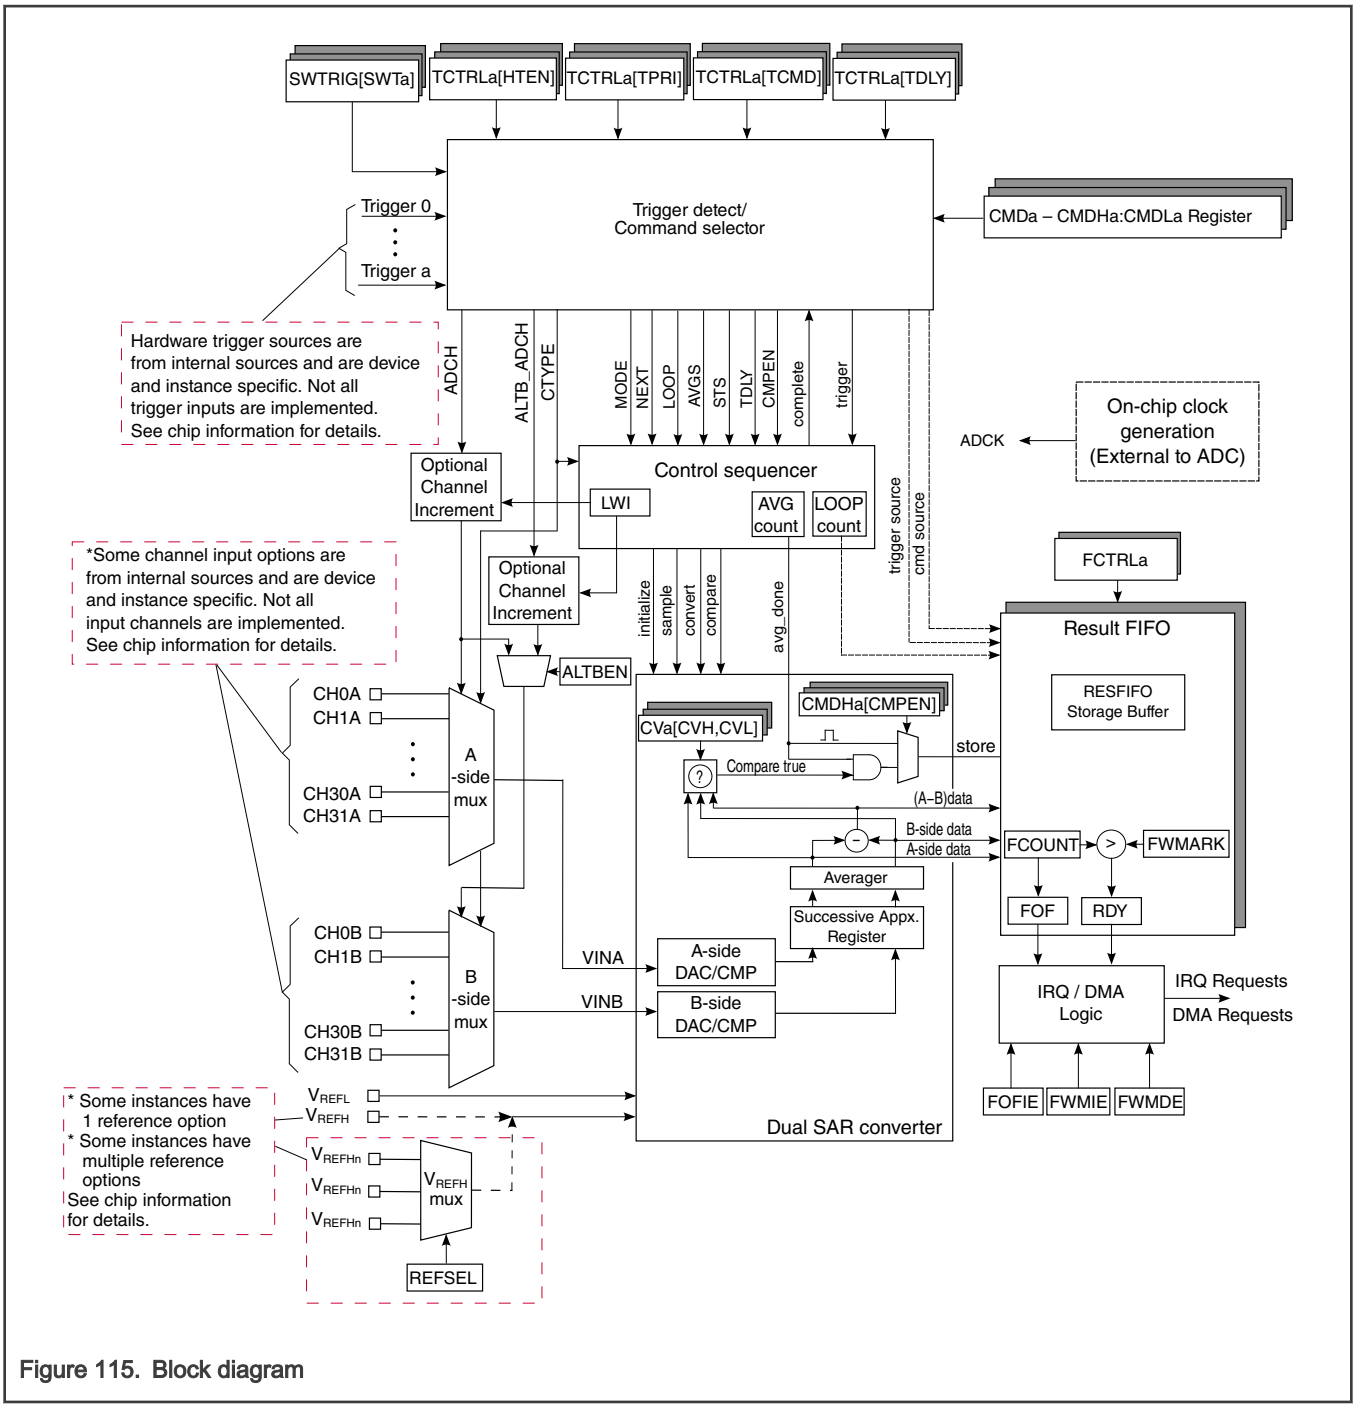

Figure 115. Block diagram

38.2.2 Features

- Linear successive approximation algorithm:
  - Differential operation with 16-bit or 13-bit resolution
  - Single-ended operation with 16-bit or 12-bit resolution
  - One ADC supports two simultaneous single-ended conversions
- Configurable analog input sample time

- Configurable speed options to accommodate operations in low-power modes
- Trigger detection with up to 2 trigger sources with priority-level configuration (with a software or hardware trigger option for each)
- Independent option selection and channel sequence scanning with 15 command buffers
- "Store on true" and "repeat until true" options for automatic compare of less-than, greater-than, within range, or out-of-range detection
- 2 independent result FIFOs, each containing 16 entries (each having a configurable watermark and overflow detection)
- Interrupt, DMA, or polled operations
- Linearity and gain adjustment calibration logic

38.3 Functional description

ADC performs analog-to-digital conversions on any of the software-selectable analog input channels through a successive approximation algorithm. ADC initializes to its lowest power state during reset. The ADC analog circuits can optionally be pre-enabled for faster conversions at the expense of higher idle currents. Selectable trigger events from software or hardware sources initiate the conversion. The trigger detect logic includes a configurable enable and priority scheme for the available trigger sources. ADC has multiple command buffers that provide configurable flexibility for channel scanning and independent channel selections for different trigger sources. Multiple command buffers also allow variable option selection such as differential vs. single-ended, sample time and averaging on a per-channel basis.

ADC optionally averages the result of multiple conversions on a channel before storing the calculated result. The hardware-average function is enabled by writing a nonzero value to CMDH*n*[AVGS] and operates in any of the conversion modes and configurations.

After the conversion and averaging loops are completed, the resulting data is placed in one of the 2 available FIFO data buffers along with other tag information associated with the result. A configurable watermark level supports interrupt or DMA requests when the number of stored data words exceeds the setting. You can also enable interrupts to indicate the occurrence of FIFO overflow.

ADC optionally compares the result of conversion with the contents of two value registers for less-than, greater-than, inside-range, or outside-range detection. The compare function operates in any of the conversion modes and configurations.

ADC also includes a hardware calibration logic to correct offset, gain, and linearity errors. You must execute calibration steps after every reset or power-up operation. Each SAR conversion utilizes calibration data calculated during the calibration routine.

The following flow diagram summarizes the sequencing of an ADC command.

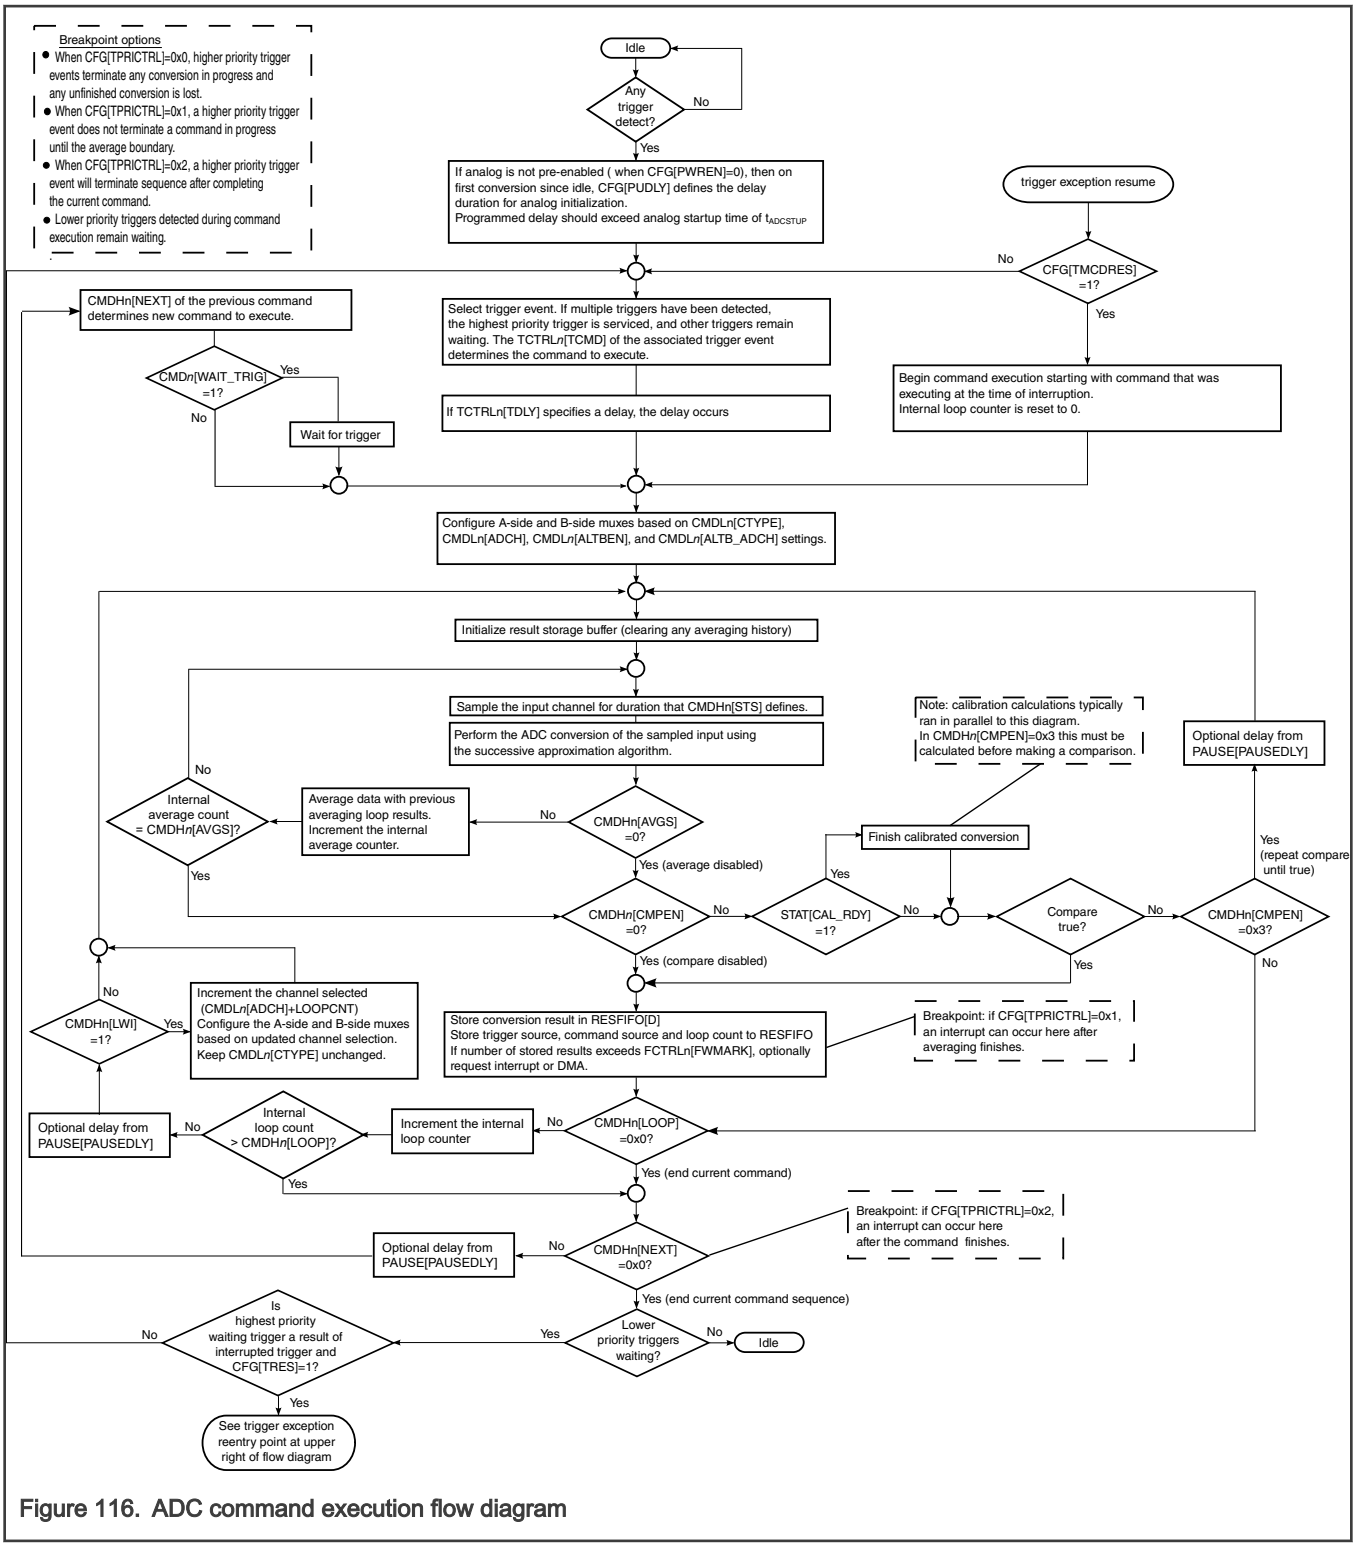

Figure 116. ADC command execution flow diagram

38.3.1 Power control mode

When ADC is in its idle state, the default setting for the ADC analog circuits is disabled. When a trigger is detected and ADC command processing is initiated, the analog circuits are enabled and require a period of initialization before the first conversion cycle. You must program CFG[PUDLY] in a way that a delay duration longer than $t_{ADCSTUP}$ is incurred. The accuracy of the initial conversion(s) after activation is degraded when CFG[PUDLY] is set to too small a value.

You can achieve faster conversion startup times by optionally writing 1 to CFG[PWREN], to pre-enable the analog circuits of ADC at the expense of power consumption even when ADC remains in the idle state. When CFG[PWREN] = 1, the power enable timer is activated and enforces the minimum startup (controlled by CFG[PUDLY]) before detected triggers are allowed to initiate ADC conversions.

38.3.2 Behavior in low-power modes

ADC supports system-level, low-power modes. In these modes, where ADC can remain functional, CTRL[DOZEN] controls the ADC behavior.

When CTRL[DOZEN] = 0, if you configure and enable ADC before Low-Power mode entry, ADC continues to operate while the system transitions to Low-Power mode. ADC does not disrupt any conversion in progress. External hardware trigger detection and active conversion are operational.

When CTRL[DOZEN] = 1, ADC waits for the current averaging iteration or FIFO storage to complete before acknowledging low-power entry requests. After the system enters Low-Power mode, ADC remains in an inactive state until the system exits the mode.

When entering a low-power mode where ADC cannot remain functional, it ignores CTRL[DOZEN]. ADC waits for the current average iteration or FIFO storage to complete before acknowledging a low-power entry request. After the system enters Low-Power mode, ADC remains inactive until the system exits this mode. The configuration of CFG[PWREN] is ignored and the ADC analog is forced to its lowest power state. After wake-up from Low-Power mode, if you preenable the analog before it enters Stop mode (CFG[PWREN] = 1) and the control registers retain the state in Low-Power mode, the analog is automatically reenabled and the power up delay timer begins. Any triggered conversion is stalled until the power-up delay associated with CFG[PUDLY] is complete.

38.3.3 Voltage reference

ADC uses the voltage reference high (V_{REFH}) that is supplied from either an on-chip voltage reference source or from an off-chip source through external pins. V_{REFL} is always from an external pin and must be at the same voltage potential as V_{SSA}. See the chip configuration information on the voltage reference options specific to this packaged device.

ADC supports a programmable selection of the voltage reference used for conversions (through CFG[REFSEL]). See the chip configuration information related to voltage reference options specific to this packaged device.

38.3.4 Trigger detect and command execution

See Figure 116 for a flow diagram of command execution sequencing.

ADC command execution is initiated from up to 2 trigger sources. You can generate each trigger by writing 1 to the corresponding SWTRIG[SWT*n*]. Alternatively, hardware triggers can be generated from asynchronous input sources at the periphery of the module. The number and sources of hardware triggers implemented is chip-specific (see the chip-specific ADC information for a description of available hardware trigger sources on this chip).

Writing 1 to the associated TCTRL*n*[HTEN] enables the hardware trigger source. Each trigger source is assigned a priority through the associated priority control field (TCTRL*n*[TPRI]), and each of the trigger sources is linked to a command buffer through the associated command select field (TCTRL*n*[TCMD]).

When you enable the hardware trigger input, it detects hardware trigger events on the rising-edge of the associated hardware trigger source.

Each trigger source has an associated priority field (TCTRL*n*[TPRI]) that allows arbitration between trigger sources. Arbitration controls the selection of the trigger sequence to execute next and how to handle a trigger exception. Trigger exceptions are defined as allowing a higher priority trigger sequence to interrupt operations of a lower-priority sequence. When a trigger exception occurs, programmable arbitration allows the configurable stop and resume points for low-priority sequences. The fields affecting arbitration are CFG[HPT_EXDI], CFG[TCMDRES], CFG[TRES], and CFG[TPRICTRL]:

- When CFG[HPT_EXDI] = 1b, trigger exceptions are disabled and any higher priority triggers are left pending until the current sequence completes.

NOTE

New triggers are accepted based on priority.

- When CFG[HPT_EXDI] = 0b (default), exceptions are enabled and the higher priority sequence begins executing at a breakpoint that you specify.

CFG[TPRICTRL] determines breakpoint locations, and CFG[TPRICTRL] affects latency for accepting a trigger exception:

- When CFG[TPRICTRL] = 0h, a higher priority trigger causes an immediate command abort and the new command specified by the trigger is immediately started.
- When CFG[TPRICTRL] = 1h, the current conversion is allowed to complete (including averaging) before the higher priority exception is initiated. In this mode, if the command is running through a series of averages, this series completes. However, it is not required to finish the entire command before interruption. For example, if the command consists of four loop iterations, it is not required to complete all four iterations before the interrupt occurs.
- When CFG[TPRICTRL] = 2h, a higher priority trigger begins on completion of the current command. If a command consists of five loop iterations, each containing eight averages, then all 5×8 conversions must complete before accepting the trigger exception.

CFG[TCMDRES] and CFG[TRES] determine what ADC does after accepting a trigger exception. You can program ADC to resume commands after returning from a trigger exception:

- If CFG[TRES] = 0h, commands do not resume automatically after stopped by an exception. However, an interrupt is set to indicate this case has occurred. TSTAT[TEXC_NUM] is used to resolve the trigger that was stopped by an exception.
- If CFG[TRES] = 1h, ADC automatically resumes commands after being stopped by an exception.

By utilizing CFG[TRES] in conjunction with CFG[TCMDRES], you can program ADC to resume commands at one of the two possible locations:

- If CFG[TCMDRES] = 0h, then the trigger that was stopped by an exception is resumed from the beginning of its associated command sequence.

NOTE

Triggers waiting to be resumed take the same priority as TCTRL*n*[TPRI].

- If CFG[TCMDRES] = 1h, then the trigger resumes from the command that it was executing before being interrupted by an exception.

If a lower-priority trigger occurs (that is, a trigger event occurs that is configured for a lower-priority than the trigger source associated with the currently executing command), the trigger detect is left pending until the current command sequence is completed. ADC cannot service lower-priority trigger events until a higher-priority triggered command (or command sequence) completes.

After a conversion is complete (including hardware averaging when CMDH*n*[AVGS] is a nonzero value), ADC places the result in a RESFIFO buffer. When an ADC command selects looping (CMDH*n*[LOOP] is a nonzero value), a command stores multiple conversion results to the FIFO during execution of that command.

At the end of command execution, CMDH*n*[NEXT] selects the next command to be executed. You can execute multiple commands sequentially by configuring each command's CMDH*n*[NEXT]. Writing 0 to CMDH*n*[NEXT] terminates conversions at the completion of the current command. ADC allows unending circular command execution when you write 1 to CMDH*n*[NEXT], in the last command in a sequence to the first command in the sequence.

By default, the command sequence executes automatically in the order you program CMDH*n*[NEXT]. However, you can stall and launch the command execution utilizing CMDH*n*[WAIT_TRIG] based on trigger inputs. For example, if you program TRIGGER2 to start the command sequence CMD1, CMD2, CMD3, then receiving TRIGGER2 one time unconditionally runs this sequence to completion. If you write 1 to CMDH2[WAIT_TRIG], then the sequence pauses after CMD1 until TRIGGER2 is received again. Therefore, sequences can be stalled until receiving a trigger assertion.

Disabling ADC by writing 0 to CTRL[ADCEN] terminates any active ADC command processing. Writing 0 to CTRL[ADCEN] causes the current command (or command sequence) to terminate, clears any pending triggers, and sends ADC to an idle state.

38.3.5 Pause option

If an application does not require maximum conversion rate, you can reduce the effective conversion rate by:

- Implementing periodic trigger events to initiate ADC conversions.
- Selecting a reduced frequency clock as the ADACK source.

Both options are chip-specific and depend on ADC triggering and clocking options external to ADC. The latency associated with ADC analog power-up delay results in a limit on the maximum conversion rate when using periodic triggering.

Another means of reducing conversion rates is by inserting a pause of a programmable duration between LOOP iterations, between commands in a sequence, and between conversions when a command is executing in the "compare until true" configuration. When PAUSE[PAUSEEN] = 1, PAUSE[PAUSEDLY] controls the pause duration during command execution sequencing. The pause delay is a count of (PAUSE[PAUSEDLY] × 4) ADCK cycles.

NOTE

You must not write to Pause (PAUSE) when CTRL[ADCEN] = 1. This can lead to a metastable operation.

See Figure 116 for the places where the pause is optionally inserted during command execution sequencing.

38.3.6 Resynchronization functionality

You can configure any software or hardware trigger source to act as a resynchronization trigger. You can use the trigger-based resynchronization functionality to interrupt a running trigger (resynchronization target) and clear the FIFO it's writing to. This can either be used to abort a running sequence, or restart a running sequence depending on the configuration of CFG[TRES].

If CFG[TRES] = 1, the target sequence is aborted and the FIFO is cleared after the resynchronization occurs. The sequence restarts after resynchronization occurs. If CFG[TRES] = 0, it aborts the target sequence and FIFO is cleared after the resynchronization occurs.

NOTE

The FIFO(s) cleared depend on the resynchronization targets TCTRL*m*[FIFO_SEL_A] and TCTRL*m*[FIFO_SEL_B]. To only clear one FIFO, TCTRL*m*[FIFO_SEL_A] == TCTRL*m*[FIFO_SEL_B]. Results not associated with the resynchronization target are lost if they are stored in either TCTRL*m*[FIFO_SEL_A] or TCTRL*m*[FIFO_SEL_B] at the time of resynchronization.

The resynchronization trigger must have a specific target. Resynchronization occurs only if the resynchronization target is running at the time of the trigger. For the following description, assume that *n* is the resynchronization trigger number and *m* is the resynchronization target number. According to these variables, trigger *n* must resynchronize trigger *m*. To enable a trigger source to act as a resynchronization trigger, the following conditions must be applied:

- TCTRL*n*[RSYNC] must be 1.
- The resynchronization trigger must have a higher priority than the resynchronization target (TCTRL*n*[TPRI] must be less than TCTRL*m*[TPRI]).
- The resynchronization target is specified by using TCTRL*n*[TCMD]. In this case, the resynchronization target, *m*, must be equal to TCTRL*n*[TCMD].
- The resynchronization target, *m*, must be executing commands when the resynchronization trigger, *n*, is asserted.
- Trigger *m* must have at least one conversion left to begin when trigger *n* is received.

If a trigger source *n* has TCTRL*n*[RSYNC] = 1, but some of the aforesaid conditions are not fulfilled, then the trigger source *n* is ignored.

Figure 117 illustrates a resynchronization trigger sequence executing. According to this figure:

- Trigger source 0 executes a sequence of commands when you assert trigger source 1.
- Trigger source 1 is configured to resynchronize trigger source 0.

- Trigger source 0 stops when trigger source 1 is asserted (after some synchronization delay). In addition, the FIFO that trigger source 0 writes to is cleared (FIFO0 in this example).

After the trigger 0 sequence stops, ADC runs the next trigger pending with the highest priority. This is marked as NXT for the next trigger. If you enable the resume functionality, and trigger source 0 has the highest priority pending, then NXT = 0h.

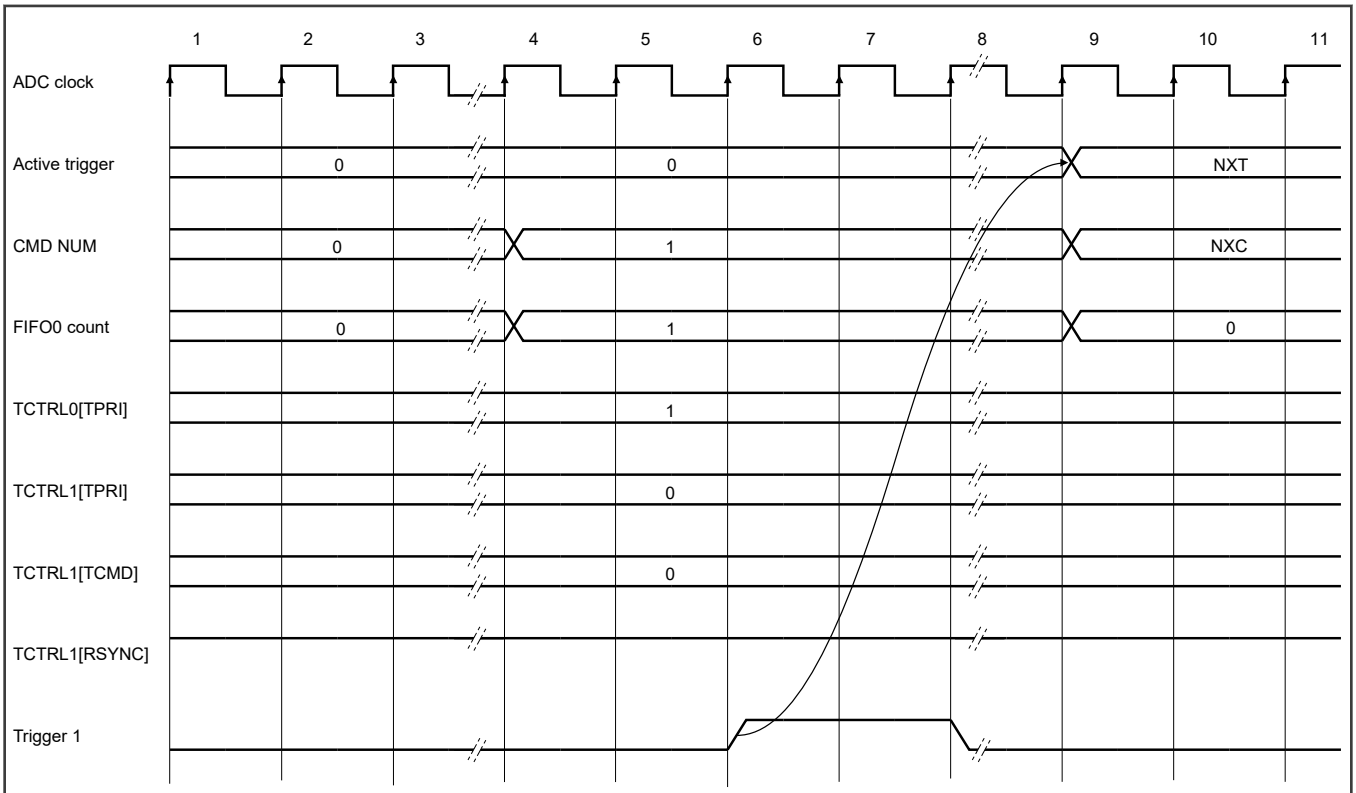

Figure 117. ADC resynchronization example

38.3.7 Temperature sensor

ADC has a dedicated input channel for an on-chip temperature sensor. See the chip-specific channel definition to determine which channel is connected to the on-chip temperature sensor.

To calculate the temperature, you must first execute a conversion of the temperature sensor channel with some configuration requirements. See the chip-specific channel definition to determine which channel corresponds to the temperature sensor. Perform the following procedure to convert the temperature sensor channel:

1. Configure a command buffer register to convert the temperature sensor channel. CMDL*n*[ADCH] = temperature sensor channel.
2. Program the command buffer with the following parameters:
   - 16-bit mode (CMDL*n*[MODE] = 1h)
   - Differential (CMDL*n*[CTYPE] = 2h)
   - Max averaging (CMDH*n*[AVGS] = Ah)
   - Max sample time (CMDH*n*[STS] = 7h)
   - LOOP set to 1 (CMDH*n*[LOOP] = 1h)
   - Loop with increment disabled (CMDH*n*[LWI] = 0h)
   - Compare function disabled (CMDH*n*[CMPEN] = 0h)

3. Configure Trigger Control (TCTRL0 - TCTRL1) with the following parameters:
   - TCTRL*n*[TCMD] = command buffer used in steps 2 and 3
   - TCTRL*n*[FIFO_SEL_A] directs conversion results to FIFO0 or FIFO1
4. Write 1 to the associated field in Software Trigger (SWTRIG) to trigger a conversion of the temperature sensor channel.

After conversion of the temperature sensor channel is complete, two results are stored in the FIFO selected with TCTRL*n*[FIFO_SEL_A]. Each result corresponds to a component of the overall temperature value. Read these values from the FIFO and use the following equation to calculate the ambient temperature.

$$Temp = A \times [\frac{\alpha \times (Vbe8 - Vbe1)}{Vbe8 + (\alpha \times (Vbe8 - Vbe1))}] - B$$

Figure 118. Temperature sensor function

Where:

- Vbe1 is the first value stored in the FIFO as a result of temperature sensor channel conversion.
- Vbe8 is the second value stored in the FIFO as a result of temperature sensor channel conversion.
- A is the slope factor.
- B is the offset factor.
- α is the bandgap coefficient

A, B, and α are specified constant values from the ADC electrical information in the chip data sheet.

38.3.8 Result FIFO operation

ADC includes 2 FIFOs with 16 entries each that store the result of ADC conversions. ADC also stores a valid indicator bit, the trigger source, the source command, and the loop count along with the data. FCTRL*n*[FCOUNT] indicates the number of valid datawords stored in each Data Result FIFO (RESFIFO0 - RESFIFO1).

A programmable watermark threshold supports configurable notification of data availability. When FCTRL*n*[FCOUNT] is greater than FCTRL*n*[FWMARK], it asserts the associated RDY flag. When IE[FWMIE*n*] = 1, a watermark interrupt request is issued. When DE[FWMDE*n*] = 1, a DMA request is issued. Reading RESFIFO provides the oldest unread dataword entry in the FIFO and decrements FCTRL*n*[FCOUNT]. When FCTRL*n*[FCOUNT] falls equal to or below FCTRL*n*[FWMARK], RDY is cleared.

Successive reads of RESFIFO*n* can empty FIFO. When RESFIFO*n*[VALID] = 1, the associated FIFO entry is valid. Reading RESFIFO*n* when the FIFO is empty (when RESFIFO*n*[VALID] = 0 and FCTRL*n*[FCOUNT] = 0h) provides an undefined dataword. All FIFOs are reset by writing 1 to CTRL[RSTFIFO*n*].

If ADC attempts to store a dataword in the FIFO when the FIFO is full, the FIFO overflow flag (FCTRL*n*[FOF]) becomes 1. When IE[FOFIE*n*] = 1, an overflow interrupt request is issued. You can clear STAT[FOF*n*] by writing 1 to it. During an overflow event, no new data is stored, and the data associated with the store that triggered the overflow is lost.

You can steer the conversion results to any FIFO in the design. Utilize TCTRL*n*[FIFO_SEL_A] and TCTRL*n*[FIFO_SEL_B] to determine the FIFO to write the final result. Therefore, depending on the executing trigger, you can steer the result to different locations. Depending on the type of conversion selected, the FIFO destination register fields are interpreted differently. During either differential or single-ended mode (CMDL*n*[CTYPE] ≠ 3h), only one result is produced. The destination during these modes is determined from TCTRL*n*[FIFO_SEL_A]. Dual-single-ended mode uses TCTRL*n*[FIFO_SEL_A] and TCTRL*n*[FIFO_SEL_B] to determine the channel A and channel B destinations, respectively.

38.3.9 Sampling modes

ADC supports three different sampling modes:

- Differential

- Single-Ended
- Dual Single-Ended

You can determine the sampling mode by executing a command using CMDL*n*[CTYPE]. During the execution of a command in Dual Single-Ended mode, two independent conversion results are calculated and stored in selectable FIFO destinations.

NOTE

The command processing is not individually controlled for each independent channel sampled. When operating in Dual Single-Ended mode, both the channels are sampled and processed simultaneously.

The selection of channel B is controlled by CMDL*n*[ALTBEN]. When CMDL*n*[ALTBEN] = 1, the channel for the B-side is selected independently (through the setting of CMDL*n*[ALTB_ADCH]). When CMDL*n*[ALTBEN] = 0, channel B selection is controlled by CMDL*n*[ADCH] and channels A and B are paired (for example CH0A/CH0B, CH1A/CH1B, ...). If comparisons are enabled in Dual Single-Ended mode, then only the A-side channels (CH0A, CH1A, CH2A, and so on) are used for the comparison. The A-side comparison is used to determine whether both the A-side and B-side results are written to the FIFOs:

- If the A-side comparison passes, both the A-side and B-side results are stored.
- If the A-side comparison fails, neither the A-side nor B-side results are written to the FIFOs.

Single-Ended mode is configured to allow either A-side or B-side channels to be sampled. In Single-Ended mode, the results from each conversion can be written to a selectable FIFO using TCTRL*n*[FIFO_SEL_A]. In Differential mode, the final SAR calculation is equivalent to V(CHA) - V(CHB). If the result is negative, then the value is stored in sign-extended two's complement format. TCTRL*n*[FIFO_SEL_A] also determines where differential conversion results are stored. In Dual Single-Ended mode; however, two independent results are produced. Individual control is provided by using TCTRL*n*[FIFO_SEL_A] and TCTRL*n*[FIFO_SEL_B] to select a FIFO destination for both results during this mode.

NOTE

Both single-ended results can be written to the same destination by programming TCTRL*n*[FIFO_SEL_A] equal to TCTRL*n*[FIFO_SEL_B]. In this case, the CH_A result is always stored before the CH_B result.

38.3.10 Compare function

After you sample and convert the input and perform any averaging iterations, CMDH*n*[CMPEN] guides the operation of the automatic compare function to optionally only store the compare result when the compare operation is true. There are multiple options on command sequencing related to the compare function as summarized in Table 294.

NOTE

Latency is added to the end of a compare function until true conversion to resolve the next command or loop in a sequence is achieved. This latency is necessary to calibrate the SAR data before resolving the result of comparison. Delay for this feature is only added when resolving the result of a conversion. This means that intermediate samples during averaging do not include extra latency. Only loop and command boundaries experience this delay. The latency is always less than or equal to five ADC clock cycles.

NOTE

Command buffers do not have an associated Compare Value register. The compare function is only available on Command buffers that have a corresponding Compare Value register.

Table 294. Compare modes

CMDH*n*[CMPEN]	Compare function	Description
0b00	Compare disabled	Does not perform the compare operation and stores the conversion result to the FIFO
0b01	Reserved	—

Table continues on the next page...

Table 294. Compare modes (continued)

CMDH*n*[CMPEN]	Compare function	Description
0b10	Store on true	Performs the compare operation and stores the conversion result in FIFO at the end of averaging when compare is true. If compare is false, it does not store the result to the FIFO. In either true or false condition, LOOP setting is considered and increments LOOP counter before deciding whether the current command has completed or additional LOOP iterations are required.
0b11	Repeat compare until true	Performs the compare operation and stores the conversion results in FIFO at the end of averaging when compare is true. When the true condition is found, the setting of LOOP is considered and increments LOOP counter before deciding whether the current command has completed or additional LOOP iterations are required. If the compare is false, it does not store the result in the FIFO. The conversion is repeated without consideration of LOOP setting and does not increment the LOOP counter.

Depending on the values that you program for CV*n*[CVH] and CV*n*[CVL], the compare operation checks whether the result is less than, greater than, or if the result falls within or outside a range determined by two compare values. Table 295 describes the usage of the compare values.

Table 295. Compare operations

CV*n*[CVL] vs. CV*n*[CVH]	Operation	Description
Set CV*n*[CVL] < CV*n*[CVH]	Outside range (General form)	Compare true if the result is less than CV*n*[CVL] OR greater than CV*n*[CVH].
Set CV*n*[CVH] to maximum value Set CV*n*[CVL] to compare point	Less than	Compare true if the result is less than CV*n*[CVL].
Set CV*n*[CVL] to minimum value Set CV*n*[CVH] to compare point	Greater than	Compare true if the result is greater than CV*n*[CVH].
Set CV*n*[CVL] > CV*n*[CVH]	Inside range	Compare true if the result is less than CV*n*[CVL] AND greater than CV*n*[CVH].

NOTE

In low-power modes where ADC continues to operate, the compare function can monitor the voltage and only wake the chip when the compare condition is met.

38.3.11 Clocking

ADC operates from the ADCK clock input provided from an on-chip clock select block and is used by the SAR conversion control sequencing logic and the FIFO storage buffer. The ADCK frequency must be within the specified frequency range for ADCK. See chip data sheet for the supported frequency range.

ADC continues operating in low-power modes if CTRL[DOZEN] = 0, and the on-chip clock select block continues to supply an ADCK clock source.

NOTE

In Low-Power mode with CTRL[DOZEN] = 0b0, you can shut off the bus clock, and can configure asynchronous interrupts and DMA requests. In addition, ADC continues processing commands and writing data to the internal FIFO.

ADC has four sources for asynchronous interrupts during Low-Power mode:

- Watermark
- FIFO overflow
- TCOMP
- TEXC

To enable them, properly configure IE[FWMIE*n*], IE[FOFIE*n*], IE[TCOMP_IE], and IE[TEXC_IE] before entering Low-Power mode. When CTRL[DOZEN] = 1, in Low-Power mode, ADC waits for the current averaging iteration and FIFO storage to complete before acknowledging the Low-Power mode entry. When a Low-Power mode request is made with CTRL[DOZEN] = 1, it drops all pending triggers. After acknowledging Low-Power mode request, ADC is forced into its lowest power setting.

38.3.12 Resets

Table 296. ADC resets

Signal	Description
Chip reset	Resets the ADC logic and registers to their default states.
Software reset	Resets, by using CTRL[RST], logic and registers (except Control (CTRL), Gain Calculation Result (GCR0 - GCR1), Calibration General A-Side (CAL_GAR0 - CAL_GAR32), and Calibration General B-Side (CAL_GBR0 - CAL_GBR32)) to their default states.
FIFO reset	Resets CTRL[RSTFIFO0] and CTRL[RSTFIFO1] by implementing write-only control. After a FIFO is reset, that FIFO becomes empty.

38.3.13 Interrupts and DMA requests

ADC includes several sources for interrupts and DMA requests. The following table summarizes these sources.

A programmable watermark threshold supports configurable notification of data availability and can generate either an interrupt exception or a DMA request. When FCTRL*n*[FCOUNT] is greater than FCTRL*n*[FWMARK], it asserts the associated RDY*n* flag. IE[FWMIE*n*] and DE[FWMDE*n*] control the masking for this exception. When RDY*n* is asserted and IE[FWMIE*n*] = 1, a watermark interrupt request is issued. When RDY*n* is asserted and DE[FWMDE*n*] = 1, a DMA request is issued.

The other exception sources can only generate interrupts and do not have a DMA request option. Each of these sources has a mask control field in Interrupt Enable (IE) and no corresponding field in DMA Enable (DE).

Table 297. ADC interrupts and DMA requests

Status (STAT)		Description	Can generate		
Flag	Name		Interrupt?	DMA request?	Low-power wake-up?
RDY*n*	Result FIFO*n* ready flag	Indicates that conversion result data is written to the result FIFO and has a watermark configurable trigger level to	Y	Y	Y

Table continues on the next page...

Table 297. ADC interrupts and DMA requests (continued)

Status (STAT)		Description	Can generate		
Flag	Name		Interrupt?	DMA request?	Low-power wake-up?
		generate an exception request as controlled by FCTRL*n*[FWMARK]			
FOF*n*	Result FIFO*n* overflow flag	Attempts to store data to the FIFO when the FIFO is full and indicates an error condition	Y	N	Y
TCOMP_INT	Trigger completion flag	Indicates that a trigger sequence is complete and all its associated commands have been run	Y	N	Y
TEXC_INT	High priority trigger flag	Indicates that a high-priority trigger exception has occurred	Y	N	Y

38.4 External signals

ADC supports analog channel inputs with differential and single-ended conversion options for all channels. ADC also requires supply and ground connections.

Table 298. ADC signal descriptions

Signal	Description	I/O
V_{DDA}	Analog power supply	I
V_{SSA}	Analog ground	I
CH*n*A–CH0A[1]	A-side analog channel inputs	I
CH*n*B–CH0B[1]	B-side analog channel inputs	I

1. *n* is the maximum channel number supported in the chip (see the chip-specific information to know the number of channels supported on your chip).

38.4.1 Analog channel inputs (CH*n*A and CH*n*B)

CMDL*n*[ADCH] and CMDL*n*[CTYPE] control the selection of paired or individual input channels. Each ADC command independently makes a channel and conversion type selection. Each CMDL*n*[ADCH] channel selection has an associated A side and an associated B side input. You can optionally convert each CMDL*n*[ADCH] pair in a differential mode, but only limited pairs are intended to be converted as differential channels (adjacent pins designed with matched impedance). For the pin pairings available for differential conversions on your chip, see the chip configuration details.

NOTE

Some input channels are from on-chip sources such as temperature sensors and reference voltage sources and can only connect to individual instances of ADC. Some of the input channel options in the bitfield-setting descriptions may not be available for your chip. See the chip-specific information for the channels supported on this chip.

38.5 Initialization

38.5.1 Calibration

ADC consists of multiple calibration functions that you must execute as part of the ADC setup to achieve the specified accuracy. You must run calibration after every reset and before initiating a conversion. Prior to offset calibration or calibration, you must configure ADC's clock source and frequency according to the application's clock source availability and needs. You must enable

ADC (write 1 to CTRL[ADCEN]) before a calibration function runs. If calibration is requested when ADC is actively converting, that sequence completes before initiating the calibration function.

You can achieve improved accuracy during the calibration routines by averaging multiple conversions. You must write 1 to CTRL[CAL_AVGS] for a minimum of 256 averaging during calibration steps. If the application uses ADC in a wide variety of configurations, the configuration for which the highest accuracy is required must be selected, or multiple calibrations can be done for different configurations.

38.5.1.1 16-bit offset calibration function

Use OFSTRIM16 to trim ADC comparator offset voltage for 16-bit ADC conversions. ADC supports an offset calibration function in which OFSTRIM16 is automatically updated. Perform the following procedure for executing the function:

1. Configure the desired averaging though CTRL[CAL_AVGS]. The minimum recommended setting is for 256 averaging (CTRL[CAL_AVGS] set to 8h or greater).
2. Initiate 16-bit offset calibration by writing 1 to CTRL[CALOFS] when CTRL[CALOFSMODE] is 1.
3. Poll STAT[CAL_RDY]. When STAT[CAL_RDY] is set, the offset calibration function is completed and OFSTRIM16 is updated.

38.5.1.2 12-bit offset calibration function

Use OFSTRIM12 to trim ADC comparator offset voltage for 12-bit ADC conversions. ADC supports an offset calibration function that automatically updates OFSTRIM12. Perform the following procedure for executing the function:

1. Configure the desired averaging through CTRL[CAL_AVGS]. The minimum recommended setting is for 256 averaging (CTRL[CAL_AVGS] set to 8h or greater).
2. Initiate 12-bit offset calibration by writing 1 to CTRL[CALOFS] when CTRL[CALOFSMODE] is 0.
3. Poll STAT[CAL_RDY]. When STAT[CAL_RDY] is set, the offset calibration function is completed and OFSTRIM12 is updated.

38.5.1.3 Calibration function

ADC includes the following hardware calibration logic in which the A-side and B-side converters are calibrated for gain error and linearity error correction of the raw conversion result:

- GCR0[GCALR] and Calibration General A-Side (CAL_GAR0 - CAL_GAR32) control calibration for the A-side converter.
- GCR1[GCALR] and Calibration General B-Side (CAL_GBR0 - CAL_GBR32) control calibration for the B-side converter.

ADC supports a calibration function that automatically updates CAL_GAR*n* and CAL_GBR*n*. The calibration function also updates GCC0[GAIN_CAL] (associated with A-side calibration) and GCC1[GAIN_CAL] (associated with B-side calibration). For A-side calibration, a software calculation is required to derive GCR0[GCALR] from GCC0[GAIN_CAL]. For B-side calibration, a corresponding calculation is needed to derive GCR1[GCALR] from GCC1[GAIN_CAL]. Perform the following procedure for completing the calibration setup:

1. Execute the 16-bit offset calibration function described in 16-bit offset calibration function. OFSTRIM16 is used during calibration to trim for comparator offset voltage.
2. Configure the desired averaging through CTRL[CAL_AVGS]. The minimum recommended setting is for 256 averaging (CTRL[CAL_AVGS] set to 8h or greater).
3. Initiate the calibration routine by writing 1 to CTRL[CAL_REQ], which remains 1 until the CAL routine is accepted by ADC. After acceptance, CTRL[CAL_REQ] becomes 0 automatically.
4. Update the A-side calibration data first. Poll GCC0[RDY]. When it is set, the hardware controlled A-side calibration operation is complete, and CAL_GAR*n* and GCC0[GAIN_CAL] are updated. The updated value in GCC0[GAIN_CAL] is further required for software processing as described in the following steps.
5. Read GCC0[GAIN_CAL] and store for use in the gain_adjustment calculation.

6. Calculate the A-side gain_adjustment as (131072) ÷ (131072-GCC0[GAIN_CAL]). GCC0[GAIN_CAL] is two's-complement value. This results in a floating point value between 0 and 2.
7. Convert the floating point value to its integer component (0 or 1) and its fractional component rounded to 16 bits. The integer value is stored in GCR0[GCALR[16]] and the fractional component is stored in GCR0[GCALR[15:0]]. Write this value to GCR0[GCALR].
8. Execute the same calculation for the B-side converter. Poll GCC1[RDY]. When it is set, the hardware controlled B-side calibration operation is complete, and CAL_GBR*n* and GCC1[GAIN_CAL] are updated. The updated value in GCC1[GAIN_CAL] requires further software processing.
9. Read GCC1[GAIN_CAL] and store for use in the gain_adjustment calculation.
10. Calculate the B-side gain_adjustment: (131072) ÷ (131072-GCC1[GAIN_CAL]). Formatting for the value is the same as that for A-side.
11. Write this value to GCR1[GCALR].
12. Set GCR0[RDY] and GCR1[RDY] flags to indicate they are valid, when GCR0[GCALR] and GCR1[GCALR] contain the results from the gain_adjustment calculations. It is acceptable for GCR*n*[GCALR] and corresponding GCR*n*[RDY] to be updated on the same write cycle.

The calibration sequence completes after the aforementioned steps are fulfilled and STAT[CAL_RDY] is set. STAT[CAL_RDY] remains set until you reset the system or request a new calibration sequence.

When STAT[CAL_RDY] is set, you must configure ADC to run in Calibration mode. Each conversion uses a combination of linearity and gain calibration results to correct SAR data. Calibration conversion latency is required to process each sample. However, because of the pipelined nature of data and control sequences, each conversion is initiated without experiencing this calibration delay.

38.5.2 Calibration general A-side and B-side register valid ranges

Calibration General A-Side (CAL_GAR0 - CAL_GAR32) and Calibration General B-Side (CAL_GBR0 - CAL_GBR32) have 33 registers in each array. The data in each register is a signed 16-bit value but has a variable range of possible values. The following table defines the valid range that each register supports.

Table 299. Calibration general registers valid values

Element CAL_G*n*R[N]	Valid range
N = 00h, 20h	–1024 to +1023
N = 01h	–2048 to +2047
N = 02h–03h	–4096 to +4095
N = 04h–07h	–8192 to +8191
N = 08h–0Fh	–16384 to +16383
N = 10h–1Fh	–32768 to +32767

These registers are typically updated automatically during the self-calibration sequence. To reduce the latency associated with the ADC setup, CAL_G*n*R values from a calibration sequence are stored in nonvolatile memory after an initial calibration, and you can write to CAL_G*n*R prior to the first ADC conversion. If you set these registers to values not generated by the calibration function, the linearity error specifications may not be met.

NOTE

You can only write these values in a single access. Byte accesses are not supported.

Fields

Field	Function
31-24 MAJOR	Major Version Number Returns the major version number for the module specification.
23-16 MINOR	Minor Version Number Returns the minor version number for the module specification.
15 —	Reserved This bit always has the value 0.
14-12 NUM_FIFO	Number of FIFOs Indicates the number of result FIFOs implemented in the design. 000b - N/A 001b - One 010b - Two 011b - Three 100b - Four
11 NUM_SEC	Number of Single-Ended Outputs Supported Indicates the number of single-ended channels that can be processed simultaneously. 0b - One conversion 1b - Two conversions
10 CALOFSI	Calibration Function Implemented Indicates whether ADC contains hardware calibration functions to implement calibration. When supported, CTRL[CALOFS] and CTRL[CAL_REQ] can be used to request the calibration routines to run.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not implemented 1b - Implemented
9 IADCKI	Internal ADC Clock Implemented Indicates whether this implementation of ADC includes or implements an internal clock source. When supported, CFG[ADCKEN] is available, implemented, and documented for enabling the clock source. When available, this clock source is used for clock selection logic external to the module for use within the system. 0b - Not implemented 1b - Implemented
8 VR1RNGI	Voltage Reference 1 Range Control Bit Implemented Indicates whether a control bit is implemented for selecting the input voltage range on voltage reference option 1. When range control is required, CFG[VREF1RNG] is available, implemented, and documented for controlling the voltage reference option 1. 0b - Range control not required 1b - Range control required
7 —	Reserved This bit always has the value 0.
6-4 CSW	Channel Scale Width Indicates whether channel scaling is supported by this implementation. When supported, each command buffer implements a control field, CMDL*n*[CSCALE], to configure input scaling. 000b - Not supported (the CSCALE field not implemented) 001b - 1-bit CSCALE supported 110b - 6-bit CSCALE supported
3 MVI	Multi Vref Implemented Indicates whether multiple voltage reference high (VREFH) inputs are supported for this implementation. When supported, CFG[REFSEL] is available and documented for selecting the voltage reference high options. 0b - Single VREFH input supported 1b - Multiple VREFH inputs supported
2 —	Reserved This bit always has the value 0.
1 DIFFEN	Differential Supported

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates whether the differential operation is supported by this implementation. When supported, each command buffer implements control fields (CMDL*n*[CTYPE]) for configuring differential operations and expanding the number of supported channels from 32 to 64. 0b - Not supported 1b - Supported
0 RES	Resolution Indicates the maximum accuracy that is supported by this implementation. When this field is 1, each command buffer has a control field (CMDL*n*[MODE]) for selecting the resolution of conversions for the associated command. 0b - Up to 13-bit differential or 12-bit single-ended resolution 1b - Up to 16-bit differential or 16-bit single-ended resolution supported

38.6.3 Parameter (PARAM)

Offset

Register	Offset
PARAM	4h

Function

Indicates the size of several variable integration options for this instance on the chip.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-24	Command Buffer Number

Table continues on the next page...

Table continued from the previous page...

Field	Function
CMD_NUM	Indicates the number of implemented command buffers.
23-16 CV_NUM	Compare Value Number Indicates the number of implemented compare value registers.
15-8 FIFOSIZE	Result FIFO Depth Indicates the maximum number of conversion data words, indicating the result FIFO depth, that can be stored in the result FIFO before an overflow occurs. 0000_0001b - 2 0000_0100b - 4 0000_1000b - 8 0001_0000b - 16 0010_0000b - 32 0100_0000b - 64
7-0 TRIG_NUM	Trigger Number Indicates the number of triggers implemented.

38.6.4 Control (CTRL)

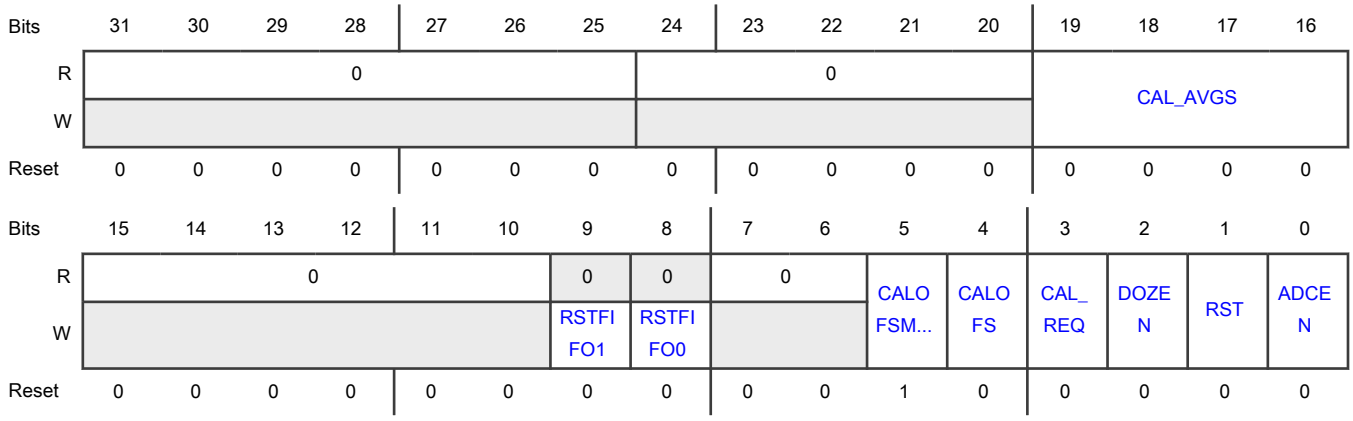
Offset

Register	Offset
CTRL	10h

Function

Includes primary control fields.

Diagram



Fields

Field	Function
31-25 —	Reserved The bit always has the value 0.
24-20 —	Reserved The bit always has the value 0.
19-16 CAL_AVGS	Auto-Calibration Averages Selects the number of ADC conversions averaged to calculate each calibration value. Selecting a higher number of averages leads to more accurate conversions after completing calibration. The recommended minimum setting is for 256 averaging (CAL_AVGS = 8h or greater). CAL_AVGS applies to both CALOFS and CAL_REQ calibration types. You must fix the value when requesting and running calibration with CAL_REQ or CALOFS. 0000b - Single conversion 0001b - 2 0010b - 4 0011b - 8 0100b - 16 0101b - 32 0110b - 64 0111b - 128 1000b - 256 1001b - 512 1010b - 1024
15-10 —	Reserved
9 RSTFIFO1	Reset FIFO 1 0b - No effect 1b - FIFO 1 is reset
8 RSTFIFO0	Reset FIFO 0 0b - No effect 1b - FIFO 0 is reset
7-6 —	Reserved The bit always has the value 0.
5 CALOFSMODE	Configure Mode for Offset Calibration Function

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Configures offset calibration for 16-bit and 12-bit modes. When CALOFSMODE = 1, executing the offset calibration function configures the analog block for 16-bit mode and the results are updated in Offset Trim 16 Bits (OFSTRIM16). When CALOFSMODE = 0, executing the offset calibration function configures the analog block for 12-bit mode and the results are updated in Offset Trim 12 Bits (OFSTRIM12). 0b - 12-bit mode 1b - 16-bit mode
4 CALOFS	Offset Calibration Request Initiates a hardware-offset calibration calculation. The setting of CALOFSMODE controls whether a 16-bit offset calibration or a 12-bit offset calibration is executed. Any conversions in progress are completed before launching the offset calibration function. After being accepted, ADC calculates the offset value, and depending on the setting of CALOFSMODE, updates either Offset Trim 16 Bits (OFSTRIM16) or Offset Trim 12 Bits (OFSTRIM12) automatically. Hardware clears this field after completion of the offset calibration calculation. STAT[CAL_RDY] indicates the completion of the offset calibration routine. 0b - Disable calibration function 1b - Request for offset calibration function
3 CAL_REQ	Auto-Calibration Request Requests the hardware calibration routine to run. This field automatically becomes 0 when the system accepts the hardware calibration request. STAT[CAL_RDY] indicates the calibration routine completion. 0b - Request for hardware calibration not made 1b - Request for hardware calibration made
2 DOZEN	Doze Enable Controls system transition to low-power modes when ADC is converting. When this field is 0, immediate entries to low-power modes are allowed and ADC conversion functions remain enabled. Any conversion in progress is not disrupted. Note that the selected clock sources provided from the on-chip clock source must continue operating. If this field is 1 and ADC is actively converting, and the system is entering Low-Power mode, ADC waits for the current averaging iteration or FIFO storage to complete before acknowledging low-power entry request. After the system enters the low-power state, ADC remains in an inactive state until the system exits the low-power state. When the system enters Low-Power mode in which the ADC operation is not supported, this field is ignored and ADC waits for the current transfer to complete any pending operation. 0b - ADC conversions enabled in Low-Power mode 1b - ADC conversions disabled in Low-Power mode
1 RST	Software Reset Resets all internal logic and registers, except for Control (CTRL), Gain Calculation Result (GCR0 - GCR1), Calibration General A-Side (CAL_GAR0 - CAL_GAR32), and Calibration General B-Side (CAL_GBR0 - CAL_GBR32). This field remains 1 until you write 0 to it. 0b - Do not reset ADC logic

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Reset ADC logic
0 ADCEN	ADC Enable Enables ADC. 0b - Disable 1b - Enable

38.6.5 Status (STAT)

Offset

Register	Offset
STAT	14h

Function

Indicates the current status of ADC.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-28 —	Reserved This bit always has the value 0.
27-24 CMDACT	Command Active

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Works with ADC_ACTIVE to determine which conversion is running. This field indicates the command that is being actively processed. Commands are only shown here when they are being actively processed by the SAR routine. 0000b - No command 0001b - Command 1 0010b - Command 2 0011b-1111b - Associated command number
23-17 —	Reserved
16 TRGACT	Trigger Active Indicates the trigger that is being actively processed, running through a trigger delay, or is being converted by the SAR routine. This field indicates the command associated with TRGACT that is running through a conversion when CMDACT is a nonzero value. 0b - Trigger 0 1b - Trigger 1
15-12 —	Reserved
11 ADC_ACTIVE	ADC Active Indicates whether ADC is currently processing a conversion or has pending triggers to service. When this field is 0, ADC is in the Idle state with no pending triggers to service and no active commands to process. If this field is 1, it indicates that this field is processing a conversion (running through the power-up delay or servicing a trigger). 0b - Idle 1b - Processing a conversion
10 CAL_RDY	Calibration Ready Indicates whether the calibration request received from CTRL[CAL_REQ] or CTRL[CALOFS] is complete and the results are ready. This flag is automatically cleared when a new hardware calibration or offset calibration request is made. 0b - Calibration is incomplete or not ready 1b - Calibration complete
9 TCOMP_INT	Interrupt Flag for Trigger Completion Indicates whether a trigger sequence is complete (all associated commands are run). If complete, TCOMP_INT is asserted. **NOTE** IE[TCOMP_IE] must be 1 for the specific trigger source to flag an interrupt after completion.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - Either IE[TCOMP_IE] is 0 or no trigger sequences are complete 1b - Trigger sequence completed; all data stored in the associated FIFO When writing 0b - No effect 1b - Clear the flag
8 TEXC_INT	Interrupt Flag for High Priority Trigger Exception Indicates whether a high-priority trigger exception occurred. In case it occurred and CFG[TRES] = 0, this flag is asserted, which happens only if trigger exception interrupts are enabled (IE[TEXC_IE] = 1h). TEXC_INT and TSTAT[TEXC_NUM] can be used in conjunction to resolve the trigger source that was interrupted. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No trigger exceptions occurred 1b - Trigger exceptions occurred; acknowledgment is pending When writing 0b - No effect 1b - Clear the flag
7-4 —	Reserved
3 FOF1	Result FIFO1 Overflow Flag Indicates whether more data is written to this field than it can hold since the last time the flag was cleared. The new data is not stored and the FIFO contains the original contents. This flag asserts regardless of the value of IE[FOFIE1]. However, an interrupt request is issued only when IE[FOFIE1] is 1. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No result FIFO1 overflow occurred 1b - At least one result FIFO1 overflow occurred When writing

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No effect 1b - Clear the flag
2 RDY1	Result FIFO1 Ready Flag Indicates whether the number of valid datawords in the result FIFO1 is greater than the watermark level defined in FCTRL*n*[FWMARK]. When it is above the watermark level, the flag asserts regardless of the value of IE[FWMIE1]. However, an interrupt request or DMA request occurs only when the associated fields, IE[FWMIE1] and DE[FWMDE1], are 1. This flag is cleared when FCTRL*n*[FCOUNT] (which decrements on each read of Data Result FIFO (RESFIFO0 - RESFIFO1)) is less than or equal to the watermark level set in FCTRL*n*[FWMARK]. 0b - Below watermark level 1b - Above watermark level
1 FOF0	Result FIFO 0 Overflow Flag Indicates whether more data is written to the result FIFO 0 than it can hold since the last time the flag was cleared. Newer data is not stored and the FIFO keeps holding the original content. This flag asserts regardless of the value of IE[FOFIE0]. However, an interrupt request is issued only if IE[FOFIE0] = 1. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No result FIFO 0 overflow occurred 1b - At least one result FIFO 0 overflow occurred When writing 0b - No effect 1b - Clear the flag
0 RDY0	Result FIFO 0 Ready Flag Indicates whether the number of valid datawords in the result FIFO 0 is greater than the watermark level set in FCTRL*n*[FWMARK]. This flag asserts regardless of the value of IE[FWMIE0]. However, an interrupt request or DMA request occurs only when the associated control fields, IE[FWMIE0] and DE[FWMDE0], are 1. This flag is cleared when FCTRL*n*[FCOUNT] (which decrements on each read of Data Result FIFO (RESFIFO0 - RESFIFO1)) is less than or equal to the watermark level set in FCTRL*n*[FWMARK]. 0b - Below watermark level 1b - Above watermark level

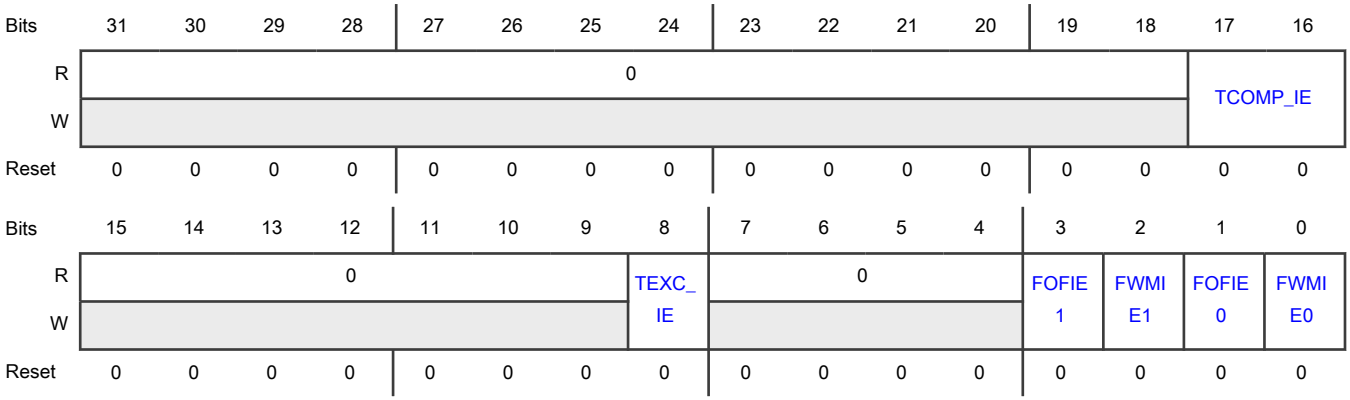
38.6.6 Interrupt Enable (IE)

Offset

Register	Offset
IE	18h

Function
Includes system interrupt masking control fields.

Diagram



Fields

Field	Function
31-18 —	Reserved This field always has the value 0.
17-16 TCOMP_IE	Trigger Completion Interrupt Enable Enables trigger completion interrupts. Each bit in this field corresponds to a trigger source (TCOMP_IE[0] corresponds to trigger 0, TCOMP_IE[1] corresponds to trigger 1, and so on). A trigger completion interrupt is used to indicate when a complete trigger command sequence has been executed. All results are stored in the FIFO when a sequence is considered complete. 00b - Disable 01b - Enable for trigger source 0 only 10b - Enable for trigger source 1 only 11b - Enable trigger 0 and trigger 1 completion interrupts for both trigger sources
15-9 —	Reserved This field always has the value 0.
8 TEXC_IE	Trigger Exception Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Enables ADC to assert an interrupt request when a high-priority trigger exception occurs. TSTAT[TEXC_NUM] contains the value of the corresponding trigger affected by the exception. 0b - Disable 1b - Enable
7-4 —	Reserved
3 FOFIE1	Result FIFO1 Overflow Interrupt Enable Enables ADC to generate overflow interrupt requests when STAT[FOF1] is asserted. This field specifies whether the FIFO 1 overflow interrupts are enabled. 0b - Disable 1b - Enable
2 FWMIE1	FIFO1 Watermark Interrupt Enable Enables ADC to generate watermark interrupt requests when STAT[RDY1] is asserted. This field specifies whether the FIFO1 watermark interrupts are enabled. 0b - Disable 1b - Enable
1 FOFIE0	Result FIFO 0 Overflow Interrupt Enable Enables ADC to generate overflow interrupt requests when the FOF*n* flag is asserted. This field specifies whether the FIFO 0 overflow interrupts are enabled. 0b - Disable 1b - Enable
0 FWMIE0	FIFO 0 Watermark Interrupt Enable Enables ADC to generate watermark interrupt requests when STAT[RDY0] is asserted. This field specifies whether the FIFO 0 watermark interrupts are enabled. 0b - Disable 1b - Enable

38.6.7 DMA Enable (DE)

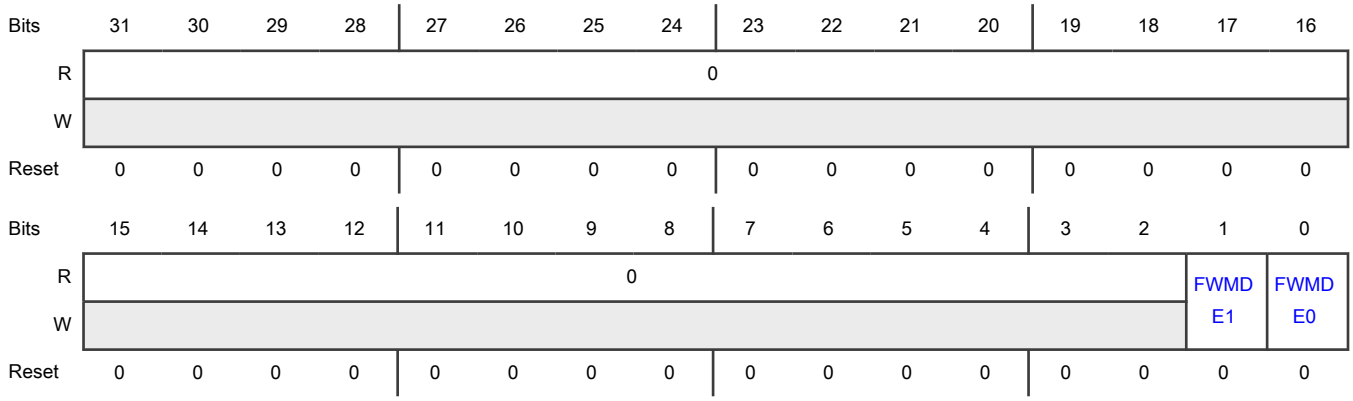
Offset

Register	Offset
DE	1Ch

Function

Includes DMA request masking control fields.

Diagram



Fields

Field	Function
31-2 —	Reserved This bit always has the value 0.
1 FWMDE1	FIFO1 Watermark DMA Enable Enables ADC to generate DMA requests when STAT[RDY1] is asserted. 0b - Disable 1b - Enable
0 FWMDE0	FIFO 0 Watermark DMA Enable Enables ADC to generate DMA requests when STAT[RDY0] is asserted. 0b - Disable 1b - Enable

38.6.8 Configuration (CFG)

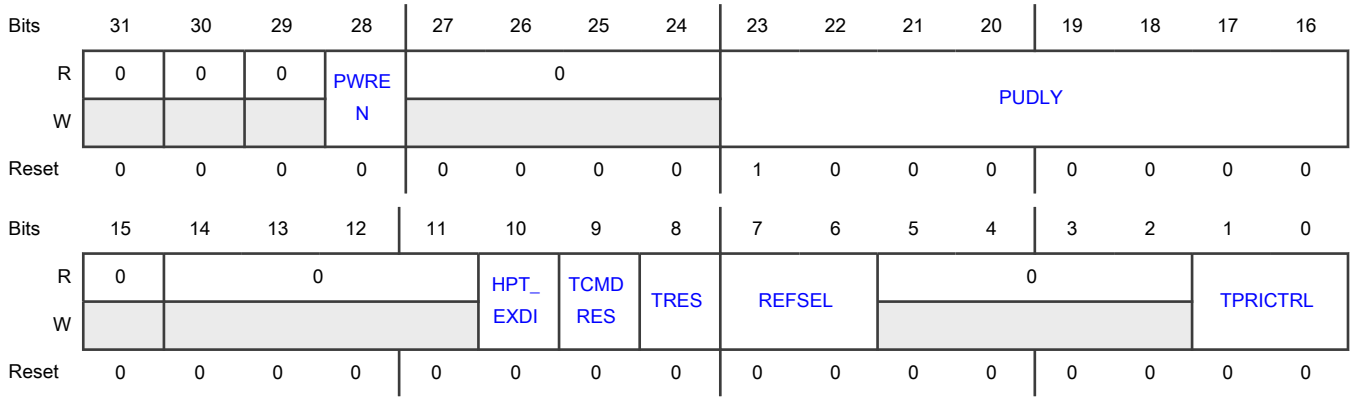
Offset

Register	Offset
CFG	20h

Function

Controls ADC functions that are common to all commands. You cannot make changes to this register when CTRL[ADCEN] is 1. Any writes to this register when CTRL[ADCEN] is 1 are ignored.

Diagram



Fields

Field	Function
31 —	Reserved This bit always has the value 0.
30 —	Reserved This bit always has the value 0.
29 —	Reserved This bit always has the value 0.
28 PWREN	ADC Analog Pre-Enable Enables the ADC analog circuits. When you write 1 to this field, the user code must be delayed for a period exceeding the analog startup time of $t_{ADCSTUP}$ before enabling ADC for operation. ADC is still operational even when CFG[PWREN] = 0 but command execution start is delayed for a period defined by PUDLY. See the chip data sheet for ADC idle and ADC active power consumption parameters. If this field is 0, ADC analog circuits are only enabled when conversions are active. Performance is affected because of analog startup delays. If this field is 1, ADC analog circuits are pre-enabled and ready to execute conversions without startup delays (at the cost of higher DC consumption). **NOTE** A single power up delay (PUDLY) is executed immediately after you write 1 to this field. The detected trigger does not begin ADC operations until the power up delay time has passed. After this initial delay expires, the analog remains pre-enabled and no additional delays are executed. 0b - Not pre-enabled 1b - Pre-enabled and ready to execute conversions
27-24 —	Reserved This bit always has the value 0.
23-16	Power Up Delay

Table continues on the next page...

Table continued from the previous page...

Field	Function
PUDLY	Specifies power up delay. You must program PUDLY to a nonzero value to enable ADC. **NOTE** PUDLY is executed in one of the two modes depending on the value configured in PWREN. If CFG[PWREN] = 0, ADC analog circuits are powered on only when ADC is active. The delay defined by PUDLY is executed after an initial trigger transitions ADC from its Idle state. This delay allows time for the analog circuits to stabilize after being powered on. The startup delay count of (PUDLY×4) ADCK cycles must result in a longer delay than the analog startup time of $t_{ADCSTUP}$. Accuracy of the initial conversion(s) after activation is degraded if PUDLY is set to too small a value. At the end of active conversions, if there are no subsequent pending conversions, the ADC analog is automatically reverted to its low-power idle state and PUDLY runs again after ADC is awakened with a later trigger. If CFG[PWREN] = 1 prior to ADC activation, the analog circuits are pre-enabled and the activation delay defined by PUDLY is executed immediately. After the delay has been executed, the analog remains enabled regardless of ADC activity. This configuration has the benefit of beginning conversions immediately after trigger event detection at the cost of increased DC power consumption of the analog circuits. **NOTE** ADC does not begin an initial conversion until you execute PUDLY regardless of the PWREN setting.
15 —	Reserved This bit always has the value 0.
14-11 —	Reserved This bit always has the value 0.
10 HPT_EXDI	High Priority Trigger Exception Disable Disables high-priority exception. This field controls how higher priority trigger events are handled. See Trigger detect and command execution for a detailed description on trigger exception handling. 0b - Enable 1b - Disable
9 TCMDRES	Trigger Command Resume Determines where to resume from a high-priority trigger exception. CFG[TRES] must be 1 for TCMDRES to be used. If TCMDRES is 1, the trigger sequences interrupted by a high-priority trigger exception are automatically resumed from the command executing before the exception. If TCMDRES is 0, the trigger sequences interrupted by a high-priority trigger exception are automatically restarted from the beginning. **NOTE** The trigger that was interrupted when TCMDRES was 1 resumes at the command it was interrupted and if in LOOP mode, the CMDH*n*[LOOP] count always restarts at the first loop count iteration. 0b - Restart automatically 1b - Resume command execution

Table continues on the next page...

Table continued from the previous page...

Field	Function
8 TRES	Trigger Resume Enable Determines what happens after completing a high-priority trigger exception. If this field is 1, the trigger sequences interrupted by a high-priority trigger exception are automatically resumed or restarted. The sequence can be resumed along command boundaries or restarted from the beginning of a sequence. This is controlled through TCMDRES. If this field is 0, the trigger sequences interrupted by a high-priority trigger exception do not resume or restart automatically. In this case, you can resume interrupted triggers by monitoring STAT[TEXC_INT] (or ISR handling for a trigger exception interrupt when IE[TEXC_IE] is 1). By reading TSTAT[TEXC_NUM], you can determine the trigger that was interrupted and restart the trigger by writing 1 to the corresponding SWTRIG[SWT*n*] field. 0b - Do not resume or restart automatically 1b - Resume or restart automatically
7-6 REFSEL	Voltage Reference Selection Selects the voltage reference high used for conversions. **NOTE** See the chip-specific ADC information on the voltage reference options specific to this packaged device. 00b - Option 1 (default) 01b - Option 2 10b - Option 3 11b - Reserved
5-2 —	Reserved This bit always has the value 0.
1-0 TPRICTRL	ADC Trigger Priority Control Controls the way higher-priority trigger exceptions are handled. See Trigger detect and command execution for more information on trigger event handling. If this field is 0b and a higher-priority trigger is detected during command processing, the current conversion is aborted and the new command specified by the trigger is started. If this field is 1b and a higher-priority trigger is received during command processing, the current command is stopped after completing the current conversion. If averaging is enabled, the averaging loop is completed. However, CMDH*n*[LOOP] is ignored and the higher-priority trigger is serviced. If this field is 10b and a higher-priority trigger is received during command processing, the current command is completed (averaging, looping, comparing) before servicing the higher-priority trigger. 00b - Abort the current conversion and start the new command specified by the trigger 01b - Stop the current command after completing the current conversion 10b - Complete the current command before servicing the higher-priority trigger

Table continues on the next page...

Table continued from the previous page...

Field	Function
	11b - Reserved

38.6.9 Pause (PAUSE)

Offset

Register	Offset
PAUSE	24h

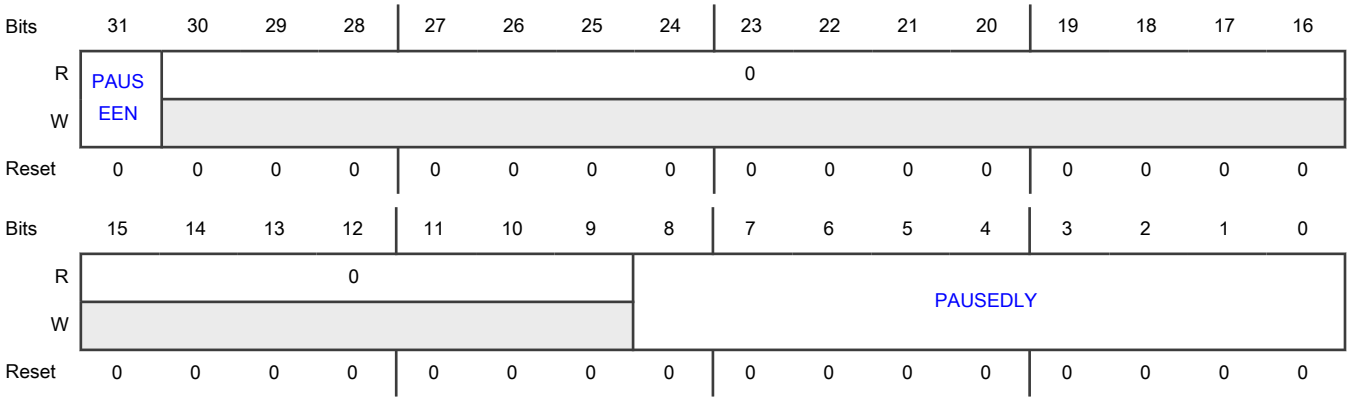
Function

Controls an optionally inserted delay between conversions.

NOTE

Do not make modifications to this register when CTRL[ADCEN] = 1.

Diagram



Fields

Field	Function
31 PAUSEEN	Pause Option Enable Enables the ADC pause function. When enabled, a programmable delay is inserted during command execution sequencing between LOOP iterations, between commands in a sequence, and between conversions when a command is executing for the "Compare Until True" configuration. **NOTE** CMDH*n*[WAIT_TRIG] and Pause (PAUSE) are mutually exclusive. CMDH*n*[WAIT_TRIG] takes priority over Pause (PAUSE) between commands when both are enabled. 0b - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enable
30-9 —	Reserved This bit always has the value 0.
8-0 PAUSEDLY	Pause Delay Controls the duration of pause during command execution sequencing when PAUSEEN = 1. The pause delay is a count of (PAUSEDLY × 4) ADCK cycles.

38.6.10 Software Trigger (SWTRIG)

Offset

Register	Offset
SWTRIG	34h

Function

Initiates software-triggered conversations. Writes to this register are ignored when CTRL[ADCEN] = 0.

NOTE

There is an approximate synchronization delay of three ADC clock cycles in asserting CTRL[ADCEN] until SWTRIG can be accepted.

Diagram

Fields

Field	Function
31-18 —	Reserved This bit always has the value 0.
17-16 TCOMP_FLAG	Trigger Completion Flag Indicates trigger completion. Each bit corresponds to a trigger. When the corresponding trigger sequence is completed, a bit in TCOMP_FLAG is set. For example, if trigger 1 is completed, then bit 17 is set in TCOMP_FLAG. This register is active only if the corresponding bit in IE[TCOMP_IE] = 1. **NOTE** A synchronization delay may be added to the end of the final conversion in a sequence prior to this flag is set. This delay can range from 2-4 ADC clock cycles. 00b - No trigger is complete (trigger completion interrupts are disabled) 01b - Trigger 0 is complete (trigger 0 has enabled completion interrupts) 10b - Trigger 1 is complete (trigger 1 has enabled completion interrupts) 11b - Trigger 0 and trigger 1 sequences are complete (both triggers have enabled completion interrupts)
15-2 —	Reserved This bit always has the value 0.
1-0 TEXC_NUM	Trigger Exception Number Indicates whether a trigger is interrupted by a high-priority exception. Each bit corresponds to a trigger. When the corresponding trigger sequence is interrupted by a high-priority trigger exception, 1 is set in its bit position. For example, if trigger 1 is interrupted, then bit 1 is set in TEXC_NUM. This register is active regardless of the value in IE[TEXC_IE]. 00b - No trigger is interrupted (or CFG[TRES] = 1) 01b - Trigger 0 is interrupted 10b - Trigger 1 is interrupted 11b - Trigger 0 and trigger 1 sequences are interrupted

38.6.12 Offset Trim 16 Bits (OFSTRIM16)

Offset

Register	Offset
OFSTRIM16	40h

Function

Trims comparator offset for 16-bit ADC conversions (CMDL*n*[MODE] == 0b1). ADC supports an offset calibration function in which this register is updated automatically.

To trigger an automatic update of this register, write 1 to CTRL[CALOFS] with CTRL[CALOFSMODE] = 1. After completing the offset calibration sequence, STAT[CAL_RDY] becomes 1 and OFSTRIM16[OFSTRIM_A] and OFSTRIM16[OFSTRIM_B] are updated with 10-bit signed values.

OFSTRIM16[OFSTRIM_A] and OFSTRIM16[OFSTRIM_B] are used to minimize the offset for normal 16-bit conversions (when CMDL*n*[MODE] = 1). This register set supports a range of -512 to 511. Each increment is 1/2 LSB, resulting in a programmable offset range of -256 to +255.5 LSB for 16-bit conversions.

The OFSTRIM16 trim values are also used for the calibration function.

Diagram

R	0						OFSTRIM_A									
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-26 —	Reserved This bit always has the value 0.
25-16 OFSTRIM_B	Trim for Offset in B-side Converter for 16-bit Conversions Specifies the trim for offset in B-side converter for 16-bit conversions. OFSTRIM_B is a 10-bit signed value between -512 and 511. This value is subtracted from the raw ADC B-side conversion result.
15-10 —	Reserved
9-0 OFSTRIM_A	Trim for Offset in A-side Converter for 16-bit Conversions Specifies the trim for offset in A-side converter for 16-bit conversions. OFSTRIM_A is a 10-bit signed value between -512 and 511. This value is subtracted from the raw ADC A-side conversion result.

38.6.13 Offset Trim 12 Bits (OFSTRIM12)

Offset

Register	Offset
OFSTRIM12	44h

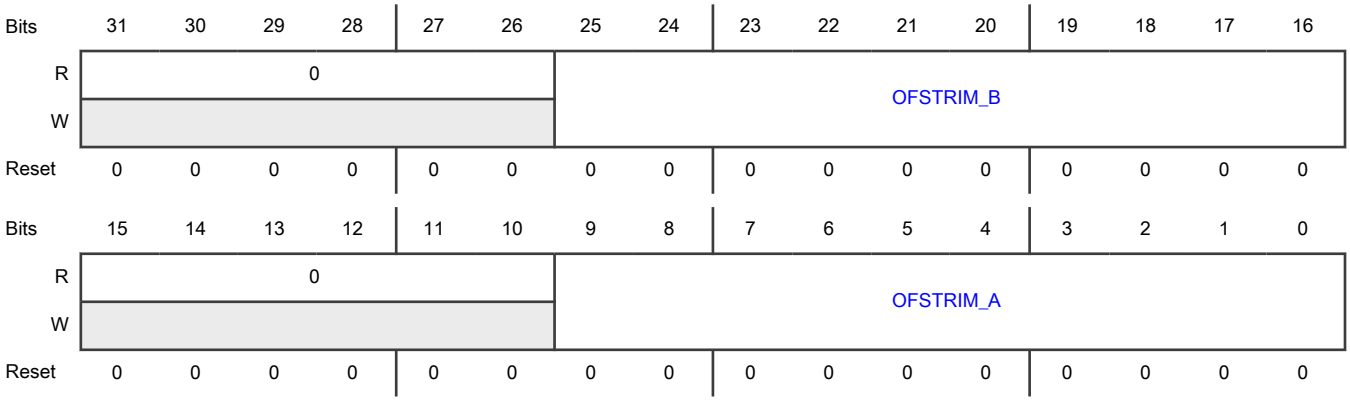
Function

Trims comparator offset for 12-bit ADC conversions (CMDL*n*[MODE] == 0b0). ADC supports an offset calibration function in which this register is updated automatically.

To trigger an automatic update of this register, write 1 to CTRL[CALOFS] with CTRL[CALOFSMODE] = 0b0. On completion of the offset calibration sequence, STAT[CAL_RDY] becomes 1, and OFSTRIM12[OFSTRIM_A] and OFSTRIM12[OFSTRIM_B] are updated with 10-bit signed values.

OFSTRIM12[OFSTRIM_A] and OFSTRIM12[OFSTRIM_B] are used to minimize the offset for normal 12-bit conversions (when CMDL*n*[MODE] = 0). The OFSTRIM registers support a range of -512 to 511. Each increment is 1/32 LSB, resulting in a programmable offset range of -16 to +15.96875 LSB for 12-bit conversions.

Diagram



Fields

Field	Function
31-26 —	Reserved This bit always has the value 0.
25-16 OFSTRIM_B	Trim for Offset in B-side Converter for 12-bit Conversions Specifies the trim for offset in B-side converter for 12-bit conversions. OFSTRIM_B is a 10-bit signed value between -512 and 511. This value is subtracted from the raw ADC B-side conversion result.
15-10 —	Reserved This bit always has the value 0.
9-0 OFSTRIM_A	Trim for Offset in A-side Converter for 12-bit Conversions Specifies the trim for offset in A-side converter for 12-bit conversions. OFSTRIM_A is a 10-bit signed value between -512 and 511. This value is subtracted from the raw ADC A-side conversion result.

38.6.14 Trigger Control (TCTRL0 - TCTRL1)

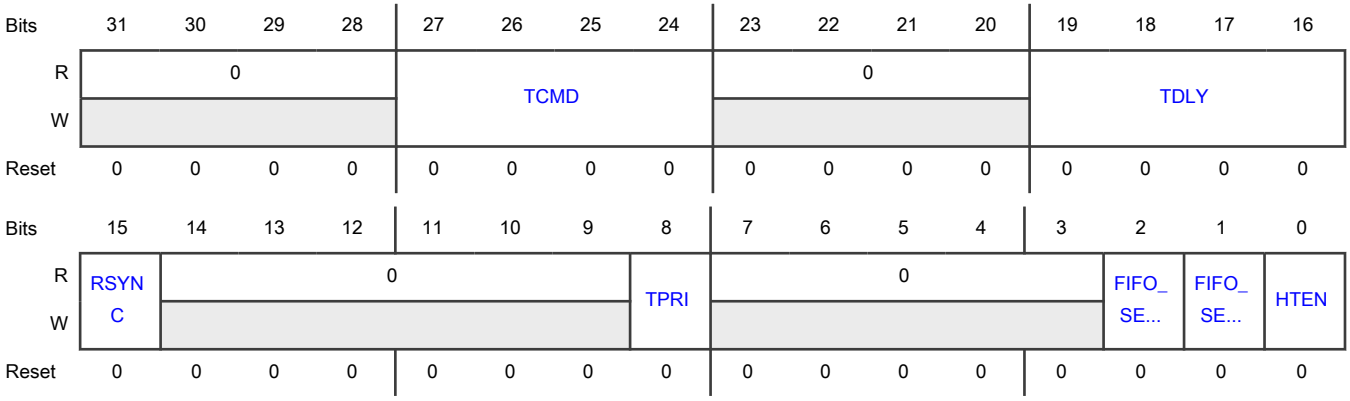
Offset

Register	Offset
TCTRL0	A0h
TCTRL1	A4h

Function

Implements control fields associated with each implemented trigger source. When ADC is actively executing commands, only one of the TCTRL*n* registers is actively controlling ADC conversions. You must not update that register when ADC is active. Any write to TCTRL*n* registers when that trigger control register is controlling the ADC operation can cause unpredictable behavior.

Diagram



Fields

Field	Function
31-28 —	Reserved This bit always has the value 0.
27-24 TCMD	Trigger Command Select Selects the command from command buffer to execute on detection of the associated trigger event. If a trigger is received when ADC is busy converting and the new trigger has a higher priority than the trigger associated with the current command being executed, the command in this register, associated with the new trigger, is executed under the control of CFG[TPRICTRL]. See section Trigger detect and command execution for more information on the relationship between CFG[TPRICTRL] and TCMD. 0000b - Not a valid selection from the command buffer (trigger event is ignored) 0001b - CMD1 is executed 0010b-1110b - Corresponding CMD is executed 1111b - CMD15 is executed
23-20	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	This bit always has the value 0.
19-16 TDLY	Trigger Delay Select Selects the trigger delay duration to wait at the start of servicing a trigger event. Each trigger source has an associated programmable delay before beginning an initial conversion. When this field is 0, then no delay is incurred. When this field is a nonzero value, the duration for the delay is 2^{TDLY} ADCK cycles.
15 RSYNC	Trigger Resynchronization Specifies trigger resynchronization. If this field is 1, the trigger source is used as a resynchronization trigger. You can configure the resynchronization trigger to restart or abort a running trigger sequence (the target). Configure each resynchronization trigger to have a resynchronization target. When a resynchronization trigger is asserted, the target sequence is aborted, the target FIFO destination(s) are cleared, and the target sequence can optionally be restarted depending on CFG[TRES]. Multiple conditions must be met for a resync trigger to execute properly: • The resynchronization trigger must have a higher priority than the resynchronization target. • This field, RSYNC, which is the resynchronization trigger, must be 1. • The resynchronization target, specified by TCTRL*n*[TCMD], must be executing when the resynchronization trigger is asserted. See Resynchronization functionality for more information.
14-9 —	Reserved This bit always has the value 0.
8 TPRI	Trigger Priority Setting Specifies the priority of the associated trigger source. When determining ADC trigger aborts based on a higher priority trigger interrupt, ADC hardware only considers whether the new trigger (TCTRL[TPRI]) is programmed with a lower value than the running trigger. If both triggers are programmed with the same priority, no abort occurs. Also, if two or more triggers are detected with the same TCTRL[TPRI] value, ADC only takes into account the trigger number and order when determining the next active trigger. In such cases, the lower order trigger is set first. 0b - Set to highest priority, level 1 1b - Set to lower priority, level 2
7-3 —	Reserved
2 FIFO_SEL_B	SAR Result Destination for Channel B Specifies the SAR result destination for channel B. This register is used only during dual single-ended mode (CMDL*n*[CTYPE] = 0b11). In this mode, the SAR result from channel B is written to the FIFO number specified by this field. See Sampling modes for more information. 0b - Result written to FIFO 0 1b - Result written to FIFO 1

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 FIFO_SEL_A	SAR Result Destination for Channel A Specifies the SAR result destination for channel A. The conversion results are stored in the FIFO number specified by this field under the following conditions: • Single-ended mode: CMDL*n*[CTYPE] = 0b01 or CMDL*n*[CTYPE] = 0b00 • Differential mode: CMDL*n*[CTYPE] = 0b10 • Dual single-ended mode: CMDL*n*[CTYPE] = 0b11 This field provides the destination for all single-ended conversions, differential conversions, and A-side conversions in dual single-ended mode. 0b - Result written to FIFO 0 1b - Result written to FIFO 1
0 HTEN	Trigger Enable Enables the hardware trigger source to initiate conversion on the rising-edge of the input trigger source. **NOTE** Enabling a hardware trigger does not disable software triggers. 0b - Disable 1b - Enable

38.6.15 FIFO Control (FCTRL0 - FCTRL1)

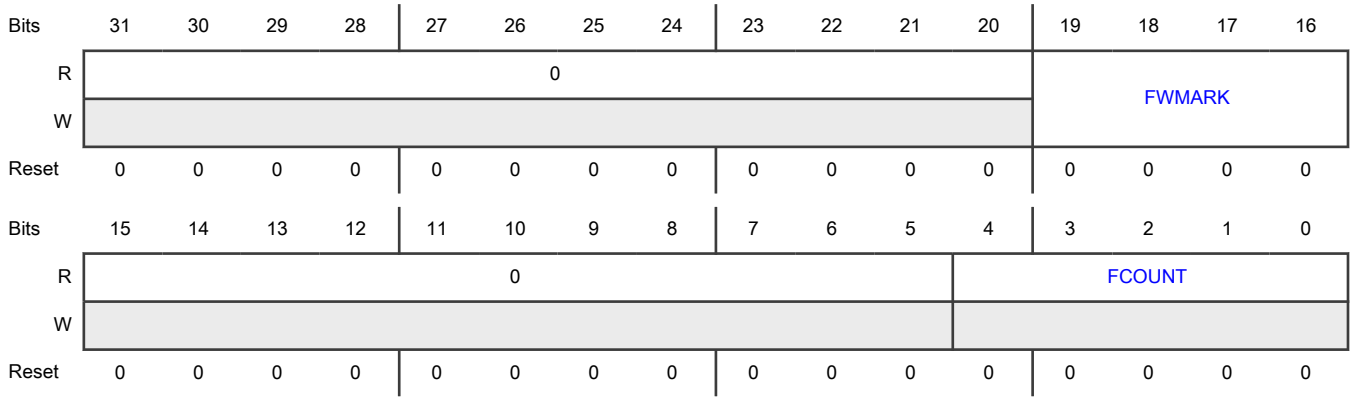
Offset

Register	Offset
FCTRL0	E0h
FCTRL1	E4h

Function

Contains control and status fields for each FIFO. You can set a programmable watermark for each FIFO that can be used to trigger an interrupt. In addition, the number of entries stored in each FIFO can be monitored by reading FCOUNT.

Diagram



Fields

Field	Function
31-20 —	Reserved This field always has the value 0.
19-16 FWMARK	Watermark Level Selection Specifies watermark level selection. FWMARK is a programmable threshold setting. When the number of datawords stored in the ADC result FIFO is greater than the value in FWMARK, the STAT[RDY] flag is asserted to indicate stored data that has reached the programmable threshold. When IE[FWMIE*n*] is 1, an interrupt request is generated. When DE[FWMDE*n*] is 1, a DMA request is generated.
15-5 —	Reserved This field always has the value 0.
4-0 FCOUNT	Result FIFO Counter Indicates the number of data words that are stored in the result FIFO. This value may be used in conjunction with PARAM[FIFOSIZE] to calculate how much room is left in the result FIFO. This field is incremented with each store of new data to the result FIFO and decrements with each read of the result FIFO. The FIFO is reset by writing to CTRL[RSTFIFO*n*], resulting in FCOUNT initialized to 0h.

38.6.16 Gain Calibration Control (GCC0 - GCC1)

Offset

Register	Offset
GCC0	F0h
GCC1	F4h

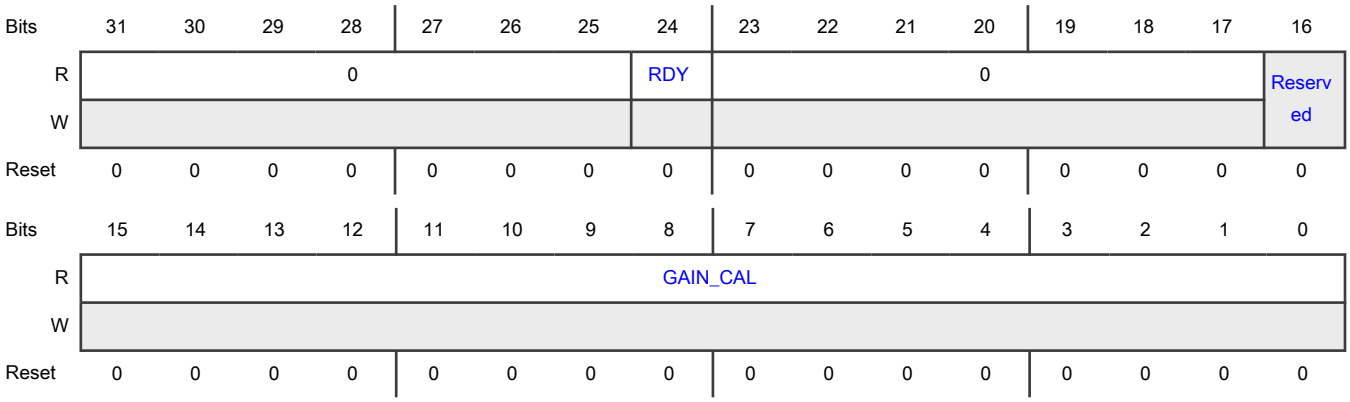
Function

Holds intermediate values that are utilized as part of the calibration steps. GCC0 is associated with the A-side converter, and GCC1 is associated with the B-side converter. ADC calculates GCC*n*[GAIN_CAL] and the field is updated automatically during the calibration steps. After the hardware calibration sequence updates GCC*n*[GAIN_CAL], GCC*n*[RDY] becomes 1 automatically.

NOTE

Requesting a calibration routine automatically writes 0 to GCC*n*[RDY] until the new value for GCC*n*[GAIN_CAL] is calculated. To complete the calibration steps, you need further software processing where you use the value of GCC*n*[GAIN_CAL] to calculate the gain adjustment. The result is stored to GCR*n*[GCALR]. For more information, see Calibration.

Diagram



Fields

Field	Function
31-25 —	Reserved
24 RDY	Hardware Calculated GAIN_CAL Value Ready Indicates whether the data stored in GCC*n*[GAIN_CAL] is valid. If this field is 0, the value of GAIN_CAL is invalid. Run the hardware calibration routine for this value to be set. If this field is 1, the value of GAIN_CAL is valid. You must use GAIN_CAL to derive GCR*n*[GCALR]. 0b - Invalid 1b - Valid
23-17 —	Reserved
16 —	Reserved After a calibration initialization function, this field may read as 0 or 1.
15-0 GAIN_CAL	Gain Calibration Value Indicates the gain calibration value. As part of the hardware calibration steps, GAIN_CAL is automatically updated with a 16-bit signed number and is used in the gain adjustment calculations to derive the value to be written to GCR*n*[GCALR]. For more information, see Calibration.

38.6.17 Gain Calculation Result (GCR0 - GCR1)

Offset

Register	Offset
GCR0	F8h
GCR1	FCh

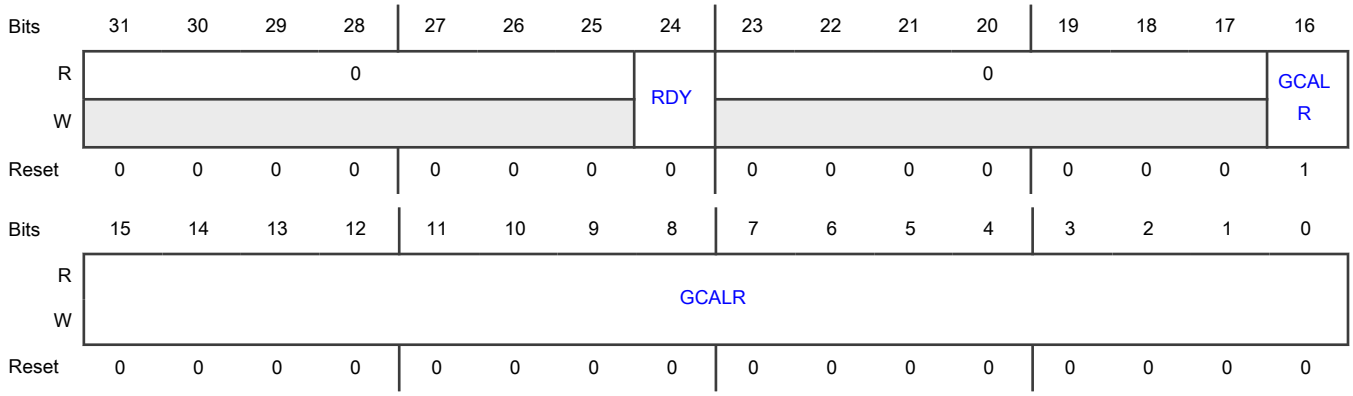
Function

Performs ADC conversions for automated gain error adjustment. GCR0 is associated with the A-side converter, and GCR1 is associated with the B-side converter. Determining the values to store in GCR0[GCALR] and GCR1[GCALR] is the result of software calculations described in Calibration.

GCR*n*[RDY] indicates whether the value of GCR*n*[GCALR] is valid. When you write a value to GCR*n*[GCALR], you must write 1 to GCR*n*[RDY] to indicate that the gain adjustment result is valid.

When you begin the calibration sequence by writing 1 to CTRL[CAL_REQ], the calibration sequence is not complete until GCR*n*[GCALR] is calculated and GCR*n*[RDY] becomes 1. The gain adjustment calculation results in a floating point value between 0 and 2. GCALR[16] holds the integer value (0 or 1), and GCALR[15:0] holds the 16-bit fractional component of the gain adjustment calculation. To convert the value of GCALR back into the gain adjustment value in decimal format, perform this calculation: 1 × GCR*n*[16] + 0.5 × GCR*n*[15] + 0.25 × GCR*n*[14] + 0.125 × GCR*n*[13] +...

Diagram



Fields

Field	Function
31-25 —	Reserved
24 RDY	Gain Calculation Ready Indicates to ADC whether the data stored in GCR*n*[GCALR] is valid and used for gain adjustment. GCALR must be written from memory or calculated each time the calibration routine is run. You must write 1 to this field after writing valid data to GCALR. This field becomes 0 automatically when requesting a new calibration sequence.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Invalid 1b - Valid
23-17 —	Reserved This field always has the value 0.
16-0 GCALR	Gain Calculation Result Holds the 17-bit value generated from the gain adjustment calculation during the calibration steps.

38.6.18 Command Low Buffer (CMDL1 - CMDL15)

Offset

For a = 1 to 15:

Register	Offset
CMDLa	F8h + (a × 8h)

Function

Consists of 15 command buffers (CMD*n*), each constructed from two 32-bit registers (CMDH*n*: CMDL*n*) that can be configured for different channel selections and varying conversion options. Any of the command buffers is selected and used as the controlling command by association to a trigger event via configuration of TCTRL*n*[TCMD]. When ADC is actively executing commands, only one of the CMD buffers is actively controlling ADC conversions. The actively controlling CMD buffer must not be updated when ADC is active. A write to a CMD buffer when that CMD buffer is controlling the ADC operation can cause unpredictable behavior.

NOTE

The 15 command buffers are numbered [CMDH1:CMDL1] through [CMDH15:CMDL15]. In NXP-supplied header files, these are likely to be defined as two 15-element arrays that are indexed from 0. The type declaration is:

```
unsigned int CMDH[15];
unsigned int CMDL[15];
```

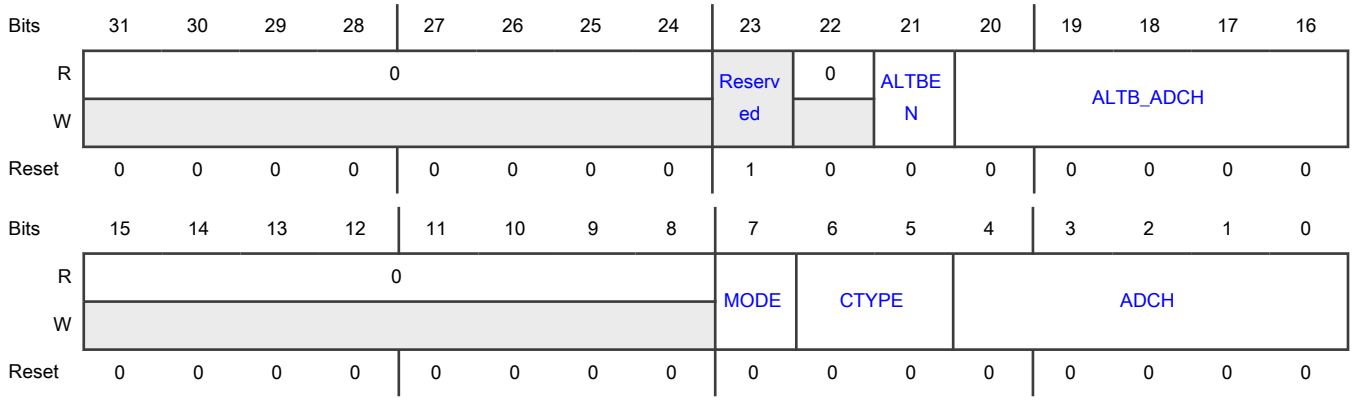
You access ADC0 CMDH1 as `ADC0->CMDH[0]` and ADC0 CMDL15 as `ADC0->CMDL[14]`.

CMDL*n*[ADCH] and CMDL*n*[CTYPE] control the selection of paired or individual input channels. Each ADC command independently makes a channel and conversion type selection. Each ADCH channel selection has an associated A-side and B-side input. You can optionally convert each ADCH pair in a differential mode, but only limited pairs are intended to be converted as differential channels (that is, adjacent pins designed with matched impedance). For the pin pairings available for differential conversions on your chip, see the chip configuration details.

NOTE

Some of the input channels are from on-chip sources such as temperature sensors and reference voltage sources and may only be connected to individual instances of ADC. Some of the input channel options in the field descriptions may not be available for your chip. See the chip-specific information for the channels supported on this chip.

Diagram



Fields

Field	Function
31-24 —	Reserved This field always has the value 0.
23 —	Reserved This field resets to the value 1.
22 —	Reserved This field always has the value 0.
21 ALTBEN	Alternate Channel B Select Enable Enables ALTB_ADCH to select the input for channel B independent of ADCH settings when CTYPE is 0b01 or 0b11. If this field is 0, ALTB_ADCH is disabled. Channel A and channel B inputs are selected based on the settings of ADCH. If this field is 1, ALTB_ADCH is enabled. Channel A inputs are selected by the ADCH setting and channel B inputs are selected by the ALTB_ADCH setting. **NOTE** Writing 10b (differential) to CMDL*n*[CTYPE] works, but is not recommended. 0b - Disable 1b - Enable
20-16 ALTB_ADCH	Alternate Channel B Input Channel Select Selects the alternate channel B input channel. If ALTBEN is 1, ALTB_ADCH selects the channel B input when CTYPE is configured as 0b01 or 0b11. **NOTE** Some of the input channels are from internal resources such as temperature sensors and bandgap voltage sources and may not be connected to individual instances of ADC. Also, some of the input channel options in the field descriptions may not be available for your chip. For the ADC channel assignments on your chip, see the chip-specific information.

38.6.19 Command High Buffer (CMDH1 - CMDH4)

Offset

Register	Offset
CMDH1	104h
CMDH2	10Ch
CMDH3	114h
CMDH4	11Ch

Function

Consists of 15 command buffers (CMD*n*), each constructed from two 32-bit registers (CMDH*n*: CMDL*n*) that can be configured for different channel selections and varying conversion options. Any of the command buffers is selected and used as the controlling command by association to a trigger event via configuration of TCTRL*n*[TCMD]. When ADC is actively executing commands, only one of the CMD buffers is actively controlling ADC conversions. The actively controlling CMD buffer must not be updated while ADC is active. A write to a CMD buffer while that CMD buffer is controlling ADC operation can result in unpredictable behavior.

NOTE

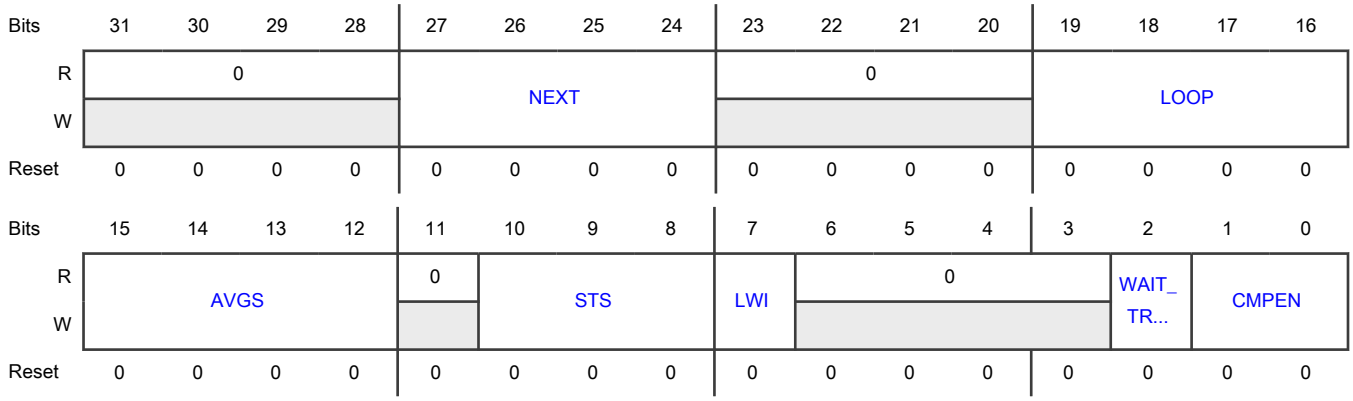
The 15 command buffers are numbered [CMDH1:CMDL1] through [CMDH15:CMDL15]. In NXP-supplied header files, these are likely to be defined as two 15-element arrays that are indexed from 0. The type declaration is:

```
unsigned int CMDH[15];

unsigned int CMDL[15];
```

You access ADC0 CMDH1 as `ADC0->CMDH[0]` and ADC0 CMDL15 as `ADC0->CMDL[14]`.

Diagram



Fields

Field	Function
31-28 —	Reserved This field always has the value 0.
27-24 NEXT	Next Command Select Selects the next command to execute after the current command completes. You can configure multiple commands in a scan configuration by linking the next command in a daisy-chain sequence. The command buffer number is not indicative of any particular order, and the order of execution is strictly controlled by this field (for example, a sequence of commands could be CMD2 to CMD1 to CMD3). Unending circular command execution is allowed by writing 1 to this field in the last command in a sequence to the first command in the sequence. It also allows a command to set the next command to itself, resulting in a continuous conversion configuration. Setting the next command to 0h causes conversions to terminate after command completion. Lower-priority trigger events cannot be serviced until a higher-priority triggered command (or sequence of commands) completes. When this field is 0, no next command is defined. The field terminates conversions at the completion of the current command. If the lower-priority trigger is pending, the command associated with the lower-priority trigger begins. 0000b - No next command defined 0001b - CMD1 command buffer register 0010b-1110b - Corresponding CMD command buffer register 1111b - CMD15 command buffer register
23-20 —	Reserved This field always has the value 0.
19-16 LOOP	Loop Count Select Selects the number of times this command executes (and stores conversion result to RESFIFO) before completion and transition to the next command or Idle state. LWI controls whether a single channel is converted on each iteration or the auto-channel increment results in a channel scanning functionality.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0000b - Looping not enabled; command executes one time 0001b - Loop one time; command executes two times 0010b - Loop two times; command executes three times 0011b-1110b - Loop corresponding number of times; command executes LOOP + 1 times 1111b - Loop 15 times; command executes 16 times
15-12 AVGS	Hardware Average Select Selects the number of ADC conversions averaged to create the ADC result (2^{AVGS}). During the execution of average iterations, an internal storage buffer is used to capture temporary results. Hardware averaging is a nested loop control and does not extend across LOOP boundaries. See Functional description to understand the usage of AVGS, LOOP, and NEXT in command execution sequencing. 0000b - Single conversion 0001b - 2 conversions 0010b - 4 conversions 0011b - 8 conversions 0100b - 16 conversions 0101b - 32 conversions 0110b - 64 conversions 0111b - 128 conversions 1000b - 256 conversions 1001b - 512 conversions 1010b - 1024 conversions
11 —	Reserved This field always has the value 0.
10-8 STS	Sample Time Select Selects the total sample time. If you write 0 to this field, the minimum sample time of 3.5 ADCK cycles is selected. When STS is programmed to a nonzero value, the sample time is ($3.5 + 2^{STS}$) ADCK cycles. The shortest sample time maximizes conversion speed for lower impedance inputs. Extending sample time allows higher impedance inputs to be sampled accurately. You can use longer sample times to lower the overall power consumption if you configure command looping and sequencing and high conversion rates are not required. 000b - Minimum sample time of 3.5 ADCK cycles 001b - $3.5 + 2^1$ ADCK cycles; 5.5 ADCK cycles 010b - $3.5 + 2^2$ ADCK cycles; 7.5 ADCK cycles 011b - $3.5 + 2^3$ ADCK cycles; 11.5 ADCK cycles 100b - $3.5 + 2^4$ ADCK cycles; 19.5 ADCK cycles

Table continues on the next page...

Table continued from the previous page...

Field	Function
	101b - 3.5 + 2^5 ADCK cycles; 35.5 ADCK cycles 110b - 3.5 + 2^6 ADCK cycles; 67.5 ADCK cycles 111b - 3.5 + 2^7 ADCK cycles; 131.5 ADCK cycles
7 LWI	Loop with Increment Enables auto-channel increment. If this field is 0, LOOP selects the number of times the selected channel is converted consecutively. When LWI = 1, auto channel incrementing is enabled and the LOOP field defines how many consecutive channels are converted as part of the command execution. Example 1: LOOP = 8h, LWI = 0b0, CMDL*n*[CTYPE] = 0h, CMDL*n*[ADCH] = Dh. Convert on channel 13A 9 times. Example 2: LOOP = 8h, LWI = 0b1, CMDL*n*[CTYPE] = 0h, CMDL*n*[ADCH] = Dh. Run channels 13A, 14A, 15A, ... 21A each one time. Maximum channel scanning using a single command buffer is then defined by the maximum value of LOOP[16]. 0b - Disable 1b - Enable
6-3 —	Reserved
2 WAIT_TRIG	Wait for Trigger Assertion Before Execution Specifies whether commands are executed automatically or an active trigger must be received before executing this command. If WAIT_TRIG is 1, wait states are added before the command until the active trigger is asserted again, which must happen before executing this command. If WAIT_TRIG is 0, each command is automatically executed when called. 0b - Execute automatically 1b - Receive trigger before execution
1-0 CMPEN	Compare Function Enable Enables the compare function. This field guides the operation of the automatic compare function to optionally store the compare result only when the compare function is true, after an ADC channel input is sampled and converted and any averaging iterations are performed. When the compare function is enabled, the conversion result is compared to the compare value registers (CV*n*[CVH] and CV*n*[CVL]). There are multiple options on command sequencing related to the compare function. See Compare function for a detailed explanation of the compare options. **NOTE** Not all command buffers implement CMPEN, which is only available in command buffers that have a corresponding Compare Value register. 00b - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	01b - Reserved 10b - Enable; store on true 11b - Enable; repeat channel acquisition (sample, convert, and compare) until true

38.6.20 Command High Buffer (CMDH5 - CMDH15)

Offset

For a = 5 to 15:

Register	Offset
CMDHa	FCh + (a × 8h)

Function

Consists of 15 command buffers (CMD*n*), each constructed from two 32-bit registers (CMDH*n*: CMDL*n*) that can be configured for different channel selections and varying conversion options. Any of the command buffers is selected and used as the controlling command by association to a trigger event via configuration of TCTRL*n*[TCMD]. When ADC is actively executing commands, only one of the CMD buffers is actively controlling ADC conversions. The actively controlling CMD buffer must not be updated while ADC is active. A write to a CMD buffer while that CMD buffer is controlling ADC operation can result in unpredictable behavior.

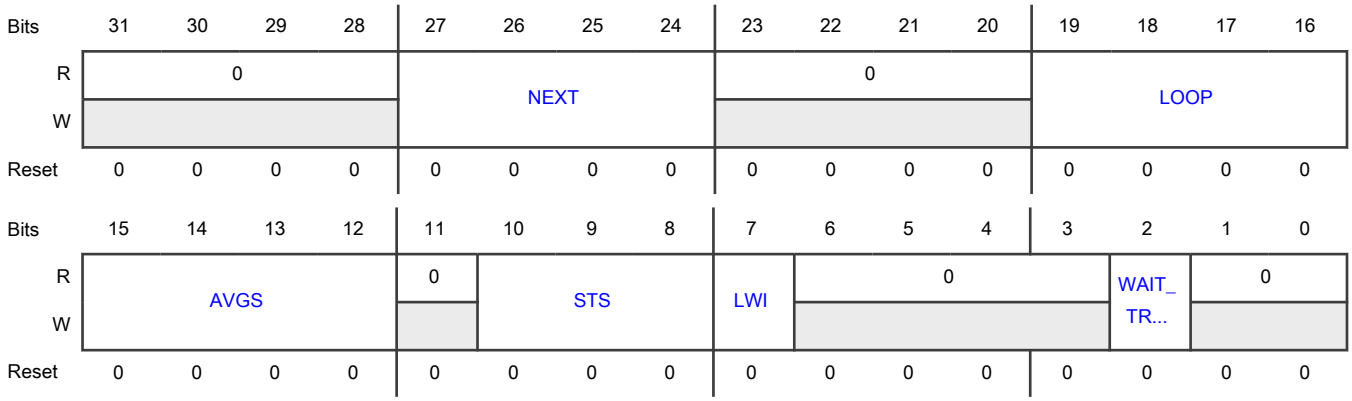
NOTE

The 15 command buffers are numbered [CMDH1:CMDL1] through [CMDH15:CMDL15]. In NXP-supplied header files, these are likely to be defined as two 15-element arrays that are indexed from 0. The type declaration is:

```
unsigned int CMDH[15];
unsigned int CMDL[15];
```

You access ADC0 CMDH1 as `ADC0->CMDH[0]` and ADC0 CMDL15 as `ADC0->CMDL[14]`.

Diagram



Fields

Field	Function
31-28 —	Reserved This field always has the value 0.
27-24 NEXT	Next Command Select Selects the next command to execute after the current command completes. You can configure multiple commands in a scan configuration by linking the next command in a daisy-chain sequence. The command buffer number is not indicative of any particular order, and the order of execution is strictly controlled by this field (for example, a sequence of commands could be CMD2 to CMD1 to CMD3). Unending circular command execution is allowed by writing 1 to this field in the last command in a sequence to the first command in the sequence. It also allows a command to set the next command to itself, resulting in a continuous conversion configuration. Setting the next command to 0h causes conversions to terminate after command completion. Lower-priority trigger events cannot be serviced until a higher-priority triggered command (or sequence of commands) completes. When this field is 0, no next command is defined. The field terminates conversions at the completion of the current command. If the lower-priority trigger is pending, the command associated with the lower-priority trigger begins. 0000b - No next command defined 0001b - CMD1 command buffer register 0010b-1110b - Corresponding CMD command buffer register 1111b - CMD15 command buffer register
23-20 —	Reserved This field always has the value 0.
19-16 LOOP	Loop Count Select Selects the number of times this command executes (and stores conversion result to RESFIFO) before completion and transition to the next command or Idle state. LWI controls whether a single channel is converted on each iteration or the auto-channel increment results in a channel scanning functionality. 0000b - Looping not enabled; command executes one time 0001b - Loop one time; command executes two times 0010b - Loop two times; command executes three times 0011b-1110b - Loop corresponding number of times; command executes LOOP + 1 times 1111b - Loop 15 times; command executes 16 times
15-12 AVGS	Hardware Average Select Selects the number of ADC conversions averaged to create the ADC result (2^{AVGS}). During the execution of average iterations, an internal storage buffer is used to capture temporary results. Hardware averaging is a nested loop control and does not extend across LOOP boundaries. See Functional description to understand the usage of AVGS, LOOP, and NEXT in command execution sequencing. 0000b - Single conversion

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0001b - 2 conversions 0010b - 4 conversions 0011b - 8 conversions 0100b - 16 conversions 0101b - 32 conversions 0110b - 64 conversions 0111b - 128 conversions 1000b - 256 conversions 1001b - 512 conversions 1010b - 1024 conversions
11 —	Reserved This field always has the value 0.
10-8 STS	Sample Time Select Selects the total sample time. If you write 0 to this field, the minimum sample time of 3.5 ADCK cycles is selected. When STS is programmed to a nonzero value, the sample time is (3.5 + 2^{STS}) ADCK cycles. The shortest sample time maximizes conversion speed for lower impedance inputs. Extending sample time allows higher impedance inputs to be sampled accurately. You can use longer sample times to lower the overall power consumption if you configure command looping and sequencing and high conversion rates are not required. 000b - Minimum sample time of 3.5 ADCK cycles 001b - 3.5 + 2^1 ADCK cycles; 5.5 ADCK cycles 010b - 3.5 + 2^2 ADCK cycles; 7.5 ADCK cycles 011b - 3.5 + 2^3 ADCK cycles; 11.5 ADCK cycles 100b - 3.5 + 2^4 ADCK cycles; 19.5 ADCK cycles 101b - 3.5 + 2^5 ADCK cycles; 35.5 ADCK cycles 110b - 3.5 + 2^6 ADCK cycles; 67.5 ADCK cycles 111b - 3.5 + 2^7 ADCK cycles; 131.5 ADCK cycles
7 LWI	Loop with Increment Enables auto-channel increment. If this field is 0, LOOP selects the number of times the selected channel is converted consecutively. When LWI = 1, auto channel incrementing is enabled and the LOOP field defines how many consecutive channels are converted as part of the command execution. Example 1: LOOP = 8h, LWI = 0b0, CMDL*n*[CTYPE] = 0h, CMDL*n*[ADCH] = Dh. Convert on channel 13A 9 times. Example 2: LOOP = 8h, LWI = 0b1, CMDL*n*[CTYPE] = 0h, CMDL*n*[ADCH] = Dh. Run channels 13A, 14A, 15A, ... 21A each one time.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Maximum channel scanning using a single command buffer is then defined by the maximum value of LOOP[16]. 0b - Disable 1b - Enable
6-3 —	Reserved
2 WAIT_TRIG	Wait for Trigger Assertion Before Execution Specifies whether commands are executed automatically or an active trigger must be received before executing this command. If WAIT_TRIG is 1, wait states are added before the command until the active trigger is asserted again, which must happen before executing this command. If WAIT_TRIG is 0, each command is automatically executed when called. 0b - Execute automatically 1b - Receive trigger before execution
1-0 —	Reserved

38.6.21 Compare Value (CV1 - CV4)

Offset

Register	Offset
CV1	200h
CV2	204h
CV3	208h
CV4	20Ch

Function

Contains the value used to compare the conversion result when the compare function is enabled. This register is formatted in the same way as RESFIFO*n*[D] in different modes of operation for both bit position definition and value format using unsigned or signed two's-complement. This register has a direct association with the specific command buffer register (that is, CV1 is used only during the execution of the CMD1 command).

NOTE

The compare function is only available for command buffers that have a corresponding Compare Value register.

When ADC is actively executing commands, Compare Value (CV1 - CV4) associated with the active command (CMD*n*) must not be updated. Writes to the associated CV*n* register during this time can result in unpredictable behavior.

NOTE

The 4 compare value registers are numbered [CV1] through [CV4]. In NXP-supplied header files, this is likely to be defined as a 4-element array that is indexed from 0. Therefore, the type declaration is:

```
unsigned int CV[4];
```

You must access ADC0 CV1 as `ADC0->CV[0]` and ADC0 CV4 as `ADC0->CV[3]`.

Fields

Field	Function
31-16 CVH	Compare Value High Checks whether the result is less than, greater than, or if the result falls within or outside a range determined by two compare values. After the input is sampled and converted and any averaging iterations are performed, the compare values in CVL and CVH are optionally used in a compare operation on the result. See Compare function for a description on how CVH is used.
15-0 CVL	Compare Value Low Checks whether the result is less than, greater than, or if the result falls within or outside a range determined by two compare values. After the input is sampled and converted and any averaging iterations are performed, the compare values in CVL and CVH are optionally used in a compare operation on the result. See Compare function for a description on how CVL is used.

38.6.22 Data Result FIFO (RESFIFO0 - RESFIFO1)

Offset

Register	Offset
RESFIFO0	300h
RESFIFO1	304h

Function

Stores the data result of ADC conversions. RESFIFO is a 16 entry FIFO. Additionally, several tag fields of the source command and trigger information are stored along with the data. FCTRL*n*[FCOUNT] indicates the number of valid data words stored in

RESFIFO. Reading RESFIFO provides the oldest unread data word entry in the FIFO and decrements FCTRL*n*[FCOUNT]. The FIFO can be emptied by successive reads of RESFIFO. Write 1 to CTRL[RSTFIFO*n*] to reset the FIFO.

The following table describes the format of data in result FIFO in the different modes of operation. The sign bit is the MSB in signed two's-complement modes. For example, when configured for 12-bit single-ended mode, D[15] and D[2:0] become 0. When configured for 13-bit differential mode, D[15] is the sign bit and D[2:0] becomes 0.

Table 300. Data result register format description

Conversion mode	D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0	Format
16-bit differential	S	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	Signed two's-complement, JLEFT = X
16-bit single-ended	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	D	Unsigned, 16-bit magnitude, JLEFT = X
13-bit differential	S	D	D	D	D	D	D	D	D	D	D	D	D	0	0	0	Signed two's-complement, left-justified, zero extended, JLEFT = X
12-bit single-ended	0	D	D	D	D	D	D	D	D	D	D	D	D	0	0	0	Unsigned, JLEFT = 0, zero in D[15] and D[2:0]
12-bit single-ended	D	D	D	D	D	D	D	D	D	D	D	D	0	0	0	0	Unsigned, JLEFT = 1, zero in D[3:0]

NOTE

S: Sign bit

D: Data, which is two's-complement data if indicated

Fields

Field	Function
31 VALID	FIFO Entry is Valid Indicates whether the FIFO entry is valid. This field becomes 1 when the FIFO is holding data. Also, the FIFO record read from RESFIFO is valid. When the FIFO is empty, the field becomes 0 and any read from RESFIFO is discarded. 0b - Not valid 1b - Valid
30-28 —	Reserved This field always has the value 0.
27-24 CMDSRC	Command Buffer Source Indicates the command buffer used as control settings for this conversion. If this field is 0, 0h is only found in the initial FIFO state prior to an ADC conversion result dataword being stored in a RESFIFO buffer. 0000b - Not a valid CMDSRC value for a dataword in RESFIFO 0001b - CMD1 0010b-1110b - Corresponding command 1111b - CMD15
23-20 LOOPCNT	Loop Count Value Indicates the loop count value during command execution that generated this result. If CMDH*n*[LOOP] is a nonzero value, the command execution stores off a result multiple times during command execution (at the loop boundary). 0000b - Initial conversion 0001b - Second conversion 0010b-1110b - LOOPCNT + 1 conversion 1111b - 16th conversion
19-17 —	Reserved This field always has the value 0.
16 TSRC	Trigger Source Indicates the trigger source that initiated a conversion and generated this result. When multiple commands are chained together using CMDH*n*[NEXT], the TSRC value for all datawords stored in Data Result FIFO (RESFIFO0 - RESFIFO1) indicates the trigger source that started the sequence of commands. 0b - Trigger source 0 1b - Trigger source 1
15-0	Data Result

D	Indicates the data result. The formatting of the data in this field is summarized in Table 300.

38.6.23 Calibration General A-Side (CAL_GAR0 - CAL_GAR32)

Offset

For a = 0 to 32:

Register	Offset
CAL_GARa	400h + (a × 4h)

Function

Corrects linearity errors of the A-side converter. This set of registers contains calibration information that is automatically updated during the self-calibration sequence. See Calibration for more information on completing ADC calibration steps.

The calibration values in this register set affect the end conversion result by conditionally being subtracted from the conversion before the end result is transferred into the FIFOs. Calibration must be run each time ADC is powered down or a hard reset is issued. To reduce the latency required to run calibration, the values in this register must be stored in a nonvolatile memory after an initial calibration and recovered prior to the first ADC conversion. If these registers are set to values that are not generated by the calibration function, the linearity error specifications may not be met.

This CAL_GAR set of registers is only read-write accessible when ADC is disabled with CTRL[ADCEN] = 0b0. When writing to these registers, the access time is larger than three ADC clock cycles. Wait states are inserted on the bus to meet synchronization timing to the associated CAL_GAR register.

Each CAL_GAR register has a 16-bit signed value with a nonuniform supported range of values. The valid range of each register is summarized in Calibration general A-side and B-side register valid ranges.

Diagram

Fields

Field	Function
31-16 —	Reserved This field always has the value 0.
15-0 CAL_GAR_VAL	Calibration General A-Side Register Element Specifies a 16-bit signed value with a nonuniform supported range of values.

38.6.24 Calibration General B-Side (CAL_GBR0 - CAL_GBR32)

Offset

For a = 0 to 32:

Register	Offset
CAL_GBRa	500h + (a × 4h)

Function

Corrects linearity errors of the B-side converter. This set of registers contains calibration information that is automatically updated during the self-calibration sequence. See Calibration for more information on completing ADC calibration steps.

The calibration values in the CAL_GBR registers affect the end conversion result by conditionally being subtracting from the conversion before the end result is transferred into the FIFOs. Calibration must be run each time ADC is powered down or a hard reset is issued. To reduce the latency required to run calibration, the CAL_GBR values can be stored in a nonvolatile memory after an initial calibration and recovered prior to the first ADC conversion. If you set these registers to values that are not generated by the calibration function, the linearity error specifications may not be met.

The CAL_GBR registers are read-write accessible only when ADC is disabled with CTRL[ADCEN] = 0b0.

NOTE

- The access time when writing to these registers is greater than three ADC clock cycles. Wait states are inserted on the bus to meet synchronization timing to the associated CAL_GBR register.
- The value in each CAL_GBR register is a 16-bit signed value but has nonuniform supported range of values. The valid range of each register is summarized in Calibration general A-side and B-side register valid ranges.

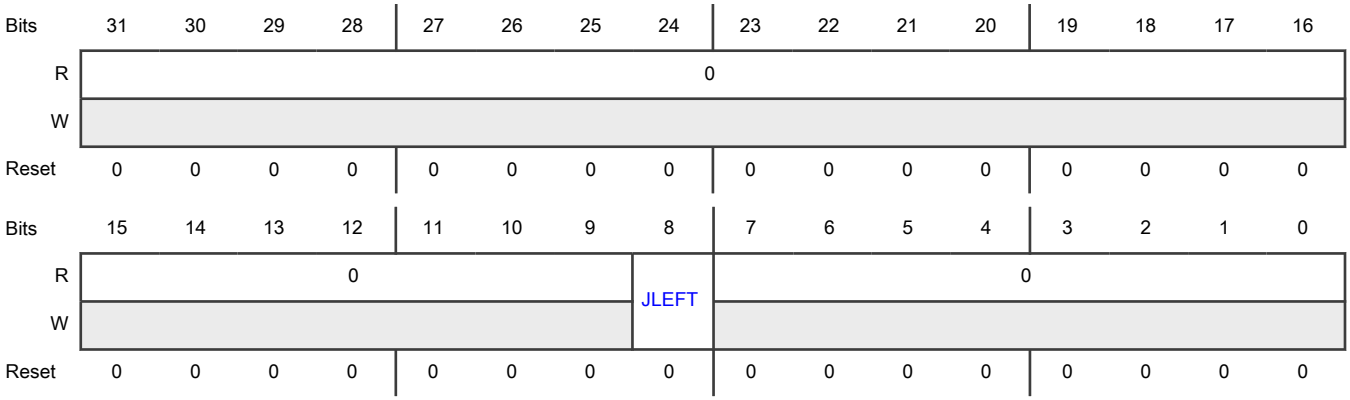
38.6.25 Configuration 2 (CFG2)

Offset

Register	Offset
CFG2	FF8h

Function
Controls ADC functions that are common to all commands.

Diagram



Fields

Field	Function
31-9 —	Reserved This field always has the value 0.
8 JLEFT	Justified Left Enable Enables the data to be stored in Data Result FIFO (RESFIFO0 - RESFIFO1) in left-justified format, in 12-bit single-ended mode. The formatting for the data in RESFIFO*n*[D] is summarized in Table 300.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When CTRL[ADCEN] is 1, you cannot change this field. Any writes are ignored. If this field is 0, for 12-bit single-ended conversions, the RESFIFO data format is in the standard format with data presented in RESFIFO*n*[D][14:3]. If this field is 1, for 12-bit single-ended conversions, the RESFIFO data format is left-justified. **NOTE** In JLEFT mode, you must program CV*n*[CVL] and CV*n*[CVH] in the left-justify format to generate the correct compare results. 0b - Standard format 1b - Left-justified format
7-0 —	Reserved This field always has the value 0.

Chapter 39
Comparator (ACMP)

39.1 Chip-specific ACMP information

Table 301. Reference links to related information

Topic	Related module	Reference
Full description	ACMP	ACMP
Peripheral memory map		Memory map overview
Power management	PMC	Power overview PMC
Clocking		Clock overview Clock controller
Signal multiplexing	IOPCTL	External signals and pin multiplexing IO PAD controller

39.1.1 Module instances

This device has one instance of the ACMP module, ACMP0.

Table 302. ACMP instance

Features	ACMP0
Located in	VDD1_SENSE
Access	CPU0, CPU1, HiFi4, HiFi1, eDMA0, eDMA1, eDMA2, eDMA3

39.1.2 External pin signals

In order to use the CMP's analog input comparison function, you need to enable the analog function of the related pins by writing 1 to the IOPCTL1_PIO10_xx[AMENA].

The following table lists the pins that can be configured as CMP analog inputs.

Table 303. ACMP external pin signals

Chip pin	Module external signal
PIO10_8/CMP0_INA	INA_1P8_1
PIO10_9/CMP0_INB	INA_1P8_2
PIO10_16/CMP0_INC	INA_1P8_3
PIO10_17/CMP0_IND	INA_1P8_4

39.1.3 Internal input 0

In this chip, the internal positive input 0 and internal negative input 0 are not connected, 000b in C1[PSEL] and C1[MSEL] is reserved.

39.1.4 DAC supply voltage reference source

The following table lists the supply voltage reference sources.

Table 304. DAC supply voltage reference source

Voltage reference (Vin)	Source
Vin1	Unused
Vin2	VDD1V8

39.1.5 Initialization

Initial configuration of a comparator peripheral is accomplished as follows:

- Enable the clock to the ACMP0 register interface by writing 1 to the CLKCTL3_PSCCTL0_COMP[ACMP0] or CLKCTL3_PSCCTL0_COMP_SET[ACMP0].
- Clear the ACMP0 reset by writing 0 to the RSTCTL3_PRSTCTL1[ACMP0] or writing 1 to the RSTCTL3_PRSTCTL1_CLR[ACMP0].

39.2 Overview

ACMP includes the following submodules:

- High-speed comparator (CMP) (see CMP block diagram)
- Digital-to-analog converter (DAC) (see DAC block diagram)
- Analog mux (ANMUX) (see ANMUX key features)

CMP provides a circuit to compare two analog input voltages. The comparator circuit operates across the full range of the supply voltage, known as rail-to-rail operation.

ANMUX provides a circuit to select an analog input signal from eight channels. DAC provides one signal. The mux circuit operates across the full range of the supply voltage.

DAC is a 256-tap resistor ladder network that provides a selectable voltage reference for applications requiring a voltage reference. It divides the supply reference, V_{in}, into 256 voltage levels. An 8-bit digital register input selects the output voltage level, which varies from V_{in} to $V_{in}/256$. You can select V_{in} from two voltage sources: V_{in1} or V_{in2}.

39.2.1 ACMP block diagram

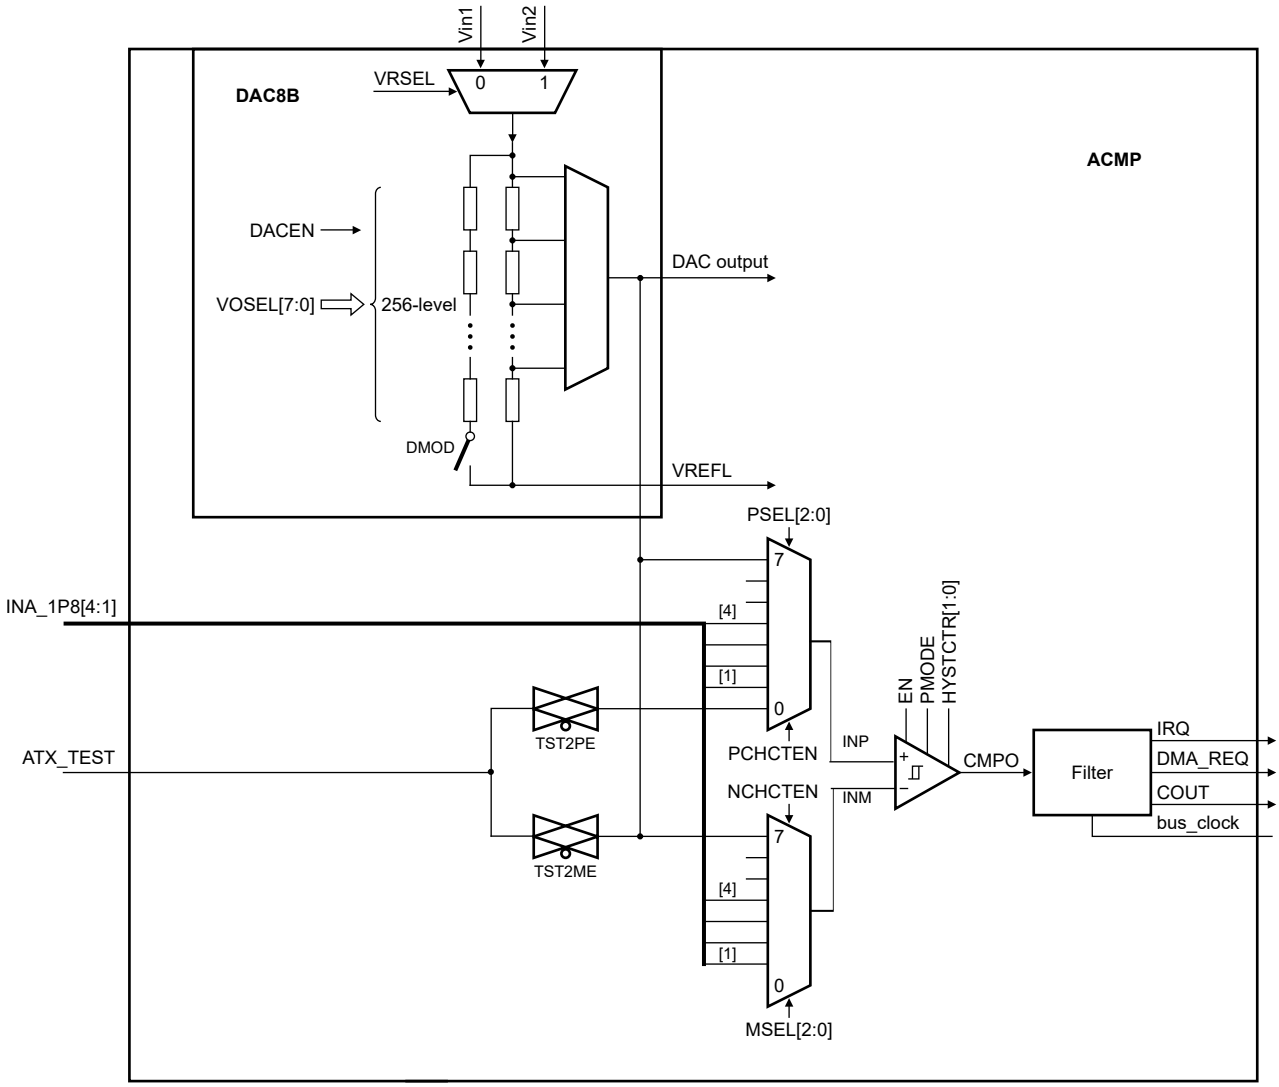


Figure 119. ACMP block diagram

39.2.2 CMP block diagram

In Figure 120 CMP:

- Bypasses the filter block when it is not in use.

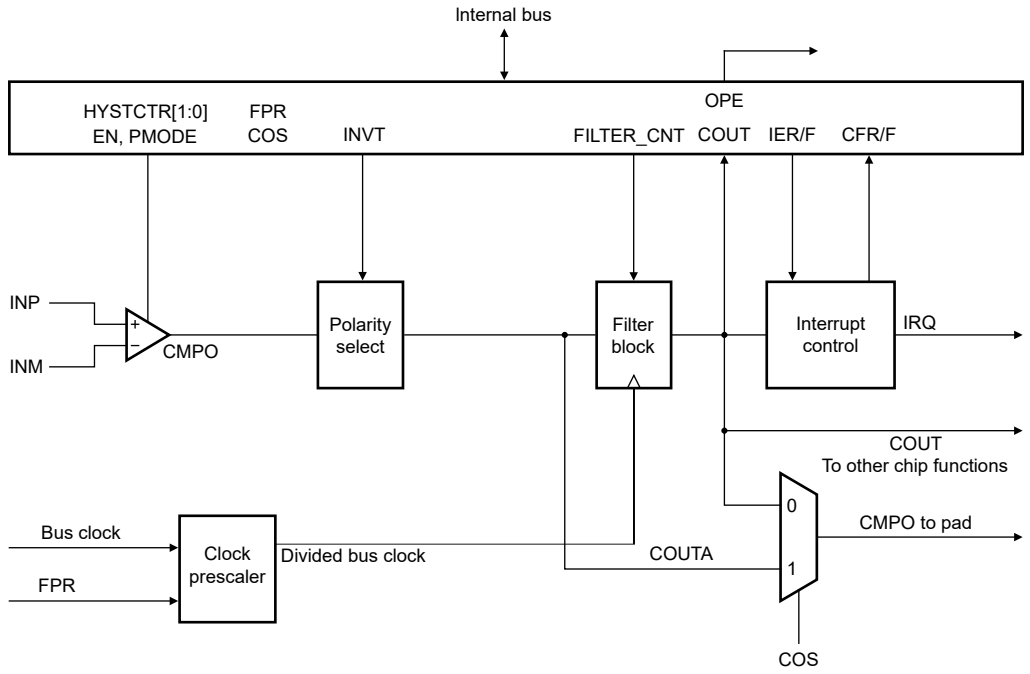

Figure 120. CMP block diagram

The filter block bypass operates as follows:

- If enabled, the filter block incurs an additional latency penalty of up to one bus clock on COUT. This is because COUT, which crosses clock domain boundaries, must resynchronize with the bus clock.

39.2.3 Features

The following subsections list the features of high-speed CMP, 8-bit DAC, and ANMUX.

39.2.3.1 CMP features

- Operates over the entire supply range
- Supports rail-to-rail inputs
- Supports programmable hysteresis control
- Provides a selectable interrupt on rising-edge, falling-edge, or both comparator outputs
- Provides a selectable inversion on comparator output
- Includes the capability to produce a wide range of outputs, such as:
  - Digitally filtered:
    - Bypass filter
- Uses external hysteresis at the same time that the output filter is used for internal functions
- Supports two software selectable performance levels:
  - Shorter propagation delay at the expense of higher power
  - Low power, with a longer propagation delay
- Supports DMA transfer (CMP can select a comparison event to trigger a DMA transfer)
- Functional in all MCU power modes

CMP's filter functions are unavailable in Stop modes.

Other peripherals trigger the comparator.

39.2.3.2 8-bit DAC key features

- 8-bit resolution
- Selectable supply reference source
- Low-Power mode or High-Speed mode that you can configure
- Power-Down mode to conserve power when not in use
- Routing of the output of the 8-bit DAC to the internal comparator input, where you can select it as one of the CMP inputs as a reference for comparison

39.2.3.3 ANMUX key features

- Two 8-to-1 channel MUXes that can be selected as the source for comparator input
- Operation over the entire supply range

39.3 CMP functional description

CMP can compare two analog input voltages applied to INP and INM. CMPO is high when the non inverting input is greater than the inverting input, and it is low when the non inverting input is less than the inverting input. Write 1 to C0[INVT] to selectively invert this signal.

C0[IER] and C0[IEF] select the condition that causes CMP to assert an interrupt to the processor. C0[CFF] sets on a falling edge, and C0[CFR] sets on a rising edge of the comparator output. You can read the optionally filtered CMPO directly through C0[COUT].

39.3.1 CMP functional modes

CMP includes the following main sub-blocks:

- Comparator

For cases where a comparator drives a fault input, for example, for a motor-control module such as FTM or FlexPWM, it must configure to operate in Continuous mode so that an external fault can immediately pass through the comparator to the target fault circuitry.

39.3.1.1 Disabled mode

In this mode:

- The analog comparator is nonfunctional and consumes no power.
- CMPO is 0.

39.3.1.2 Continuous mode

In this mode, the analog comparator block is powered and active. CMPO may be optionally inverted but is not subject to filtering. CMP completely bypasses the filter block and update C0[COUT] continuously. The path from comparator input pins to output pins operates in a combinational unclocked mode. COUT and COUTA are identical.

See CMP block diagram section for control configurations that result in disabling the filter block.

Figure 121 describes the comparator operation in Continuous mode.

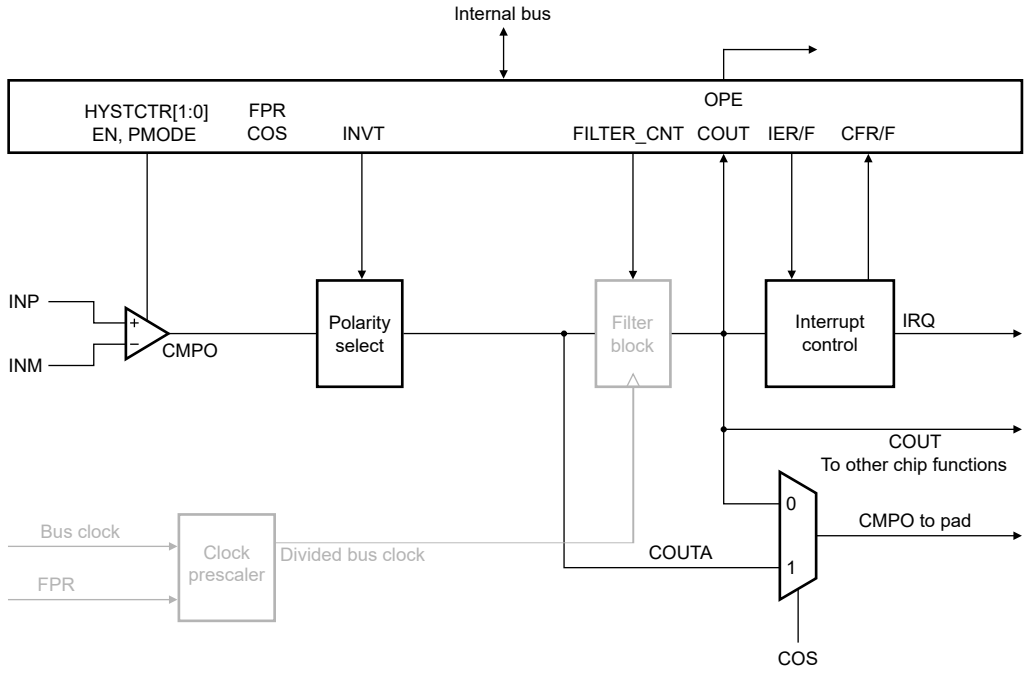

Figure 121. Comparator operation in Continuous mode

39.3.2 Low-pass filter

The low-pass filter operates on the unfiltered, unsynchronized, and optionally inverted comparator output, COUTA, and generates the filtered and synchronized output, COUT. You can configure both COUTA and COUT as module outputs, and use them for different purposes within the system.

Synchronization and edge detection always determine the status register bit values. .

The need for digital filtering and the amount of filtering depends on your requirements. Filtering can become more useful in the absence of an external hysteresis circuit, without which you can generate high-frequency oscillations at COUTA when the selected INM and INP input voltages differ by less than the offset voltage of the differential comparator.

39.3.3 CMP clocks

This module contains the following clocks:

- Bus clock (ipg_clk/ipg_clk_s) for access to registers and filter operation

39.3.4 Interrupts

CMP generates an interrupt on either the rising-edge or falling-edge of the comparator output, or both. Assuming that C0[DMAEN] is not 1, the following table presents the conditions in which the interrupt request is asserted and deasserted.

Table 305. CMP interrupt generations

Condition	Result
C0[IER] and C0[CFR] are 1.	The interrupt request is asserted.
C0[IEF] and C0[CFF] are 1.	The interrupt request is asserted.
C0[IER] and C0[CFR] are 0 for a rising-edge interrupt.	The interrupt request is deasserted.
C0[IEF] and C0[CFF] are 0 for a falling-edge interrupt.	The interrupt request is deasserted.

39.3.5 DMA support

CMP generates a CPU interrupt if there is a change on COUT. The corresponding change on COUT forces a DMA transfer request rather than a CPU interrupt after writing 1 to C0[DMAEN] to enable the DMA support, and writing 1 to C0[IER], C0[IEF], or both to enable the interrupt. After the DMA completes transfer, it sends a transfer-completing indicator signal that deasserts the DMA transfer request and clears the flags (C0[CFR] and C0[CFF]) to allow a subsequent change on the comparator output to occur and force another DMA request.

39.4 DAC functional description

39.4.1 DAC block diagram

The following figure shows a 256-tap resistor ladder network and a 256-to-1 multiplexer. They select an output voltage from one of the 256 distinct levels that outputs from DACO.

CMP Control 1 (C1) controls DAC. You can select its supply reference source from two sources, V_{in1} and V_{in2}. Power down or disable the module when not in use. In Disabled mode, DACO is connected to the analog ground.

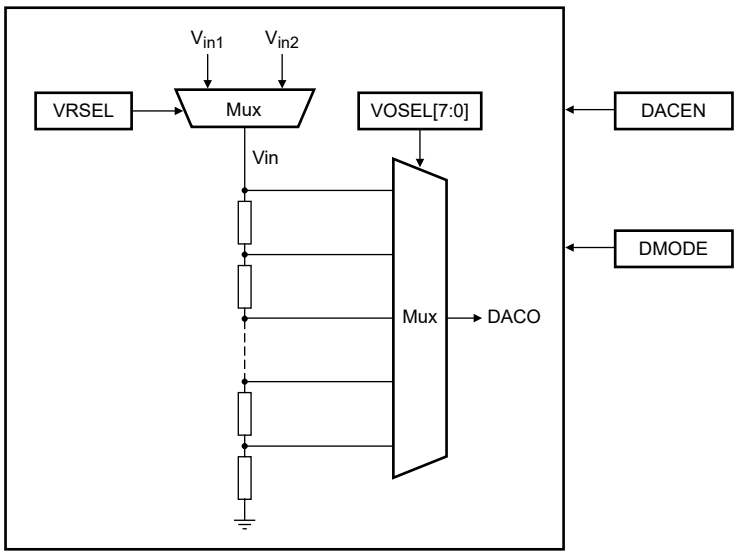

Figure 122. 8-bit DAC block diagram

39.4.2 Voltage reference source select

You must use:

- V_{in1} to connect to the primary voltage source as a supply reference of the 256-tap resistor ladder.
- V_{in2} to connect to an alternate voltage source, or primary source, if an alternate voltage source is not available.

39.4.3 DAC reset

This module contains a single reset input corresponding to the chip-wide peripheral reset.

39.4.4 DAC clocks

This module contains a single clock input: bus clock (ipg_clk/ipg_clk_s) for access to registers and filter operation.

39.4.5 DAC interrupts

This module has no interrupts.

39.5 CMP external signals

C1[PSEL] and C1[MSEL] mux the external 1.8 V domain inputs, INA_1P8 [4:1], before going to the positive port (INP) and negative port (INM) of the comparator, respectively.

Each pin can accept an input voltage that varies across the full operating range of the MCU. If the module is not enabled, you can use each pin as a digital input or output. See the specific MCU documentation for more information on what functions are shared with these analog inputs.

You can select either filtered or unfiltered comparator outputs for use on an external I/O pad.

Table 306. CMP external signals

Signal	Description	I/O
INA_1P8 [4:1]	Analog 1.8 V input channels [4:1]	I

39.6 Initialization

The time required to stabilize COUT is the power on delay of the comparators plus the largest propagation delay from a selected analog source through the analog comparator and filter. Low-pass filter specifies the filter delay.

During operation, you must always consider the propagation delay of the selected data paths. It may take many bus clock cycles for COUT and C0[CFR] or C0[CFF] to reflect an input change or a configuration change to one of the components involved in the data path.

When programmed for filtering modes, COUT initially equals 0 until sufficient clock cycles have elapsed to fill all stages of the filter. This occurs even if COUTA is at a logic 1.

39.7 ACMP register descriptions

39.7.1 ACMP memory map

ACMP0 base address: 4020_B000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Version ID (VERID)	32	R	0100_0000h

Field	Function
CFF	Detects a falling edge on COUT, when set, during normal operation. In Stop mode, this field is level sensitive. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag
24 COUT	Analog Comparator Output Returns the current value of the analog comparator output, when read. The field resets to 0 and reads as C0[INVT] when ACMP is disabled, that is, when C0[EN] = 0. Writes to this field are ignored.
23-16 FPR	Filter Sample Period Specifies the sampling period, in bus clock cycles, of the comparator output filter. Writing 0h to this field disables the filter. See CMP functional description for more information on filter programming and latency.
15-14 —	Reserved
13 —	Reserved
12 PMODE	Power Mode Select Selects the power mode. 0b - Low-speed (LS) 1b - High-speed (HS)
11 INVT	Comparator Invert Selects the polarity of the analog comparator function. It is also driven to the COUT output (on the chip pin and as C0[COUT]) when C0[OPE] = 0. If this field is 1, the comparator output is inverted. If this field is 0, the comparator output is not inverted. 0b - Do not invert 1b - Invert
10	Comparator Output Select

Table continues on the next page...

Table continued from the previous page...

Field	Function
COS	Specifies whether CMPO must be set to equal COUT (filtered comparator output) or COUTA (unfiltered comparator output). 0b - COUT 1b - COUTA
9 OPE	Comparator Output Pin Enable Enables the path from the comparator output to a selected pin. If the value of this field is 0, the comparator output (after filter settings depending on software configuration) is not available to a packaged pin. If the value of this field is 1 and the software configures the comparator to own a packaged pin, the comparator is available in a packaged pin. 0b - Disable 1b - Enable
8 EN	Analog Comparator Module Enable Enables ACMP. When the module is not enabled, the analog part remains in the off state, and consumes no power. 0b - Disable 1b - Enable
7 —	Reserved
6-4 FILTER_CNT	Filter Sample Count Specifies the number of consecutive samples that must agree prior to the comparator output filter accepting a new output state. 000b - Filter is disabled 001b - One consecutive sample 010b - Two consecutive samples 011b - Three consecutive samples 100b - Four consecutive samples 101b - Five consecutive samples 110b - Six consecutive samples 111b - Seven consecutive samples

40.2 Overview

uSDHC provides the interface between the host system and the eMMC, SD card, and SDIO as shown in Figure 124. The module acts as a bridge, passing host bus transactions to the eMMC, SD card, and SDIO by sending commands and performing data accesses to/from the cards. It handles the SD card/SDIO/eMMC protocols at the transmission level.

40.2.1 Block diagram

The following figure illustrates the block diagram for uSDHC. Dual port SRAM is FIFO for write/read. For more information, see Data buffer.

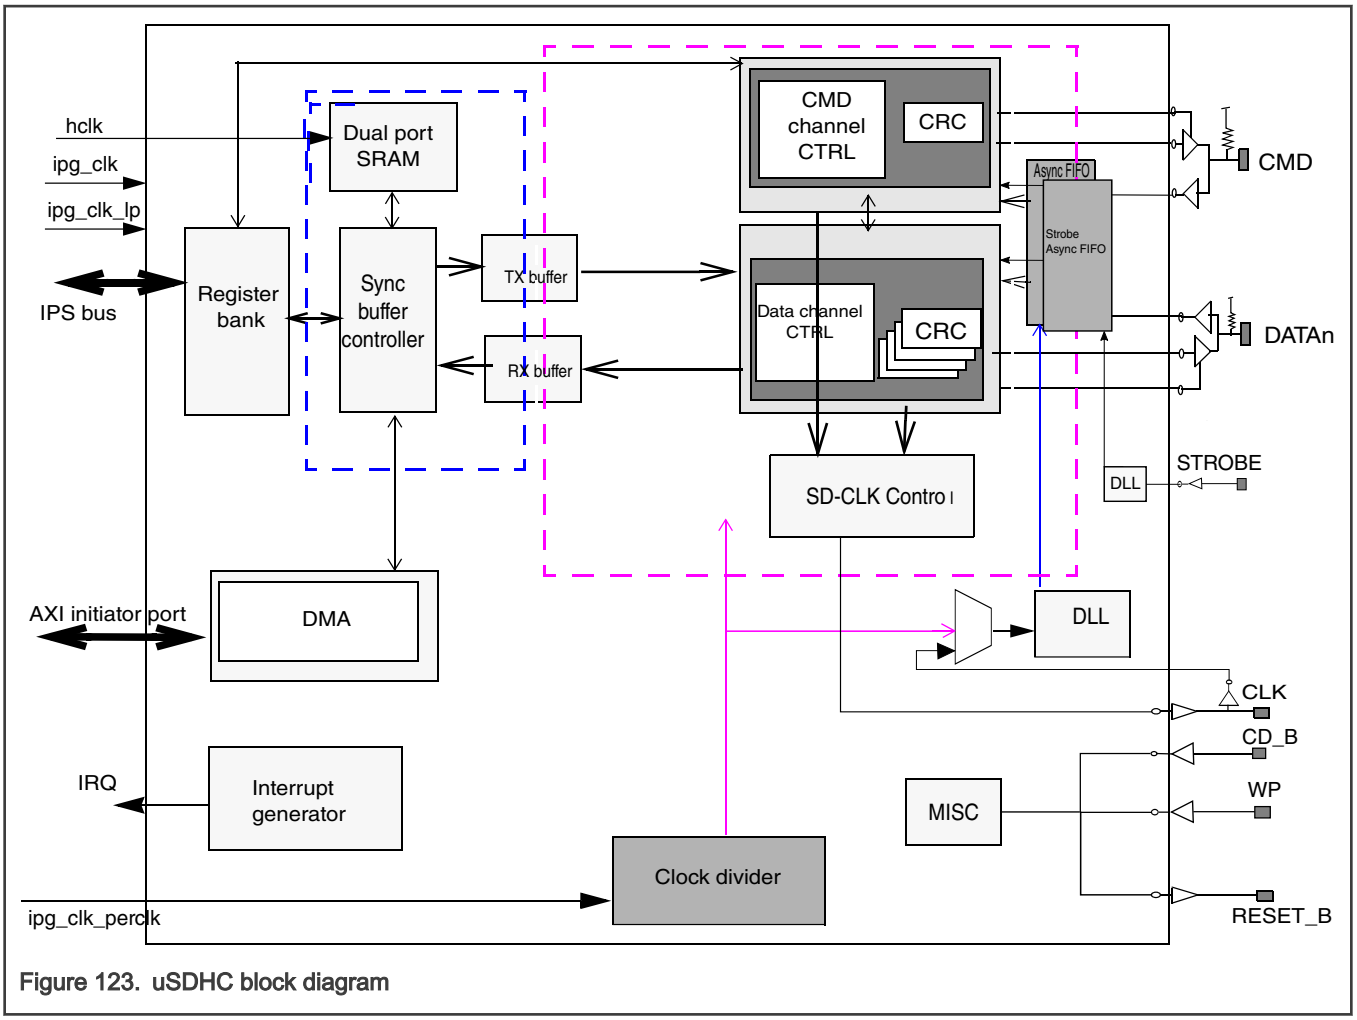

Figure 123. uSDHC block diagram

The figure below shows the System connection of uSDHC:

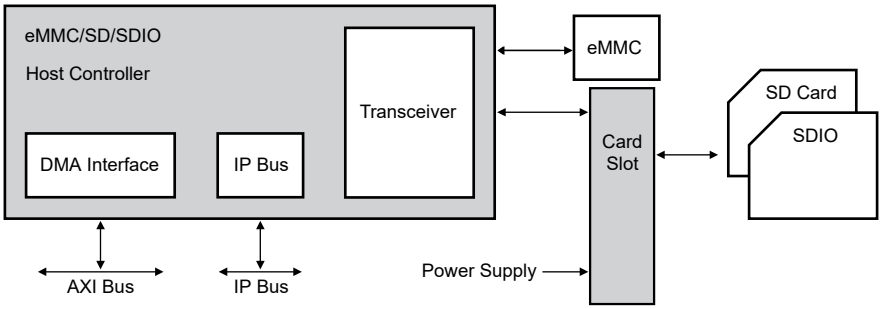

Figure 124. System connection of uSDHC

The following are brief descriptions of the cards supported by uSDHC:

- The Embedded MultiMediaCard (eMMC) is a universal low-cost data storage and communication media designed to cover a wide array of applications including mobile video and gaming. Previous eMMC were based on a 7-pin serial bus with a single data pin, while the new high speed eMMC communication is based on an advanced 11-pin serial bus designed to operate in the low-voltage range.
- The Secure Digital Card (SD) is an evolution of the old eMMC technology. It is specifically designed to meet the security, capacity, performance, and environmental requirements inherent in newly emerging audio and video consumer electronic

devices. The physical form factor, pin assignment, and data transfer protocol are backward compatible with the old eMMC (with some additions).

- Under the SD protocol, system connection can be categorized into memory card, I/O card, and combo card, which have both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI (Secure Digital Music Initiative) standard. The I/O card, which is also known as SDIO, provides high-speed data I/O with low-power consumption for mobile electronic devices.

40.2.2 Features

The list given below shows the features of the uSDHC module:

- Conforms to the SD Host Controller Standard Specification version 2.0/3.0
- Compatible with the eMMC System Specification version 4.2/4.3/4.4/4.41/4.5/5.0/5.1
- Compatible with the SD Memory Card Specification version 3.0 and supports the Extended Capacity SD Memory Card
- Compatible with the SDIO Specification version 2.0/3.0
- Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, eMMC, MMC plus, and MMC RS cards
- For card bus clock frequency: See the product Data Sheet for the clock frequency of each supported mode.
- Supports 1-bit/4-bit SD and SDIO modes, and 1-bit/4-bit/8-bit eMMC modes
  - Up to 832 Mbps of data transfer for SDIO using four parallel data lines in the Single Data Rate (SDR) mode
  - Up to 400 Mbps of data transfer for SDIO using four parallel data lines in the Dual Data Rate (DDR) mode
  - Up to 832 Mbps of data transfer for SDXC cards using four parallel data lines in the Single Data Rate (SDR) mode
  - Up to 400 Mbps of data transfer for SDXC card using four parallel data lines in the Dual Data Rate (DDR) mode
  - Up to 1600 Mbps of data transfer for eMMC using eight parallel data lines in the Single Data Rate (SDR) mode
  - Up to 3200 Mbps of data transfer for eMMC using eight parallel data lines in the Dual Data Rate (DDR) mode
- Supports single block/multi-block read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports Auto CMD12 for multi-block transfer for memory device
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes; also supports interrupt period
- Supports internal DMA capabilities
- Supports voltage selection by configuring vendor-specific register bit VEND_SPEC[VSELECT]
- Supports Advanced DMA to perform linked memory access
- Supports Command Queue mechanism

NOTE

This block can support all the above-listed speed mode and maximum data throughput. However, these may be specific to the device. See the corresponding chip-specific information or the device data sheet for accurate details.

40.3 Functional description

The following sections provide a brief functional description of the major system blocks, including the data buffer, DMA AXI interface, register bank as well as IP Bus interface, dual-port memory wrapper, data/command controller, clock and reset manager, and clock generator.

40.3.1 Modes and operations

40.3.1.1 Data transfer modes

The uSDHC module can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- eMMC 1-bit
- eMMC 4-bit
- eMMC 8-bit
- Identification mode (up to 400 kHz)
- eMMC full-speed mode (up to 26 MHz)
- eMMC high-speed mode (up to 52 MHz)
- eMMC HS200 mode (up to 200 MHz)
- eMMC HS400 mode (200 MHz both edges)
- eMMC DDR mode (52 MHz both edges)
- SD card or SDIO full-speed mode (up to 25 MHz)
- SD card or SDIO high-speed mode (up to 50 MHz)
- SD card or SDIO UHS-I mode (up to 208 or 100 MHz in SDR mode, up to 50 MHz in the DDR mode)

NOTE

This block can support all the above listed speed mode and maximum clock frequency. However, these may be specific to the device. See the corresponding chip-specific information or the device data sheet for accurate details.

40.3.2 Data buffer

The uSDHC module uses one configurable data buffer to transfer data between the system bus (IP bus or advanced extensible interface (AXI) bus) and the SD card in an optimized manner, maximizing throughput between the two clock domains (IP peripheral clock and the AXI initiator clock). The buffer is used as a temporary storage for transferring data between the host system and the card. The watermark levels for read and write are both configurable and can range between 1 to 128 words. When using internal DMA mode, The watermark level for read should be configured to 16 and watermark level for write should be configured to integral multiple of 16 to get max AXI bus throughput. The next figure provides the uSDHC buffer scheme as buffer control and buffer RAM wrapper.

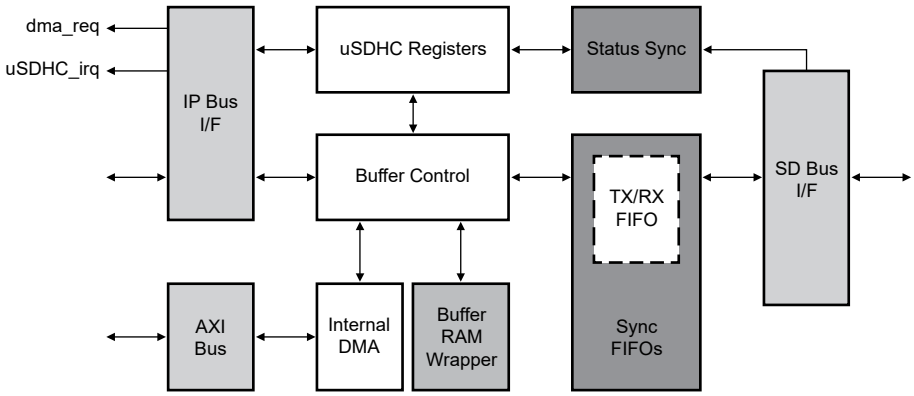

Figure 125. uSDHC buffer scheme

Here are 2 transfer modes to access the data buffer:

- CPU polling mode:
  - For a host-read operation, when the number of words received in the buffer meets or exceeds the RD_WML watermark value, by polling the BRR bit, the host driver can read the Buffer Data Port register to fetch the amount of words set in the RD_WML register from the buffer. The write operation is similar. For more information on the process of writing operation, see Write operation sequence.
- Internal DMA mode (includes simple and advanced DMA accesses):
  - The internal DMA access, either by simple or advanced DMA, is over the AXI bus.

For a read operation, when there are more words in the buffer than the amount set in WTMK_LVL[RD_WML], the internal DMA starts fetching data over the AXI bus.

The Write operation functions in a similar manner—sequential and contiguous access is necessary to ensure that the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actual byte order is swapped inside the buffer, according to the endian mode configured by software (see the following figures). For a host write operation, the byte order is swapped after the data is fetched from the buffer and ready to send to the SD Bus. For a host read operation, the byte order is swapped before the data is stored in the buffer.

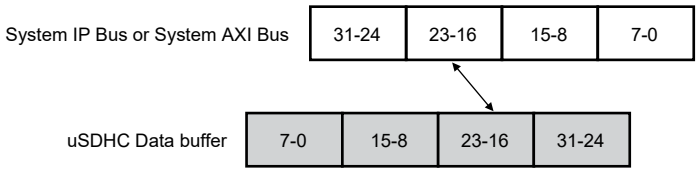

Figure 126. Data swap between system bus and uSDHC data buffer in the byte little endian mode

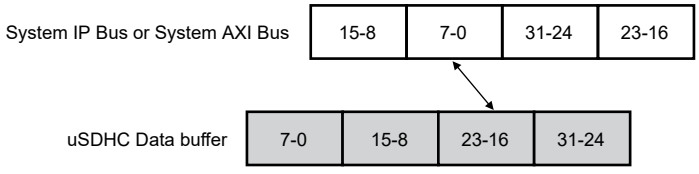

Figure 127. Data swap between system bus and uSDHC data buffer in half word big endian mode

40.3.2.1 Write operation sequence

There are 2 ways to write data into the buffer when the user transfers data to the card:

- Processor core polling through the BWR bit in the Interrupt Status register (interrupt or polling)
- Internal DMA

When the internal DMA is not used, the DMAEN bit in the Transfer Type register is not set when the command is sent, uSDHC asserts a DMA request when the amount of buffer space exceeds the value set in WTMK_LVL[WR_WML] and is ready for receiving new data. At the same time, uSDHC sets the BWR bit. The buffer write ready interrupt is generated if it is enabled by software.

When internal DMA is used, uSDHC does not inform the system before all the required number of bytes are transferred (if no error is encountered). When an error occurs during the data transfer, uSDHC stops the data transfer and abandons the current block. The host driver should read the contents of the DMA System Address register to obtain the starting address of the abandoned data block. If the current data transfer is in multi-block mode, uSDHC does not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The host driver sends CMD12 in this scenario and restarts the write operation from that address. It is recommended that a software reset for Data be applied before the transfer is restarted.

The uSDHC module does not start data transmission until the buffer has been filled with the number of words set in the WR_WML register. If the buffer is empty and the host system does not write data in time, uSDHC stops the CLK to avoid the data buffer underrun situation.

40.3.2.2 Read operation sequence

There are 2 ways to read data from the buffer when the data is received from the card:

- Processor core polling through the BRR bit in the Interrupt Status register (interrupt or polling)
- Internal DMA

When internal DMA is not used (DMAEN bit in Transfer Type register is not set when the command is sent), uSDHC asserts a DMA request when the amount of data exceeds the value set in the RD_WML register, which is available and ready for system fetching data. At the same time, uSDHC sets the BRR bit. The buffer read ready interrupt is generated if it is enabled by the software.

When internal DMA is used, uSDHC does not inform the system before all the required number of bytes are transferred (if no error is encountered). When an error occurs during the data transfer, uSDHC stops the data transfer and abandons the current block. The host driver should read the content of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi-block mode, uSDHC does not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The host driver sends CMD12 in this scenario and restarts the read operation from that address. It is recommended that a software reset (in register RSTD) for data be applied before the transfer is restarted.

For any read transfer mode, uSDHC does not start data transmission until the number of words set in the RD_WML register are in buffer. If the buffer is full and the host system does not read data in time, uSDHC stops the CLK to avoid the data buffer overrun situation.

40.3.2.3 Data buffer and block size

In the uSDHC module, the data buffer can hold up to 256 words (32-bit) and the watermark levels for write and read can be configured accordingly. The user needs to know the buffer size for the buffer operation during a data transfer to utilize it in the most optimized way. The host driver may configure the value according to the system and requirement.

During a multi-block data transfer, the block length can be set to any value between 1 and 4096 bytes, satisfying the requirements of the external card. The only restriction is from the external card, which can be limited in size or support of a partial block access (which is not the integer times of 512 bytes). That means, the largest block size is 512 bytes.

As uSDHC treats each block individually, for block sizes which are not multiples of four (not word-aligned), stuffed bytes are required at the end of each block. For example, if the block size is 7 bytes and there are 12 blocks to write, the software side must write twice for each block. For each block, the ending byte is abandoned by uSDHC because it only sends 7 bytes to the card and picks data from the following system write, resulting in 24 beats of write access in total.

40.3.2.4 Dividing large data transfer

This SDIO command CMD53 definition limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in multiples of block size. If the total data length cannot be divided evenly into a multiple of the block size, then there are two options to transfer the data. These two options depend on the function and the card design. Option 1 is for the host driver to split the transaction. The remainder of the block size data is then transferred by using a single block command at the end. Option 2 is to add placeholder data in the last block to fill the block size. For option 2, the card must manage the removal of the placeholder data. Only for write, uSDHC sends data to the card.

See Figure 128 for an example showing the division of large data transfers, assuming a kind of WLAN SDIO that only supports a block size of up to 64 bytes. Although uSDHC supports a block size of up to 4096 bytes, SDIO can only accept a block size of less than 64 bytes, so the data must be divided (see the example below).

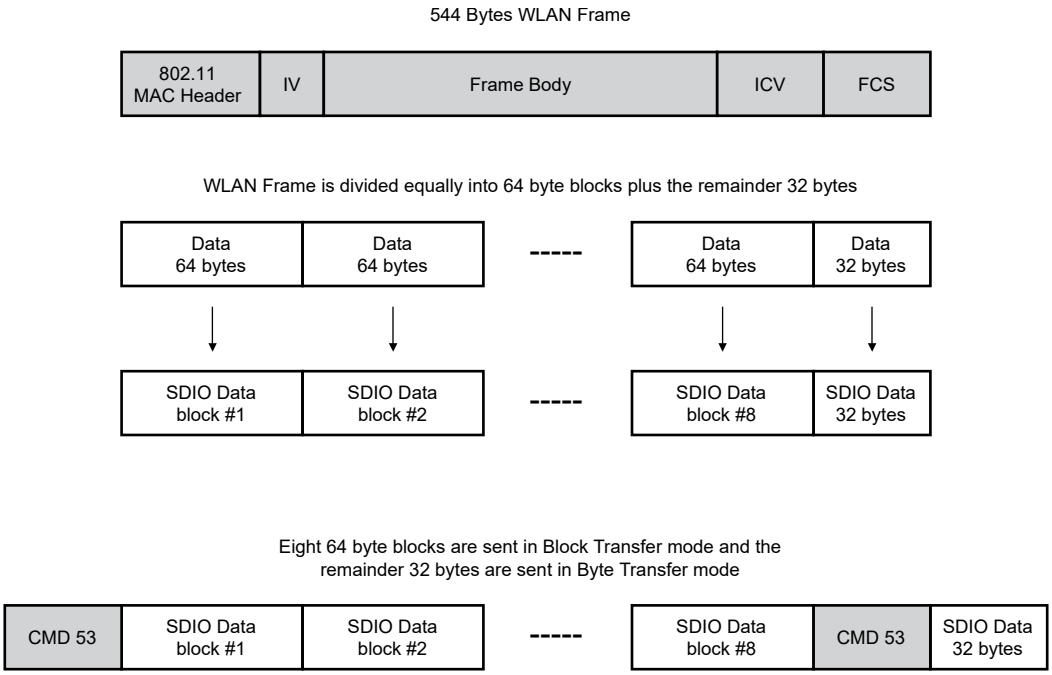

Figure 128. Example for dividing large data transfers

40.3.3 DMA AXI interface

The internal DMA implements a DMA engine and the AXI initiator. When the internal DMA is enabled, but the BWR and BRR bits are set if the BWRSEN and BRRSEN bits have been set in the Interrupt Status Enable register. See Figure 129 for an illustration of the DMA AXI interface block.

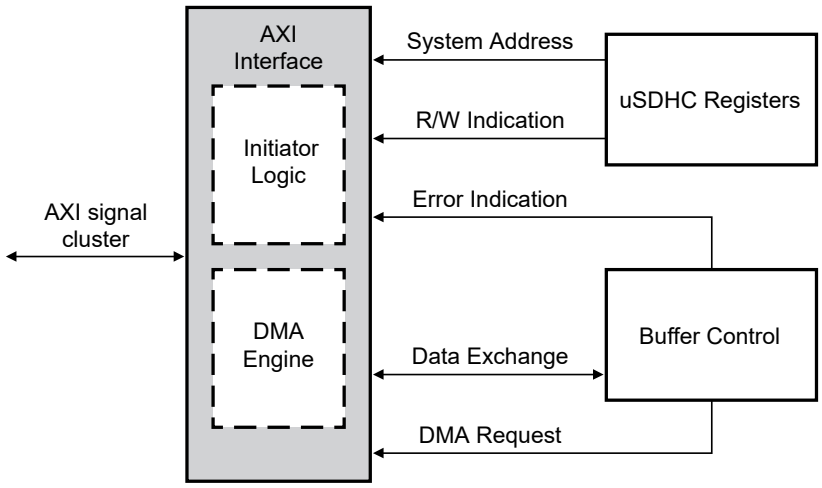

Figure 129. DMA AXI interface block

40.3.3.1 Internal DMA request

If the watermark level requirement is met in data transfer or if the last data of current block is ready in the data buffer, and the Internal DMA is enabled, the data buffer block sends a DMA request to AXI interface.

The delay in response from the internal DMA engine depends on the system AXI bus loading and the priority assigned to uSDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The data buffer de-asserts the request if the data buffer space (for write) or bytes in data buffer is smaller than the watermark level. Upon access to the buffer by internal DMA, the data buffer updates its internal buffer pointer, and when the watermark level is satisfied or the last data of the current block is ready in the data buffer, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always automatically set as the remaining number of words. For instance, for a multi block data read with each block size of 31 bytes, and the watermark level set to six words (24 bytes). After the first burst transfer, if there are greater than or equal to two words in the buffer, which might contain some data of the next block), another DMA request is sent. This is because the remaining number of words to transfer for the current block is ceiling((31 - 6 * 4) / 4) = 2. The uSDHC module reads two words out of the buffer, with seven valid bytes and one stuffed byte.

40.3.3.2 AXI initiator interface

It is possible that the internal AXI DMA engine could fail during the data transfer. Upon detection of an AXI bus error during DMA transfer, the DMA engine stops the transfer and goes to the idle state. At that point, the internal data buffer stops receiving incoming data and sending out data. The DMAE bit in the Interrupt Status register is generated to host CPU to report a bus error condition.

After the DMAE interrupt is received, the software sends a CMD12 to abort the current transfer and read the DS_ADDR bits of the DMA System Address register to get the starting address of the corrupted block. After the DMA error is fixed, the software should apply a data reset and restart the transfer from this address to recover the corrupted block.

40.3.3.3 ADMA engine

In the SD host controller standard, a new DMA transfer algorithm called the Advanced DMA (ADMA) is defined. For simple DMA, after the page boundary is reached, a DMA interrupt is generated and the new system address is programmed by the host driver. The ADMA defines the programmable descriptor table in the system memory. The host driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized because the host MCU intervention is not be needed during long DMA-based data transfers.

There are two types of ADMA in host controller: ADMA1 and ADMA2. ADMA1 can support data transfer of 4KB aligned data in system memory, and ADMA2 eliminates the restriction so that the data of any location (word aligned) and any size (less than 64 KB) can be transferred in system memory. Their formats of Descriptor Table are different.

ADMA can recognize all kinds of descriptors defined in SD host controller Standard, and if the "End" flag is detected in the descriptor, ADMA stops after this descriptor is processed.

40.3.3.3.1 ADMA concept and descriptor format

ADMA1 includes the following descriptors:

- Valid/invalid descriptor
- Nop descriptor
- Set data length descriptor
- Set data address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

ADMA2 includes the following descriptors:

- Valid/invalid descriptor
- Nop descriptor
- Rsv descriptor (new in ADMA2)
- Set data length and address descriptor
- Link descriptor
- Interrupt flag and end flag in descriptor

ADMA starts read/write operation after it reaches the tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last set type descriptor before the tran type descriptor. Every tran type descriptor triggers a transfer, and the transfer data length is extracted from the most recent set type descriptor. If there is no set type descriptor after the previous Trans descriptor, the data length is the value for previous transfer, or 0 if no set descriptor is ever met.

For ADMA2, the tran type descriptor contains both data length and transfer data address, so the tran type descriptor itself can start a data transfer.

See Figure 130 for the format of the descriptor table for ADMA1.

Address/ Page Field		Address/ Page Field		Attribute Field					
31	12	11	6	5	4	3	2	1	0
Address or Data Length		000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	31- 28	27- 12
0	0	Nop	No Operation	Don't Care	
0	1	Set	Set Data Length	0000	Data Length
1	0	Tran	Transfer Data	Data Address	
1	1	Link	Link Descriptor	Descriptor Address	

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 130. Format of the ADMA1 descriptor table

See Figure 131 for the concept and access method of the descriptor table for ADMA1.

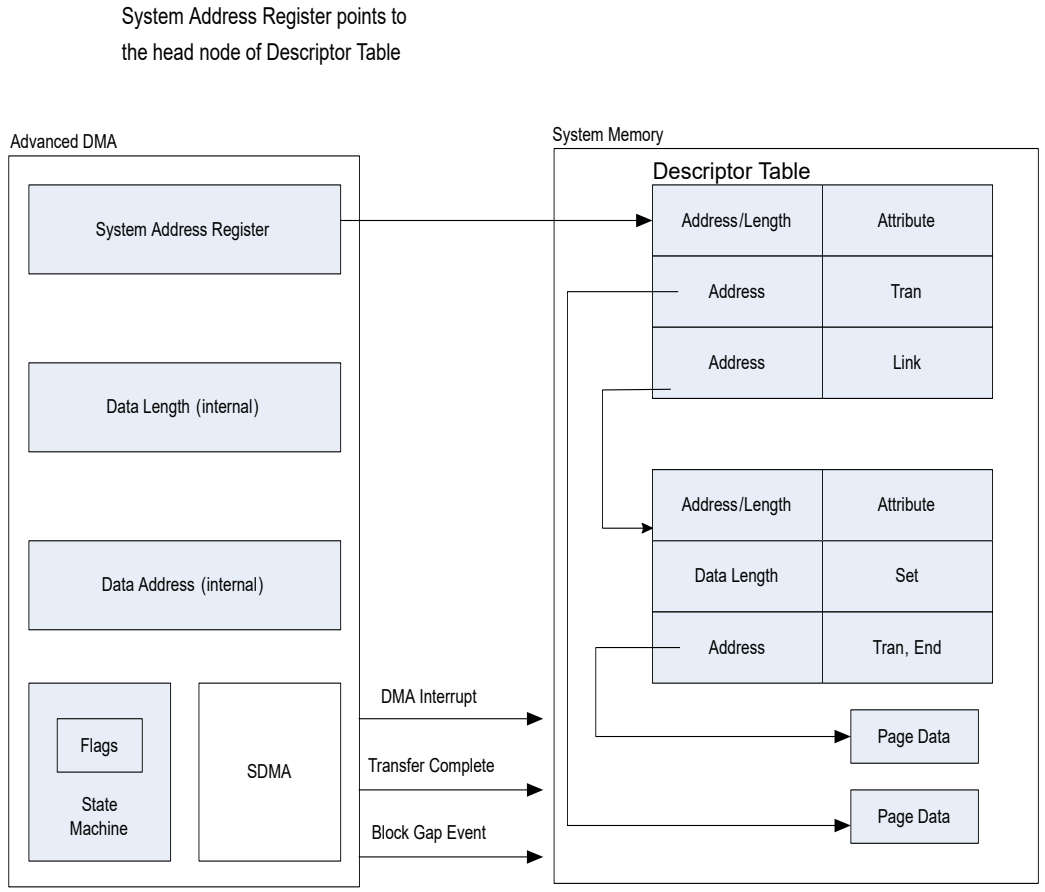

Figure 131. Concept and access method of the ADMA1 descriptor table

The figure below explains the ADMA2 format. ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the 'Valid' flag of descriptor is 0, it ignores the higher 32-bit. The Address field should be set to word aligned (lower 2-bit is always set to 0). Data length is in byte unit.

Address Field		Length		Reserved		Attribute Field					
63	32	31	16	15	06	05	04	03	02	01	00
32-bit Address		16-bit length		0000000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	Operation
0	0	Nop	No Operation	Don't Care
0	1	Rsv	Reserved	Same as Nop. Read this line and go to next one
1	0	Tran	Transfer Data	Transfer data with address and length set in this descriptor line
1	1	Link	Link Descriptor	Link to another descriptor

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 132. Format of the ADMA2 descriptor table

See Figure 133 for the concept and access method of the descriptor table for ADMA2.

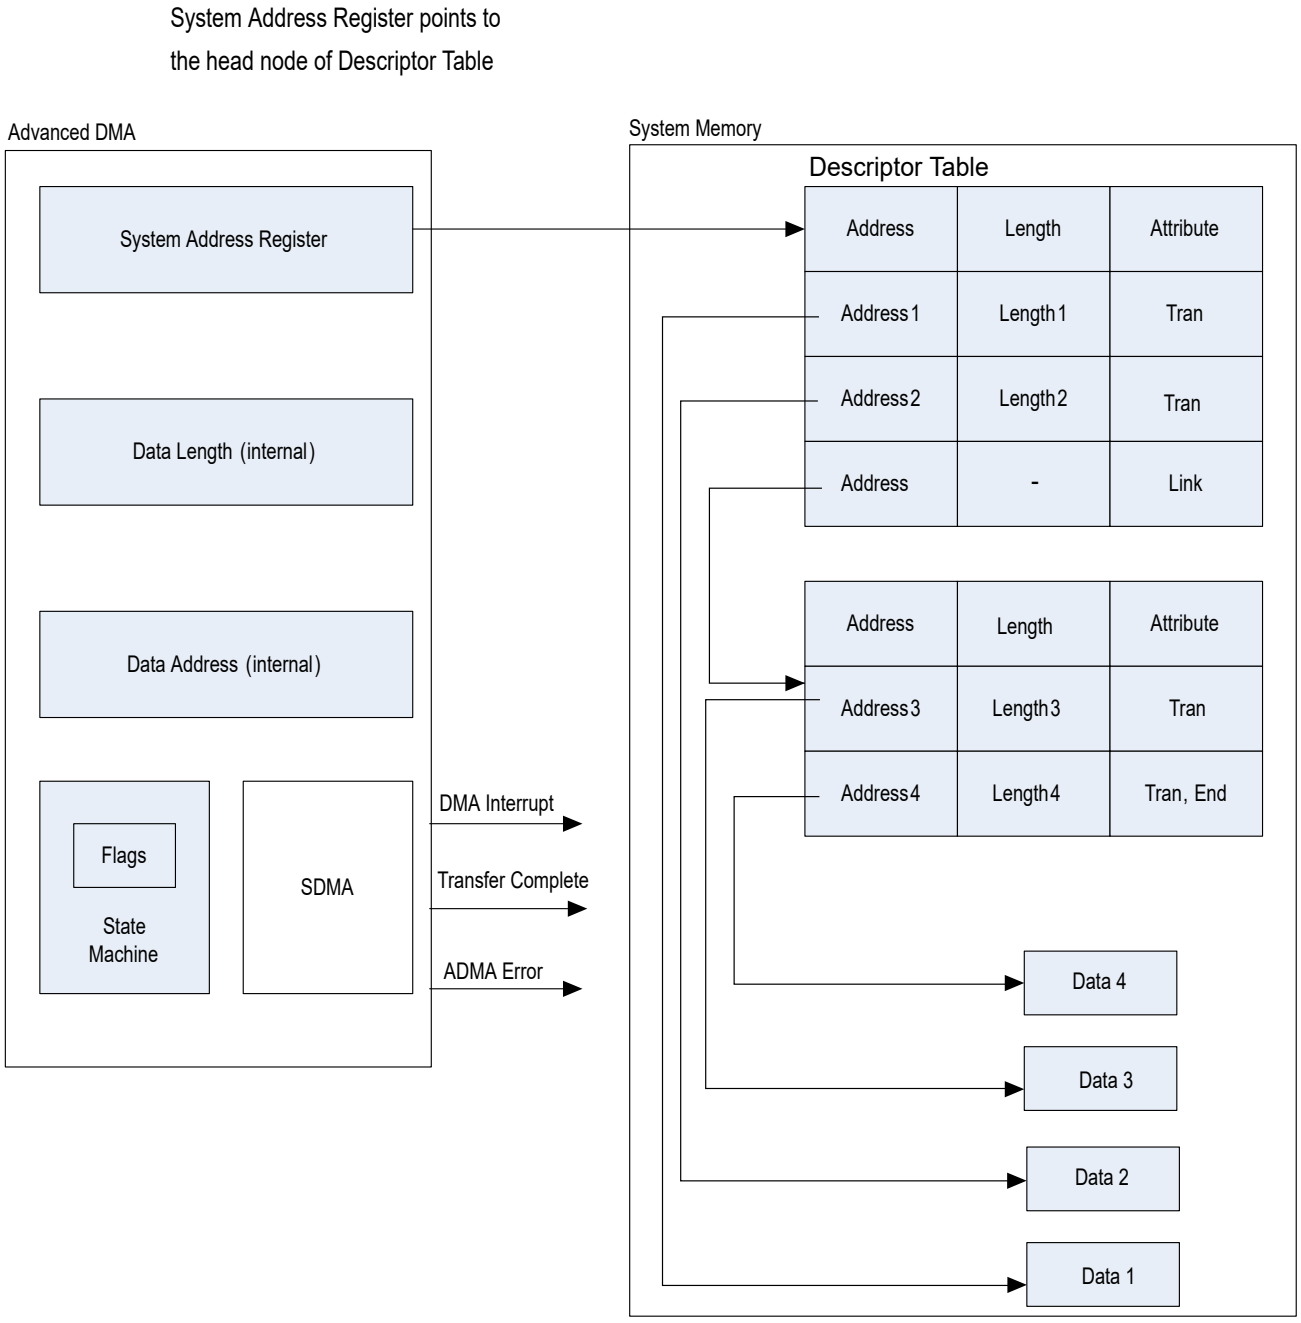

Figure 133. Concept and access method of the ADMA2 descriptor table

40.3.3.3.2 ADMA interrupt

If the interrupt flag descriptor is set, ADMA generates an interrupt according to various types of descriptors.

For ADMA1:

- Set type of descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer descriptor is complete, which means the data communication between the host system and uSDHC is finished.
- Link type of descriptor: interrupt is generated when new descriptor address is set.

- Nop type of descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type of descriptor: interrupt is generated when this transfer descriptor is complete, which means the data communication between the host system and uSDHC is finished.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type of descriptor: interrupt is generated just after this descriptor is fetched.

40.3.3.3.3 ADMA error

The ADMA stops whenever an error is encountered. These errors include:

- Fetching descriptor error
- AXI response error
- Data length mismatch error

An ADMA descriptor error is generated when it fails to detect a "valid" flag in the descriptor. If an ADMA descriptor error occurs, the interrupt is not generated even if the "Interrupt" flag of this descriptor is set.

When BLKCNTEN bit is set, data length set in register BLK_ATT must be equal to the whole data length set in descriptor, otherwise data length mismatch error is generated.

When BLKCNTEN bit is not set, then the whole data length set in descriptor is a multiple of block lengths; otherwise, when data set in the descriptor nodes are not performed at block boundaries, then data mismatch errors occur.

40.3.4 Register bank with IP bus interface

Register accesses through the IP bus interface are on the register bank. See Figure 134 for the block diagram.

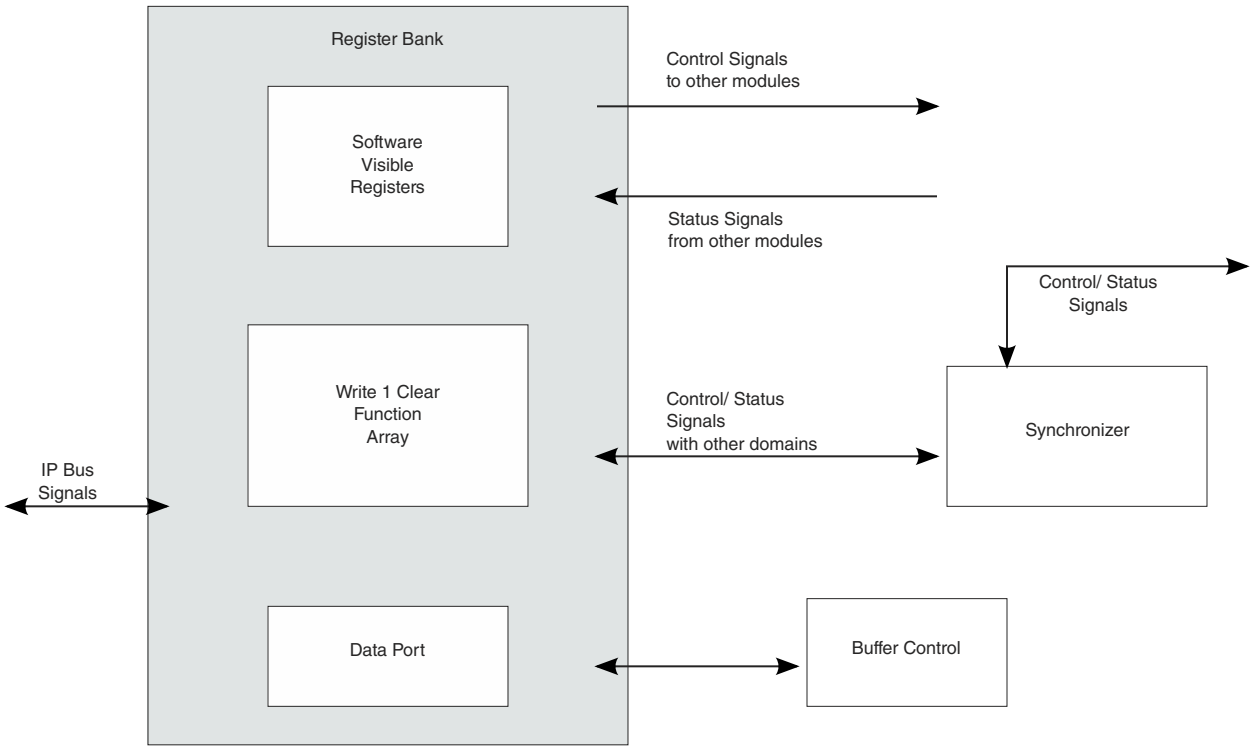

Figure 134. Register bank diagram

Only a 32-bit access is allowed, and no partial read/write is supported; therefore, all accesses are word aligned.

Access to an unimplemented address within the register memory map space does not generate a transfer error.

40.3.4.1 SD protocol unit

The SD protocol unit deals with all SD protocol affairs.

The SD protocol unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the CMD/DAT lines
- Monitors the interrupt from SDIO
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD protocol unit consists of four sub-modules:

- SD control misc
- Command control
- Data control
- Clock control

40.3.4.2 SD control miscellaneous

In the SD control miscellaneous unit:

- The card detection (including CD_B and DATA3 for card detection) and card interrupt are implemented.
- The module monitors the signal level on all the eight data lines and the command lines. It directly routes the level values into the register bank.
- The module also detects the Write Protect (WP) line. If WP is activated as '1', writes to memory and combo cards are ignored by cards. In that case, there is no need to send write command anymore.

40.3.4.3 SD clock control

If the internal data buffer is near full (for read) or near empty (for write), the SD clock must be gated off to avoid buffer over/under-run. This module asserts the gate of the output SD clock to shut the clock off. After the buffer has space (for read) or has data (for write), the clock gate of this module opens, and the SD clock is active again.

40.3.4.4 Command control

The Command Control module deals with the transactions on the CMD line.

See Figure 135 for an illustration of the structure for the Command CRC shift register.

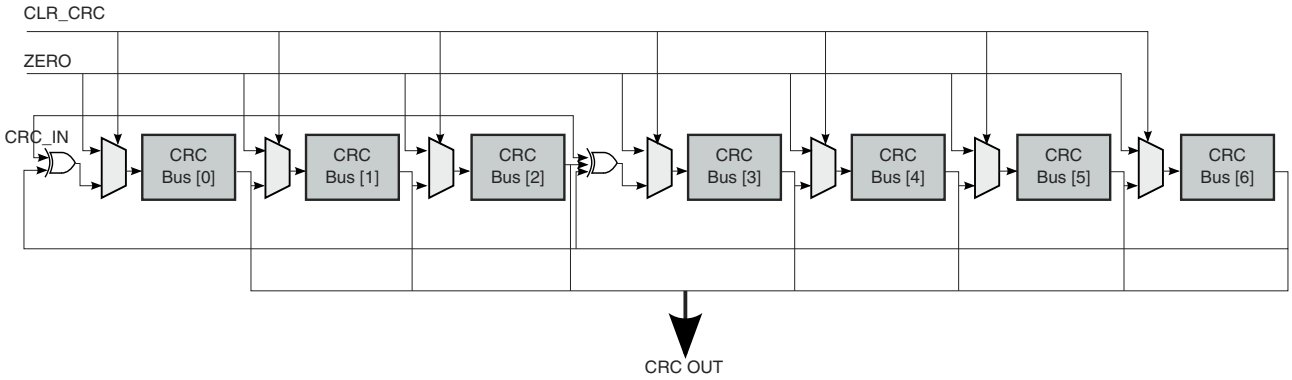

Figure 135. Command CRC shift register

The CRC polynomials for the CMD are as follows:

```
Generator polynomial: G(x) = x^7 + x^3 + 1
M(x) = (first bit) * x^n + (second bit) * x^n-1 +...+ (last bit) * x^0
CRC[6:0] = Remainder [(M(x) * x^7) / G(x)]
```

40.3.4.5 Data control

The data agent deals with the transactions on the eight data lines. Moreover, this module also detects the busy state on the DATA0 line and generates the read wait state by the request from the transceiver.

The CRC polynomials for the data are as follows:

```
Generator polynomial: G(x) = x^16 + x^12 + x^5 +1

M(x) = (first bit) * x^n + (second bit) * x^n-1 +...+ (last bit) * x^0

CRC[15:0] = Remainder [(M(x) * x^16) / G(x)]
```

40.3.5 Card insertion and removal detection

The uSDHC module uses either the DATA3 pin or the CD_B pin to detect card insertion or removal. It is controlled by SoC pad or other logic. When there is no card on the eMMC/SD bus, the DATA3 is pulled to a low voltage level by default.

When any card is inserted to or removed from the socket, uSDHC detects the logic value changes on the DATA3 pin and generates an interrupt. When the DATA3 pin is not used for card detection (for example, it is implemented in GPIO), the CD_B pin must be connected for card detection. Whether DATA3 is configured for card detection or not, the CD_B pin is always a reference for card detection. Whether the DATA3 pin or the CD_B pin is used to detect card insertion, uSDHC sends an interrupt (if enabled) to inform the Host system that a card is inserted.

40.3.6 Power management and wakeup events

When there is no operation between uSDHC and the card through the SD bus, the user can completely disable the peripheral clock and base clock in the chip-level clock control module to save power. When the user needs to use uSDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to uSDHC are disabled, for instance, when the system is in low-power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The uSDHC module can generate these interrupts even when there are no clocks enabled. The three interrupts that can be used as wakeup events are these:

- Card removal interrupt
- Card insertion interrupt
- Interrupt from SDIO (not available in multiple block data transfers)

These three wakeup events (or wakeup interrupts) can also be used to wakeup the system from low-power modes.

NOTE

To make the interrupt a wakeup event, when all the clocks to uSDHC are disabled or when the entire system is in low power mode, the corresponding wakeup enabled bit needs to be set. Refer to Protocol Control (PROT_CTRL) for more information on the uSDHC Protocol Control register.

40.3.6.1 Setting wakeup events

For uSDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters the sleep mode. Before the software disables the host clock, it should ensure that all the following conditions have been met:

- No read or write transfer is active
- Data and command lines are not active
- No interrupts are pending
- Internal data buffer is empty

40.3.7 eMMC fast boot

The Embedded MultiMediaCard (eMMC4.3 or later) specification adds a fast boot feature that requires hardware support. There are two types of fast boot modes in the eMMC4.3 or later specification: boot operation and alternative boot operation. Each type also has with-acknowledge and without-acknowledge modes.

In the boot operation mode, the uSDHC controller (eMultiMediaCard host) can read boot data from the target (eMMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFA (optional for target), before issuing CMD1.

NOTE

For the eMMC4.3 setting, please see the eMMC4.3 specification.

40.3.7.1 Boot operation

If the CMD line is held low for 74 clock cycles and more after power-up before the first command is issued, the target recognizes that boot mode is being initiated and starts preparing boot data internally.

Within one second after the CMD line goes low, the target starts to send the first boot data to the uSDHC controller on the DATA line(s). The uSDHC controller must keep the CMD line low to read all of the boot data.

NOTE

For the purposes of this documentation, fast boot is called "normal fast boot mode".

If boot acknowledge is enabled, the target has to send acknowledge pattern '010' to the uSDHC controller within 50ms after the CMD line goes low. If boot acknowledge is disabled, the target does not send out acknowledge pattern '010'.

The uSDHC controller can terminate the boot mode with the CMD line high.

The boot operation is terminated when all the contents of the enabled boot data are sent to the uSDHC controller. After the boot operation is executed, the target gets ready for the CMD1 operation and the uSDHC controller needs to start a normal eMMC initialization sequence by sending CMD1.

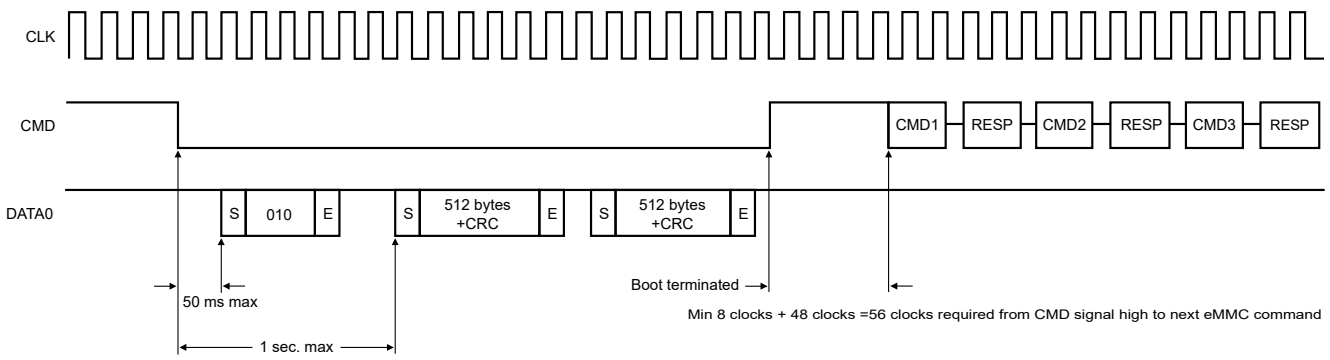

Figure 136. Embedded MultiMediaCard state diagram (normal boot mode)

40.3.7.2 Alternative boot operation

This boot function is optional for the device. If bit 0 in the extended CSD byte[228] is set to '1', the device supports the alternative boot operation.

After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFA after 74 clock cycles, before CMD1 is issued or the CMD line goes low, the target recognizes that boot mode is being initiated and starts preparing boot data internally.

Within one second after CMD0 with the argument of 0xFFFFFFFA is issued, the target starts to send the first boot data to the uSDHC controller on the DATA line(s).

If boot acknowledge is enabled, the target must send the acknowledge pattern '010' to the uSDHC controller within 50ms after the CMD0 with the argument of 0xFFFFFFFA is received. If boot acknowledge is disabled, the target does not send out acknowledge pattern '010'.

The uSDHC controller can terminate the boot mode by issuing CMD0 (Reset).

Boot operation is terminated when all the contents of the enabled boot data are sent to the uSDHC controller. After the boot operation is executed, the target gets ready for the CMD1 operation and the uSDHC controller needs to start a normal eMMC initialization sequence by sending CMD1.

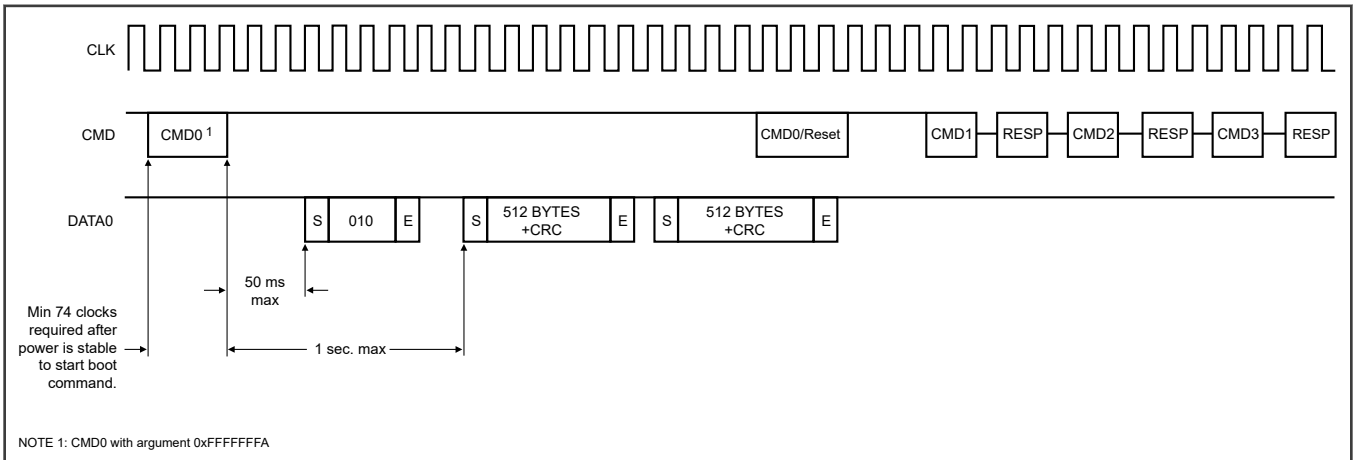

Figure 137. Embedded MultiMediaCard state diagram (alternative boot mode)

40.3.8 Commands for SD card, SDIO, and eMMC

A table containing the list of commands for the eMMC/SD card/SDIO is provided here.

Refer to the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the SD card, SDIO, and eMMC:

- Broadcast commands (bc), no response
- Broadcast commands with response (bcr), response from all cards simultaneously
- Addressed (point-to-point) commands (ac), no data transfer on the DATA
- Addressed (point-to-point) data transfer commands (adtc)

Response: A response is a token that is sent from the card to the host as an answer to a previously received command. A response is transferred serially on the CMD line.

Table 311. Commands for eMMC/SD card/SDIO

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	-	GO_IDLE_STATE	Resets all eMMC and SD memory cards to idle state.
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all eMMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.
CMD3[1]	ac	[31:16] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/ SEND_RELATIVE_ADDR	Assigns relative address to the card.
CMD4	bc	[31:16] DSR [15:0] stuff bits	-	SET_DSR	Programs the DSR of all cards.
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO in idle state to send them operation conditions register contents in the response on the CMD line.
CMD6[2]	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details.

Table continues on the next page...

Table 311. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD6[3]	ac	[31:26] Set to 0 [25:24] Access [23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The Embedded MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.
CMD7	ac	[31:16] RCA [15:0] stuff bits	R1b	SELECT/ DESELECT_CARD	Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.
CMD9	ac	[31:16] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:16] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission. Only supported by memory device.
CMD13	ac	[31:16] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	Reserved				
CMD15	ac	[31:16] RCA [15:0] stuff bits	-	GO_INACTIVE_STATE	Sets the card to inactive state in order to protect the card stack against communication breakdowns.

Table continues on the next page...

Table 311. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19	adtc	[31:0] reserved bits(all 0)	R1	SEND_TUNING_BLOCK	64 bytes tuning pattern is sent for SDR50 and SDR104.
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISION follows.
CMD21	adtc	[31:0] stuff bits	R1	SEND_TUNING_BLOCK	128 clocks of tuning pattern (64 byte in 4 bit mode or 128 byte in 8 bit mode) is sent for HS200 optimal sampling point detection.
CMD22	Reserved				
CMD23	ac	[31] reliable write request [30:16] set to 0 [15:0] number of blocks	R1	SET_BLOCK_COUNT	Defines the number of blocks (read/write) and the reliable writer parameter (write) for a block read or write command.
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command is issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.

Table continues on the next page...

Table 311. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase.
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GROUP	Removes one previously selected erase group from the erase selection.
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.

Table continues on the next page...

Table 311. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD39	ac	[31:16] RCA [15] register write flag [14:8] register address [7:0] register data	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the eMMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode.
CMD41	Reserved				
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43~51	Reserved				
CMD52	ac	[31:0] stuff bits	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	[31:0] stuff bits	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.
CMD54	Reserved				
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather than a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57-59	Reserved				

Table continues on the next page...

Table 311. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
CMD60	adtc	[31] WR [30:24] stuff bits [23:16] address [15:8] stuff bits [7:0] byte count	R1b	RW_MULTIPLE_REGISTER	These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 is used to read and write these registers. MMC command defined by CE-ATA Digital Protocol.
CMD61	adtc	[31] WR [30:16] stuff bits [15:0] data unit count	R1b	RW_MULTIPLE_BLOCK	The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer. MMC command defined by CE-ATA Digital Protocol.
CMD62-63	Reserved				
ACMD6[4]	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.
ACMD13[4]	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD Memory Card status.
ACMD22[4]	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.
ACMD23[4]	ac	[31:23] stuff bits [22:0] Number of blocks	R1	SET_WR_BLK_ERASE_COUNT	Set the number of write blocks to be pre-erased before writing (to be used for fast Multiple Block WR command). "1"=default(one write block).
ACMD41[4]	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.
ACMD42[4]	ac	[31:1] stuff bits [0] set_cd	R1	SET_CLR_CARD_DETECT	Connect(1)/Disconnect(0) the 50KOhm pull-up resistor on CD_B/DATA3 of the card.

Table continues on the next page...

Table 311. Commands for eMMC/SD card/SDIO (continued)

CMD INDEX	Type	Argument	Response type	Abbreviation	Description
ACMD51[4]	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).

1. CMD3 differs for eMMC and SD cards. For eMMC, it is referred to as SET_RELATIVE_ADDR, with a response type of R1. For SD cards, it is referred to as SEND_RELATIVE_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed eMMC and high-speed SD cards. Command SWITCH_FUNC is for high-speed SD cards.
3. Command SWITCH is for high speed eMMC. The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH_ERROR status bit in the EXT_CSD register is set. The Access Bits are shown in Table 312.
4. ACMDs is preceded with the APP_CMD command. Commands listed are used for SD only, other SD commands not listed are not supported on this module.

The access bits for the EXT_CSD access modes are listed in the following table.

Table 312. EXT_CSD access modes

Bits	Access name	Operation
00	Command set	The command set is changed according to the Cmd Set field of the argument.
01	Set bits	The bits in the pointed byte are set, according to the bits set to 1 in the Value field.
10	Clear bits	The bits in the pointed byte are cleared, according to the bits set to 1 in the Value field.
11	Write byte	The Value field is written into the pointed byte.

40.3.9 SDIO interrupt

Information on interrupts in 1-bit mode, interrupts in 4-bit mode, and card interrupt handling are detailed in the sections below.

40.3.9.1 Interrupts in 1-bit mode

In this case, the DATA1 pin provides the interrupt function. An interrupt is asserted by pulling the DATA1 low from SDIO, until the interrupt service is finished to clear the interrupt.

40.3.9.2 Interrupt in 4-bit mode

As the interrupt and data line 1 share pin 8 in a 4-bit mode, an interrupt is only sent by the card and recognized by the host during a specific time. This is known as the interrupt period. The uSDHC module only provides samples the level on pin 8 during the interrupt period. At all other times, the host treats it as the data signal. The definition of the interrupt period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the interrupt period becomes active two clock cycles after the completion of a data packet. This interrupt period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in a 4-bit mode, there is only a limited period of time that the interrupt period can be active because of the limited period of data line availability between the multiple blocks of data. This requires stricter definition of the interrupt period. For this case, the interrupt period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DATA1 line holds low for one clock cycle, then pulls high for the next clock cycle . On completion of the interrupt period, the card releases the DATA1 line into the high Z state. The uSDHC module provides sample of the DATA1 during the interrupt period when the IABG bit in the Protocol Control register is set.

Refer to SDIO Specification v1.10 for further information about the SDIO interrupt.

40.3.9.3 Card interrupt handling

When the CINTIEN bit in the Interrupt Signal Enable Register is set to 0, uSDHC clears the interrupt request to the host system. The host driver should clear this bit before servicing the SDIO interrupt, and should set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO Interrupt Status can be cleared by writing 1 to this bit. But as the interrupt source from SDIO does not clear, this bit is set again. To clear this bit, it is required to reset the interrupt source from the external card followed by writing 1 to this bit. In a 1-bit mode, uSDHC detects the SDIO interrupt with or without the SD clock (to support wakeup). In a 4-bit mode, the interrupt signal is sampled during the interrupt period, so there are some sample delays between the interrupt signal from SDIO and the interrupt to the Host System Interrupt Controller. When the SDIO status is set and the host driver needs to service this interrupt, the SDIO bit in the Interrupt Control Register of SDIO is cleared. This is required to clear the SDIO interrupt status latched in uSDHC and to stop driving the interrupt signal to the System Interrupt Controller. The host driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Status Enable bit is set to 1 and uSDHC starts sampling the interrupt signal again.

See Figure 138 for an illustration of the SDIO interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

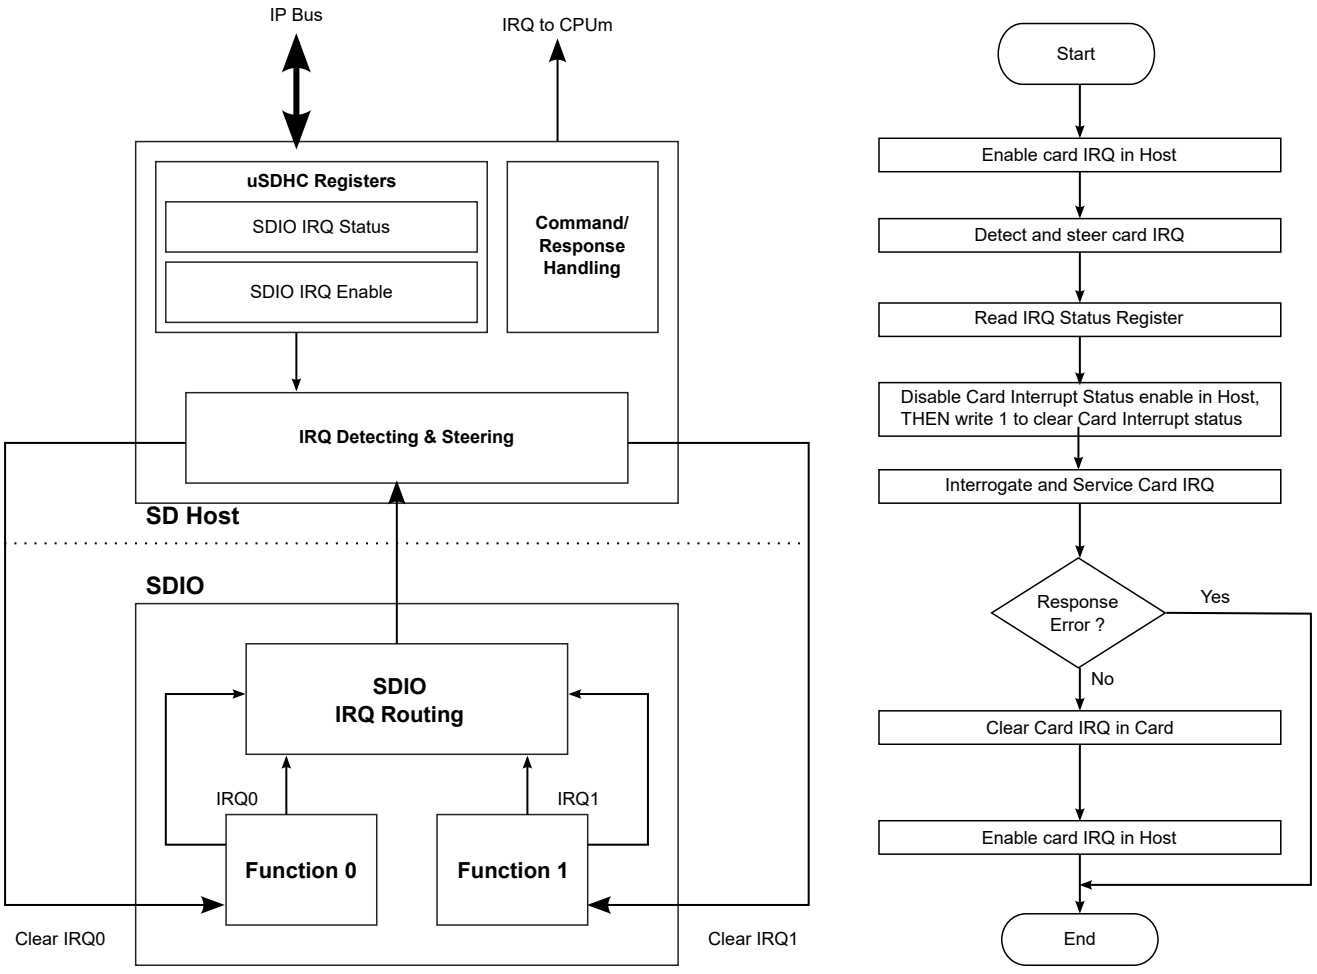

Figure 138. Card interrupt scheme, card interrupt detection, and handling procedure

40.3.10 Speed mode selection

To switch to HS200 or HS400 from High Speed (26 MHz-52 MHz), see the procedure below.

NOTE

While the actual timing change is done, the behavior of any command given (such as CMD13) cannot be guaranteed due to the asynchronous operation. Therefore, you must not use CMD13 to check the busy completion of the timing change indication. In case, CMD13 is used, the host must ignore CRC errors, if appear.

The max frequency for HS200 mode and HS400 mode could be slower than 200 MHz based on the chip implementation, you must set the target frequency for these two speed modes accordingly. Following sections describe the mode selections for HS200 mode and HS400 mode in detail.

40.3.10.1 HS200 mode selection

To switch to HS200, the Driver must perform the following steps:

1. Select the chip (through sending CMD7) and make sure it is unlocked (through CMD42).
2. Read the DEVICE_TYPE [196] field of the Extended CSD register to validate if the chip supports HS200 at the IO voltage appropriate for both host and chip (through CMD8).
3. Read the DRIVER_STRENGTH [197] field of the Extended CSD register to find the supported chip Driver Strengths (through CMD8). The default setting is 50 Ohm. The Host Designer might simulate its specific system, using a device driver models. Host can select the optimal Driver Type that might drive the host system load at the required operating frequency with the minimal noise generated.

   NOTE

   This step can be skipped if changes of Driver strength is not needed.

4. Check the setting of PROT_CTRL[DTW], make sure the data transfer width is set as expected.

   Make sure the I/O pad voltage is 1.8V and corresponding drive strength is set to proper value.

   Set HS200 bit and Driver Strength value in the HS_TIMING [185] field of the Extended CSD register by issuing CMD6. If the host attempts to write an invalid value, the HS_TIMING byte is not changed, the HS200 interface timing is not enabled, the Driver Strength is not changed, and the SWITCH_ERROR field is set. After the chip responds with R1, it might assert Busy signal. Once the busy signal gets de-asserted, the host may send a SEND_STATUS Command (CMD13) using the HS200 timing and after it receives a Trans State indication and No Error it means that the chip is set to HS200 timing and the Driver Strength is set to the selected settings.
5. At this point, the host can set the frequency to ≤ 200 MHz.
6. The host might invoke the HS200 standard tuning procedure, by sending CMD21 to the chip.

NOTE

The host must switch to the required bus width before starting the tuning operation to allow the tuning sequence to be done using the proper bus operating conditions.

40.3.10.2 Standard tuning procedure

By default, lower frequency operation, a fixed sampling clock is used to receive signals on CMD and DAT[3:0]. Before using the HS200, HS400, SDR104, or SDR50 modes, the Host Driver executes the tuning procedure at the mode switch sequence.

1. Issue uSDHC SW reset, set SYS_CTRL[RSTT] to 1.
2. Clear VEND_SPEC[FRC_SDCLK_ON] to 0.
3. Set TUNING_CTRL to 0x01312880 to enable the standard tuning and disable the CMD line check.
4. Start the tuning procedure by setting AUTOCMD12_ERR_STATUS[EXECUTE_TUNING] to 1.

5. Issue CMD19(SD) / CMD21(eMMC) with the proper Command Transfer Type (CMD_XFR_TYP) and Mixer Control (MIX_CTRL) settings.
6. Wait for uSDHC BRR (Buffer Read Ready) interrupt signal is 1.
7. Check AUTOCMD12_ERR_STATUS[EXECUTE_TUNING]. If AUTOCMD12_ERR_STATUS[EXECUTE_TUNING] = 1, write 1 to clear INT_STATUS[BRR] and then repeat steps 6~7. If AUTOCMD12_ERR_STATUS[EXECUTE_TUNING] = 0, standard tuning has completed, or the tuning has not completed within 40 attempts. The Host Driver might abort this loop if the number of loops exceeds 40 or 150 ms timeout occurs. In this case, a fixed sampling clock should be used (AUTOCMD12_ERR_STATUS[SMP_CLK_SEL] = 0).
8. Sampling Clock Select (AUTOCMD12_ERR_STATUS[SMP_CLK_SEL]) is valid after AUTOCMD12_ERR_STATUS[EXECUTE_TUNING] has changed from 1 to 0.
   AUTOCMD12_ERR_STATUS[SMP_CLK_SEL] = 1, indicates tuning procedure passed.
   AUTOCMD12_ERR_STATUS[SMP_CLK_SEL] = 0, indicates tuning procedure failed. The tuning result is applied to the delay chain, CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS) [30:16], upon the successful tuning procedure completion.
9. Set MIX_CTRL[AUTO_TUNE_EN] to 1.

While the tuning sequence is being performed, the Host Controller does not generate interrupts (including Command Complete), except Buffer Read Ready. CMD19 response errors are not indicated.

Writing AUTOCMD12_ERR_STATUS[SMP_CLK_SEL] to 0 forces the Host Controller to use a fixed sampling clock and resets the tuning circuit of the Host Controller.

NOTE

- There could be slight difference on delay cell delay in each project, and this difference can lead to different loop number needed. TUNING_CTRL[TUNING_STEP] can be used to control how may taps are to be added for each step.
- Manual tuning might be required in cases where standard tuning is not able to close passing window with CMD19/21 transfer fail.

40.3.10.3 Manual tuning procedure

Manual tuning controls more details in the tuning procedure, and some corner cases. Manual tuning provides control to tuning start point, tuning steps, and delay chains. To start manual tuning:

1. Clear TUNING_CTRL[STD_TUNING_EN] to 0.
2. Clear VEND_SPEC[FRC_SDCLK_ON] and MIX_CTRL[FBCLK_SEL] to 0, set MIX_CTRL[SMP_CLK_SEL] and MIX_CTRL[EXE_TUNE] to 1 to start tuning.
3. Set SYS_CTRL[RSTA] to 1, and wait for self-clear.
4. Config delay chain, CLK_TUNE_CTRL_STATUS[DLY_CELL_SET_PRE] with the valueA.

NOTE

The valueA must start from 0.

5. Set SYS_CTRL[RST_FIFO] to 1 and wait for self-clear.
6. Send CMD19/21 to card.
7. Poll for CC, CIE, CEBE, CCE and CTOE of Interrupt Status (INT_STATUS) assertion.
8. Poll for TC, DEBE, DCE and DTOE of Interrupt Status (INT_STATUS) assertion.
9. Check TP of Interrupt Status (INT_STATUS); TP = 1 & no command/data error indicates the current CMD19/21 transfer is passed; otherwise, indicates failed.
10. If TP = 0 or command/data error is observed, increase the valueA with the required tuning step(1 to 127) and repeat steps 3~9.

11. If TP = 1 & no command/data error is met after a loop with TP=0 (or command/data error), save the current valueA as value_start. Increase valueA with the required tuning step, and repeat steps 3~9 until TP = 0 (or command/data error) again. Save the current valueA as value_end.
12. Clear MIX_CTRL[EXE_TUNE] to 0.
13. Set SYS_CTRL[RSTA] to 1, and wait for self-clear.
14. Set MIX_CTRL[SMP_CLK_SEL] to 1.
15. Set bit[14:0] of CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS) with the output of expression {[(((value_start+value_end)/2)< < 8)& 0xffffff00] -0x300 } | 0x33.
16. Poll bit[30:16] of CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS) until the value written in the previous step is read.
17. Set MIX_CTRL[AUTO_TUNE_EN] to 1.

The manual tuning procedure defines a passing window, inside which the tuned clock can capture the correct data, and delay chain is to be configured as centered within the passing window.

It is not a fixed flow as the standard tuning. Any step can be changed based on the real case. In cases where passing window is not closed with a tuning fail, the center of the passing region must be applied for the delay chain setting. In cases where two passing windows separated by tuning fail(s) is observed, the center of the first passing window must be applied for the delay chain setting.

NOTE

Both the standard tuning and manual tuning are only for tuning of SD_CLK, cannot be used to tune STROBE clock of HS400 and HS400 enhanced mode.

40.3.10.4 Switch to HS400 mode

The valid IO voltage for HS400 is 1.8 V. The bus width is set to only DDR 8bit in HS400 mode. HS400 supports the same commands as DDR52. To switch to HS400 mode, the host must perform the following steps:

1. Initialize chip with “Backward Compatible Timings", after power-on or software reset (CMD0), the interface timing of the chip is set as the default "Backward Compatible Timing".
2. Select the chip with CMD7.
3. Read the DEVICE_TYPE [196] field of the Extended CSD register to validate whether the chip supports HS400 by sending CMD8.
4. Read the DRIVER_STRENGTH [197] field of the Extended CSD register to find the supported chip's Driver Strengths by sending CMD8.

NOTE

You may skip this step if changes of driver strength is not needed.

5. Set the "Selected Driver Strength" parameter in the HS_TIMING [185] field of the Extended CSD register to the appropriate driver strength for HS400 operation and set the "Timing Interface" parameter to 0x2 to switch to HS200 mode with CMD6. Send CMD13 to make sure mode switch to HS200 mode has been successfully done.
6. Perform the tuning procedure (standard or manual) at the HS400 target operating frequency, save the tuning result (CLK_TUNE_CTRL_STATUS[30:16]), clear TUNING_CTRL[STD_TUNING_EN] to 0, set SYS_CTRL[RSTT] to 1 and wait for self-clear.

NOTE

Tuning procedure in HS200 mode is required to synchronize the command response on the CMD line to CLK for HS400 operation.

7. Set the "Timing Interface" parameter in the HS_TIMING [185] field of the Extended CSD register to 0x1 to switch to High Speed mode with CMD6 and then set the clock frequency to a value not greater than 52 MHz.

8. Set BUS_WIDTH[183] to 0x06 to select the dual data rate x8 bus mode. Check the setting of PROT_CTRL[DTW]. Make sure the data transfer width is set as expected.
9. Set the "Timing Interface" parameter in the HS_TIMING [185] field of the Extended CSD register to 0x3 to switch to HS400 mode with CMD6. Set the MIX_CTRL[DDR_EN] and MIX_CTRL[HS400_MODE] to 1 to enable HS400 mode in controller.
10. Set bit[14:0] of CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS) with saved tuning result value of 0x68 from standard tuning flow in step 6).
11. Poll bit[30:16] of CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS) until the value written in the step 10 is read.
12. Set MIX_CTRL[SMP_CLK_SEL] to 1'b1 to apply the delay on capture clock of CMD channel, then set the clock frequency to ≤ 200 MHz.

    Ensure that uSDHC function clock source is 2x HS400 mode target frequency, and both SDCLKFS and DVS are configured to 0.
13. Set Strobe DLL control (STROBE_DLL_CTRL) to 0x00400039 to have strobe clock automatically tuned to 1/4 cycle of input ipp_strobe to capture data. Ensure that both STROBE_DLL_STATUS[STROBE_DLL_STS_REF_LOCK] and STROBE_DLL_STATUS[STROBE_DLL_STS_SLV_LOCK] are set before any transfer is started.

NOTE

For speed mode switch like from High Speed mode to HS200 mode or HS400(enhanced) mode, you must calibrate the right configuration of slew rate and drive strength for chip pad that are used for uSDHC.

40.3.10.5 Switch to HS400 enhanced mode

This selection flow describes how to initialize the eMMC device in HS400 mode while enabling enhanced strobe without the need for tuning procedure. To switch to HS400 mode with enhanced strobe, the host must perform the following steps:

1. Initialize device with "Backward Compatible Timings", after power-on or software reset (CMD0), the interface timing of the device is set as the default "Backward Compatible Timing".
2. Select the device with CMD7
3. Read the DEVICE_TYPE [196] field of the Extended CSD register to validate whether the device supports HS400 with CMD8.
4. Read the STROBE_SUPPORT[184] field of the Extended CSD register to validate whether the device supports enhanced strobe with CMD8.
5. Set the "Timing Interface" parameter in the HS_TIMING [185] field of the Extended CSD register to 0x1 to switch to High Speed mode by sending CMD6 and then set the clock frequency to a value not greater than 52 MHz.
6. Set BUS_WIDTH[183] to 0x86 to select the dual data rate x8 bus mode and enable enhanced strobe (this is active only after HS400 mode is selected) with CMD6. Check the setting of PROT_CTRL[DTW]. Make sure the data transfer width is set as expected.
7. Read the DRIVER_STRENGTH [197] field of the Extended CSD register to find the supported device Driver Strengths with CMD8.

NOTE

You may skip this step if changes of driver strength is not needed, if needed host may change the device Driver Strength.

8. Set the "Timing Interface" parameter in the HS_TIMING [185] field of the Extended CSD register to 0x3 to switch to HS400 mode with CMD6.
9. Set the MIX_CTRL[DDR_EN], MIX_CTRL[HS400_MODE], and MIX_CTRL[EN_HS400_MODE] bits to 1 to enable enhanced HS400 mode in controller.

10. Host may set the clock frequency to a value not greater than 200 MHz. Ensure uSDHC function clock source is 2x HS400 mode target frequency, and both SDCLKFS and DVS are configured to 0 .
11. Set Strobe DLL control (STROBE_DLL_CTRL) to 0x00400039 to have strobe clock automatically delayed 1/4 cycle of input ipp_strobe to capture data. Make sure both STROBE_DLL_STATUS[STROBE_DLL_STS_REF_LOCK] and STROBE_DLL_STATUS[STROBE_DLL_STS_SLV_LOCK] are set before any transfer is started.

NOTE

For speed mode switch like from high speed mode to HS200 mode or HS400(enhanced) mode, you must calibrate the right configuration of slew rate and drive strength for chip pad that are used for uSDHC.

40.3.11 Software restrictions

40.3.11.1 Initialization active

The driver cannot set INITA bit in System Control register when any of the command line or data lines are active, so the driver must ensure both CDIHB and CIHB bits are cleared.

40.3.11.2 Software polling procedure

For polling read or write, after the software begins a buffer read or write, it must access exactly the number of times as the values set in the Watermark Level Register; moreover, if the block size is not a multiple of the value in the Watermark Level Register (read and write respectively), the software must access exactly the remaining number of words at the end of each block. For example, for a read operation, if the RD_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

40.3.11.3 Suspend operation

To suspend the data transfer, the software must inform uSDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by SDIO, software must send another normal command marked as suspend command (CMDTYP bits set as '01') to inform uSDHC that the transfer is suspended.

If software needs to resume the suspended transfer, it should read the value in BLKCNT register to save the remaining number of blocks before sending the normal command marked as suspend, otherwise on sending such a 'suspend' command, uSDHC treats the current transfer is stopped and change the BLKCNT register to its original value, instead of retaining the remaining number of blocks.

40.3.11.4 Data length setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be a multiple of 4.

ADMA1 is 4KB aligned.

40.3.11.5 (A)DMA address setting

To configure the ADMA1/ADMA2/DMA address register, when TC bit is set, the register always updates itself with the internal address value to support dynamic address synchronization, so the software must ensure that the TC bit is cleared prior to configuring the ADMA1/ADMA2/DMA address register.

40.3.11.6 Data port access

Data port does not support parallel access. For example, during an internal DMA access, it is not allowed to write any data to the data port by CPU; or during a CPU read operation, it is also prohibited to write any data to the data port, by either CPU or internal DMA. Otherwise the data is corrupted inside the uSDHC buffer.

40.3.11.7 Change clock frequency

The uSDHC module does not automatically gate off the card clock when the host driver changes the clock frequency. To prevent possible glitch on the card clock, clear the FRC_SDCLK_ON bit when changing the clock divisor value (SDCLKFS or DVS in System Control Register) or setting the RSTA bit.

Also, before changing the clock divisor value, the host driver should make sure that the SDSTB bit is high.

40.3.11.8 Multi-block read

For pre-defined multi-block read operation, that is, the number of blocks to read has been defined by previous CMD23 for eMMC, or pre-defined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual CMD12/CMD52, is still required by uSDHC after the pre-defined number of blocks are done, to drive the internal state machine to idle mode. In this case, the card may not respond to this extra abort command and uSDHC gets response timeout. It is recommended to manually send an abort command with RSPTYP[1:0] both bits cleared.

40.3.12 Clocking

The table found here describes the clock sources for uSDHC. For more information on clocking, see the Clocking chapter.

Table 313. Clocks

Clock name	Description
hclk	Bus clock
ipg_clk	Peripheral clock
ipg_clk_perclk	Base clock
ipg_clk_lp	Low power clock

40.3.12.1 Clock and reset manager

This module controls all four kinds reset signals within uSDHC:

- Hardware reset
- Software reset for all logic
- Software reset for the data logic
- Software reset for the command logic

All these signals are fed into this module and stable signals are generated inside the module to reset all other modules. The module also gates off all the inside signals.

40.3.12.2 Clock generator

The clock generator generates the card CLK by peripheral source clock in two stages. The clock divisor can be configured through register SYS_CTRL[SDCLKFS] for prescaler configuration while the [DVS] for divisor configuration. Details can be found in the register function description. See the following figure for the structure of the divider. The term "Base" represents the frequency of peripheral source clock (see ipg_clk_perclk in Table 313).

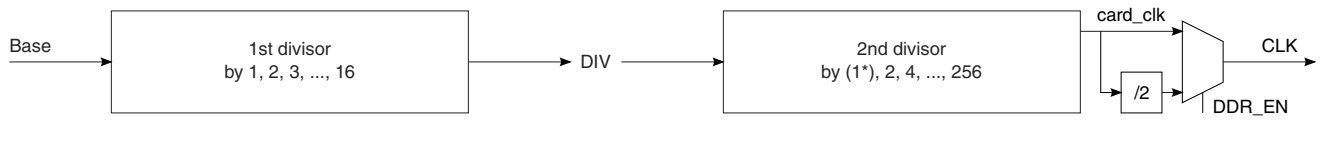

Figure 139. Two stages of the clock divider

The first stage outputs an intermediate clock (DIV) that can be Base, Base/2, Base/3, ..., or Base/16.

The second stage is a prescaler and outputs the actual internal working clock (card_clk). This clock is the driving clock for all the sub modules of the SD protocol unit, and helps in syncing FIFOs (see Figure 125) to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage can be DIV, DIV/2, DIV/4,..., or DIV/256. Therefore, the highest frequency of the card_clk is base, and the next highest is Base/2, while the lowest frequency is Base/4096. If the duty cycle of the base clock is 50%, the duty cycle of card_clk is also 50%, even when the compound divisor is an odd value.

NOTE

CLK is different for the SDR and DDR modes.

- In the SDR mode, CLK is equal to the internal working clock (card_clk).

$$f_{card_clk} = \frac{f_{Base}}{SYS_CTRL[DVS] \times SYS_CTRL[SDCLKFS]}$$

$$f_{CLK} = f_{card_clk}$$

Equation 2. Equation for f_{card_clk} in SDR mode

For HS200 mode, if the source clock f_{Base} = 400 MHz, and the target clock f_{CLK} = 200 MHz, then configuring DVS to 'h00 and SDCLKFS to 'h01, the mapping value of SYS_CTRL[DVS] is 1 and the mapping value of SYS_CTRL[SDCLKFS] is 2.

$$f_{card_clk} = \frac{400MHz}{1x(2)} = 200MHz$$

$$f_{CLK} = f_{card_clk} = 200\ MHz$$

- In the DDR mode, CLK is equal to card_clk/2

$$f_{card_clk} = \frac{f_{Base}}{SYS_CTRL[DVS] \times (SYS_CTRL[SDCLKFS]/2)}$$

$$f_{CLK} = \frac{f_{card_clk}}{2}$$

Equation 3. Equation for f_{card_clk} in DDR mode

For HS400 mode, if the source clock f_{Base} = 400 MHz, and the target clock f_{CLK} = 200 MHz, then configuring DVS to 'h00 and SDCLKFS to 'h00, the mapping value of SYS_CTRL[DVS] is 1 and the mapping value of SYS_CTRL[SDCLKFS] is 2.

$$f_{card_clk} = \frac{400MHz}{1x(2/2)} = 400MHz$$

$$f_{CLK} = \frac{f_{card_clk}}{2} = \frac{400MHz}{2} = 200MHz$$

40.3.13 Command Queuing (CQE) operation

To facilitate command queuing in eMMC, the device manages an internal task queue that the host can queue data transfer tasks. Initially, the task queue is empty. Every task is issued by the host and initially queued as pending. The device controller works to prepare the pending tasks for execution. The software flow is described below:

1. Read CMDQ_SUPPORT[308] and CMDQ_DEPTH[307] of the extended CSD register (through CMD8) to verify eMMC chip support of command queue.
2. Set CMDQ_MODE_EN in CMD_MODE_EN[15] field of the extended CSD by issuing CMD6.

3. Send CMD13 to ensure a successful mode switch.
4. Define Task Descriptor List (TDL) comprised of task descriptor and transfer descriptor sets.
    a. 0x0010002b,0x00000000,0x20000023,0x34300000, //Write example
    b. 0x0010102b,0x00000000,0x20000023,0x34500000, //Read example
5. Set PROT_CTRL[DMASEL] to 2 to select ADMA2. CMDQ descriptors are in ADMA2 format.
6. Set CQSSC2[SSC2] to RCA.
7. Set Command Queuing Task Descriptor List Base Address (CQTDLBA) and Command Queuing Task Descriptor List Base Address Upper 32 Bits (CQTDLBAU) to TDL start address.
8. Set CQCFG[CQUE] to 1 to enable the command queuing.
9. Set CQTDBR[TDBR] field(s) to trigger the required task(s).
10. Read CQTCN[TCN] field(s) to confirm the task completion(s).
11. Set CQTCN[TCN] field(s) to 1 to clear status.

40.3.14 Abort transaction

Abort command

There are two types of abort command: CMD12 and I/O abort.

- CMD12 is used for memory device: such as eMMC, SD Card, SD Combo Card (Memory portion).
- I/O abort is used for SDIO card, SDCombo (I/O portion). I/O abort stops an infinite block transfer (block count = 0) by writing the ASx bit in CCCR.

If an exact number of blocks are to be transferred, it is recommended that the uSDHC issues a block command with the correct block count, rather than using an infinite count and aborting the data at the correct time.

Asynchronous and synchronous abort

There are two ways to issue an abort command (CMD12 or I/O abort): asynchronous abort and synchronous abort.

- In an asynchronous abort sequence, uSDHC can issue an abort command (CMD12 or I/O abort) at anytime unless Command Inhibit (PRES_STATE[CIHB]) in the Present State register is set to 1.
- In a synchronous abort sequence, uSDHC shall issue an abort command (CMD12 or I/O abort) after data transfer is stopped by using Stop At Block Gap Request (SABGREQ).

Read wait

This function uses DATA2 to allow uSDHC to signal the SDIO or Combo Card to temporarily halt the sending of read data by a card during the block gap.

40.4 External signals

The following table describes the uSDHC external signals:

Table 314. uSDHC external signals

Signal	Description	Direction
CLK	Is an Internally generated clock used to drive the eMMC, SD card, and SDIO.	O

Table continues on the next page...

Table 314. uSDHC external signals (continued)

Signal	Description	Direction
CMD	Is used to send commands and receive responses to and from the card.	I/O
DAT7	DAT7 line in the 8-bit mode — Not used in other modes	I/O
DAT6	DAT6 line in the 8-bit mode — Not used in other modes	I/O
DAT5	DAT5 line in the 8-bit mode — Not used in other modes	I/O
DAT4	DAT4 line in the 8-bit mode — Not used in other modes	I/O
NOTE If uSDHC needs to support a 4-bit data transfer, DAT7~DAT4 can also be optional and tied to high.		
DAT3	DAT3 line in the 4/8-bit mode or configured as card detection pin. The bit may be configured as card detection pin in the 1-bit mode.	I/O
DAT2	DAT2 line or Read Wait in the 4-bit mode Read Wait in 1-bit mode	I/O
DAT1	DAT1 line in the 4/8-bit mode Also, used to detect interrupt in 1/4-bit mode	I/O
DAT0	DAT0 line in all the modes Also, used to detect busy state	I/O
CD_B	Card detection signal directly routed from the socket. Low value (0) indicates there is a card inserted. In the case the pin is not used (for the embedded memory), tie low. Optional for system implementation.	I
WP	Write protection signals directly routed from the socket. Low value (0) indicates it is not write protected. In the case the pin is not used (for the embedded memory), tie low. Optional for system implementation.	I
RESET_B	Is used to reset the eMMC or control Card power. Active Low. • eMMC: connect eMMC RST_n pin.	O

Table continues on the next page...

Table 314. uSDHC external signals (continued)

Signal	Description	Direction
	• Card: instead of hardware reset to enable/disable Card power during warm reset.	
VSELECT	Is used to change the voltage of the external power supplier. Optional for system implementation.	O
STROBE	Input clock for eMMC HS400 mode. **NOTE** If the uSDHC does not support the HS400 mode, STROBE can also be optional and tied to low.	I

40.5 Application information

All communication between the system and cards are controlled by the host. The host sends commands of two types: broadcast and addressed (point-to-point).

Broadcast commands are intended for all cards, such as GO_IDLE_STATE, SEND_OP_COND, and ALL_SEND_CID. In the Broadcast mode, eMMC are in the open-drain mode to avoid bus contention. See Commands for SD card, SDIO, and eMMC for the commands of bc and bcr categories.

After the broadcast command CMD3 is issued, the cards enter the standby mode. Addressed type commands are used from this point. In this mode, for eMMC, the CMD/DATA I/O pads turns to the push-pull mode to have the driving capability for maximum frequency operation. See Commands for SD card, SDIO, and eMMC for the commands of ac and adtc categories.

40.5.1 Command send and response receive basic operation

Assuming that the data type WORD is an unsigned 32-bit integer, the flow indicated below presents a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)

{

    WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
recommended to implement in a bit-field manner

    wCmd = (<cmd_index> & 0x3f) << 24; // set the first 8 bits as '00'+<cmd_index>

    set CMDTYP, DPSEL, CICEN, CCCEN, RSTTYP, DTDSEL according to the command index;

    if (internal DMA is used) wCmd |= 0x1;

    if (multi-block transfer) {

        set MSBSEL bit;

        if (finite block number) {

            set BCEN bit;

            if (auto12 command is to use) set AC12EN bit;
```

```
        }

    }

    write_reg(CMDARG, <cmd_arg>); // configure the command argument

    write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command

}

wait_for_response(cmd_index)

{

    while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set

    read IRQ Status register and check if any error bits about Command are set

    if (any error bits are set) report error;

    write 1 to clear CC bit and all Command Error bits;

}
```

For the sake of simplicity, the function wait_for_response is implemented here by means of polling. For an effective and formal way, the response is usually checked after the Command Complete Interrupt is received. When doing this, make sure that the corresponding interrupt status bits are enabled.

For some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and move to the Standby state no response to the Host when CMD2 is sent. The host driver deals with "fake" errors like this with caution.

40.5.2 Card identification mode

When a card is inserted to the socket or the card is reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the Relative Card Address (RCA) or to set the RCA for eMMC.

40.5.2.1 Card detect

See Figure 140 for a flow diagram showing the detection of SD card and SDIO using uSDHC.

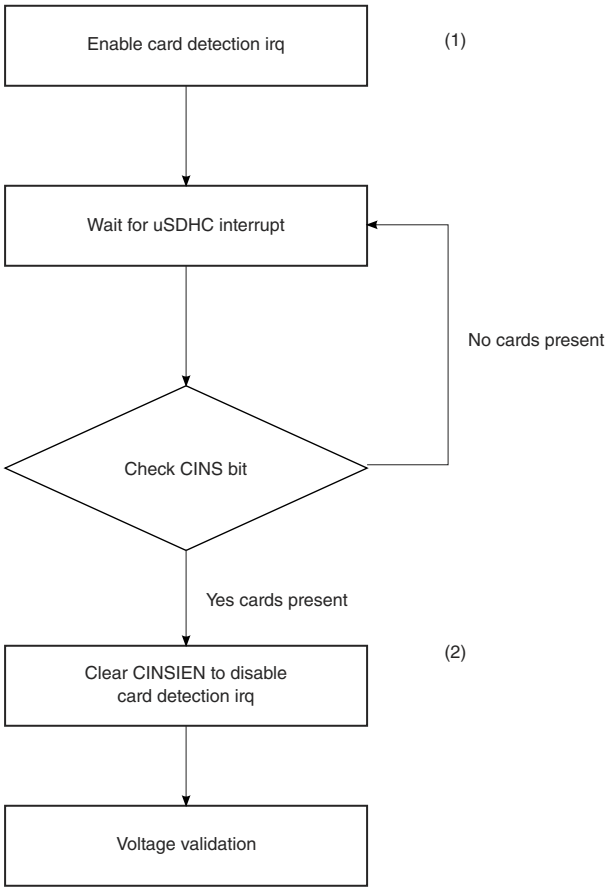

Figure 140. Flow diagram for card detection

Here is the card detect sequence:

- Set the CINSIEN bit to enable card detection interrupt.
- When an interrupt from uSDHC is received, check the CINS bit in the Interrupt Status register to see if it was caused by card insertion.
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards.

40.5.2.2 Reset

The host consists of three types of resets:

- Hardware reset (Card and Host) that is driven by Power On Reset (POR).
- Software reset (Host only) is initiated by the write operation on the RSTD, RSTC, or RSTA bits of the System Control register to reset the data part, command part, or all parts of the host controller, respectively.
- Card reset (Card only): The command, "Go_Idle_State" (CMD0), is the software reset command for all types of eMMC and SD memory cards. This command sets each card into the idle state regardless of the current card state. For an SDIO, CMD52 is used to write an I/O reset in CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. See the figure below for the software flow to reset both uSDHC and the card.

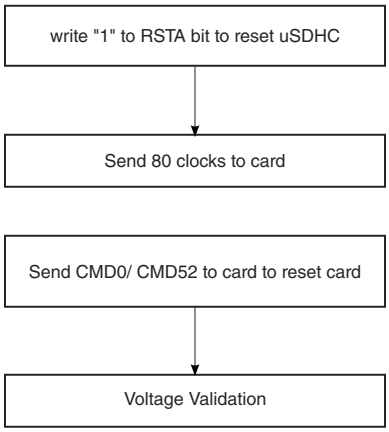

Figure 141. Flow chart for resetting uSDHC and SD card or SDIO

```
software_reset() {
    set_bit(SYSCTRL, RSTA); // software reset the Host set DTOCV and SDCLKFS fields to get the CLK of
    //frequency around 400kHz
    //configure IO pad to set the power voltage of external card to around 3.0V
    //poll bits CIHB and CDIHB
    //bits of PRSSTAT to wait both fields are cleared
    set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
    send_command(CMD_GO_IDLE_STATE, <other parameter>); // reset the card with CMD0 or
    send_command(CMD_IO_RW_DIRECT, <other parameter>);
}
```

40.5.2.3 Voltage validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for VDD are defined in the Operation Conditions Register (OCR) and may not cover the whole range. Cards that store the CID and CSD data in the preload memory are only able to communicate this information under data transfer VDD conditions. This means that if the host and card have non-common VDD ranges, the card is neither able to complete the identification cycle nor able to send CSD data.

Therefore, special commands Send_Op_Cont (CMD1 for eMMC), SD_Send_Op_Cont (ACMD41 for SD Memory), and IO_Send_Op_Cont (CMD5 for SD I/O) are used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards that do not match the VDD range(s) desired by the host. This is accomplished when the host sends the desired VDD voltage window as the operand of this command. Cards that cannot perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive state. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the Inactive state. This query should be used if the host is able to select a common voltage range or if a notification is sent to the system when a non-usable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```
voltage_validation(voltage_range_argument) {
    label the card as UNKNOWN;
    send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO operation
voltage, command argument is zero
    if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
        if (0 < number of IO functions) {
            label the card as SDIO;
            IORDY = 0;
```

```
            while (!(IORDY in IO OCR response)) { // set voltage range for each IO function
                send_command(IO_SEND_OP_COND, <voltage range>, <other parameter>);
                wait_for_response(IO_SEND_OP_COND);
            } // end of while ...
        } // end of if (0 < ...
        if (memory part is present inside SDIO)
            Label the card as SDCombo; //this is an SD-Combo card
    } // end of if (RESP_TIMEOUT ...
    if (the card is labeled as SDIO)
        return; // card type is identified and voltage range is set, so exit the function;
    send_command(APP_CMD, 0x0, <other parameter>); // CMD55, Application specific CMD prefix
    if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
        send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage range for
memory part or SD card
        wait_for_response(SD_APP_OP_COND); // voltage range is set
        if (card type is UNKNOWN)
           label the card as SD;
        return; //
    } // end of if (no error ...
    else if (errors other than time-out occur) { // command/response pair is corrupted
        deal with it by program specific manner;
    } // of else if (response time-out
    else { // CMD55 is refuse, it must be eMMC
        if (card is already labeled as SDCombo) { // change label
            re-label the card as SDIO;
            ignore the error or report it;
            return; // card is identified as SDIO
        } // end of if (card is ...
        send_command(SEND_OP_COND, <voltage range>, <...>);
        if(RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted,
            either label the card as UNKNOWN;
            return;
        } // end of if (RESP_TIMEOUT ...
    } // end of else
}
```

40.5.2.4 Card registry

This section briefly describes the registry flow. For details, please refer to the card specifications. Card registry for the eMMC and SD/SDIO/SD combo cards are different. For the SD card, the identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V (as defined by the card spec). Currently, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host requests the card to send their valid operation conditions. The response to ACMD41 is the operation condition register of the card. The same command is sent to all the new cards in the system. Incompatible cards are put into the Inactive state. The host then issues the command, All_Send_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified (in the Ready state), send their CID number as the response. After the CID is sent by the card, the card goes into the Identification state.

The host then issues Send_Relative_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA is used to address the card for future data transfer operations. After the RCA is received, the card changes its state to the Standby state. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send_Relative_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in the system.

For eMMC operation, the host starts the card identification process in the open-drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line to allow parallel card operation during card identification. After the bus is activated, the host requests the cards to send their valid operation conditions

(CMD1). The response to CMD1 is the "wired AND " operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive state. The host then issues the broadcast command All_Send_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards (the cards in the Ready state) simultaneously start sending their CID numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. As the CID is unique for each card, only one card can be successfully sent its full CID to the host. This card then goes into the Identification state. Thereafter, the host issues Set_Relative_Addr (CMD3) to assign a relative card address (RCA) to the card. After the RCA is received, the state of the card changes to standby, and the card does not react in further identification cycles. Also, its output driver switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

The following steps show how to perform an operation using eMMC:

```
card_registry() {
    do { // decide RCA for each card until response time-out
        if(card is labelled as SDCombo or SDIO) { // for SDIO like device
            send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO to publish its RCA
            retrieve RCA from response;
        } // end if (card is labelled as SDCombo ...
        else if (card is labelled as SD) { // for SD card
            send_command(ALL_SEND_CID, <...>);
            if(RESP_TIMEOUT == wait_for_response(ALL_SEND_CID))
                break;
            send_command(SET_RELATIVE_ADDR, <...>);
            retrieve RCA from response;
        } // else if (card is labelled as SD ...
        else if (card is labelled as eMMC) {
            send_command(ALL_SEND_CID, <...>);
            rca = 0x1; //arbitrarily set RCA, 1 here for example
            send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper 16 bits
        } // end of else if (card is labelled as eMMC...
    } while (response is not time-out);
}
```

40.5.3 Card access

Information about Block Write, Block Read, Suspense Resume, ADMA Usage, Transfer Error, and Card Interrupt are detailed in the sections below.

40.5.3.1 Block write

Information on Normal Write, DDR Write, and Write with Pause are detailed in the sections below.

40.5.3.1.1 Normal Write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card indicates that the failure on the DATA line. The transferred data is discarded and not written, and all further transmitted blocks (in multiple block write mode) are ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set), the card detects the block misalignment error and stops the programming before the beginning of the first misaligned block. The card sets the ADDRESS_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-data-State for a stop command. The write operation also stops if the host tries to write over a write-protected area.

For eMMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card reports an error and does not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card begins writing and holds the DATA line low if its write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) or other means for SDIO at any time, and the card responds with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby state and release the DATA line without interrupting the write operation. When re-selecting the card, it reactivates the busy indication by pulling data to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card that incorporates the internal DMA and the write operation is a multi-block write. For the other methods (CPU polling status with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:
   - For eMMC and SD cards, use SET_BLOCKLEN (CMD16).
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Clear INT_SIGNAL_EN[BWRIEN] to 0 to disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer.

   For multi-block write, set AC12EN to 1 if the device is memory device: such as eMMC, SD Card, SD Combo Card (memory portion). SDIO does not support CMD12, but only supports using IO_RW_DIRECT (CMD52) to abort.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or any other error that occurred during the auto12 command sending and response receiving, if the device is memory device: such as eMMC, SD Card, SD Combo Card (memory portion).

40.5.3.1.2 DDR write

uSDHC supports the dual data rate mode.

The software flow to write to a card in the DDR mode is described as below:

1. Check the card status and wait until the card is ready for data.

   NOTE

   For eMMC, block length can only be set to 512 Byte.
2. Set the uSDHC number block register (NOB), where nob is 5, for instance.
3. Set the eMMC, SD card to high-speed mode and use SWITCH (CMD6); or set SDIO to high-speed mode and use IO_RW_DIRECT (CMD52).
4. Set the eMMC bus or SD with 4-bit/8-bit DDR mode and use SWITCH (CMD6); or set SDIO to with 4-bit DDR mode and use IO_RW_DIRECT (CMD52).
5. Clear INT_SIGNAL_EN[BWRIEN] to 0 to disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. Set DDR_EN to 1.

   For multi-block write, set AC12EN to 1 if the device is memory device: such as eMMC, SD Card, SD Combo Card (Memory portion). SDIO does not support CMD12, but only supports using IO_RW_DIRECT (CMD52) to abort.
6. Wait for the Transfer Complete interrupt.

7. Check the status bit to see if a write CRC error occurred, or any other error that occurred during the auto12 command sending and response receiving if the device is memory device: such as eMMC, SD Card, SD Combo Card (Memory portion).

40.5.3.1.3 Write with Pause

The write operation can be paused during the transfer. Instead of stopping the CLK at any time to pause all the operations, which is also inaccessible to the host driver, the driver can set the Stop At Block Gap Request (SABGREQ) bit in the Protocol Control register to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DATA0 line is not required to de-assert to release the busy state, no suspend command is needed.

Similar to the flow described in Normal Write, the write with pause is shown with the same kind of write operation:

1. Check the card status and wait until the card is ready for data.
2. Set the card block length/size:
   - For eMMC and SD cards, use SET_BLOCKLEN (CMD16).
   - For SDIO or the I/O portion of SD Combo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Clear INT_SIGNAL_EN[BWRIEN] to 0 to disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer.

   For multi-block write, set AC12EN to 1 if the device is memory device: such as eMMC, SD Card, SD Combo Card (Memory portion). SDIO does not support CMD12, but only supports using IO_RW_DIRECT (CMD52) to abort.
6. Set the SABGREQ bit.
7. Wait for the Transfer Complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the Transfer Complete interrupt.
12. Check the status bit to see if a write CRC error occurred, or any other error that occurred during the auto12 command sending and response receiving if the device is memory device: such as eMMC, SD Card, SD Combo Card (Memory portion).

The number of blocks left during the data transfer is accessible by reading the contents of BLK_ATT[BLKCNT]. As the data transfer and the setting of the SABGREQ bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The host driver reads the value of BLKCNT after the transfer is paused and the Transfer Complete interrupt (INT_STATUS[TC]) is received.

It is also possible that the last block has begun when the Stop At Block Gap Request is sent to the buffer. In this case, the next block gap is the end of the transfer. These types of requests are ignored, the driver should treat these as a non-pause transfer, and deal with it as a common write operation.

40.5.3.2 Block read

Information about Normal read, DDR read, Read with Pause, and Delay Line (DLL) in Read Path are detailed in the sections below.

40.5.3.2.1 Normal read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer state. For multi blocks read, data blocks are continuously transferred until a stop command is issued.

The software flow to read from a card that incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other methods (CPU polling status with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status and wait until card is ready for data.
2. Set the card block length/size:
   - For eMMC and SD cards, use SET_BLOCKLEN (CMD16).
   - For SDIO or the I/O portion of SD Combo Cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7).
3. Set the uSDHC block length register to be the same as the block length set for the card in step 2.
4. Set the uSDHC number block register (NOB), where nob is 5, for instance.
5. Clear INT_SIGNAL_EN[BRRIEN] to 0 to disable the buffer read ready interrupt, configure the DMA settings, and enable the uSDHC DMA when sending the command with data transfer.

   For multi-block read, set AC12EN to 1 if the device is memory device: such as eMMC, SD Card, Combo Card (Memory portion). SDIO does not support CMD12, but only supports using IO_RW_DIRECT (CMD52) to abort.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a read CRC error occurred, or any other error occurred during the auto12 command sending and response receiving if the device is memory device: such as eMMC, SD Card, Combo Card (Memory portion).

40.5.3.2.2 DDR read

The uSDHC module supports dual data rate mode.

The software flow to write to a card in the DDR mode is described below:

1. Check the card status and wait until the card is ready for data.

   NOTE

   For eMMC, block length can only be set to 512 Bytes.
2. Set the uSDHC number block register (NOB) where nob is 5, for instance.
3. Set the eMMC, SD card to high-speed mode and use SWITCH (CMD6); or set SDIO to high-speed mode and use IO_RW_DIRECT (CMD52).
4. Set the eMMC bus or SD with 4-bit/8-bit DDR mode and use SWITCH (CMD6); or set SDIO to with 4-bit DDR mode and use IO_RW_DIRECT (CMD52).
5. Clear INT_SIGNAL_EN[BRRIEN] to 0 to disable the buffer write ready interrupt, configure the DMA settings, and enable the uSDHC DMA when sending the command with data transfer. Set DDR_EN to 1.

   For multi-block read, set AC12EN to 1 if the device is memory device: such as eMMC, SD Card, Combo Card (Memory portion). SDIO does not support CMD12, but only supports using IO_RW_DIRECT (CMD52) to abort.
6. Wait for the Transfer Complete interrupt.

7. Check the status bit to see if a write CRC error occurred, or any other error that occurred during the auto12 command sending and response receiving if the device is memory device: such as eMMC, SD Card, Combo Card (Memory portion).

40.5.3.2.3 Read with Pause

The read operation can be paused during the transfer. Instead of stopping the CLK at any time to pause all the operations, which is also inaccessible to the host driver, the driver can set the Stop At Block Gap Request (SABGREQ) bit in Control register to pause the transfer between the data blocks.

Only SDIO and SD Combo Card support Read Wait feature while Read with Pause. Read Wait feature means that it uses DATA2 to allow uSDHC to signal the SDIO or SD Combo Card to temporarily halt the sending of read data by a card during the block gap. Before setting SABGREQ to 1, ensure to set the RWCTL bit to 1 after recognizing the read wait capability of SDIO (SRW bit in CCCR register is 1).

Similar to the flow described in Normal read, the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCCR register on SDIO or SD Combo Card (I/O portion) to confirm that the card supports the Read Wait mode.
2. If SDIO or Combo Card (I/O portion) supports Read Wait, set RWCTL to 1.

   If the device is meemory device: such as eMMC, SD Card, or SD Combo Card (Memory portion), set RD_DONE_NO_8CLK to 1.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:
   - For eMMC and SD cards, use SET_BLOCKLEN (CMD16).
   - For SDIO or the I/O portion of SD Combo Cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bitfield in the CCCR register (for function 0) or FBR register (for functions 1~7).
5. Set the uSDHC block length register to be the same as the block length set for the card in step 4.
6. Set the uSDHC number block register (NOB), where nob is 5, for instance.
7. Clear INT_SIGNAL_EN[BRRIEN] to 0 to disable the buffer read ready interrupt, configure the DMA setting, and enable the uSDHC DMA when sending the command with data transfer.

   For multi-block read, set AC12EN to 1 if the device is memory device: such as eMMC, SD Card, Combo Card (Memory portion). SDIO does not support CMD12, but only supports using IO_RW_DIRECT (CMD52) to abort.
8. Set the SABGREQ bit.
9. Wait for the Transfer Complete interrupt.
10. Clear the SABGREQ bit.
11. Check the status bit to see if read CRC error occurred.
12. Set the CREQ bit to continue the read operation.
13. Wait for the Transfer Complete interrupt.
14. Check the status bit to see if a read CRC error occurred, or any other error occurred during the auto12 command sending and response receiving if the device is memory device: such as eMMC, SD Card, Combo Card (Memory portion).

Similar to the Write operation, it is possible to meet the ending block of the transfer when paused. In this case, uSDHC ignores the Stop At Block Gap Request and treats it as a command read operation.

If the Suspend command is sent and the transfer is later resumed by means of a Resume command, uSDHC takes the command as a normal one accompanied with data transfer. It is left for the host driver to set all the relevant registers before the transfer

is resumed. For momory device, if there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. Then uSDHC automatically sends CMD12 to mark the end of multi-block transfer.

40.5.3.2.4 Delay Line (DLL) in read path

The DLL is newly added to assist in sampling read data. The DLL provides the ability to programmatically select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage, and temperature (PVT).

The reasons why DLL is needed for uSDHC are these:

- The path of read data traveling from card to host varies.
- In the eMMC and SD cards DDR mode, the minimum input setup and hold time are both at 2.5 ns.

The data sampling window is so small that the delay of loopback clock needs to be accurate and consistent regardless of PVT. The DLL takes the divided card_clk as the reference clock and loopback clock as the input clock. It then generates a delayed version of the input clock according to the programmed target delay.

The DLL can be disabled or bypassed, and it can also be manually set for a fixed delay in the override mode. The override value set is the number of delay cells. In the override mode, there is no need to set the DLL_enable. Another DLL mode is target value mode. In this mode, the DLL automatically adjusts the number of delay cells according to the target value set by the user and PVT changes. Be aware that the target value is in units of 1/32 of the clock reference period. If the card_clk is 100Mhz, then the reference clock period is 10ns; setting target value of 16 means 5ns =(16/32)*10ns. The software can disable automatic update by the setting dll_gate_update bit.

As you might change the frequency of card_clk from time to time by changing SDCLKFS[7:0]/DVS[3:0], the software must adjust the delay value to ensure it works correctly when the reference clock (card_clk) is changed. If DLL is to be used, make sure SDCLKFS is used (at least be set to divided by 2) so that the REF_CLK generated are the same frequency as card_clk. There are two DLLs, PARTS DLL and STROBE DLL. PARTS DLL controls the SD_CLK loop back delay for which DLL (Delay Line) Control (DLL_CTRL) and DLL Status (DLL_STATUS) are used. STROBE DLL controls the STROBE loop back delay for which Strobe DLL control (STROBE_DLL_CTRL) and Strobe DLL status (STROBE_DLL_STATUS) are used. For PARTS DLL, below flow can be taken as reference. For STROBE DLL, similar register field with prefix STROBE in Strobe DLL control (STROBE_DLL_CTRL) and Strobe DLL status (STROBE_DLL_STATUS) must be used.

Step 1: Set the DLL_CTRL_RESET and DLL_CTRL_ENABLE fields

Step 2: Configure the SDCLKFS[7:0] and DVS[3:0]

Step 3: Wait until SDSTB is asserted

Step 4: Clear the DLL_CTRL_RESET field

Step 5: Wait until both the DLL_STS_SLV_LOCK and DLL_STS_REF_LOCK are asserted

Step 6: Set the DLL_CTRL_SLV_FORCE_UPD

Step 7: Clear the DLL_CTRL_SLV_FORCE_UPD

NOTE

The software should make sure that the DLL_CTRL_SLV_FORCE_UPD lasts for at least one card_clk. So, the software may need to add some delay between step 6 and step 7.

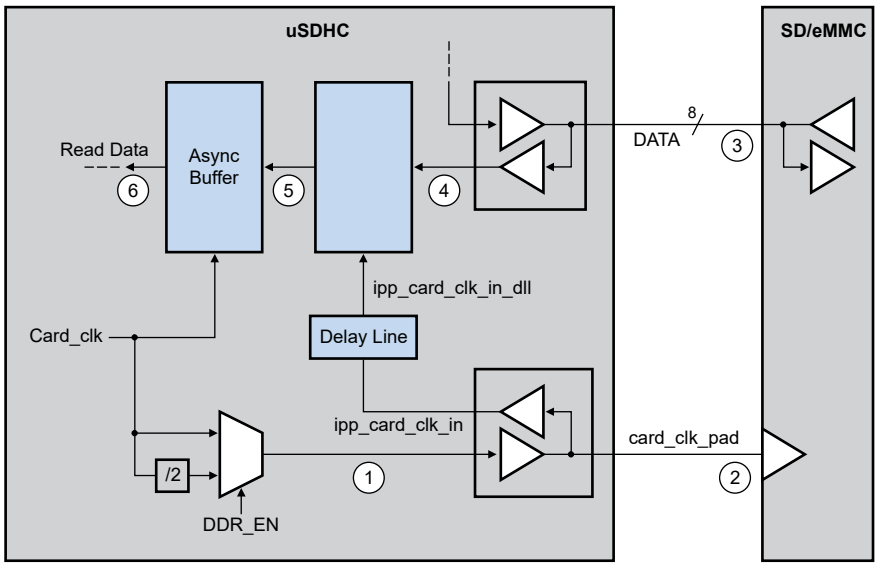

Figure 142. DLL in read path

40.5.3.3 Suspend Resume

The uSDHC module supports the Suspend Resume operations of SDIO and Combo Card, although slightly different than the suggested implementation of Suspend in the SDIO specification. Both Read and Write support Suspend and Resume, however ADMA operation does not support this function.

40.5.3.3.1 Suspend

After setting the SABGREQ bit, the host driver may send a Suspend command to switch to another function of SDIO and Combo Card. The uSDHC module does not monitor the content of the response, so it does not know if the Suspend command succeeded or not. Accordingly, it does not de-assert Read Wait for read pause. To solve this problem, the host driver does not mark the Suspend command as "Suspend", i.e., setting the CMDTYP bits to 01. Instead, the driver sends this command as if it were a normal command, and only when the command succeeds, and the BS bit is set in the response, can the Driver send another command marked as "Suspend" to inform uSDHC that the current transfer is suspended. Here is the sequence for the Suspend operation:

1. Check CCCR[SRW] on SDIO or SD Combo Card (I/O portion) to confirm that the card supports the Read Wait mode. If SDIO or Combo Card (I/O portion) supports Read Wait, set the RWCTL bit to 1.
2. Set the SABGREQ bit to 1 to pause the current data transfer at block gap. Wait for the BGE bit set as 1, and wait for the Transfer Complete interrupt. Save the context registers in the system memory for later use, including the DMA System Address Register DS_ADDR (for internal DMA operation), and the Block Attribute Register BLK_ATT.
3. Send the Suspend command to suspend the active function. The CMDTYP bit field must be 2'b00.

   The following steps show an example of CMD52 function0 suspend with CMDTYP=2'b00:

   a. Set CMD_ARG to 0x88001802

   b. Set MIX_CTRL to 0x80000000

   c. Set CMD_XFR_TYP to 0x341A0000
4. Check the BS bit of the CCCR in the response (CMD_RSP0[0]). If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
5. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 2'b01, so uSDHC can detect this special setting and be informed that the paused operation has successfully suspended.

The following steps show an example of CMD52 function0 suspend with CMDTYP=2'b01:

a. Set CMD_ARG to 0x00001800

b. Set MIX_CTRL to 0x80000000

c. Set CMD_XFR_TYP to 0x345A0000

6. Clear the BGE bit to 0, and clear the SABGREQ bit to 0. Begin operation for another function on SDIO and Combo Card (I/O portion).

40.5.3.3.2 Resume

To resume the data transfer, a Resume command is issued:

1. To resume the suspended function, restore the context registers (DS_ADDR and BLK_ATT) with the saved value in the step #2 of the Suspend operation.
2. Send the Resume command: In the Transfer Type register, all the bitfields are set to the value as if this were another ordinary data transfer instead of a transfer resume (except the CMDTYP is set to 2'b10).

   The following steps show an example of CMD52 function0 resume with CMDTYP=2'b10:

   a. Set CMD_ARG to 0x88001A01

   b. Set MIX_CTRL either to 0x80000023 (Suspend Write, Host to Card) or to 0x80000033 (Suspend Read, Card to Host)

   c. Set CMD_XFR_TYP to 0x34BA0000

3. If the Resume command (INT_STATUS[CC]) has responded, the data transfer is resumed.

40.5.3.4 ADMA usage

To use the ADMA in a data transfer, the host driver must prepare the correct descriptor chain prior to sending the read/write command. The steps to prepare the correct descriptor chain are as follows:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4KB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1 ~ 3.
4. Repeat steps 1 ~ 3 until all descriptors are created.
5. In the last descriptor, set the End flag to 1 and make sure the total length of all descriptors matches the product of the block size and block number configured in the Block Attribute Register.
6. Set the ADMA System Address Register to the address of the first descriptor and set the DMAS field in the Protocol Control Register to 01 to select the ADMA.
7. Issue a write or read command with the DMAEN bit set to 1 in the Transfer Type Register.
8. Once the ADMA transfer is complete, clear PROT_CTRL[DMASEL] to 00b.

Steps 1 ~ 5 are independent of step 6, so step 6 can finish before steps 1 ~ 5. Regarding the descriptor configuration, it is recommended not to use the Link descriptor as it requires extra system memory access.

40.5.3.5 Transfer error

Information about CRC, Internal DMA, Transfer ADMA, and Auto CMD12 errors are detailed in the sections below.

40.5.3.5.1 CRC error

It is possible at the end of a block transfer that a write CRC status error or read CRC error occurs. For this type of error, the latest block received is discarded. This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one. For a multi-block transfer, the host driver issues a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the AC12EN and BCEND bits are set, uSDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 is sent by uSDHC. In this case, the host driver re-sends or re-obtains the last block with a single block transfer.

40.5.3.5.2 Internal DMA error

During the data transfer with internal Simple DMA, if the DMA engine encounters an error on the AXI bus, the DMA operation stops, and the DMA error interrupt is sent to the host system. When acknowledged by such an interrupt, the host driver calculates the start address of data block in which the error occurs. The start address can be calculated by either:

- Reading the DMA System Address register: The error occurs during the previous burst. Considering the block size, and the start address of the next burst transfer, it is straight forward to obtain the start address of the corrupted block.
- Reading the BLKCNT field of the Block Attribute register: Considering the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined.To use this method, MIX_CTRL[BCEN] bit has to be set to enable Block Attribute register update.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and restart the transfer from the corrupted block to recover from the error.

40.5.3.5.3 Transfer ADMA error

There are three kinds of possible ADMA errors: The AXI transfer, invalid descriptor, and data-length mismatch. Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set. For acknowledging the status, the host driver should recover the error as shown below and re-transfer from the place of interruption.

- AXI transfer error: Such errors may occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or to the next block if no block is corrupted.
- Invalid descriptor error: For such errors, it is recommended to retrieve the transfer context, reset for the data part and recreate the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
- Data-length mismatch error: It is similar to recover from this error. The Host Driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

40.5.3.5.4 Auto CMD12 error

After the last block of the multi-block transfer is sent or received, and the AC12EN bit is set when the data transfer is initiated by the data command, uSDHC automatically sends a CMD12 to the card to stop the transfer. When errors with this command occur, it is recommended to the host driver to deal with the situations in the following manner:

- Auto CMD12 response time-out: It is not certain whether the command is accepted by the card or not. The host driver clears the auto CMD12 error status bits and re-send CMD12 until it is accepted by the card.
- Auto CMD12 response CRC error: As the card responds to CMD12, it stops the transfer. The host driver may ignore the error and clear the error status bit.
- Auto CMD12 conflict error or not sent: The command is not sent; therefore, the host driver sends a CMD12 manually.

40.5.3.6 Card interrupt

The external cards can inform the host controller by means of some special signals. For SDIO, it can be the low-level on the DATA1 line during some special period. The uSDHC module only monitors the DATA1 line and supports the SDIO interrupt.

When the SDIO interrupt is captured by uSDHC, and the host system is informed by uSDHC asserting the uSDHC interrupt line, the interrupt service from the host driver is called.

As the interrupt source is controlled by the external card, the interrupt from SDIO must be serviced before the CINT bit is cleared. Refer to Card interrupt handling for the card interrupt handling flow.

40.5.4 Switch function

A switch command is issued by the host driver to enable new features added to the eMMC and SD cards. The eMMC and SD cards can transfer data at bus widths other than 1-bit. Different speed modes are also defined. To enable these features, a switch command is issued by the host driver.

For SDIO, the high-speed mode /DDR50/SDR50/SDR104 are enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed as high. For SD cards, the high-speed mode/DDR50/SDR50/SDR104 are queried and enabled by a CMD6 (with the mnemonic symbol as SWITCH_FUNC). For eMMC, the high-speed mode HS200 or HS400 is queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol as SWITCH).

The SDR4-bit, SDR8-bit, DDR4-bit, and DDR8-bit width of eMMC is also enabled by the SWITCH command, but with a different argument.

These new functions can also be disabled by a software reset. For SDIO, it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following pseudo-code examples do not show current capability check, which is recommended in the function switch process.

40.5.4.1 Query, enable, and disable SDIO high-speed mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report SDIO does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into uSDHC to generate the card_clk
of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is cleared;
change clock divisor value or configure the system clock feeding into uSDHC to generate the card_clk
of the desired value below 25MHz;
(data transactions like normal peers)
}
```

40.5.4.2 Query, enable, and disable SD high-speed mode/DDR50 /SDR50 /SDR104

```
enable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFFx and read 64 bytes of data accompanying the R1 response;(high speed
mode,x=1; SDR50,x=2; SDR104,x=3; DDR50,x=4;)
wait data transfer done bit is set;
check if the bit x of received 512 bits is set;
```

```
if (bit 401 is '0') report the SD card does not support high speed mode and return;
if (bit 402 is '0') report the SD card does not support SDR50 mode and return;
if (bit 403 is '0') report the SD card does not support SDR104 mode and return;
if (bit 404 is '0') report the SD card does not support DDR50 mode and return;
      send CMD6, with argument 0x80FFFFFx and read 64 bytes of data accompanying the R1 response;
(high speed mode,x=1; SDR50,x=2; SDR104,x=3; DDR50,x=4;)
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the card_clk
of around 50MHz for high speed mode, 100MHz for SDR50, 200MHz for SDR104, 50MHz for DDR50;
(data transactions like normal peers)
}
disable_sd_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

40.5.4.3 Query, enable, and disable eMMC high-speed mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of eMMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the eMMC does not support high speed mode and return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of eMMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this eMMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of eMMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report eMMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of eMMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}
```

40.5.4.4 Set eMMC bus width

```
change_mmc_bus_width(void)
{
send CMD9 to get CSD value of eMMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the eMMC does not support multiple bit width and return;
send CMD6 with argument 0x3B70x00; (8-bit(dual data rate), x=6; 4-bit(dual data rate), x=5;8-bit,
x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}
```

40.5.5 ADMA operation

Here are the codes for the ADMA1 and ADMA2 operations.

40.5.5.1 ADMA1 operation

```
Set_adma1_descriptor
{
if (to start data transfer) {
// Make sure the address is 4KB align.
Set 'Set' type descriptor;
{
Set Act bits to 01;
Set [31:12] bits data length (byte unit);
}
Set 'Tran' type descriptor;
{
Set Act bits to 10;
Set [31:12] bits address (4KB align);
}
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to 11;
Set [31:12] bits the next descriptor address (4KB aligned);
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set End bit to 1;
}
if (to generate interrupt for this descriptor) {
Set Int bit to 1;
}
Set Valid bit to 1;
}
```

40.5.5.2 ADMA2 operation

```
Set_adma2_descriptor
{
if (to start data transfer) {
// Make sure the address is a 32-bit boundary (lower 2-bit are always '00').
Set higher 32-bit of descriptor for this data transfer initial address;
Set [31:16] bits data length (byte unit);
```

```
Set Act bits to '10';
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to '11';
// Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
Set higher 32-bit of descriptor for the next descriptor address;
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set 'End' bit '1';
}
if (to generate interrupt for this descriptor) {
Set 'Int' bit '1';
}
Set the 'Valid' bit to '1';
}
```

40.5.6 Fast boot operation

40.5.6.1 Normal fast boot flow

Here are the steps for normal fast boot flow:

1. Software must configure the SYS_CTRL[INITA] bit to make sure that 74 card clocks are finished.
2. Software must configure the eMMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 0 (normal fast boot), and bit 4 to select the ack mode. If the data is sent through the DMA mode, the software should configure bit 7 to enable the automatic stop at block gap feature, and configure bit 3-bit 0 to select the ack timeout value according to the SD CLK frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software must configure the Protocol control register to set Data Transfer Width (DTW). If in the DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure the Command Argument Register to set argument if needed (no need in normal fast boot).
6. Software must configure the Transfer Type Register to start the boot process. In normal boot mode, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN retain the default value, where DPSEL bit is set to 1, DTDSEL is set to 1 and MSBSEL is set to 1.
7. DMAEN should be configured as 0 in the polling mode and if BCEN is configured as 1, it is recommended to configure the number of blocks in the Block Attributes Register to the maximum value. If in DDR fast boot mode, DDR_EN needs to be set to 1.
8. When step 6 is configured, the boot process begins. The software needs to poll the data buffer ready status to read the data from the buffer in time. If a boot timeout happens (ack times out or the first data read times out), an interrupt is triggered, and the software must configure eMMC Boot Register to bit 6 to 0 to disable boot. This makes CMD high, then after at least 56 clocks, it is ready to begin a normal initialization process.
9. If there is no timeout, software needs to determine when the data read is finished and then configure eMMC Boot Register bit 6 to 0 to disable boot. This render CMD line high and command completed asserted. After at least 56 clocks, it is ready to begin the normal initialization process.
10. You must reset the host and begin the normal process.

40.5.6.2 Alternative fast boot flow

Here are the steps for alternative fast boot flow:

1. Software needs to configure SYS_CTRL[INITA] to make sure 74 card clocks are finished.
2. Software needs to configure eMMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 1 (alternative boot), and bit 4 to select the ack mode or not. If data needs to be sent through the DMA mode, then configure bit 7 to enable the automatic stop at block gap feature. Software should also configure bit 3-bit 0 to select the ack timeout value according to the SD clock frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in the DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software needs to configure the Protocol control register to set the data transfer width (DTW). If in the DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFA.
6. Software needs to configure the Transfer Type Register to start the boot process by CMD0 with the 0xFFFFFFFA argument. In alternative boot, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN, and DMAEN retain the default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. Note DMAEN should be configured as 0 in the polling mode, and if BCEN is configured as 1 in polling mode, it is recommended to configure the block count in the Block Attributes Register to the maximum value. If in the DDR fast boot mode, DDR_EN needs to be set to 1.
7. When step 6 is configured, the boot process begins. Software needs to poll the data buffer ready status to read the data from the buffer in time. If there is a boot timeout (ack data timeout in 50ms or data timeout in 1s), the host sends out the interrupt and the software needs to send CMD0 with reset and then configure the boot enable bit to 0 to stop this process.
8. If there is no time out, the software needs to decide when to stop the boot process, and send out the CMD0 with reset and then after the command is completed, configure the eMMC Boot Register bit 6 to stop the process. After 8 clocks from the command completion, the target (card) is ready for the identification step.
9. You must reset the host and begin the normal process.

40.5.6.3 Fast boot application case (in DMA mode)

In the boot application case, because the image destination and the image size are contained in the beginning of the image, it is necessary to switch DMA parameters on the fly during eMMC fast boot.

In fast boot, the host can use Advanced DMA2 (ADMA2) with two destinations.

The detailed flow is described below:

1. The software needs to configure INIT_ACTIVE bit (system control register bit 27) to make sure that 74 card clocks are finished.
2. The software needs to configure the eMMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot) or 1 (alternative boot); and bit 4 to select the ack mode. In DMA mode, configure bit 7 to 1 to enable the automatic stop at block gap feature. Also configure bits[31-16] to set the (BLK_CNT - VALUE1). Here VALUE1 is the value of the block count that needs to transfer the first time, so that the host stops at the block gap when the uSDHC controller gets VAULE1 blocks from the device. Also, configure bits[3-0] to select the ack timeout value according to the SD clock frequency.
3. The software then needs to configure the Block Attributes Register to set block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes. In DMA mode, it is recommended to set the block count (BLK_CNT) to the max value (16'hffff).
4. The software needs to configure Protocol Control Register to set DTW (data transfer width). If in DDR fast boot mode, the DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software enable ADMA2 by configuring Protocol Control Register bits [9-8].
6. The software needs to set at least three pairs of ADMA2 descriptor in boot memory (that is, in IRAM, at least six words). The first pair descriptor defines the start address (that is, IRAM) and data length (that is,512byte*VALUE1) of the first part boot code. The software also needs to set the second pair descriptor, the second start address (any value that

is writable), and data length is suggested to set 1~2word (record as VALUE2). Note that the second couple desc also transfers useful data even at lease 1 word, because our ADMA2 cannot support 0 data_length data transfer descriptor.

7. The software needs to configure Command Argument Register to set argument to 0xFFFFFFFA in alternative fast boot and do not need to be set in normal fast boot.
8. The software needs to configure Transfer Type Register to start the boot process. CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN, and DMAEN retain the default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. DMAEN is configured as 1 in the DMA mode. And, if BCEN is configured as 1, then configure blk no in Bock Attributes Register to the max value. And, if in the DDR fast boot mode, DDR_EN needs to be set to 1.
9. When step 8 is configured, boot process begins, the first VALUE1 block number data gets transferred. The software needs to poll the TC bit (bit1 in Interrupt Status Register) to determine first transfer is ended. Also, the software needs to polling the BGE bit (bit2 in Interrupt Status Register) to determine if the first transfer stops at the block gap.
10. When TC and BGE bits are set to 1, the software can analyze the first code of VALUE1 block, initializes the new memory device, if required, and sets the third pair of descriptors to define the start address and length of the remaining part of the boot code (VALUE3, the remain boot code block). Remember to set the last descriptor with END.
11. The software needs to configure the eMMC Boot Register (offset 0xc4) again. Set bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot), to 1 (alternative boot); and bit 4 to select the ack mode or not. In the DMA mode, configure bit 7 to 1 for enabling the automatically stop at block gap feature. Also, configure bit31-bit16 to set the (BLK_CNT - (VALUE1+1+VALUE3)), that host stops at block gap when the uSDHC controller gets (VALUE1+1+VALUE3)) blocks from device totally include the blocks received in step 9. And need to configure bit 3-bit0 to select the ack timeout value according to the sd clk frequency. Note that the software does not need to configure the BLK_CNT again, because it is counted down automatically by the uSDHC controller.
12. The software needs to clear the TC and BGE bits and the software needs to clear SABGREQ (bit 16 in the Protocol control register) and set CREQ (bit17 in the Protocol control register) to 1 to resume the data transfer. Host transfers the VALUE2 and VALUE3 data to the destination that is set by descriptor.
13. The software needs to do poll BGE bit to determine if the fast boot is over.

Note:

- When ADMA boot flow starts, for uSDHC, it is like a normal ADMA read operation. So, set ADMA2 descriptor as the normal ADMA2 transfer.
- Need a few words length memory to keep descriptor.
- For the 1~2-word data in second descriptor setting, it is a useful data, so the software needs to deal the data because of the application case.

40.6 uSDHC memory map and register definition

40.6.1 USDHC register descriptions

This section includes the module memory map and detailed descriptions of all registers.

See the table below for the register memory map of uSDHC. All these registers only support 32-bit accesses.

NOTE

The uSDHC registers are 32-bit wide and only support 32-bit access.

40.6.1.1 USDHC memory map

USDHC0 base address: 4041_2000h

USDHC1 base address: 4041_3000h

Offset	Register	Width (In bits)	Access	Reset value
0h	DMA System Address (DS_ADDR)	32	RW	0000_0000h
4h	Block Attributes (BLK_ATT)	32	RW	0001_0000h
8h	Command Argument (CMD_ARG)	32	RW	0000_0000h
Ch	Command Transfer Type (CMD_XFR_TYP)	32	RW	0000_0000h
10h	Command Response0 (CMD_RSP0)	32	R	0000_0000h
14h	Command Response1 (CMD_RSP1)	32	R	0000_0000h

40.6.1.2 DMA System Address (DS_ADDR)

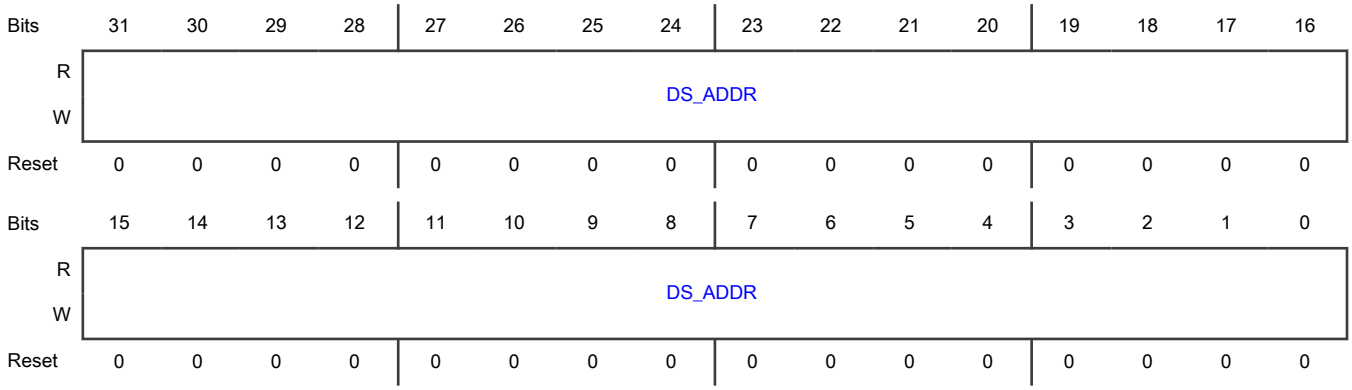
Offset

Register	Offset
DS_ADDR	0h

Function

This register contains the physical system memory address used for DMA transfers.

Diagram



Fields

Field	Function
31-0 DS_ADDR	System address **DMA system address / argument 2** When ACMD23_ARGU2_EN is set to 0, SDMA uses this register as system address and supports only 32-bit addressing mode. Auto CMD23 cannot be used with SDMA. When ACMD23_ARGU2_EN is set to 1, SDMA uses ADMA System Address register (05Fh – 058h) instead of this register to support both ADMA1 and ADMA2. This register is used only for Argument2 and SDMA may use Auto CMD23. 1. **SDMA system address** Because the address must be word (4 bytes) aligned, the least two bits are reserved and always set to 0. When uSDHC stops a DMA transfer, this register points out the system address of the next contiguous data position. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operation during transfers may return an invalid value. The host driver initializes this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register. This register is protected during a data transfer. When data lines are active, write to this register is ignored. The host driver waits until the DLA field in the Present State register is cleared, before writing to this register. The uSDHC internal DMA does not support a virtual memory system. It only supports continuous physical memory access. Because this register supports dynamic address reflecting, when TC field is set, it automatically alters the value of internal address counter, so the software cannot change this register when TC field is set. Such restriction is also listed in Software restrictions. 2. **Argument 2** This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23. If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without ADMA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case.

40.6.1.3 Block Attributes (BLK_ATT)

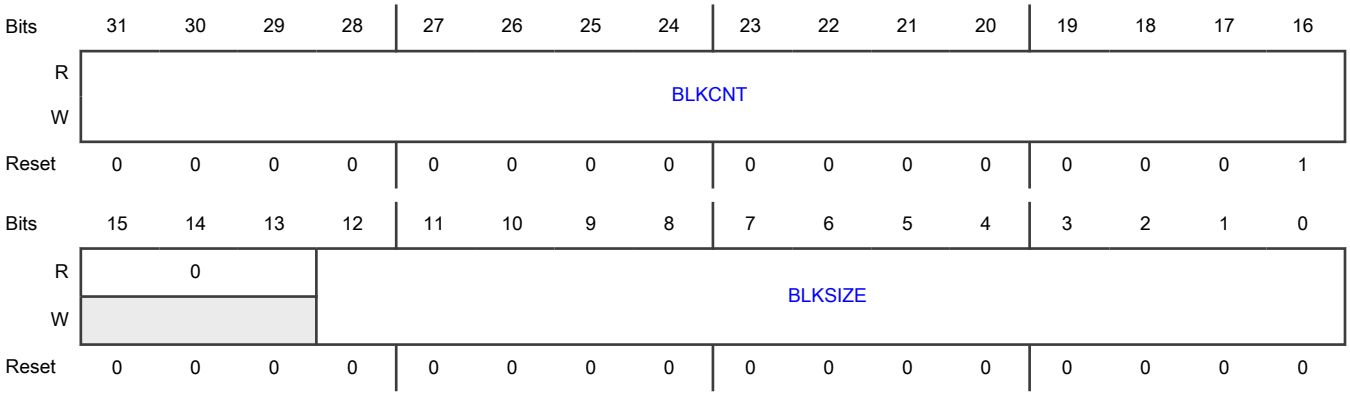
Offset

Register	Offset
BLK_ATT	4h

Function

This register is used to configure the number of data blocks and the number of bytes in each block.

Diagram



Fields

Field	Function
31-16 BLKCNT	Blocks count for current transfer This field is enabled when the Block Count Enable field in the Transfer Mode register is set to 1 and is valid only for multiple block transfers. For single block transfer, this field always reads as 1. The host driver sets this field to a value between 1 and the maximum block count. The uSDHC module decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to zero results in no data blocks being transferred. This field should be accessed only when no transaction is executing (that is, after transactions are stopped). During data transfer, read operations on this field may return an invalid value and write operations are ignored. When saving transfer content because of a Suspend command, the number of blocks yet to be transferred can be determined by reading this field. The reading of this field should be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend. This is because when the Suspend command is sent out, uSDHC treats the current transfer as stopped and change the BLKCNT field back to its original value instead of keeping the dynamical indicator of the remaining block count. When restoring transfer content prior to issuing a Resume command, the host driver restores the previously saved block count.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE Although the BLKCNT field is 0 after reset, the read of reset value is 0x1. This is because when MSBSEL field is indicating a single block transfer, the read value of BLKCNT is always 1. 0000_0000_0000_0000b - Stop count 0000_0000_0000_0001b - 1 block 0000_0000_0000_0010b - 2 blocks 1111_1111_1111_1111b - 65535 blocks
15-13 —	Reserved
12-0 BLKSIZE	Transfer block size This field specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations are ignored. 0_0000_0000_0000b - No data transfer 0_0000_0000_0001b - 1 byte 0_0000_0000_0010b - 2 bytes 0_0000_0000_0011b - 3 bytes 0_0000_0000_0100b - 4 bytes 0_0001_1111_1111b - 511 bytes 0_0010_0000_0000b - 512 bytes 0_1000_0000_0000b - 2048 bytes 1_0000_0000_0000b - 4096 bytes

40.6.1.4 Command Argument (CMD_ARG)

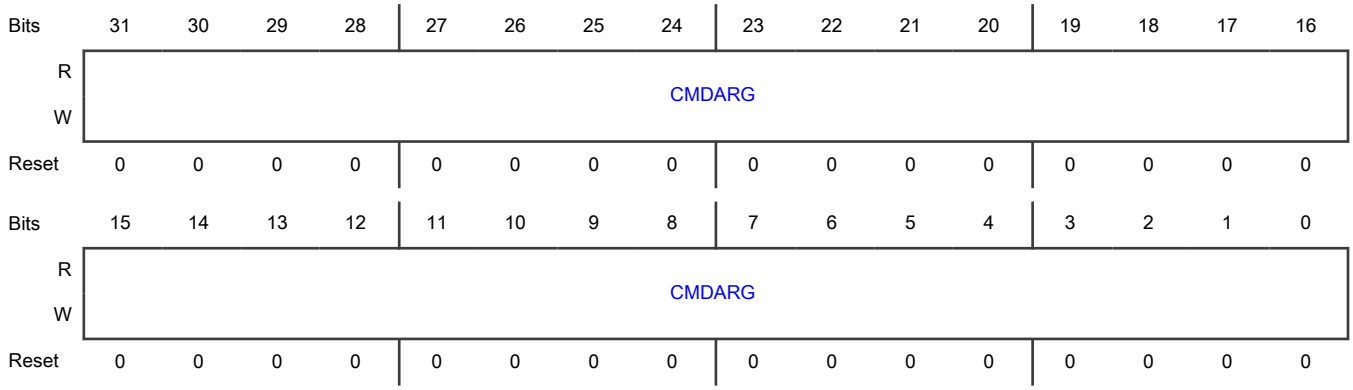
Offset

Register	Offset
CMD_ARG	8h

Function

This register contains the SD/eMMC command argument.

Diagram



Fields

Field	Function
31-0 CMDARG	Command argument The SD/eMMC command argument is specified as bits 39-8 of the command format in the SD or eMMC specification. This field is write protected when the Command Inhibit (CMD) field in the Present State register is set.

40.6.1.5 Command Transfer Type (CMD_XFR_TYP)

Offset

Register	Offset
CMD_XFR_TYP	Ch

Function

This register is used to control the operation of data transfers. The host driver sets this register before issuing a command followed by a data transfer or before issuing a Resume command. To prevent data loss, uSDHC prevents writing to the bits, which are involved in the data transfer of this register, when data transfer is active. These fields are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

The host driver checks the Command Inhibit DAT field (PRES_STATE[CDIHB]) and the Command Inhibit CMD field (PRES_STATE[CIHB]) in the Present State register before writing to this register. When the CDIHB field in the Present State register is set, any attempt to send a command with data by writing to this register is ignored; when the CIHB field is set, any write to this register is ignored.

On sending commands with data transfer involved, it is mandatory that the block size is non-zero. Block count must also be non-zero, or indicated as a single block transfer (bit 5 of this register is '0' when written), or block count is disabled (bit 1 of this register is '0' when written), otherwise uSDHC ignores the sending of this command and do nothing. For write command, with all above restrictions, it is also mandatory that the write protect switch is not active (PRES_STATE[WPSPL] field of Present State register is '1'); otherwise, WP is activated as '1', write to memory and combo cards are ignored by cards (in that case, there is no need to send write command anymore).

If the commands with data transfer do not receive the response in 64 clock cycles, that is, if response time-out happens, uSDHC treats the external device, does not accept the command, and stops the data transfer. In this scenario, the driver should issue the command again to retry the transfer. It is also possible that for some reason the card responds to the command but uSDHC does

not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The table below shows the summary of how register settings determine the type of data transfer.

Table 315. Transfer type register setting for various transfer types

Multi/single block select	Block count enable	Block count	Function
0	Do not care	Do not care	Single transfer
1	0	Do not care	Infinite transfer
1	1	Positive number	Multiple transfer
1	1	Zero	No data transfer

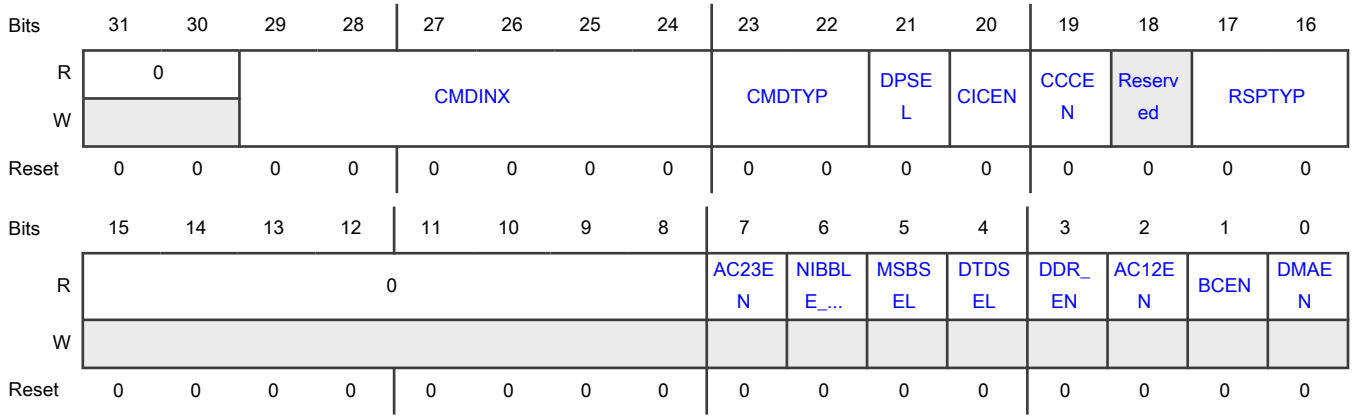
The table below shows the relationship between the Command Index Check Enable and the Command CRC Check Enable, regarding the Response Type bits as well as the name of the response type.

Table 316. Relationship between parameters and the name of the response type

Response type	Index check enable	CRC check enable	Name of response type
00	0	0	No response
01	0	1	R2
10	0	0	R3, R4
10	1	1	R1, R5, R6
11	1	1	R1b,R5b

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification, but R5b is defined in this specification to specify that uSDHC checks the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command is used with R5b.
- The CRC fields for R3 and R4 are expected to be all 1 bits. The CRC check is disabled for these response types.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-24 CMDINX	Command index These fields are set to the command number that is specified in bits 45-40 of the command-format in the SD Memory Card Physical Layer Specification and SDIO Specification.
23-22 CMDTYP	Command type There are three types of special commands: Suspend, Resume, and Abort. These fields are set to 00b for all other commands. • Suspend command: If the Suspend command succeeds, uSDHC assumes that the card bus has been released and that it is possible to issue the next command that uses the DATA line. Because uSDHC does not monitor the content of command response, it does not know if the Suspend command succeeded or not. It is the host driver's responsibility to check the status of the Suspend command and send another command marked as Suspend to inform uSDHC that a Suspend command was successfully issued. See Suspend Resume for more details. After the end bit of command is sent, uSDHC deasserts Read Wait for read transactions and stops checking busy for write transactions. In a 4-bit mode, the interrupt cycle starts. If the Suspend command fails, uSDHC maintains its current state, and the host driver restarts the transfer by setting the Continue Request field in the Protocol Control register. • Resume command: The host driver re-starts the data transfer by restoring the registers saved before sending the Suspend command and then sends the Resume command. The uSDHC module checks for a pending busy state before starting write transfers. • Abort command: If this command is set when executing a read transfer, uSDHC stops reads to the buffer. If this command is set when executing a write transfer, uSDHC stops driving the DATA line. After issuing the Abort command, the host driver should issue a software reset (Abort Transaction). 00b - Normal other commands 01b - Suspend CMD52 for writing bus suspend in CCCR 10b - Resume CMD52 for writing function select in CCCR 11b - Abort CMD12, CMD52 for writing I/O Abort in CCCR
21 DPSEL	Data present select This field is set to 1 to indicate that data is present and is transferred using the DATA line. It is set to 0 for the following: • Commands using only the CMD line (for example, CMD52) • Commands with no data transfer, but using the busy signal on DATA0 line (R1b or R5b (for example, CMD38)) **NOTE** In resume command, this field is set, and other bits in this register is set the same as when the transfer was initially launched. When the write protect switch is on, (that is, the WPSPL field is active as '0'), any command with a write operation ignored. When this field is set, while the DTDSEL field is 0, writes to the register Transfer Type are ignored.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No data present 1b - Data present
20 CICEN	Command index check enable If this field is set to 1, uSDHC checks the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this field is set to 0, the Index field is not checked. 0b - Disable command index check 1b - Enables command index check
19 CCCEN	Command CRC check enable If this field is set to 1, uSDHC checks the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this field is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response. See RSPTYP[1:0] and Command Transfer Type (CMD_XFR_TYP). 0b - Disables command CRC check 1b - Enables command CRC check
18 —	Reserved
17-16 RSPTYP	Response type select 00b - No response 01b - Response length 136 10b - Response length 48 11b - Response length 48, check busy after response
15-8 —	Reserved
7 AC23EN	AC23EN This field is read when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is tied to '0'. When this field is set to 1, the host controller issues a CMD23 automatically before issuing a command specified in the Command Register. 0b - Disable 1b - Enable
6 NIBBLE_POS	NIBBLE_POS This field indicates the nibble position in the DDR 4-bit mode. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. 0- the sequence is 'odd high nibble -> even high nibble -> odd low nibble -> even low nibble'; 1- the sequence is 'odd high nibble -> odd low nibble -> even high nibble -> even low nibble'.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
5 MSBSEL	MSBSEL This field enables multiple block DATA line data transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. For any other commands, this field can be set to 0. If this field is 0, it is not necessary to set the Block Count register. See Command Transfer Type (CMD_XFR_TYP). 0b - Disable 1b - Enable
4 DTDSEL	DTDSEL This field defines the direction of DATA line data transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. The field is set to 1 by the host driver to transfer data from the SD card to uSDHC and is set to 0 for all other commands. 0b - Disable 1b - Enable
3 DDR_EN	DDR_EN Dual data rate mode selection. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. 0b - Disable 1b - Enable
2 AC12EN	AC12EN Multiple block transfers for memory require a CMD12 to stop the transaction. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. When this field is set to 1, uSDHC issues a CMD12 automatically when the last block transfer has completed. The host driver is not set this field to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, uSDHC ignores this field no matter it is set or not. 0b - Disable 1b - Enable
1 BCEN	BCEN This field is used to enable the Block Count register, which is only relevant for multiple block transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. When this field is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer. 0b - Disable 1b - Enable
0	DMAEN

Table continues on the next page...

Table continued from the previous page...

Field	Function
DMAEN	This field enables DMA functionality. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is enabled; otherwise, this field is read-only. If this field is set to 1, a DMA operation begins when the host driver sets the DPSEL field of this register. Whether the simple DMA or the advanced DMA is active depends on the DMA Select field of the Protocol Control register. 0b - Disable 1b - Enable

40.6.1.6 Command Response0 (CMD_RSP0)

Offset

Register	Offset
CMD_RSP0	10h

Function

This register is used to store part 0 of the response bits from the card.

Field	Function
31-0 CMDRSP1	Command response 1 See Command Response3 (CMD_RSP3) for the mapping of command responses from the SD bus to this field for each response type.

40.6.1.8 Command Response2 (CMD_RSP2)

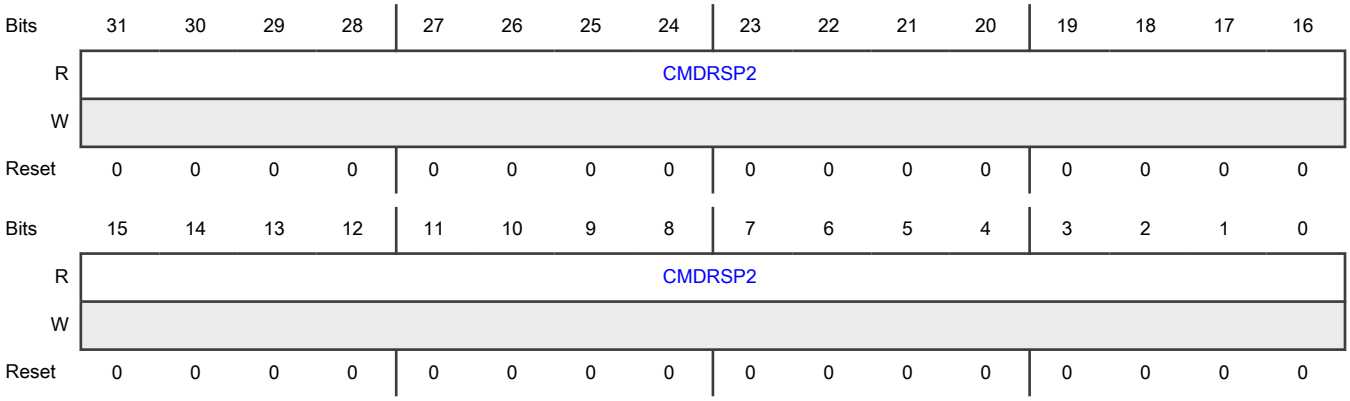
Offset

Register	Offset
CMD_RSP2	18h

Function

This register is used to store part 2 of the response bits from the card.

Diagram



Fields

Field	Function
31-0 CMDRSP2	Command response 2 See Command Response3 (CMD_RSP3) for the mapping of command responses from the SD bus to this field for each response type.

40.6.1.9 Command Response3 (CMD_RSP3)

Offset

Register	Offset
CMD_RSP3	1Ch

Function

This register is used to store part 3 of the response bits from the card.

The table below describes the mapping of command responses from the SD bus to Command Response registers for each response type. In this table, R[ ] refers to a bit range within the response data as transmitted on the SD bus.

Table 317. Response bit definition for each response type

Response type	Meaning of response	Response field	Response register
R1,R1b (normal response)	Card status	R[39:8]	CMDRSP0
R1b (auto CMD12 response)	Card status for auto CMD12	R[39:8]	CMDRSP3
R2 (CID, CSD register)	CID/CSD register [127:8]	R[127:8]	{CMDRSP3[23:0], CMDRSP2, CMDRSP1, CMDRSP0}

Table continues on the next page...

Table 317. Response bit definition for each response type (continued)

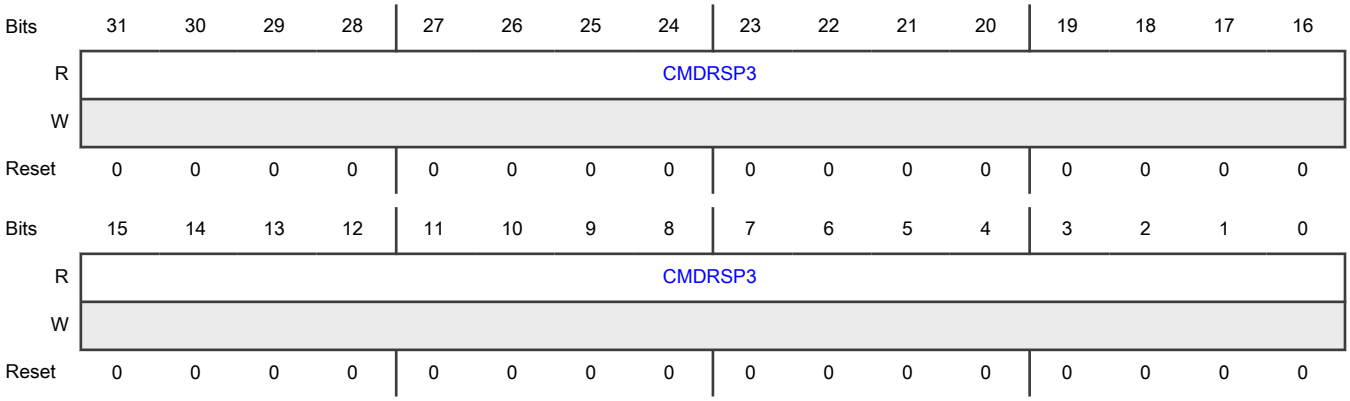
Response type	Meaning of response	Response field	Response register
R3 (OCR register)	OCR register for memory	R[39:8]	CMDRSP0
R4 (OCR register)	OCR register for I/O etc.	R[39:8]	CMDRSP0
R5, R5b	SDIO response	R[39:8]	CMDRSP0
R6 (publish RCA)	New published RCA[31:16] and card status[15:0]	R[39:9]	CMDRSP0

This table shows that most responses with a length of 48 (R[47:0]) have 32-bits of the response data (R[39:8]) stored in the CMDRSP0 register. Responses of type R1b (Auto CMD12 responses) have response data bits (R[39:8]) stored in the CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bits of the response data (R[127:8]) stored in the CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, uSDHC only stores part of the response data in the Command Response registers. This enables the host driver to efficiently read 32-bits of response data in one read cycle on a 32-bit bus system. Parts of the response, the Index field and the CRC, are checked by uSDHC (as specified by the Command Index Check Enable and the Command CRC Check Enable bits in the Transfer Type register) and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, uSDHC checks R[47:1], and if the response length is 136 the uSDHC checks R[119:1].

Because uSDHC may have a multiple block data transfer executing concurrently with a CMD_wo_DAT command, uSDHC stores the Auto CMD12 response in the CMDRSP3 register. The CMD_wo_DAT response is stored in CMDRSP0. This allows uSDHC to avoid overwriting the Auto CMD12 response with the CMD_wo_DAT and vice versa. When uSDHC modifies part of the Command Response registers, as shown in the table above, it preserves the unmodified bits.

Diagram



Fields

Field	Function
31-0 CMDRSP3	Command response 3 See Command Response3 (CMD_RSP3) for the mapping of command responses from the SD bus to this field for each response type.

40.6.1.10 Data Buffer Access Port (DATA_BUFF_ACC_PORT)

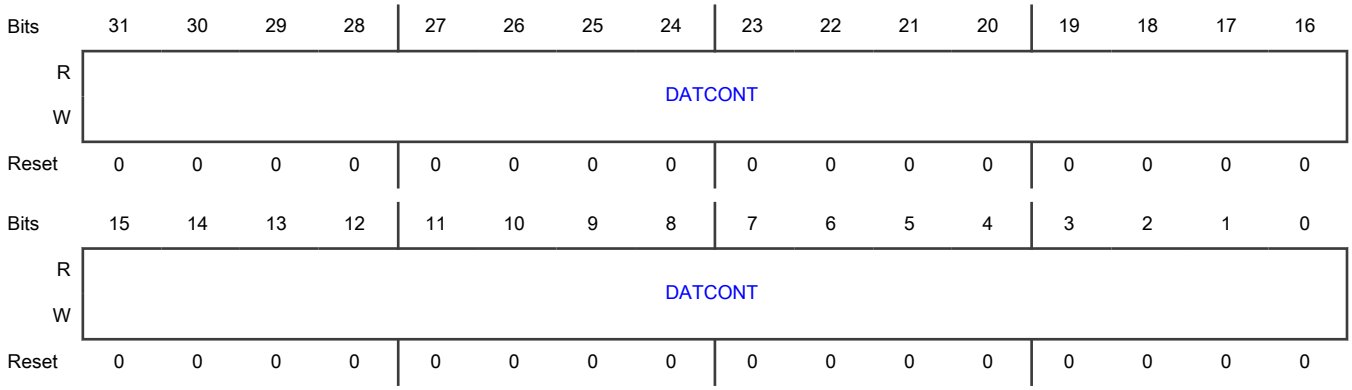
Offset

Register	Offset
DATA_BUFF_ACC_PORT	20h

Function

The Buffer Data Port register is for 32-bit data access by the Arm platform. When the internal DMA is enabled, any write to this field is ignored, and any read from this field always yields 0s.

Diagram



Fields

Field	Function
31-0 DATCONT	Data content This field is used to access the internal buffer.

40.6.1.11 Present State (PRES_STATE)

Offset

Register	Offset
PRES_STATE	24h

Function

The host driver can get status of uSDHC from this 32-bit read only register.

The host driver can issue CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DATA lines are busy during a data transfer. These commands can be issued when Command Inhibit (CMD) is set to zero. Other commands are issued when Command Inhibit (DATA) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.

NOTE

The reset value of Present State register depends on board connectivity.

Diagram

Fields

Field	Function
31-24 DLSL	DATA[7:0] line signal level This field is used to check the DATA line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DATA0. The reset value is affected by the external pull-up / pull-down resistors. By default, the read value of this field after reset is 8'b11110111, when DATA3 is pulled down and the other lines are pulled up. 0000_0001b - Data 0 line signal level 0000_0010b - Data 1 line signal level 0000_0100b - Data 2 line signal level 0000_1000b - Data 3 line signal level 0001_0000b - Data 4 line signal level 0010_0000b - Data 5 line signal level 0100_0000b - Data 6 line signal level 1000_0000b - Data 7 line signal level
23 CLSL	CMD line signal level This field is used to check the CMD line level to recover from errors, and for debugging. The reset value is affected by the external pull-up / pull-down resistor, by default, the read value of this field after reset is 1'b1, when the command line is pulled up.
22-21 —	Reserved
20	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
19 WPSPL	Write protect switch pin level The Write Protect switch is supported for memory and combo cards. This field reflects the inverted value of the WP pin of the card socket. A software reset does not affect this field. The reset value is affected by the external write protect switch. If the WP pin is not used, it should be tied low, so that the reset value of this field is high and write is enabled. 0b - Write protected (WP = 1) 1b - Write enabled (WP = 0)
18 CDPL	Card detect pin level This field reflects the inverse value of the CD_B pin for the card socket. Debouncing is not performed on this field. This field may be valid, but is not guaranteed, because of propagation delay. Use of this field is limited to testing because it must be debounced by software. A software reset does not affect this field. A write to the Force Event Register does not affect this field. The reset value is affected by the external card detection pin. This field shows the value on the CD_B pin (that is, when a card is inserted in the socket, it is 0 on the CD_B input, and consequently, the CDPL reads 1. 0b - No card present (CD_B = 1) 1b - Card present (CD_B = 0)
17 —	Reserved
16 CINST	Card inserted This field indicates whether a card has been inserted. The uSDHC module debounces this signal so that the host driver does not need to wait for it to stabilize. Changing from a 0 to 1 generates a Card Insertion interrupt in the Interrupt Status register. Changing from a 1 to 0 generates a Card Removal interrupt in the Interrupt Status register. A write to the Force Event Register does not affect this field. The Software Reset For All in the System Control register does not affect this field. A software reset does not affect this field. 0b - Power on reset or no card 1b - Card inserted
15 TSCD	Tap select change done This field indicates the delay setting is effective after write CLK_TUNE_CTRL_STATUS register. 0b - Delay cell select change is not finished. 1b - Delay cell select change is finished.
14-13 —	Reserved
12	Re-Tuning Request (only for SD3.0 SDR104 mode, and eMMC HS200 mode)

Table continues on the next page...

Table continued from the previous page...

Field	Function
RTR	Host controller may request host driver to execute re-tuning sequence by setting this field when the data window is shifted by temperature drift and a tuned sampling point does not have a good margin to receive correct data. This field is cleared when a command is issued with setting Execute Tuning field in MIX_CTRL register. Changing of this field from 0 to 1 generates Re-Tuning Event. See Interrupt status registers for more detail. This field isn't set to 1 if Sampling Clock Select in the MIX_CTRL register is set to 0 (using fixed sampling clock). 0b - Fixed or well tuned sampling clock 1b - Sampling clock needs re-tuning
11 BREN	Buffer read enable This status field is used for non-DMA read transfers. The uSDHC module implements an internal buffer to transfer data efficiently. This read only flag indicates that valid data exists in the host side buffer. If this field is high, valid data greater than the watermark level exist in the buffer. A change of this field from 1 to 0 occurs when some reads from the buffer (read DATPORT (Base + 0x20)) are made and the buffer hasn't valid data greater than the watermark level. A change of this field from 0 to1 occurs when there is enough valid data ready in the buffer and the Buffer Read Ready interrupt has been generated and enabled. 0b - Read disable 1b - Read enable
10 BWEN	Buffer write enable This status field is used for non-DMA write transfers. The uSDHC module implements an internal buffer to transfer data efficiently. This read only flag indicates if space is available for write data. If this field is 1, valid data greater than the watermark level can be written to the buffer. A change of this field from 1 to 0 occurs when some writes to the buffer (write DATPORT (Base + 0x20)) are made and the buffer hasn't valid space greater than the watermark level. A change of this field from 0 to 1 occurs when the buffer can hold valid data greater than the write watermark level and the Buffer Write Ready interrupt is generated and enabled. 0b - Write disable 1b - Write enable
9 RTA	Read transfer active This status field is used for detecting completion of a read transfer. This field is set for either of the following conditions: • After the end field of the read command • When writing a 1 to the Continue Request field in the Protocol Control register to restart a read transfer A transfer complete interrupt is generated when this field changes to 0. This field is cleared for either of the following conditions: • When the last data block as specified by block length is transferred to the System, that is, all data are read away from uSDHC internal buffer.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• When all valid data blocks have been transferred from uSDHC internal buffer to the System and no current block transfers are being sent because of the Stop At Block Gap Request being set to 1. 0b - No valid data 1b - Transferring data
8 WTA	Write transfer active This status field indicates a write transfer is active. If this field is 0, it means no valid write data exists in uSDHC. This field is set in either of the following cases: • After the end field of the write command • When writing 1 to the Continue Request field in the Protocol Control register to restart a write transfer This field is cleared in either of the following cases: • After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple) • After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request During a write transaction, a Block Gap Event interrupt is generated when this field is changed to 0, as result of the Stop At Block Gap Request being set. This status is useful for the host driver in determining when to issue commands during Write Busy state. 0b - No valid data 1b - Transferring data
7-4 —	Reserved
3 SDSTB	SD clock stable This status field indicates that the internal card clock is stable. This field is for the host driver to poll clock status when changing the clock frequency. It is recommended to clear FRC_SDCLK_ON field in System Control register to remove glitches on the card clock when the frequency is changing. Before changing clock divisor value (SDCLKFS or DVS), host driver should make sure the SDSTB field is high. 0b - Clock is changing frequency and not stable. 1b - Clock is stable.
2 DLA	Data line active This status field indicates whether one of the DATA lines on the SD bus is in use. In the case of read transactions: This status indicates if a read transfer is executing on the SD bus. Changes in this value from 1 to 0, between data blocks, generates a Block Gap Event interrupt in the Interrupt Status register.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field is set in either of the following cases: • After the end field of the read command • When writing a 1 to the Continue Request field in the Protocol Control register to restart a read transfer This field is cleared in either of the following cases: • When the end field of the last data block is sent from the SD bus to uSDHC. • When the Read Wait state is stopped by a Suspend command and the DATA2 line is released. The uSDHC module waits at the next block gap by driving Read Wait at the start of the interrupt cycle. If the Read Wait signal is already driven (data buffer cannot receive data), uSDHC can wait for a current block gap by continuing to drive the Read Wait signal. It is necessary to support Read Wait to use the suspend / resume function. This field remains 1 during Read Wait. In the case of write transactions: This status indicates that a write transfer is executing on the SD bus. Changes in this value from 1 to 0 generate a Transfer Complete interrupt in the Interrupt Status register. This field is set in either of the following cases: • After the end field of the write command • When writing to 1 to the Continue Request field in the Protocol Control register to continue a write transfer This field is cleared in either of the following cases: • When the SD card releases Write Busy of the last data block, uSDHC also detects if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, uSDHC assumes the card drive "Not Busy". • When the SD card releases write busy, prior to waiting for write transfer, and because of a Stop At Block Gap Request. In the case of command with busy pending: This status indicates that a busy state follows the command and the data line is in use. This field is cleared when the DATA0 line is released. 0b - DATA line inactive 1b - DATA line active
1 CDIHB	Command Inhibit Data (DATA) This status field is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this field is 0, it indicates that uSDHC can issue the next SD / eMMC Command. Commands with a busy signal belong to Command Inhibit (DATA) (for example. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Interrupt Status register. **NOTE** The SD host driver can save registers for a suspend transaction after this field has changed from 1 to 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Can issue command that uses the DATA line 1b - Cannot issue command that uses the DATA line
0 CIHB	Command inhibit (CMD) If this status bit is 0, it indicates that the CMD line is not in use and uSDHC can issue a SD / eMMC command using the CMD line. This field is set also immediately after the Transfer Type register is written. This field is cleared when the command response is received. Even if the Command Inhibit (DATA) is set to 1, commands using only the CMD line can be issued if this field is 0. Changing from 1 to 0 generates a Command Complete interrupt in the Interrupt Status register. If uSDHC cannot issue the command because of a command conflict error (see Command CRC Error) or because of a Command Not Issued By Auto CMD12 Error, this field remains 1 and the Command Complete is not set. The Status of issuing an auto CMD12 does not show on this field. 0b - Can issue command using only CMD line 1b - Cannot issue command

40.6.1.12 Protocol Control (PROT_CTRL)

Offset

Register	Offset
PROT_CTRL	28h

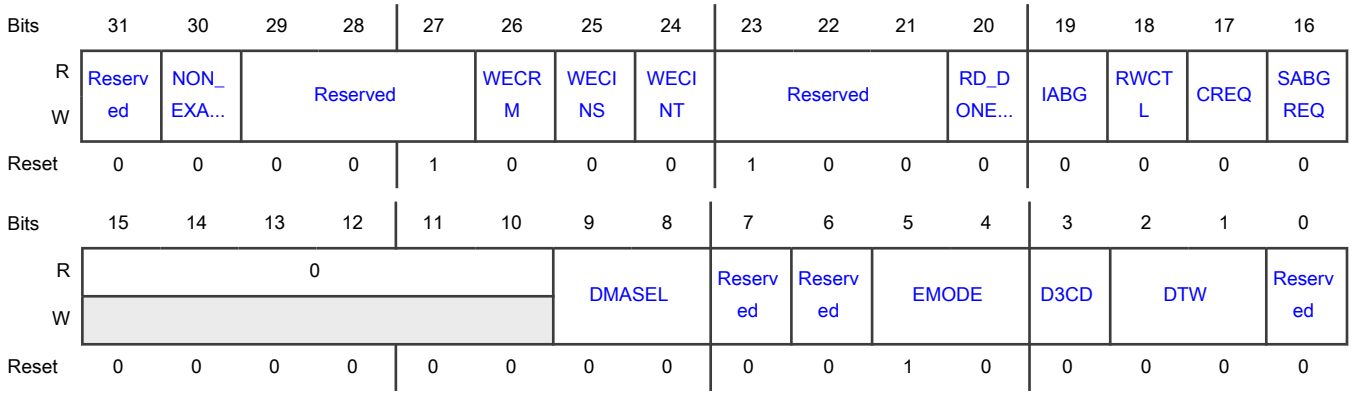
Function

This register controls three cases to restart the transfer after stop at the block gap. Which case is appropriate depends on whether uSDHC issues a Suspend command or the SD card accepts the Suspend command.

- If the host driver does not issue a Suspend command, the Continue request is used to restart the transfer.
- If the host driver issues a Suspend command and the SD card accepts it, a Resume command is used to restart the transfer.
- If the host driver issues a Suspend command and the SD card does not accept it, the Continue request is used to restart the transfer.

Any time stop at block gap request stops the data transfer, the host driver waits for a Transfer Complete (in the Interrupt Status register), before attempting to restart the transfer. When restarting the data transfer by Continue Request, the host driver clears the Stop At Block Gap Request before or simultaneously.

Diagram



Fields

Field	Function
31 —	Reserved Always write as 0
30 NON_EXACT_BLK_RD	Non-exact block read Current block read is non-exact block read. It is only used for SDIO. 0b - The block read is exact block read. Host driver does not need to issue abort command to terminate this multi-block read. 1b - The block read is non-exact block read. Host driver needs to issue abort command to terminate this multi-block read.
29-27 —	Reserved
26 WECRM	Wakeup event enable on SD card removal This field enables a wakeup event, via a card removal, in the Interrupt Status register. FN_WUS (Wakeup Support) in CIS does not affect this field. When this field is set, the Card Removal Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Removal Status and uSDHC interrupt. 0b - Disables wakeup event enable on SD card removal 1b - Enables wakeup event enable on SD card removal
25 WECINS	Wakeup event enable on SD card insertion This field enables a wakeup event, via a card insertion, in the Interrupt Status register. FN_WUS (Wakeup Support) in CIS does not affect this field. When this field is set, the Card Insertion Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Insertion Status and uSDHC interrupt. 0b - Disable wakeup event enable on SD card insertion 1b - Enable wakeup event enable on SD card insertion

Table continues on the next page...

Table continued from the previous page...

Field	Function
24 WECINT	Wakeup event enable on card interrupt This field enables a wakeup event, via a card interrupt, in the Interrupt Status register. This field can be set to 1 if FN_WUS (Wakeup Support) in CIS is set to 1. When this field is set, the Card Interrupt Status and uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active to assert the Card Interrupt Status and uSDHC interrupt. 0b - Disables wakeup event enable on card interrupt 1b - Enables wakeup event enable on card interrupt
23-21 —	Reserved Always write as 3'b100
20 RD_DONE_NO_8CLK	Read performed number 8 clock According to the SD/eMMC spec, for read data transaction, 8 clocks are needed after the end field of the last data block. So, by default(RD_DONE_NO_8CLK=0), eight clocks are active after the end field of the last read data transaction. However, these 8 clocks should not be active if user wants to use stop at block gap (include the auto stop at block gap in boot mode) feature for read and the RWCTL field (bit18) is not enabled. In this case, software should set RD_DONE_NO_8CLK to avoid these 8 clocks. Otherwise, the device might send extra data to uSDHC while uSDHC ignores these data. In a summary, this field should be set only if the use case needs to use stop at block gap feature while the device can't support the read wait feature.
19 IABG	Interrupt at block gap This field is valid only in 4-bit mode, of SDIO, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If SDIO cannot signal an interrupt during a multiple block transfer, this field should be set to 0 to avoid an inadvertent interrupt. When the host driver detects an SDIO insertion, it sets this field according to the CCCR of the card. 0b - Disables interrupt at block gap 1b - Enables interrupt at block gap
18 RWCTL	Read wait control The read wait function provided by this field is optional for SDIO. If the card supports read wait, set this field to enable use of the read wait protocol to stop read data using the DATA2 line. Otherwise, uSDHC has to stop the SD clock to hold read data, which restricts commands generation. When the host driver detects an SDIO insertion, it sets this field according to the CCCR of the card. If the card does not support read wait, this field should never be set to 1; otherwise, DATA line conflicts might occur. If this field is set to 0, stop at block gap during read operation is also supported, but uSDHC stops the SD clock to pause reading operation. 0b - Disables read wait control and stop SD clock at block gap when SABGREQ field is set 1b - Enables read wait control and assert read wait without stopping SD clock at block gap when SABGREQ field is set
17	Continue request

Table continues on the next page...

Table continued from the previous page...

Field	Function
CREQ	This field is used to restart a transaction which was stopped using the stop at block gap request. When a suspend operation is not accepted by the card, it is also by setting this field to restart the paused transfer. To cancel stop at the block gap, set stop at block gap request to 0 and set this field to 1 to restart the transfer. The uSDHC module automatically clears this field, therefore it is not necessary for the host driver to set this field to 0. If both stop at block gap request and this field are 1, the continue request is ignored. 0b - No effect 1b - Restart
16 SABGREQ	Stop at block gap request This field is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the transfer complete is set to 1, indicating a transfer completion, the host driver leaves this field set to 1. Clearing both the stop at block gap request and continue request does not cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The uSDHC module supports the stop at block gap request for write transfers, but for read transfers it requires that SDIO support read wait. Therefore, the host driver does not set this field during read transfers unless SDIO supports Read Wait and has set the read wait control to 1; otherwise, uSDHC stops the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the host driver writes data to the Data Port register, the host driver sets this field after all block data is written. If this field is set to 1, the host driver does not write data to the Data Port register after a block is sent. Once this field is set, the host driver does not clear this field before the Transfer Complete field in Interrupt Status register is set, otherwise uSDHC's behavior is undefined. This field effects read transfer active, write transfer active, DATA Line Active and Command Inhibit (DATA) in the Present State register. 0b - Transfer 1b - Stop
15-10 —	Reserved
9-8 DMASEL	DMA select This field is valid while DMA (SDMA or ADMA) is enabled and selects the DMA operation. 00b - No DMA or simple DMA is selected. 01b - ADMA1 is selected. 10b - ADMA2 is selected. 11b - Reserved
7 —	Reserved
6 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
5-4 EMODE	Endian mode This field supports all three endian modes in data transfer. See Data buffer for more details. 00b - Big endian mode 01b - Half word big endian mode 10b - Little endian mode 11b - Reserved
3 D3CD	DATA3 as card detection pin If this field is set, DATA3 should be pulled down to act as a card detection pin. Be cautious when using this feature, because DATA3 is also a chip-select for the SPI mode. A pull-down on this pin and CMD0 might set the card into the SPI mode, which uSDHC does not support. 0b - DATA3 does not monitor card insertion 1b - DATA3 as card detection pin
2-1 DTW	Data transfer width This field selects the data width of the SD bus for a data transfer. The host driver sets it to match the data width of the card. Possible data transfer width is 1-bit, 4-bits or 8-bits. 00b - 1-bit mode 01b - 4-bit mode 10b - 8-bit mode 11b - Reserved
0 —	Reserved

40.6.1.13 System Control (SYS_CTRL)

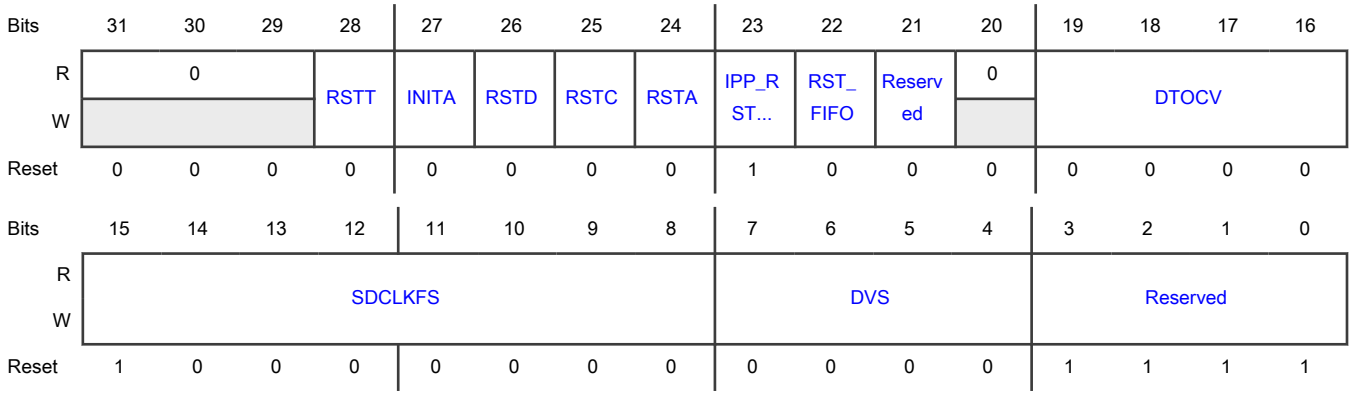
Offset

Register	Offset
SYS_CTRL	2Ch

Function

This register provides control of the system. See detail in the field description.

Diagram



Fields

Field	Function
31-29 —	Reserved
28 RSTT	Reset tuning When set this field to 1, it resets tuning circuit. After tuning circuits are reset, bit value is 0. Clearing execute_tuning field in AUTOCMD12_ERR_STATUS also sets this field to 1 to reset tuning circuit
27 INITA	Initialization active When this field is set, 80 SD-clocks are sent to the card. After the 80 clocks are sent, this field is self cleared. This field is very useful during the card power-up period when 74 SD-clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this field is already 1 has no effect. Writing 0 to this field at any time has no effect. When either of the CIHB and CDIHB fields in the Present State register are set, writing 1 to this field is ignored (that is, when command line or data lines are active, write to this field is not allowed). On the other-hand, when this field is set, that is, during initialization active period, it is allowed to issue command, and the command bit stream appears on the CMD pad after all 80 clock cycles are done. So, when this command ends, the driver can make sure the 80 clock cycles are sent out. This is very useful when the driver needs to send 80 cycles to the card and does not want to wait till this field is self cleared.
26 RSTD	Software reset for data line Only part of the data circuit is reset. DMA circuit is also reset. After this field is set, the software waits for self-clear. The following registers and bits are cleared by this field: • Data Port register — Buffer is cleared and initialized • Present State register — Buffer read enable — Buffer write enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	— Read transfer active — Write transfer active — DATA line active — Command Inhibit (DATA) • Protocol Control register — Continue request • Interrupt Status register — Buffer read ready — Buffer write ready — DMA interrupt — Block gap event — Transfer complete **NOTE** When reset, the software must make sure there is no incomplete data transferring. If there is data transfer going on, the software needs to wait TC or DC INT_STATUS register is set. 0b - No reset 1b - Reset
25 RSTC	Software reset for CMD line Only part of the command circuit is reset. After this field is set, the software waits for self-clear. The following registers and bits are cleared by this field: • Present State Register — Command Inhibit (CMD) • Interrupt Status Register — Command Complete 0b - No reset 1b - Reset
24 RSTA	Software reset for all This reset affects the entire host controller except for the card detection circuit. RSTA resets all the registers that can be reset by RSTC/RSTD. During its initialization, the host driver is set this field to 1 to reset uSDHC. The uSDHC module resets this field to 0 when the capabilities registers are valid and the host driver can read them. Additional use of Software Reset For All does not affect the value of the capabilities registers. After this field is set, it is recommended that the host driver reset the external card and re-initialize it. After this field is set, the software should wait for self-clear. In tuning process, after every CMD19 is finished, this field is set to retest uSDHC.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE When reset, the software must make sure there is no incomplete data transferring. If there is data transfer going on, the software needs to wait TC or DC INT_STATUS register is set. 0b - No reset 1b - Reset
23 IPP_RST_N	Hardware reset This field has alternative function as below: • eMMC: be used to reset eMMC, through pad directly to eMMC RST_n pin. • Card: be used to control SD Card power enable or disable during warm reset, through pad directly to hardware reset on board.
22 RST_FIFO	Reset the async FIFO Reset the async FIFO between card interface and the internal logic. After this field is set, the software waits for self-clear.
21 —	Reserved
20 —	Reserved
19-16 DTOCV	Data timeout counter value This value determines the interval by which DAT line timeouts are detected. See the Data Timeout Error field in the Interrupt Status register for information on factors that dictate time-out generation. Time-out clock frequency is generated by dividing the base clock SDCLK value by this value. The host driver can clear the Data Timeout Error Status Enable (in the Interrupt Status Enable register) to prevent inadvertent time-out events. 0000b - SDCLK x 2^{32} 0001b - SDCLK x 2^{33} 0010b - SDCLK x 2^{18} 0011b - SDCLK x 2^{19} 1101b - SDCLK x 2^{29}, recommend to use for supported speed modes except HS200, HS400, SDR104 mode 1110b - SDCLK x 2^{30}, recommend to use for HS200 and SDR104 mode 1111b - SDCLK x 2^{31}, recommend to use for HS400 mode
15-8 SDCLKFS	SDCLK frequency select

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field is used to select the frequency of the SDCLK pin. The frequency is not programmed directly, rather this field holds the prescaler (of this register) and divisor (next register) of the Base Clock Frequency register. In Single Data Rate mode (DDR_EN field of MIXERCTRL is '0') Only the following settings are allowed: 80h) Base clock divided by 256 40h) Base clock divided by 128 20h) Base clock divided by 64 10h) Base clock divided by 32 08h) Base clock divided by 16 04h) Base clock divided by 8 02h) Base clock divided by 4 01h) Base clock divided by 2 00h) Base clock divided by 1 While in Dual Data Rate mode (DDR_EN field of MIXERCTRL is '1') Only the following settings are allowed: 80h) Base clock divided by 512 40h) Base clock divided by 256 20h) Base clock divided by 128 10h) Base clock divided by 64 08h) Base clock divided by 32 04h) Base clock divided by 16 02h) Base clock divided by 8 01h) Base clock divided by 4 00h) Base clock divided by 2 When the software changes the DDR_EN field, SDCLKFS might need to be changed also. In Single Data Rate mode, setting 00h bypasses the frequency prescaler of the SD clock. Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of ipg_perclk and the following Divisor bits. The frequency of SDCLK is set by the following formula: Clock Frequency = (Base Clock) / (prescaler x divisor) For example, in Single Data Rate mode, if the Base Clock Frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h yields 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The reset value of this field is 80h, so if the input Base Clock (ipg_perclk) is about 96 MHz, the default SD clock after reset is 375 kHz. Before changing clock divisor value (SDCLKFS or DVS), host driver should make sure the SDSTB field is high. If setting SDCLKFS and DVS can generate the same clock frequency,(for example, in SDR mode, SDCLKFS = 01h is same as DVS = 01h.), SDCLKFS is highly recommended. For HS400 mode, SDCLKFS must be used so that REF_CLK, generated for STROBE DLL, is at the same frequency as STROBE clock. For HS200 mode, if DLL is to be used, make sure SDCLKFS is used so that REF_CLK, generated for PARTS DLL, is at the same frequency as SD_CLK. For SDR104 mode, if DLL is to be used, make sure SDCLKFS is used so that REF_CLK, generated for PARTS DLL, is at the same frequency as SD_CLK.
7-4 DVS	Divisor This field is used to provide a more exact divisor to generate the desired SD clock frequency. Note the divider can even support odd divisors without deterioration of duty cycle. Before changing clock divisor value (SDCLKFS or DVS), Host driver should make sure the SDSTB field is high. The settings are as follows: 0000b - Divide-by-1 0001b - Divide-by-2 1110b - Divide-by-15 1111b - Divide-by-16
3-0 —	Reserved Always write as 1.

40.6.1.14 Interrupt Status (INT_STATUS)

Offset

Register	Offset
INT_STATUS	30h

Function

An interrupt is generated when the normal interrupt signal enable is enabled and at least one of the status fields is set to 1. For all fields, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. For card interrupt, before writing 1 to clear, it is required that the card stops asserting the interrupt, meaning that when the card driver services the interrupt condition; otherwise, the CINT field is asserted again.

The table below shows the relationship between the command timeout error and the command complete.

Table 318. uSDHC status for command timeout error/command complete bit combinations

Command complete	Command timeout error	Meaning of the status
0	0	X
X	1	Response not received within 64 SDCLK cycles
1	0	Response received

The table below shows the relationship between the transfer complete and the data timeout error.

Table 319. uSDHC status for data timeout error/transfer complete bit combinations

Transfer complete	Data timeout error	Meaning of the status
0	0	X
0	1	Timeout occurred during transfer
1	X	Data transfer complete

The table below shows the relationship between the command CRC error and command timeout error.

Table 320. uSDHC status for command CRC error/command timeout error bit combinations

Command CRC error	Command timeout error	Meaning of the status
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

Fields

Field	Function
31 —	Reserved
30-29 —	Reserved
28 DMAE	DMA error Occurs when an Internal DMA transfer has failed. This field is set to 1, when some error occurs in the data transfer. This error can be caused by either simple DMA or ADMA, depending on which DMA is in use. The value in DMA System Address register is the next fetch address where the error occurs. Because any error corrupts the whole data block, the host driver restarts the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DS_ADDR value or from the remaining number of blocks and the block size. 0b - No error 1b - Error
27 —	Reserved
26 TNE	Tuning error: (only for SD3.0 SDR104 mode and eMMC HS200 mode) This field is set when an unrecoverable error is detected in a tuning circuit. By detecting Tuning Error, host driver needs to abort a command executing and perform tuning. This field is relevant in combination with the bus error only and must be cleared prior to all the write and read transactions.
25 —	Reserved
24 AC12E	Auto CMD12 error Occurs when detecting that one of the fields in the Auto CMD12 Error Status register has changed from 0 to 1. This field is set to 1, not only when the errors in Auto CMD12 occur, but also, when the Auto CMD12 is not executed due to the previous command error. 0b - No error 1b - Error
23 —	Reserved
22 DEBE	Data end bit error Occurs either when detecting 0 at the end field position of read data that uses the DATA line, or at the end field position of the CRC. This field is not asserted in tuning process.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No error 1b - Error
21 DCE	Data CRC error Occurs when detecting a CRC error when transferring read data that uses the DATA line, or when detecting the Write CRC status having a value other than 010. This field is not asserted in tuning process. 0b - No error 1b - Error
20 DTOE	Data timeout error Occurs when detecting one of following time-out conditions. • Busy time-out for R1b, R5b type • Busy time-out after Write CRC status • Read Data time-out. This field is not asserted in tuning process. 0b - No error 1b - Time out
19 CIE	Command index error Occurs if a command index error occurs in the command response. This field is not asserted in tuning process. 0b - No error 1b - Error
18 CEBE	Command end bit error Occurs when detecting that the end field of a command response is 0. This field is not asserted in tuning process. 0b - No error 1b - End bit error generated
17 CCE	Command CRC error Command CRC Error is generated in two cases. • If a response is returned and the Command Timeout Error is set to 0 (indicating no time-out), this field is set when detecting a CRC error in the command response. • The uSDHC module detects a CMD line conflict by monitoring the CMD line when a command is issued. If uSDHC drives the CMD line to 1, but detects 0 on the CMD line at the next SDCLK edge, then uSDHC stops the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error should also be set to 1 to distinguish CMD line conflict.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This field is not asserted in tuning process. 0b - No error 1b - CRC error generated
16 CTOE	Command timeout error Occurs only if no response is returned within 64 SDCLK cycles from the end field of the command. If uSDHC detects a CMD line conflict, in which case a Command CRC Error is also be set (as shown in Interrupt Status (INT_STATUS)), this field is set without waiting for 64 SDCLK cycles. This is because the command is stopped by uSDHC. This field is not asserted in tuning process. 0b - No error 1b - Time out
15 ERR_INT_STATUS	Error Interrupt Status This bit is set when any of the error status bit DMAE, AC12E, DEBE, DCE, DTOE, CIE, CEBE, CCE and CTOE is set.
14 CQI	Command queuing interrupt This interrupt is asserted when at least one of the bits in CQIS register is set. This interrupt is cleared only by clearing the source interrupt in CQIS register.
13 TP	Tuning pass:(only for SD3.0 SDR104 mode and eMMC HS200 mode) Current CMD19 transfer is done successfully. That is, current sampling point is correct.
12 RTE	Re-tuning event: (only for SD3.0 SDR104 mode and eMMC HS200 mode) This status is set if Re-Tuning Request in the Present State register changes from 0 to 1. host controller requests host driver to perform re-tuning for next data transfer. Current data transfer (not large block count) can be completed without re-tuning. 0b - Re-tuning is not required. 1b - Re-tuning should be performed.
11 —	Reserved
10-9 —	Reserved
8 CINT	Card interrupt This status field is set when an interrupt signal is detected from the external card. In 1-bit mode, uSDHC detects the Card Interrupt without the SD clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from SDIO and the interrupt to the host system. Writing

Table continues on the next page...

Table continued from the previous page...

Field	Function
	this field to 1 can clear this field, but as the interrupt source from SDIO does not clear, this field is set again. to clear this field, it is required to reset the interrupt source from the external card followed by a writing 1 to this field. When this status has been set, and the host driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be 0 to stop driving the interrupt signal to the host system. After completion of the card interrupt service (It should reset the interrupt sources in SDIO and the interrupt signal might not be asserted), write 1 to clear this field, set the Card Interrupt Signal Enable to 1, and start sampling the interrupt signal again. 0b - No card interrupt 1b - Generate card interrupt
7 CRM	Card removal This status field is set if the Card Inserted field in the Present State register changes from 1 to 0. When the host driver writes this field to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state might possibly be changed when the host driver clears this field and the interrupt event might not be generated. When this field is cleared, it is set again if no card is inserted. to leave it cleared, clear the Card Removal Status Enable field in Interrupt Status Enable register. 0b - Card state unstable or inserted 1b - Card removed
6 CINS	Card insertion This status field is set if the Card Inserted field in the Present State register changes from 0 to 1. When the host driver writes this field to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state might possibly be changed when the host driver clears this field and the interrupt event might not be generated. When this field is cleared, it is set again if a card is inserted. to leave it cleared, clear the Card Inserted Status Enable field in Interrupt Status Enable register. 0b - Card state unstable or removed 1b - Card inserted
5 BRR	Buffer read ready This status field is set if the Buffer Read Enable field, in the Present State register, changes from 0 to 1. See the Buffer Read Enable field in the Present State register for additional information. This field indicates that cmd19 is finished in tuning process. 0b - Not ready to read buffer 1b - Ready to read buffer
4 BWR	Buffer write ready This status field is set if the Buffer Write Enable field, in the Present State register, changes from 0 to 1. See the Buffer Write Enable field in the Present State register for additional information. 0b - Not ready to write buffer 1b - Ready to write buffer

Table continues on the next page...

Table continued from the previous page...

Field	Function
3 DINT	DMA interrupt Occurs only when the internal DMA finishes the data transfer successfully. Whenever errors occur during data transfer, this field does not be set. Instead, the DMAE field is set. Either Simple DMA or ADMA finishes data transferring, this field is set. 0b - No DMA interrupt 1b - DMA interrupt is generated.
2 BGE	Block gap event If the Stop At Block Gap Request field in the Protocol Control register is set, this field is set when a read or write transaction is stopped at a block gap. If Stop At Block Gap Request is not set to 1, this field is not set to 1. In the case of a Read Transaction: This field is set at the falling edge of the DATA Line Active Status (When the transaction is stopped at SD bus timing). The Read Wait must be supported to use this function. In the case of Write Transaction: This field is set at the falling edge of Write Transfer Active Status (After getting CRC status at SD Bus timing). 0b - No block gap event 1b - Transaction stopped at block gap
1 TC	Transfer complete This field is set when a read or write transfer is completed. In the case of a Read Transaction: This field is set at the falling edge of the Read Transfer Active Status. There are two cases in which this interrupt is generated. The first is when a data transfer is completed as specified by the data length (after the last data has been read to the host system). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request field in the Protocol Control register (after valid data has been read to the host system). In the case of a Write Transaction: This field is set at the falling edge of the DATA Line Active Status. There are two cases in which this interrupt is generated. The first is when the last data is written to the SD card as specified by the data length and the busy signal is released. The second is when data transfers are stopped at the block gap, by setting the Stop At Block Gap Request field in the Protocol Control register, and the data transfers are completed. (after valid data is written to the SD card and the busy signal released). In the case of a command with busy, this field is set when busy is deasserted. This field is not asserted in tuning process. 0b - Transfer does not complete 1b - Transfer complete
0 CC	Command complete This field is set when you receive the end field of the command response (except auto CMD12). See the Command Inhibit (CMD) in the Present State register. This field is not asserted in tuning process. 0b - Command not complete

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Command complete

40.6.1.15 Interrupt Status Enable (INT_STATUS_EN)

Offset

Register	Offset
INT_STATUS_EN	34h

Function

Setting any bit in this register to 1 enables the corresponding interrupt status be requested to the system. If any bit is set to 0, the corresponding interrupt request gets blocked.

- Depending on IABG field setting, uSDHC might be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There are some delays on the Card Interrupt, asserted from the card, to the time the host system is informed.
- To detect a CMD line conflict, the host driver must set both Command Timeout Error Status Enable and Command CRC Error Status Enable to 1.

40.6.1.16 Interrupt Signal Enable (INT_SIGNAL_EN)

Offset

Register	Offset
INT_SIGNAL_EN	38h

Function

This register is used to select which interrupt status is indicated to the host system as the interrupt. These status fields all share the same interrupt lines. Setting any of these fields to 1 enables interrupt generation. The corresponding Status register field generates an interrupt when the corresponding interrupt signal enable field is set.

Diagram

40.6.1.17 Auto CMD12 Error Status (AUTOCMD12_ERR_STATUS)

Offset

Register	Offset
AUTOCMD12_ERR_STATUS	3Ch

Function

When the Auto CMD12 Error Status field in the Status register is set, the host driver checks this register to identify what kind of error the Auto CMD12 / CMD 23 indicated. Auto CMD23 errors are indicated in field 04-01. This register is valid only when the Auto CMD12 Error status field is set.

The table below shows the relationship between the Auto CMGD12 CRC Error and the Auto CMD12 Command Timeout Error.

Table 321. Relationship between command CRC error and command timeout error for auto CMD12

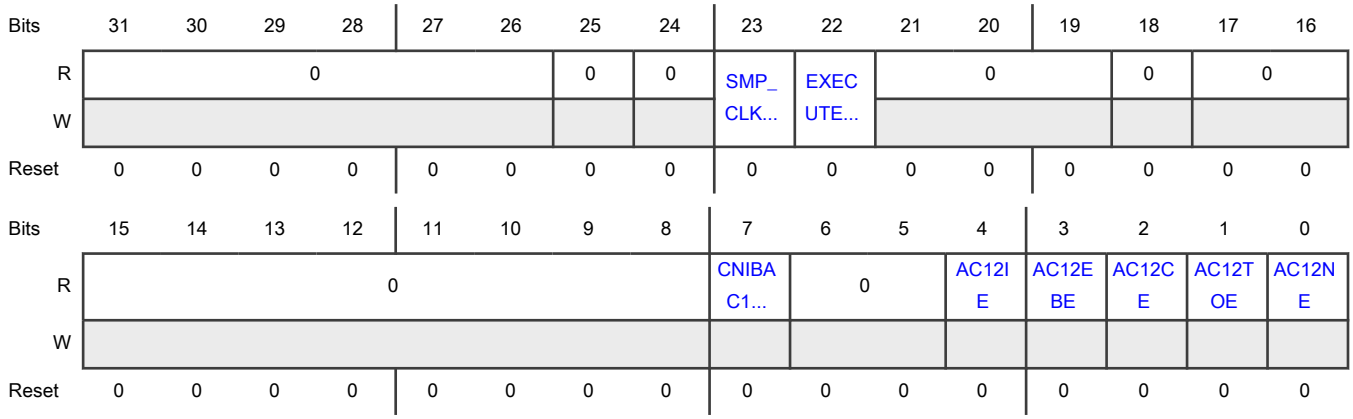
Auto CMD12 CRC error	Auto CMD12 timeout error	Type of error
0	0	No error
0	1	Response timeout error
1	0	Response CRC error
1	1	CMD line conflict

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

- When uSDHC is going to issue an Auto CMD12
  - Set field 0 to 1 if the Auto CMD12 cannot be issued due to an error in the previous command
  - Set field 0 to 0 if the Auto CMD12 is issued
- At the end field of an Auto CMD12 response
  - Check errors correspond to fields 1-4
  - Set fields 1-4 corresponding to detected errors
  - Clear fields 1-4 corresponding to detected errors
- Before reading the Auto CMD12 Error Status field 7
  - Set field 7 to 1 if there is a command that can't be issued
  - Clear field 7 if there is no command to issue

The timing for generating the Auto CMD12 Error and writing to the Command register are asynchronous. After that, field 7 is sampled when the driver is not writing to the Command register. So, it is suggested to read this register only when the AC12E field in Interrupt Status register is set. An Auto CMD12 Error Interrupt is generated when one of the error fields (0-4) is set to 1. The Command Not Issued By Auto CMD12 Error does not generate an interrupt.

Diagram



Fields

Field	Function
31-26 —	Reserved
25 —	Reserved
24 —	Reserved
23 SMP_CLK_SEL	Sample clock select This field is used to select sampling clock to receive CMD and DATA. This field is functional only when TUNING_CTRL[STD_TUNING_EN] is set. Otherwise, this field is reserved. This field is controlled by re-tuning procedure and is valid after the tuning procedure is complete (AUTOCMD12_ERR_STATUS[EXECUTE_TUNING]=0). A value of '1' means that tuning has been completed successfully and a value of '0' implies the tuning has failed. Writing '1' to this field is meaningless and ignored when the tuning has failed. The tuning circuit is reset by writing '0' to this field. This field can be cleared by setting AUTOCMD12_ERR_STATUS[EXECUTE_TUNING]=1. Once the tuning circuit is reset, it takes time to complete tuning sequence. Therefore, host driver should keep this field as 1 to perform the re-tuning sequence in a short time. This field cannot be changed while the Host controller is receiving response or a read data block. 0b - Fixed clock is used to sample data 1b - Tuned clock is used to sample data
22 EXECUTE_TUNING	Execute tuning This field is used to start the tuning procedure. This field is functional only when TUNING_CTRL[STD_TUNING_EN] is set. Otherwise, this field is reserved. This field is set to start tuning procedure and automatically cleared when tuning procedure is completed. The result of tuning is indicated to AUTOCMD12_ERR_STATUS[SMP_CLK_SEL]. 0b - Tuning procedure is stopped

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Start tuning procedure
21-19 —	Reserved
18 —	Reserved
17-8 —	Reserved
7 CNIBAC12E	Command not issued by Auto CMD12 error Setting this field to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 error (D04-D01) in this register. 0b - No error 1b - Not issued
6-5 —	Reserved
4 AC12IE	Auto CMD12 / 23 index error Occurs if the command index error occurs in response to a command. 0b - No error 1b - Error, the CMD index in response is not CMD12/23
3 AC12EBE	Auto CMD12 / 23 end bit error Occurs when detecting that the end field of command response is 0 which should be 1. 0b - No error 1b - End bit error generated
2 AC12CE	Auto CMD12 / 23 CRC error Occurs when detecting a CRC error in the command response. 0b - No CRC error 1b - CRC error met in Auto CMD12/23 response
1 AC12TOE	Auto CMD12 / 23 timeout error Occurs if no response is returned within 64 SDCLK cycles from the end field of the command. If this field is set to1, the other error status fields (2-4) have no meaning. 0b - No error 1b - Time out

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 AC12NE	Auto CMD12 not executed If memory multiple block data transfer is not started, due to a command error, this field is not set because it is not necessary to issue an Auto CMD12. Setting this field to 1 means uSDHC cannot issue the Auto CMD12 to stop a memory multiple block data transfer due to some error. If this field is set to 1, other error status fields (1-4) have no meaning. 0b - Executed 1b - Not executed

40.6.1.18 Host Controller Capabilities (HOST_CTRL_CAP)

Offset

Register	Offset
HOST_CTRL_CAP	40h

Function

This register provides the host driver with information specific to uSDHC implementation. The value in this register is the power-on-reset value and does not change with a software reset.

40.6.1.19 Watermark Level (WTMK_LVL)

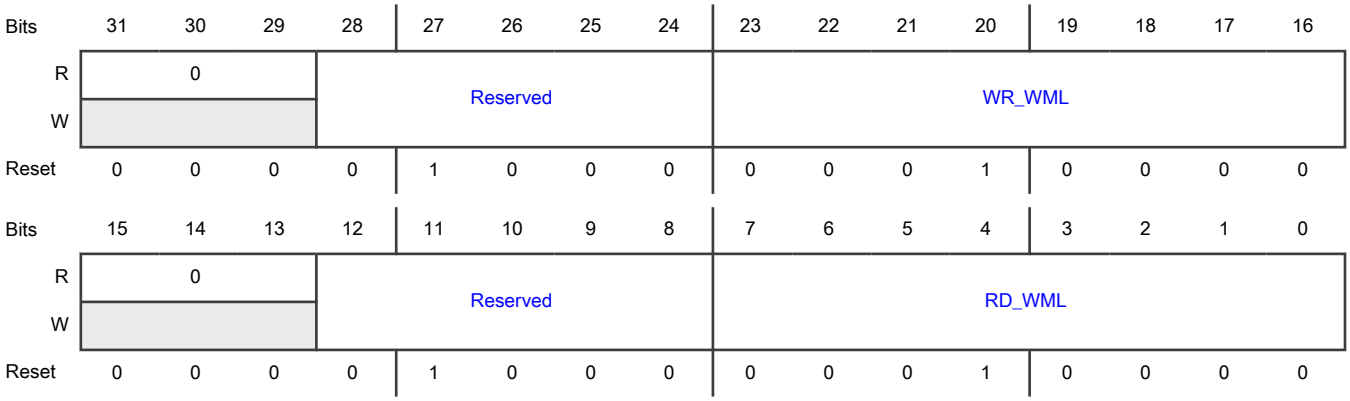
Offset

Register	Offset
WTMK_LVL	44h

Function

This register indicates configurability of write and read watermark levels (FIFO threshold). Their value can range from 1 to 128 words.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-24 —	Reserved
23-16 WR_WML	Write watermark level This field indicates the number of words used as the watermark level (FIFO threshold) in a DMA write operation. Also, the number of words as a sequence of write bursts in back-to-back mode. The maximum legal value for the write watermark level is 128.When using internal DMA, WR_WML can be set any value between 1 and 128. To get max AXI throughput, we recommend to use integer multiple of 16.
15-13 —	Reserved
12-8 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-0 RD_WML	Read watermark level This field indicates the number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also, the number of words as a sequence of read bursts in back-to-back mode. The maximum legal value for the read water mark level is 128.When using internal DMA mode, RD_WML must be set to the value less than 16. To get max AXI throughput, recommend to use 16.

40.6.1.20 Mixer Control (MIX_CTRL)

Offset

Register	Offset
MIX_CTRL	48h

Function

This register is used to DMA and data transfer. To prevent data loss, the software should check if data transfer is active before writing this register. These fields are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

Table 322. Transfer type register setting for various transfer types

Multi/single block select	Block count enable	Block count	Function
0	Do not care	Do not care	Single transfer
1	0	Do not care	Infinite transfer
1	1	Positive number	Multiple transfer
1	1	Zero	No data transfer

29 —	Reserved Always write as 0.
28 —	Reserved
27 EN_HS400_MODE	Enable enhance HS400 mode Enhance HS400 enable
26 HS400_MODE	Enable HS400 mode HS400 Enable
25 FBCLK_SEL	Feedback clock source selection (Only used for SD3.0, SDR104 mode and eMMC HS200 mode) 0b - Feedback clock comes from the loopback CLK 1b - Feedback clock comes from the ipp_card_clk_out
24 AUTO_TUNE_EN	Auto tuning enable (Only used for SD3.0, SDR104 mode and eMMC HS200 mode) 0b - Disable auto tuning 1b - Enable auto tuning
23 SMP_CLK_SEL	Clock selection When TUNING_CTRL[STD_TUNING_EN] is 0, this field is used to select Tuned clock or Fixed clock to sample data / cmd (Only used for SD3.0, SDR104 mode and eMMC HS200 mode) 0b - Fixed clock is used to sample data / cmd 1b - Tuned clock is used to sample data / cmd
22 EXE_TUNE	Execute tuning: (Only used for SD3.0, SDR104 mode and eMMC HS200 mode) When TUNING_CTRL[STD_TUNING_EN] is 0, this field is set to 1 to indicate the host driver is starting tuning procedure. Tuning procedure is stopped by writing 0. 0b - Not tuned or tuning completed 1b - Execute tuning
21-8 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
7 AC23EN	Auto CMD23 enable This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. When this field is set to 1, the host controller issues a CMD23 automatically before issuing a command specified in the Command Register.
6 NIBBLE_POS	Nibble position indication This field indicates the nibble position in the DDR 4-bit mode. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. 0- the sequence is 'odd high nibble -> even high nibble -> odd low nibble -> even low nibble'; 1- the sequence is 'odd high nibble -> odd low nibble -> even high nibble -> even low nibble'.
5 MSBSEL	Multi / Single block select This field enables multiple block DATA line data transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. For any other commands, this field can be set to 0. If this field is 0, it is not necessary to set the Block Count register. See Command Transfer Type (CMD_XFR_TYP). 0b - Single block 1b - Multiple blocks
4 DTDSEL	Data transfer direction select This field defines the direction of DATA line data transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. The field is set to 1 by the host driver to transfer data from the SD card to uSDHC and is set to 0 for all other commands. 0b - Write (Host to card) 1b - Read (Card to host)
3 DDR_EN	Dual data rate mode selection This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only.
2 AC12EN	Auto CMD12 enable Multiple block transfers for memory require a CMD12 to stop the transaction. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. When this field is set to 1, uSDHC issues a CMD12 automatically when the last block transfer has completed. The host driver is not set this field to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, uSDHC ignores this field no matter it is set or not. 0b - Disable 1b - Enable
1 BCEN	Block count enable This field is used to enable the Block Count register, which is only relevant for multiple block transfers. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. When this field is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disable 1b - Enable
0 DMAEN	DMA enable This field enables DMA functionality. This field is read/write when VEND_SPEC[CMD_BYTE_EN] is disabled; otherwise, this field is read-only. If this field is set to 1, a DMA operation begins when the host driver sets the DPSEL field of this register. Whether the simple DMA or the advanced DMA is active depends on the DMA Select field of the Protocol Control register. 0b - Disable 1b - Enable

40.6.1.21 Force Event (FORCE_EVENT)

Offset

Register	Offset
FORCE_EVENT	50h

Function

This register is not a physically implemented register. Rather, it is an address at which the Interrupt Status register can be written if the corresponding field of the Interrupt Status Enable Register is set. Writing 1 to this register sets the corresponding field of Interrupt Status register, while writing 0 to it has no effect. A read from this register always results in 0's. To change the corresponding status fields in the Interrupt Status register, make sure to set IPGEN field in System Control Register so that peripheral clock is always active.

Forcing a card interrupt generates a short pulse on the DATA1 line, and the driver might treat this interrupt as a normal interrupt. The interrupt service routine might skip polling the card interrupt factor as the interrupt is self cleared.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0 FEVTAC12NE	Force event auto command 12 not executed Forces the AC12NE field in the Auto Command12 Error Status register to be set

40.6.1.22 ADMA Error Status (ADMA_ERR_STATUS)

Offset

Register	Offset
ADMA_ERR_STATUS	54h

Function

When an ADMA Error Interrupt has occurred, the ADMA error sates field in this register holds the ADMA state and the ADMA System Address register holds the address around the error descriptor.

For recovering from this error, the host driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address.
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address.

- ST_CADR: This state is never set because it only increments the descriptor pointer and does not generate an ADMA error.
- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address.

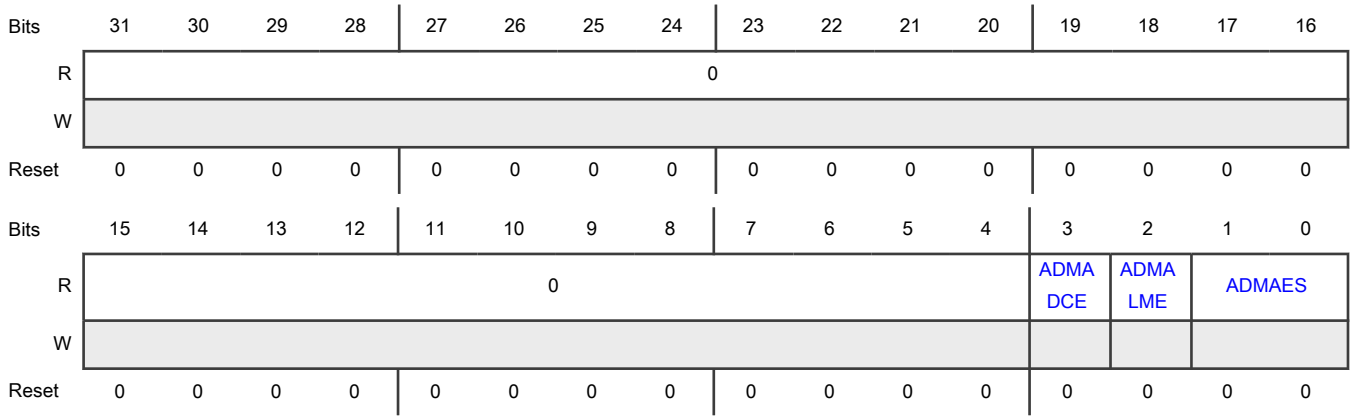
In case of a write operation, the host driver should use the ACMD22 to get the number of the written block, rather than using this information, because unwritten data might exist in the host controller.

The host controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) in the ST_FDS state. The host driver can distinguish this error by reading the Valid field of the error descriptor.

Table 323. ADMA error state coding

D01-D00	ADMA error state (when error has occurred)	Contents of ADMA System Address register
00	ST_STOP (Stop DMA)	Holds the address of the next executable descriptor command
01	ST_FDS (Fetch descriptor)	Holds the valid descriptor address
10	ST_CADR (Change address)	No ADMA error is generated
11	ST_TFR (Transfer data)	Holds the address of the next executable descriptor command

Diagram



Fields

Field	Function
31-4 —	Reserved
3 ADMADCE	ADMA descriptor error This error occurs when invalid descriptor fetched by ADMA. 0b - No error 1b - Error

Table continues on the next page...

Table continued from the previous page...

Field	Function
2 ADMALME	ADMA length mismatch error This error occurs in the following two cases: • While the block count enable is being set, the total data length specified by the descriptor table is different from that specified by the block count and block length. • Total data length cannot be divided by the block length. 0b - No error 1b - Error
1-0 ADMAES	ADMA error state (when ADMA error is occurred) This field indicates the state of the ADMA when an error has occurred during an ADMA data transfer. See ADMA Error Status (ADMA_ERR_STATUS) for more details.

40.6.1.23 ADMA System Address (ADMA_SYS_ADDR)

Offset

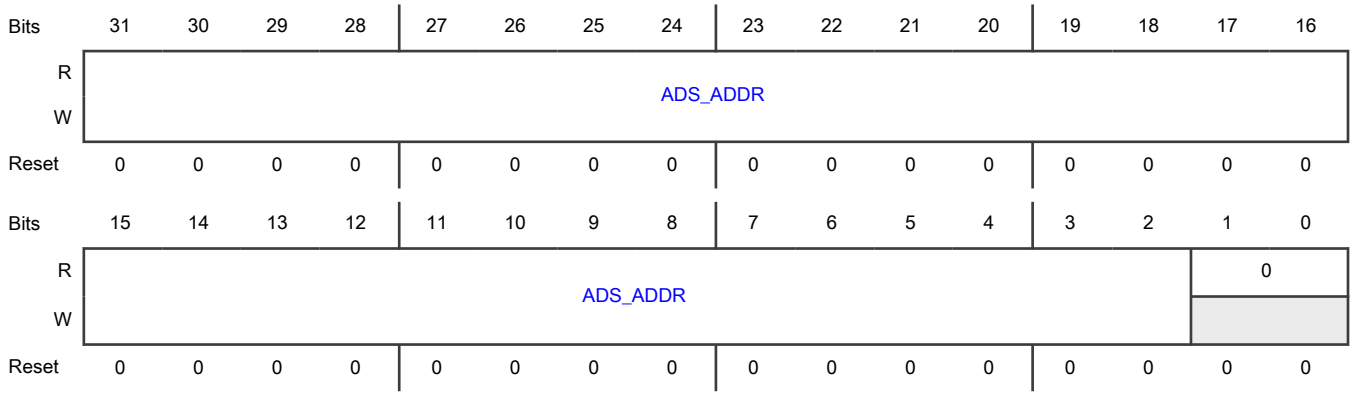
Register	Offset
ADMA_SYS_ADDR	58h

Function

This register holds the word address of the executing command in the Descriptor table. At the start of ADMA, the host driver sets the start address of the Descriptor table. The ADMA engine increments this register address whenever fetching a Descriptor command. When the ADMA is stopped at the Block Gap, this register indicates the address of the next executable Descriptor command. When the ADMA Error Interrupt is generated, this register holds the valid Descriptor address depending on the ADMA state. The lower 2 bits of this register is tied to '0' so the ADMA address is always word aligned.

Because this register supports dynamic address reflecting, when TC field is set, it automatically alters the value of internal address counter, so the software cannot change this register when TC field is set. Such restriction is also listed in Software restrictions.

Diagram



Fields

Field	Function
31-2 ADS_ADDR	ADMA system address This field contains the physical system memory address used for ADMA transfers.
1-0 —	Reserved

40.6.1.24 DLL (Delay Line) Control (DLL_CTRL)

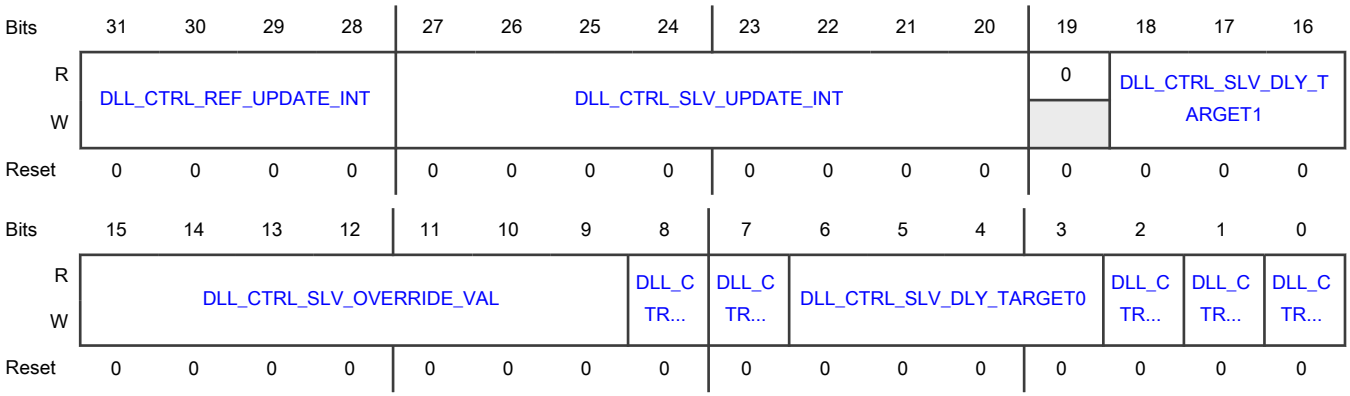
Offset

Register	Offset
DLL_CTRL	60h

Function

This register contains control fields for DLL.

Diagram



Fields

Field	Function
31-28 DLL_CTRL_REF_UPDATE_INT	DLL control loop update interval The interval cycle is (2 + REF_UPDATE_INT) * REF_CLOCK. By default, the DLL control loop updates every two REF_CLOCK cycles. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that might effect the delay (such as voltage and temperature)
27-20	Target delay line update interval

Table continues on the next page...

Table continued from the previous page...

Field	Function
DLL_CTRL_SLV_UPDATE_INT	If default 0 is used, it means 256 cycles of REF_CLOCK. A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the target-delay line using the SLV_FORCE_UPDATE register. Note that the target delay line also updates automatically when the reference DLL transitions to a locked state (from an un-locked state).
19 —	Reserved
18-16 DLL_CTRL_SLV_DLY_TARGET1	DLL target delay target1 See DLL_CTRL_SLV_DLY_TARGET0 below.
15-9 DLL_CTRL_SLV_OVERRIDE_VAL	DLL target override val When SLV_OVERRIDE = 1, this field is used to select 1 of 128 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 128.
8 DLL_CTRL_SLV_OVERRIDE	DLL target override Set this field to 1 to Enable manual override for target delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE field. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0
7 DLL_CTRL_GATE_UPDATE	DLL gate update Set this field to 1 to prevent the DLL from updating (because when clock_in exists, glitches might appear during DLL updates). This field might be used by software if such a condition occurs. Clear the bit to 0 to allow the DLL to update automatically.
6-3 DLL_CTRL_SLV_DLY_TARGET0	DLL target delay target0 The delay target for uSDHC loopback read clock can be programmed in 1/16th increments of an REF_CLOCK half-period. The delay is (DLL_CTRL_SLV_DLY_TARGET + 1)* REF_CLOCK_PERIOD[1] / 2) / 16, where DLL_CTRL_SLV_DLY_TARGET is a 7-bit value obtained by concatenating {DLL_CTRL_SLV_DLY_TARGET1, DLL_CTRL_SLV_DLY_TARGET0}. Therefore, the input read-clock can be delayed relative to the input data by (REF_CLOCK_PERIOD / 2) / 16 up to REF_CLOCK_PERIOD * 4. **NOTE** For the restrictions of delay cell implementation, the delay target must be set between REF_CLOCK_PERIOD/16 and REF_CLOCK_PERIOD*2 when REF_CLOCK is running at 200 MHz. When REF_CLOCK frequency is slower than 100 MHz, the maximum delay target might not reach REF_CLOCK_PERIOD*2.
2 DLL_CTRL_SLV_FORCE_UPD	DLL target delay line Setting this field to 1, forces the target delay line to update to the DLL calibrated value immediately. The target delay line updates automatically based on the SLV_UPDATE_INT interval or when a DLL lock

Table continues on the next page...

Table continued from the previous page...

Field	Function
	condition is sensed. Subsequent forcing of the target-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function might not work when uSDHC is working on data / cmd / response.
1 DLL_CTRL_RESET	DLL reset Setting this field to 1 force a reset on DLL. This causes the DLL to lose lock and re-calibrate to detect an REF_CLOCK half-period phase shift. This signal is used by the DLL as edge-sensitive, so to create a subsequent reset, RESET must be taken low and then asserted again.
0 DLL_CTRL_ENABLE	DLL and delay chain Set this field to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the target delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled.

1. REF_CLOCK_PERIOD is 1/REF_CLOCK.

40.6.1.25 DLL Status (DLL_STATUS)

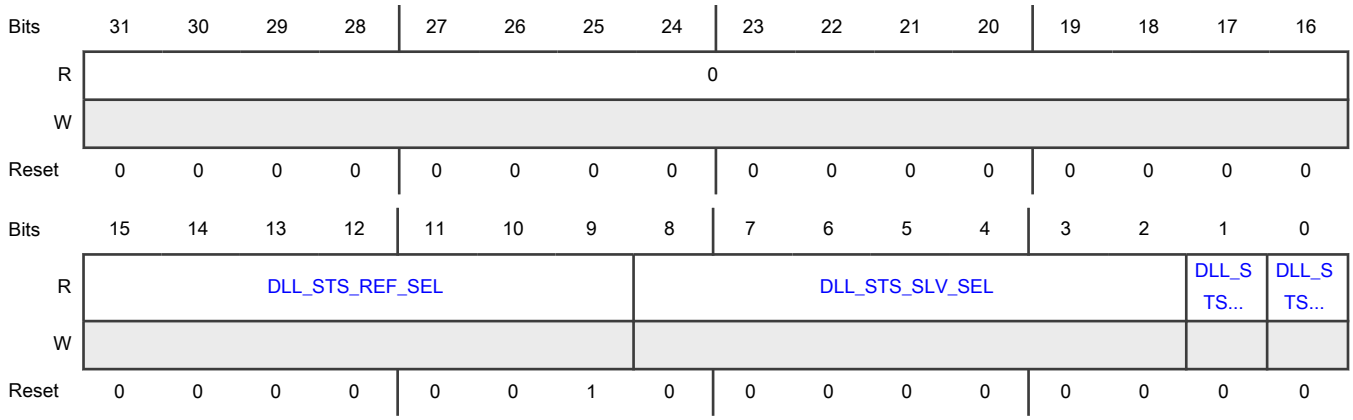
Offset

Register	Offset
DLL_STATUS	64h

Function

This register contains the DLL status information. All fields are read only and reads the same as the power-reset value.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-9 DLL_STS_REF_SEL	Reference delay line select taps This is encoded by 7 fields for 127 taps.
8-2 DLL_STS_SLV_SEL	Target delay line select status This is the instant value generated from reference chain. Because the reference chain can only be updated when REF_CLOCK is detected, this value should be the right value to be updated when the reference is locked.
1 DLL_STS_REF_LOCK	Reference DLL lock status This signifies that the DLL has detected and locked to an REF_CLOCK half-period phase shift , allowing the target delay-line to perform programmed clock delays
0 DLL_STS_SLV_LOCK	Target delay-line lock status This signifies that a valid calibration has been set to the target-delay line and that the target-delay line is implementing the programmed delay value

40.6.1.26 CLK Tuning Control and Status (CLK_TUNE_CTRL_STATUS)

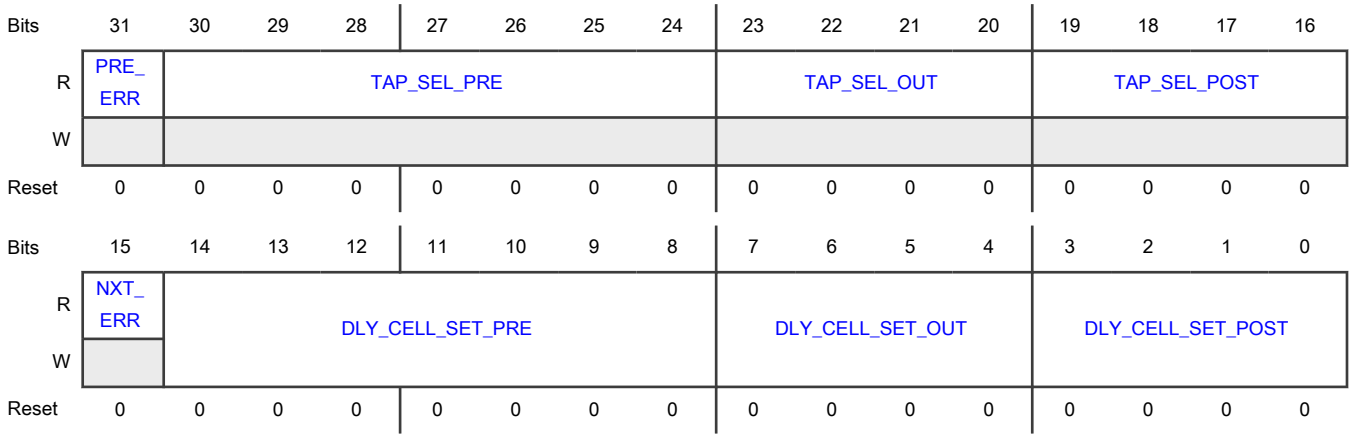
Offset

Register	Offset
CLK_TUNE_CTRL_STATUS	68h

Function

This register contains the Clock Tuning Control status information. This register is added to support SD3.0 UHS-I SDR104 mode and eMMC HS200 mode.

Diagram



Fields

Field	Function
31 PRE_ERR	PRE error PRE error which means the number of delay cells added on the feedback clock is too small. It is valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
30-24 TAP_SEL_PRE	TAP_SEL_PRE Reflects the number of delay cells added on the feedback clock between the feedback clock and CLK_PRE. When AUTO_TUNE_EN (bit24 of 0x48) is disabled, TAP_SEL_PRE is always equal to DLY_CELL_SET_PRE. When AUTO_TUNE_EN (bit24 of 0x48) is enabled, TAP_SEL_PRE is updated automatically according to the status of the auto tuning circuit to adjust the sample clock phase.
23-20 TAP_SEL_OUT	Delay cells added on the feedback clock between CLK_PRE and CLK_OUT Reflects the number of delay cells added on the feedback clock between CLK_PRE and CLK_OUT.
19-16 TAP_SEL_POST	Delay cells added on the feedback clock between CLK_OUT and CLK_POST Reflects the number of delay cells added on the feedback clock between CLK_OUT and CLK_POST.
15 NXT_ERR	NXT error NXT error which means the number of delay cells added on the feedback clock is too large. It's valid only when SMP_CLK_SEL of Mix control register (bit23 of 0x48) is enabled.
14-8 DLY_CELL_SET_PRE	delay cells on the feedback clock between the feedback clock and CLK_PRE Set the number of delay cells on the feedback clock between the feedback clock and CLK_PRE.
7-4 DLY_CELL_SET_OUT	Delay cells on the feedback clock between CLK_PRE and CLK_OUT Set the number of delay cells on the feedback clock between CLK_PRE and CLK_OUT.

Table continues on the next page...

Table continued from the previous page...

Field	Function
3-0 DLY_CELL_SET_POST	Delay cells on the feedback clock between CLK_OUT and CLK_POST Set the number of delay cells on the feedback clock between CLK_OUT and CLK_POST.

40.6.1.27 Strobe DLL control (STROBE_DLL_CTRL)

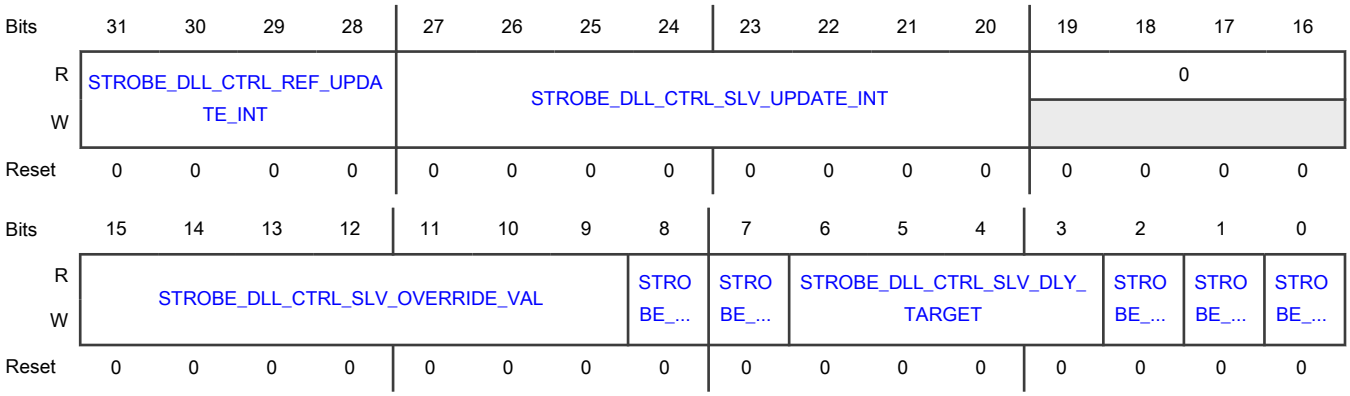
Offset

Register	Offset
STROBE_DLL_CTRL	70h

Function

This register contains the strobe DLL control information.

Diagram



Fields

Field	Function
31-28 STROBE_DLL_CTRL_REF_UPDATE_INT	Strobe DLL control reference update interval The interval cycle is (2 + STROBE_REF_UPDATE_INT) * STROBE_REF_CLOCK. By default, the DLL control loop updates every two STROBE_REF_CLOCK cycles. **NOTE** Increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that might effect the delay (such as voltage and temperature)
27-20	Strobe DLL control target update interval

Table continues on the next page...

Table continued from the previous page...

Field	Function
STROBE_DLL_CTRL_SLV_UPDATE_INT	Target delay line update interval. If default 0 is used, it means 256 cycles of STROBE_REF_CLOCK. A value of 0x0F results in 15 cycles and so on. **NOTE** software can always cause an update of the target-delay line using the STROBE_SLV_FORCE_UPDATE register. The target delay line also updates automatically when the reference DLL transitions to a locked state (from an un-locked state).
19-16 —	This field is reserved. This read-only field is reserved and always has the value 0.
15-9 STROBE_DLL_CTRL_SLV_OVERRIDE_VAL	Strobe DLL control target Override value When STROBE_SLV_OVERRIDE = 1, this field is used to manually select one of 128 physical taps. A value of 0 selects tap 1, and a value of 0x7F selects tap 128.
8 STROBE_DLL_CTRL_SLV_OVERRIDE	Strobe DLL control target override Set this field to 1 to Enable manual override for target delay chain using STROBE_SLV_OVERRIDE_VAL; set this field to 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE field. In fact to reduce power, if STROBE_SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE = 0.
7 STROBE_DLL_CTRL_GATE_UPDATE	Strobe DLL control gate update Set this field to 1 to prevent the DLL from updating (because when STROBE_CLOCK_IN exists, glitches might appear during DLL updates). This field can be used by software if such a condition occurs. Clear the field to 0 to allow the DLL to update automatically.
6-3 STROBE_DLL_CTRL_SLV_DLY_TARGET	Strobe DLL Control Target Delay Target The delay target for uSDHC loopback read clock can be programmed in 1/16th increments of an STROBE_REF_CLOCK half-period. The delay is ((STROBE_DLL_CTRL_SLV_DLY_TARGET + 1) * STROBE_REF_CLOCK_PERIOD[1] / 2) / 16, Therefore, the input read-clock can be delayed relative to the input data by (STROBE_REF_CLOCK_PERIOD / 2) / 16 up to (STROBE_REF_CLOCK_PERIOD *8)/16. **NOTE** For the restrictions of delay cell implementation, the minimum delay target that can be set is REF_CLOCK_PERIOD/16.
2 STROBE_DLL_CTRL_SLV_FORCE_UPD	Strobe DLL control target force updated Setting this field to 1, forces the target delay line to update to the DLL calibrated value immediately. The target delay line should automatically update the STROBE_SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the target-line update can only occur if STROBE_SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function might not work when uSDHC is working on data / cmd / response.

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 STROBE_DLL_CTRL_RESET	Strobe DLL control reset Setting this field to 1 to force a reset on DLL. This causes the DLL to lose lock and re-calibrate to detect an REF_CLOCK half-period phase shift. This signal is used by the DLL as edge-sensitive, to create a subsequent reset, RESET must be taken low and then asserted again.
0 STROBE_DLL_CTRL_ENABLE	Strobe DLL control enable Set this field to 1 to enable the DLL and delay chain; otherwise, set to 0 to bypasses DLL. **NOTE** Using the target delay line override feature with STROBE_SLV_OVERRIDE and STROBE_SLV_OVERRIDE VAL, the DLL does not need to be enabled.

1. which is 1/STROBE_REF_CLOCK.

40.6.1.28 Strobe DLL status (STROBE_DLL_STATUS)

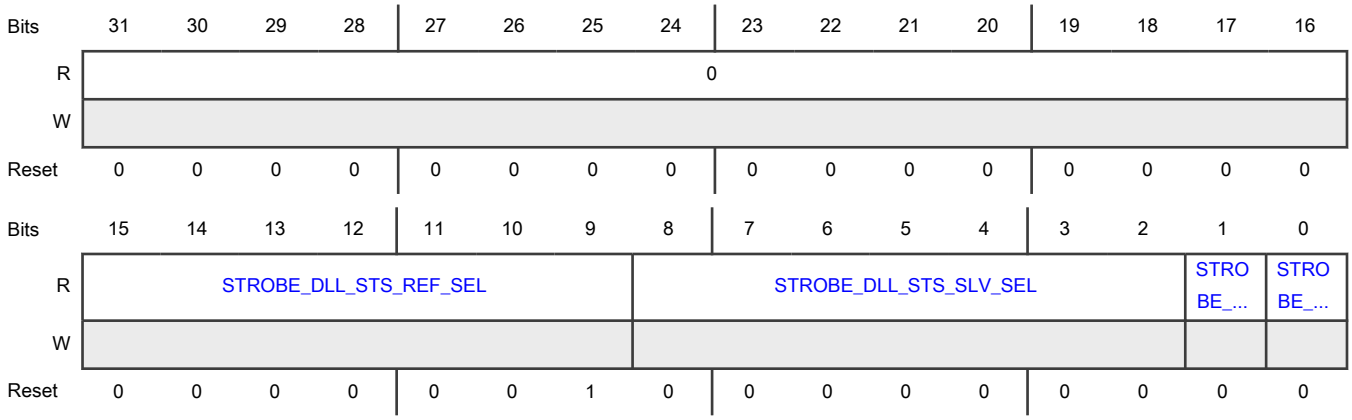
Offset

Register	Offset
STROBE_DLL_STATUS	74h

Function

This register contains the strobe DLL status information. All fields are read only and read the same as the power-reset value.

Diagram



Fields

Field	Function
31-16	This field is reserved.

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	This read-only field is reserved and always has the value 0.
15-9 STROBE_DLL_STS_REF_SEL	Strobe DLL status reference select Reference delay line select taps. This is encoded by 7 fields for 127 taps.
8-2 STROBE_DLL_STS_SLV_SEL	Strobe DLL status target select Target delay line select status. This is the instant value generated from reference chain. Because the reference chain can only be updated when STROBE_REF_CLOCK is detected, this value can be updated with the right value when the reference is locked.
1 STROBE_DLL_STS_REF_LOCK	Strobe DLL status reference lock This signifies that the DLL has detected and locked to a half-phase REF_CLOCK shift, it allows the target delay-line to perform programmed clock delays.
0 STROBE_DLL_STS_SLV_LOCK	Strobe DLL status target lock Target delay-line lock status. This signifies that a valid calibration has been set to the target-delay line, and the target-delay line is implementing the programmed delay value.

40.6.1.29 Vendor Specific Register (VEND_SPEC)

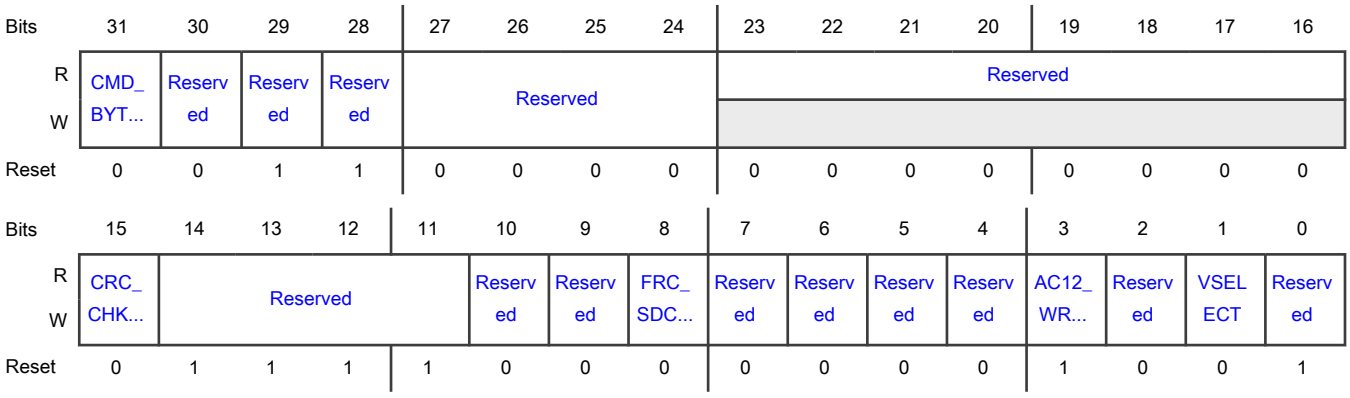
Offset

Register	Offset
VEND_SPEC	C0h

Function

This register contains the vendor specific control/status register.

Diagram



Fields

Field	Function
31 CMD_BYTE_EN	Register byte access for CMD_XFR_TYP This field controls the register byte access for Command Transfer Type (CMD_XFR_TYP). If this field is enabled, the register can be configured through byte write enable. IPS_bus can write only one byte once for one write operation. 0b - Disable. MIX_CTRL[7:0] is read/write and CMD_XFR_TYP[7:0] is read-only. 1b - Enable. MIX_CTRL[7:0] is read-only and CMD_XFR_TYP[7:0] is read/write.
30 —	Reserved Always write as 0.
29 —	Reserved Always write as 1
28 —	Reserved Always write as 0.
27-24 —	Reserved Always write as 4'b0000.
23-16 —	Reserved Always write as 8'h00.
15 CRC_CHK_DIS	CRC Check Disable 0b - Check CRC16 for every read data packet and check CRC fields for every write data packet 1b - Ignore CRC16 check for every read data packet and ignore CRC fields check for every write data packet
14-11 —	Reserved Reserved
10 —	Reserved Always write as 0.
9 —	Reserved Always write as 0.
8 FRC_SDCLK_ON	Force CLK Force CLK output active Do not set this bit to 1 unless it is necessary. Also, make sure that this bit is cleared when uSDHC's clock is about to be changed (frequency change, clock source change, or delay chain tuning). 0b - CLK active or inactive is fully controlled by the hardware. 1b - Force CLK active

Table continues on the next page...

Table continued from the previous page...

Field	Function

5 —	Reserved
4 —	Reserved
3 AC12_WR_CHKBUSY_EN	Check busy enable Check busy enable after auto CMD12 for write data packet 0b - Do not check busy after auto CMD12 for write data packet 1b - Check busy after auto CMD12 for write data packet
2 —	Reserved
1 VSELECT	Voltage selection Change the value of output signal VSELECT to control the voltage on pads for external card. There must be a control circuit out of uSDHC to change the voltage on pads. 0b - Change the voltage to high voltage range, around 3.0 V 1b - Change the voltage to low voltage range , around 1.8 V
0 —	Reserved Always write as 0.

40.6.1.30 eMMC Boot (MMC_BOOT)

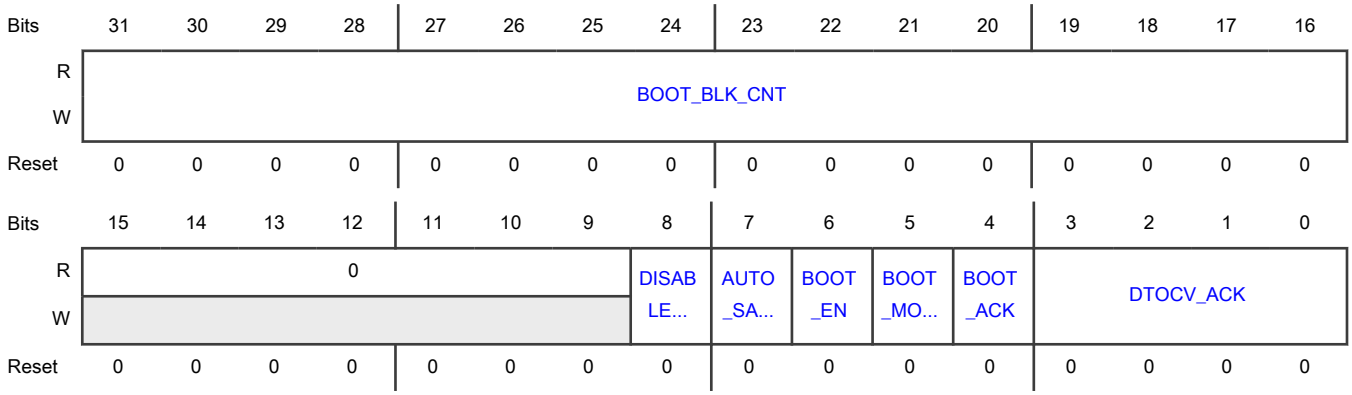
Offset

Register	Offset
MMC_BOOT	C4h

Function

This register contains the eMMC Fast Boot control register.

Diagram



Fields

Field	Function
31-16 BOOT_BLK_CNT	Stop At Block Gap value of automatic mode The value defines the Stop At Block Gap value of automatic mode. When received, card block cnt is equal to (BLK_CNT - BOOT_BLK_CNT) and AUTO_SABG_EN is 1, then Stop At Block Gap. Here, BLK_CNT is defined in the Block Attributes Register, field 31 - 16 of 0x04.
15-9 —	Reserved
8 DISABLE_TIME_OUT	Time out **NOTE** When this field is set, there is no timeout check no matter whether BOOT_EN is set or not. 0b - Enable time out 1b - Disable time out
7 AUTO_SABG_EN	Auto stop at block gap During boot, enable auto stop at block gap function. This function is triggered, and host stops at block gap when received card block cnt is equal to (BLK_CNT - BOOT_BLK_CNT).
6 BOOT_EN	Boot enable Boot mode enable 0b - Fast boot disable 1b - Fast boot enable
5 BOOT_MODE	Boot mode Boot mode select 0b - Normal boot 1b - Alternative boot

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 BOOT_ACK	BOOT ACK Boot ACK mode select 0b - No ack 1b - Ack
3-0 DTOCV_ACK	DTOCV_ACK Boot ACK time out counter value 0000b - SDCLK x 2^32 0001b - SDCLK x 2^33 0010b - SDCLK x 2^18 0011b - SDCLK x 2^19 0100b - SDCLK x 2^20 0101b - SDCLK x 2^21 0110b - SDCLK x 2^22 0111b - SDCLK x 2^23 1110b - SDCLK x 2^30 1111b - SDCLK x 2^31

40.6.1.31 Vendor Specific 2 Register (VEND_SPEC2)

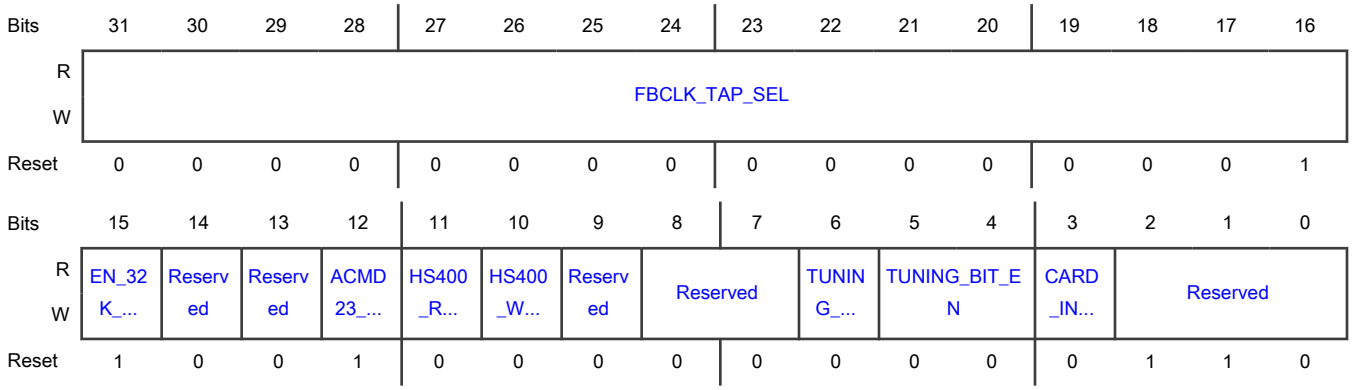
Offset

Register	Offset
VEND_SPEC2	C8h

Function

This register contains the vendor specific control 2 register.

Diagram



Fields

Field	Function
31-16 FBCLK_TAP_SEL	Enable extra delay on internal feedback clock It is a hot code. The default value is 16'h0001 that means the length of feedback delay chain is 1. The value of 16'h8000 means the length of feedback delay chain is 16.
15 EN_32K_CLK	Select the clock source for host card detection. It can use low power clock for card detection, by setting this bit to 1. 0b - Use the peripheral clock (ipg_clk) for card detection. 1b - Use the low power clock (ipg_clk_lp) for card detection.
14 —	Reserved
13 —	Reserved
12 ACMD23_ARGU2_EN	Argument2 register enable for ACMD23 0b - Disable 1b - Argument2 register enable for ACMD23 sharing with SDMA system address register. Default is enabled.
11 HS400_RD_CLK_STOP_EN	HS400 read clock stop enable Only stop clock at read block gap.
10 HS400_WR_CLK_STOP_EN	HS400 write clock stop enable Only stop clock at write block gap.
9	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
8-7 —	Reserved
6 TUNING_CMD_EN	Tuning command enable Enable the auto tuning circuit to check the CMD line. 0b - Auto tuning circuit does not check the CMD line. 1b - Auto tuning circuit checks the CMD line.
5-4 TUNING_BIT_EN	Tuning bit enable Enable the auto tuning circuit to check the DATA[7:0]. The value option is as the list below. 00b - Enable Tuning circuit for DATA[3:0] 01b - Enable Tuning circuit for DATA[7:0] 10b - Enable Tuning circuit for DATA[0] 11b - Invalid
3 CARD_INT_D3_TEST	Card interrupt detection test This field is used only for debugging. 0b - Check the card interrupt only when DATA3 is high. 1b - Check the card interrupt by ignoring the status of DATA3.
2-0 —	Reserved

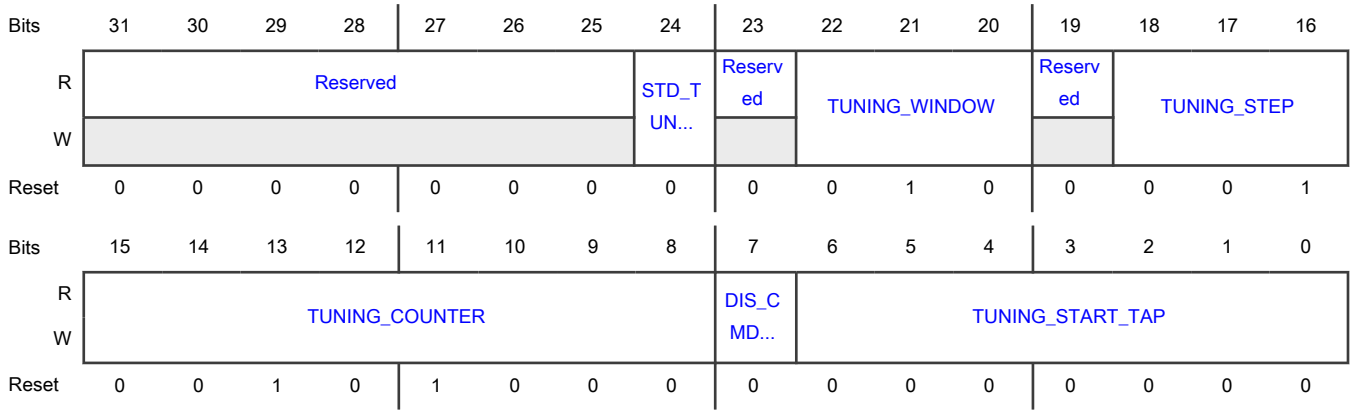
40.6.1.32 Tuning Control (TUNING_CTRL)

Offset

Register	Offset
TUNING_CTRL	CCh

Function
The register contains configuration of tuning circuit.

Diagram



Fields

Field	Function
31-25 —	Reserved
24 STD_TUNING_EN	Standard tuning circuit and procedure enable This field is used to enable standard tuning circuit and procedure.
23 —	Reserved
22-20 TUNING_WINDOW	Data window Select data window value for auto tuning
19 —	Reserved
18-16 TUNING_STEP	TUNING_STEP The increasing delay cell steps in tuning procedure.
15-8 TUNING_COUNTER	Tuning counter The MAX repeat CMD19 times in tuning procedure.
7 DIS_CMD_CHK_FOR_STD_TUNING	Disable command check for standard tuning Writing 1 to this field disables command check (command CRC, CMD end bit error, and CMD index error or CMD timeout error) for standard tuning flow after each tuning command is sent.
6-0	Tuning start

Table continues on the next page...

Table continued from the previous page...

Field	Function
TUNING_START_TAP	The start delay cell point when send first CMD19 in tuning procedure.

40.6.1.33 Command Queuing Version (CQVER)

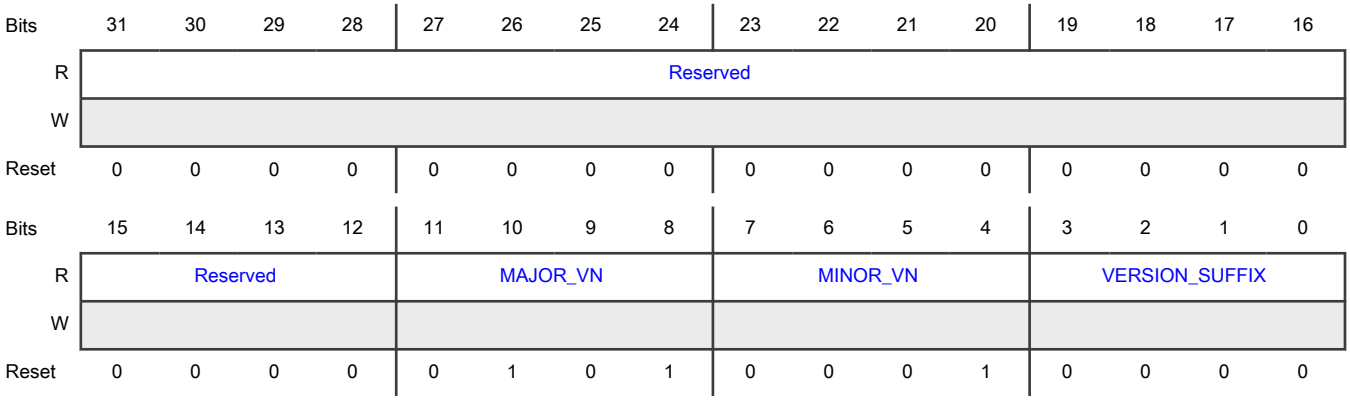
Offset

Register	Offset
CQVER	100h

Function

This register provides information about the version of the eMMC CQ standard that is implemented by CQE, in BCD format. The current version is 5.1.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-8 MAJOR_VN	eMMC major version number Digit left of decimal point, in BCD format
7-4 MINOR_VN	eMMC minor version number Digit right of decimal point, in BCD format
3-0	eMMC version suffix

Table continues on the next page...

Table continued from the previous page...

Field	Function
VERSION_SUFFIX	The second digit right of decimal point, in BCD format

40.6.1.34 Command Queuing Capabilities (CQCAP)

Offset

Register	Offset
CQCAP	104h

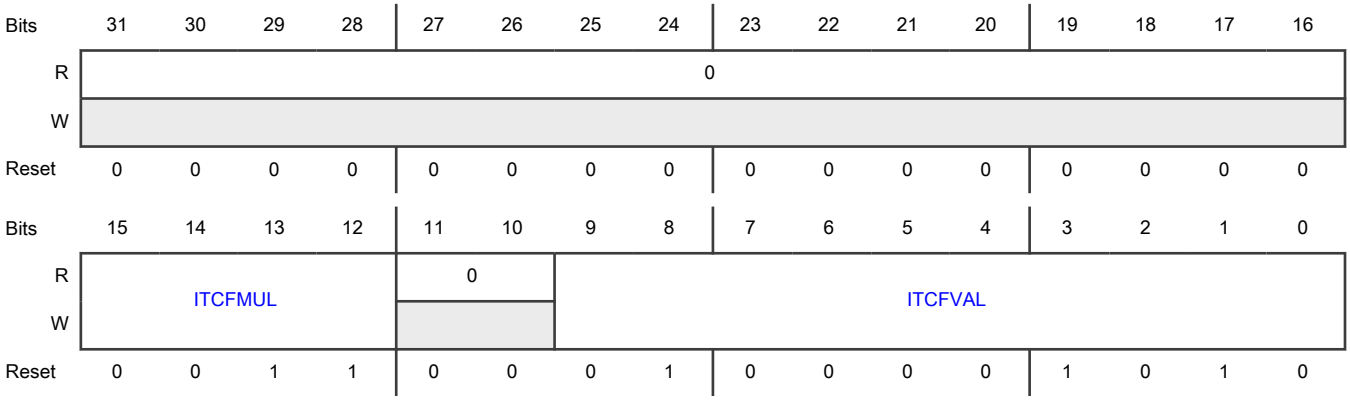
Function

This register indicates hardware capabilities.

NOTE

This register must not be configured and must be used as a read-only register. Writing to the read-write fields of this register does not affect any functionality. Reset values reflect the correct capability information.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-12 ITCFMUL	Internal timer clock frequency multiplier ITCFMUL and ITCFVAL indicate the frequency of the clock used for interrupt coalescing timer and for determining the SQS polling period. See ITCFVAL definition for details.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0001b - 0.001 MHz 0010b - 0.01 MHz 0011b - 0.1 MHz 0100b - 1 MHz 0101b - 10 MHz 0110b-1001b - Reserved
11-10 —	Reserved
9-0 ITCFVAL	Internal timer clock frequency value ITCFMUL and ITCFVAL indicate the frequency of the clock used for interrupt coalescing timer and for determining the polling period when using periodic SEND_QUEUE_ STATUS (CMD13) polling. The clock frequency is calculated as ITCFVAL* ITCFMUL. For example, to encode 19.2 MHz, ITCFVAL is C0h (= 192 decimal) and ITCFMUL is 3h (0.1 MHz): 192 * 0.1 MHz = 19.2 MHz.

40.6.1.35 Command Queuing Configuration (CQCFG)

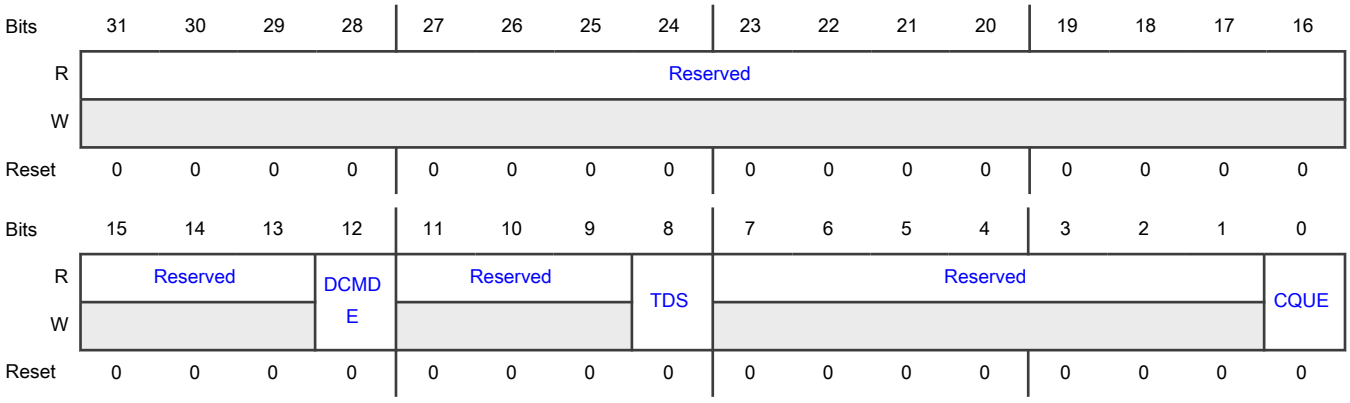
Offset

Register	Offset
CQCFG	108h

Function

This register controls CQE behavior affecting the general operation of command queuing module or operation of multiple tasks in the same time.

Diagram



Fields

Field	Function
31-13 —	Reserved
12 DCMDE	Direct command (DCMD) enable This bit indicates to the hardware whether the Task Descriptor in slot #31 of the TDL is a Data Transfer Task Descriptor, or a Direct Command Task Descriptor. CQE uses this bit when a task is issued in slot #31, to determine how to decode the Task Descriptor. 0b - Task descriptor in slot #31 is a Data Transfer Task Descriptor 1b - Task descriptor in slot #31 is a DCMD Task Descriptor
11-9 —	Reserved
8 TDS	Task descriptor size This bit indicates whether the task descriptor size is 128 bits or 64 bits as detailed in Data Structures section. This bit can only be configured when Command Queuing Enable bit is ‘0’ (command queuing is disabled) 0b - Task descriptor size is 64 bits 1b - Task descriptor size is 128 bits
7-1 —	Reserved
0 CQUE	Command queuing enable Software shall write '1' this bit when in order to enable command queuing mode (for example, enable CQE). When this bit is 0, CQE is disabled and software controls the eMMC bus using the legacy eMMC host controller. Before software writes '1' to this bit, software shall verify that the eMMC host controller is in idle state and there are no commands or data transfers ongoing. When software wants to exit command queuing mode, it shall clear all previous tasks if such exist before setting this bit to 0.

40.6.1.36 Command Queuing Control (CQCTL)

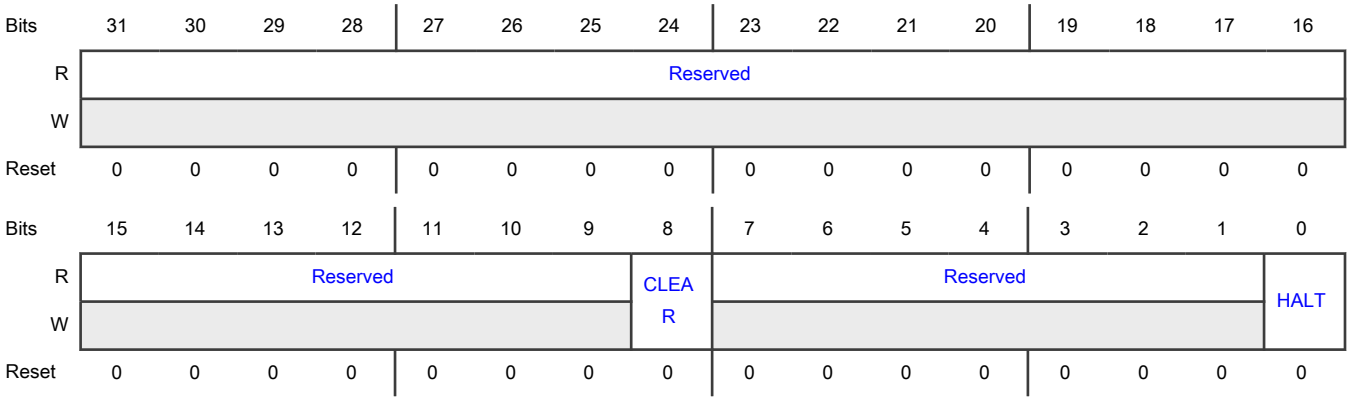
Offset

Register	Offset
CQCTL	10Ch

Function

This register controls CQE behavior affecting the general operation of command queuing module or operation of multiple tasks in the same time.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 CLEAR	Clear all tasks Software shall write '1' this bit when it wants to clear all the tasks sent to the chip. This bit can only be written when CQE is in halt state (for example, Halt bit is 1). When software writes 1, the value of the register is updated to '1', and CQE shall reset CQTDBR register and all other context information for all unfinished tasks. Then CQE will clear this bit. Software should poll on this bit until it is set to back 0 and may then resume normal operation, by clearing the Halt bit. CQE does not communicate to the chip that the tasks were cleared. It is software's responsibility to order the chip to discard the tasks in its queue using CMDQ_TASK_MGMT command. Writing '0' to this register shall have no effect.
7-1 —	Reserved
0 HALT	Halt Host software shall write '1' to the bit when it wants to acquire software control over the eMMC bus and disable CQE from issuing commands on the bus. For example, issuing a Discard Task command (CMDQ_TASK_MGMT) When software writes '1', CQE shall complete the ongoing task if such a task is in progress. Once the task is completed and CQE is in idle state, CQE shall not issue new commands and shall indicate so to software by setting this bit to 1. Software may poll on this bit until it is set to 1, and may only then send commands on the eMMC bus. In order to exit halt state (for example, resume CQE activity), software shall clear this bit (write '0'). Writing '0' when the value is already '0' shall have no effect.

40.6.1.37 Command Queuing Interrupt Status (CQIS)

Offset

Register	Offset
CQIS	110h

Function

This register indicates pending interrupts that require service. Each bit in this registers is asserted in response a specific event, only if the respective bit is set in CQISTE register.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved												TCL	RED	TCC	HAC
W													W1C	W1C	W1C	W1C
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-4 —	Reserved
3 TCL	Task cleared This status bit is asserted (if CQISTE[TCL_STE]=1) when a task clear operation is completed by CQE. The completed task clear operation is either an individual task clear (CQTCLR) or clearing of all tasks (CQCTL).
2 RED	Response error detected interrupt This status bit is asserted (if CQISTE[RED_STE]=1) when a response is received with an error bit set in the device status field. The contents of the device status field are listed in 6.13. Software uses CQRMEM register to configure which device status bit fields may trigger an interrupt, and which are masked.
1 TCC	Task complete interrupt This status bit is asserted (if CQISTE[TCC_STE]=1) when at least one of the following two conditions are met:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• A task is completed and the INT bit is set in its Task Descriptor • Interrupt caused by Interrupt Coalescing logic (see 0)
0 HAC	Halt complete interrupt This status bit is asserted (if CQISTE[HAC_STE]=1) when halt bit in CQCTL register transitions from 0 to 1 indicating that host controller has completed its current ongoing task and has entered halt state.

40.6.1.38 Command Queuing Interrupt Status Enable (CQISTE)

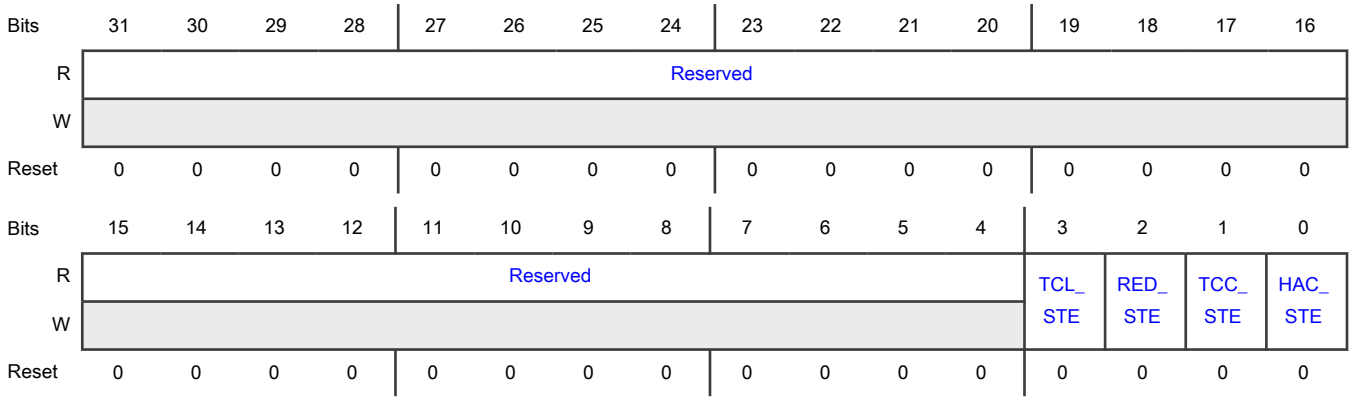
Offset

Register	Offset
CQISTE	114h

Function

This register enables and disables the reporting of the corresponding interrupt to host software in CQIS register. When a bit is set ('1') and the corresponding interrupt condition is active, then the bit is CQIS is asserted. Interrupt sources that are disabled (‘0’) are not indicated in the CQIS register. This register is bit-index matched to CQIS register.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 TCL_STE	Task cleared status enable Related to CQIS[TCL]

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - CQIS[TCL] is disabled 1b - CQIS[TCL] is set when its interrupt condition is active
2 RED_STE	Response error detected status enable Related to CQIS[RED] 0b - CQIS[RED]is disabled 1b - CQIS[RED] is set when its interrupt condition is active
1 TCC_STE	Task complete status enable Related to CQIS[TCC] 0b - CQIS[TCC] is disabled 1b - CQIS[TCC] is set when its interrupt condition is active
0 HAC_STE	Halt complete status enable Related to CQIS[HAC] 0b - CQIS[HAC] is disabled 1b - CQIS[HAC] is set when its interrupt condition is active

40.6.1.39 Command Queuing Interrupt Signal Enable (CQISGE)

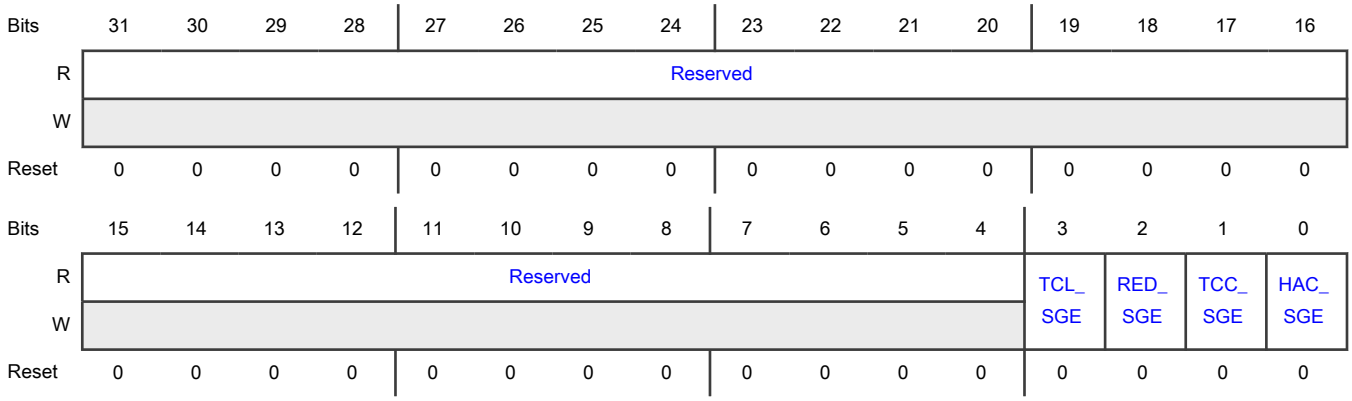
Offset

Register	Offset
CQISGE	118h

Function

This register enables and disables the generation of interrupts to host software. When a bit is set ('1') and the corresponding bit in CQIS is set, then an interrupt is generated. Interrupt sources that are disabled (‘0’) are still indicated in the CQIS register. This register is bit-index matched to CQIS register.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 TCL_SGE	Task cleared signal enable When set and CQIS[TCL] is asserted, the CQE generates an interrupt.
2 RED_SGE	Response error detected signal enable When set and CQIS[RED] is asserted, the CQE generates an interrupt.
1 TCC_SGE	Task complete signal enable When set and CQIS[TCC] is asserted, the CQE generates an interrupt.
0 HAC_SGE	Halt complete signal enable When set and CQIS[HAC] is asserted, the CQE generates an interrupt.

40.6.1.40 Command Queuing Interrupt Coalescing (CQIC)

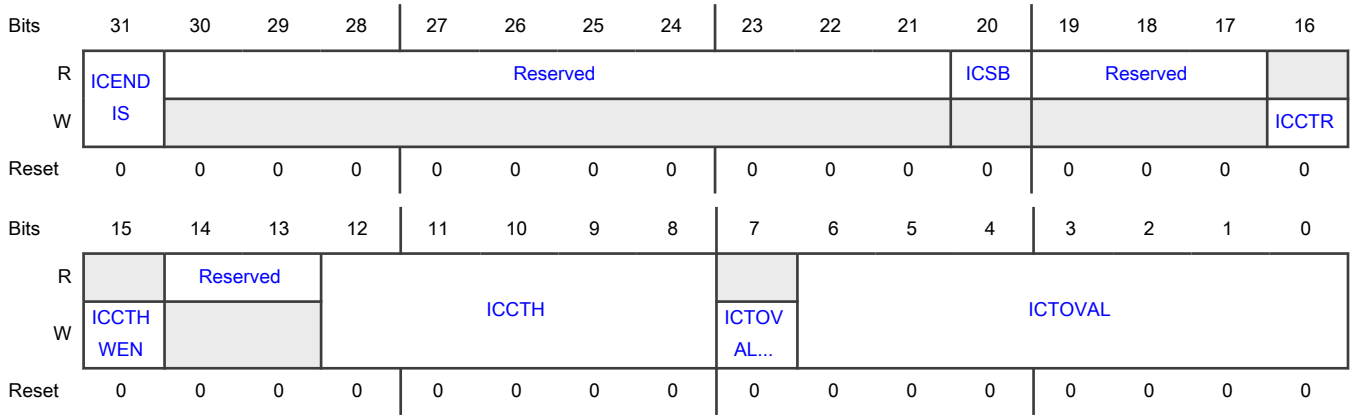
Offset

Register	Offset
CQIC	11Ch

Function

This register controls the interrupt coalescing feature.

Diagram



Fields

Field	Function
31 ICENDIS	Interrupt coalescing enable/disable When host driver writes ‘1’, the interrupt coalescing timer and counter are reset.
30-21 —	Reserved
20 ICSB	Interrupt coalescing status This bit indicates to software whether any tasks (with INT=0) have completed and counted towards interrupt coalescing (for example, ICSB is set if and only if IC counter > 0). 0b - No task completions have occurred since last counter reset (IC counter =0) 1b - At least one task completion has been counted (IC counter >0)
19-17 —	Reserved
16 ICCTR	Counter and timer reset When host driver writes ‘1’, the interrupt coalescing timer and counter are reset.
15 ICCTHWEN	Interrupt coalescing counter threshold write enable When software writes ‘1’, the value ICCTH is updated with the contents written at the same cycle. When software writes ‘0’, the value in ICCTH is not updated. **NOTE** Write operations to ICCTH are only allowed when the task queue is empty.
14-13 —	Reserved
12-8	Interrupt coalescing counter threshold

Table continues on the next page...

Table continued from the previous page...

Field	Function
ICCTH	Software uses this field to configure the number of task completions (only tasks with INT=0 in the Task Descriptor) which are required in order to generate an interrupt. Counter Operation: As data transfer tasks with INT=0 complete, they are counted by CQE. The counter is reset by software during the interrupt service routine. The counter stops counting when it reaches the value configured in ICCTH. The maximum allowed value is 31. **NOTE** When ICCTH is 0, task completions are not counted, and counting-based interrupts are not generated. In order to write to this field, the ICCTHWEN field must be set at the same write operation.
7 ICTOVALWEN	Interrupt coalescing timeout value write enable When software writes ‘1’, the value ICTOVAL is updated with the contents written at the same cycle. When software writes ‘0’, the value in ICTOVAL is not updated. **NOTE** Write operations to ICTOVAL are only allowed when the task queue is empty.
6-0 ICTOVAL	Interrupt coalescing timeout value Software uses this field to configure the maximum time allowed between the completion of a task on the bus and the generation of an interrupt. Timer Operation: The timer is reset by software during the interrupt service routine. It starts running when a data transfer task with INT=0 is completed, after the timer was reset. When the timer reaches the value configured in ICTOVAL field it generates an interrupt and stops. The timer’s unit is equal to 1024 clock periods of the clock whose frequency is specified in the Internal Timer Clock Frequency field CQCAP register. The minimum value is 01h (1024 clock periods) and the maximum value is 7Fh (127*1024 clock periods). For example, a CQCAP field value of 0 indicates a 19.2 MHz clock frequency (period = 52.08 ns). If the setting in ICTOVAL is 10h, the calculated polling period is 16*1024*52.08 ns= 853.33 us **NOTE** When ICTOVAL is 0, the timer is not running, and timer-based interrupts are not generated. In order to write to this field, the ICTOVALWEN bit must be set at the same write operation.

40.6.1.41 Command Queuing Task Descriptor List Base Address (CQTDLBA)

Offset

Register	Offset
CQTDLBA	120h

Function

This register is used for configuring the lower 32 bits of the byte address of the head of the Task Descriptor List in the host memory.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	TDLBA															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TDLBA	Task descriptor list base address This register stores the LSB bits (bits 31:0) of the byte address of the head of the Task Descriptor List in system memory. The size of the task descriptor list is 32 * (Task Descriptor size + Transfer Descriptor size) as configured by Host driver. This address shall be set on 1 KByte boundary: The lower 10 bits of this register shall be set to 0 by software and shall be ignored by CQE.

40.6.1.42 Command Queuing Task Descriptor List Base Address Upper 32 Bits (CQTDLBAU)

Offset

Register	Offset
CQTDLBAU	124h

Function

This register is used for configuring the upper 32 bits of the byte address of the head of the Task Descriptor List in the host memory.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	TDLBAU															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R W	TDLBAU															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TDLBAU	Task descriptor list base address This register stores the MSB bits (bits 63:32) of the byte address of the head of the Task Descriptor List in system memory. The size of the task descriptor list is 32 * (Task Descriptor size + Transfer Descriptor size) as configured by Host driver. This register is reserved when using 32-bit addressing mode.

40.6.1.43 Command Queuing Task Doorbell (CQTDBR)

Offset

Register	Offset
CQTDBR	128h

Function

Using this register, software triggers CQE to process a new task.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	TDBR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	TDBR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TDBR	Task doorbell Software configures TDLBA and TDLBAU, and enable CQE in CQCFG before using this register. Writing 1 to bit n of this register triggers CQE to start processing the task encoded in slot n of the TDL. CQE always processes tasks in-order according to the order submitted to the list by CQTDBR write transactions. CQE processes Data Transfer tasks by reading the Task Descriptor and sending QUEUED_TASK_PARAMS (CMD44) and QUEUED_TASK_ADDRESS (CMD45) commands to the device. CQE processes DCMD tasks (in slot #31, when enabled) by reading the Task Descriptor, and generating the command encoded by its index and argument. The corresponding bit is cleared to '0' by CQE in one of the following events: 1. When a task execution is completed (with success or error) 2. The task is cleared using CQTCLR register 3. All tasks are cleared using CQCTL register 4. CQE is disabled using CQCFG register Software may initiate multiple tasks at the same time (batch submission) by writing 1 to multiple bits of this register in the same transaction. In the case of batch submission: CQE shall process the tasks in order of the task index, starting with the lowest index. If one or more tasks in the batch are marked with QBR, the ordering of execution will be based on said processing order. Writing 0 by software shall have no impact on the hardware, and will not change the value of the register bit.

40.6.1.44 Command Queuing Task Completion Notification (CQTCN)

Offset

Register	Offset
CQTCN	12Ch

Function

This register is used by CQE to notify software about completed tasks.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	TCN															
W	W1C

R	TCN															
W	W1C															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TCN	Task complete notification CQE shall set bit n of this register (at the same time it clears bit n of CQTDBR) when a task execution is completed (with success or error). When receiving interrupt for task completion, software may read this register to know which tasks have finished. After reading this register, software may clear the relevant bit fields by writing 1 to the corresponding bits.

40.6.1.45 Command Queuing Device Queue Status (CQDQS)

Offset

Register	Offset
CQDQS	130h

Function

This register stores the most recent value of the device’s queue status.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	DQS															
W

R	DQS															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 DQS	Device queue status Every time the Host controller receives a queue status register (QSR) from the device, it updates this register with the response of status command (For example, the chip's queue status).

40.6.1.46 Command Queuing Device Pending Tasks (CQDPT)

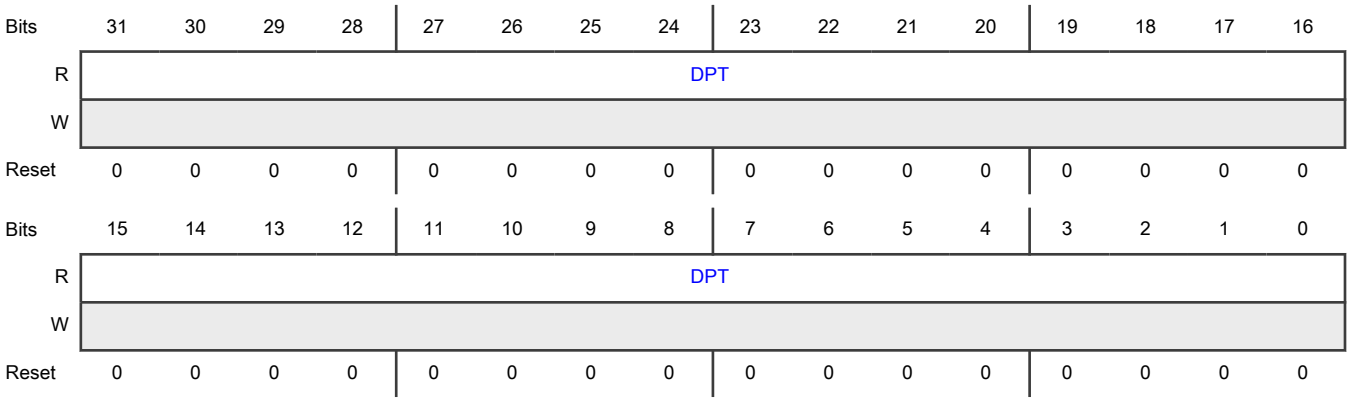
Offset

Register	Offset
CQDPT	134h

Function

This register indicates to software which tasks are queued in the device, awaiting execution.

Diagram



Fields

Field	Function
31-0 DPT	Device pending tasks Bit n of this register is set if and only if QUEUED_TASK_PARAMS (CMD44) and QUEUED_TASK_ADDRESS (CMD45) were sent for this specific task and if this task hasn't been executed yet. CQE shall set this bit after receiving a successful response for CMD45. CQE shall clear this bit after the task has completed execution. Software needs to read this register in the task-discard procedure, when the controller is halted, to determine if the task is queued in the device. If the task is queued, the driver sends a CMDQ_TASK_MGMT (CMD48) to the device ordering it to discard the task. Then software clears the task in the CQE. Only then the software orders CQE to resume its operation using CQCTL register.

40.6.1.47 Command Queuing Task Clear (CQTCLR)

Offset

Register	Offset
CQTCLR	138h

Function

This register is used for removing an outstanding task in the CQE. The register should be used only when CQE is in Halt state.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	TCLR															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	TCLR															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TCLR	Task clear Writing 1 to bit n of this register orders CQE to clear a task which software has previously issued. This bit can only be written when CQE is in Halt state as indicated in CQCFG register Halt bit. When software writes '1' to a bit in this register, CQE updates the value to '1', and starts clearing the data structures related to the task. CQE clears the bit fields (sets a value of 0) in CQTCLR and in CQTDBR once clear operation is complete. Software should poll on the CQTCLR until it is cleared to verify clear operation was complete. Writing to this register only clears the task in the CQE and does not have impact on the device. In order to discard the task in the device, host software shall send CMDQ_TASK _MGMT while CQE is still in Halt state. Host driver is not allowed to use this register to clear multiple tasks at the same time. Clearing multiple tasks can be done using CQCTL register. Writing 0 to a register bit shall have no impact.

40.6.1.48 Command Queuing Send Status Configuration 1 (CQSSC1)

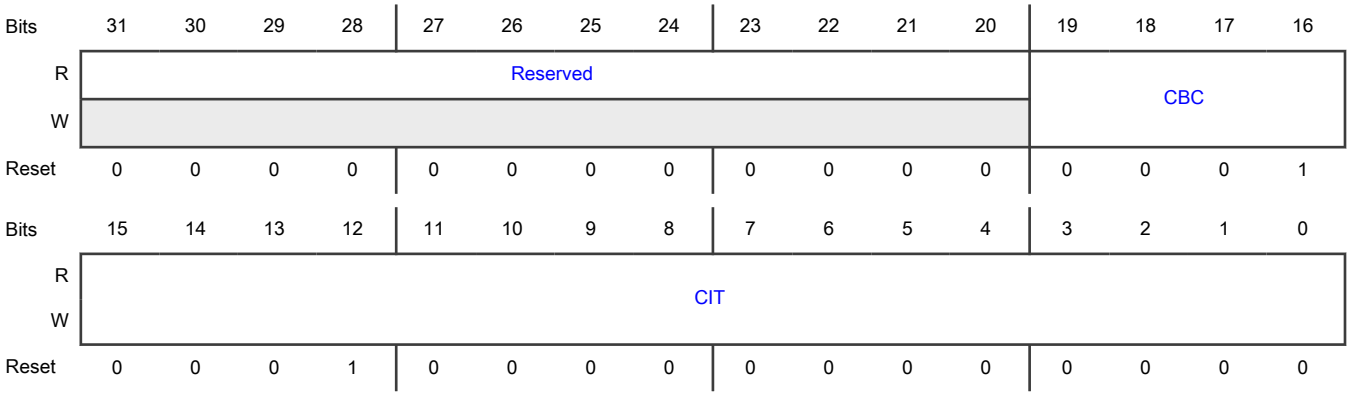
Offset

Register	Offset
CQSSC1	140h

Function

The register controls the when SEND_QUEUE_STATUS commands are sent.

Diagram



Fields

Field	Function
31-20 —	Reserved
19-16 CBC	Send status command block counter This field indicates to CQE when to send SEND_QUEUE_STATUS (CMD13) command to inquire the status of the device's task queue. A value of *n* means CQE sends status command on the CMD line, during the transfer of data block BLOCK_CNT-n, on the data lines, where BLOCK_CNT is the number of blocks in the current transaction. A value of 0 means that SEND_QUEUE_STATUS (CMD13) command is not sent during the transaction. Instead it will be sent only when the data lines are idle. A value of 1 means that STATUS command is to be sent during the last block of the transaction.
15-0 CIT	Send status command idle timer This field indicates to CQE the polling period to use when using periodic SEND_QUEUE_STATUS (CMD13) polling. Periodic polling is used when tasks are pending in the device, but no data transfer is in progress. When a SEND_QUEUE_STATUS response indicating that no task is ready for execution, CQE counts the configured time until it issues the next SEND_QUEUE_STATUS.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Timer units are clock periods of the clock whose frequency is specified in the Internal Timer Clock Frequency field CQCAP register. The minimum value is 0001h (1 clock period) and the maximum value is FFFFh (65535 clock periods). Default interval is: 4096 clock periods. For example, a CQCAP field value of 0 indicates a 19.2 MHz clock frequency (period = 52.08 ns). If the setting in CQSSC1.CIT is 1000h, the calculated polling period is 4096*52.08 ns= 213.33 us

40.6.1.49 Command Queuing Send Status Configuration 2 (CQSSC2)

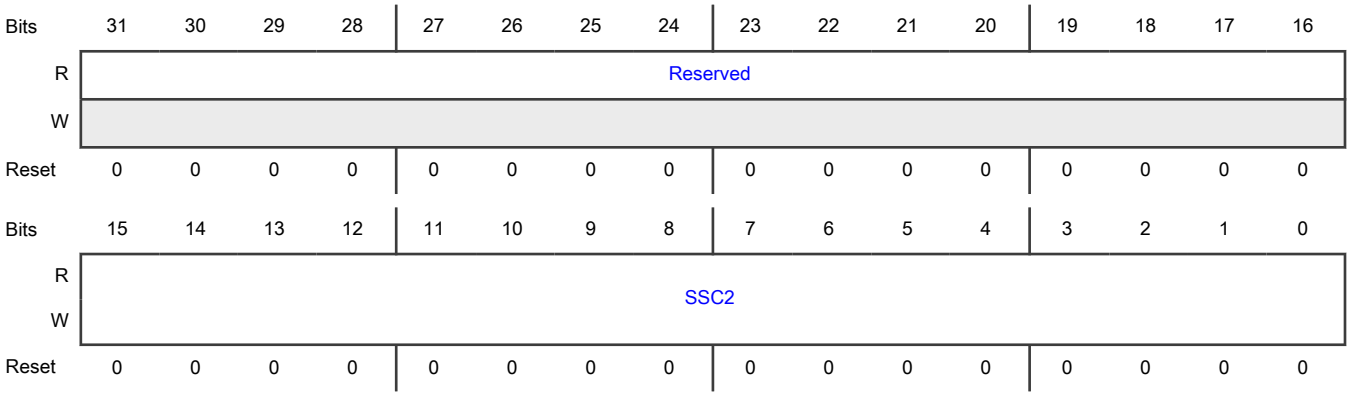
Offset

Register	Offset
CQSSC2	144h

Function

This register is used for configuring RCA field in SEND_QUEUE_STATUS command argument.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 SSC2	Send queue status RCA This field provides CQE with the contents of the 16-bit RCA field in SEND_QUEUE_ STATUS (CMD13) command argument. CQE copies this field to bits 31:16 of the argument when transmitting SEND_ QUEUE_STATUS (CMD13) command.

40.6.1.50 Command Queuing Command Response for Direct-Command Task (CQCRDCT)

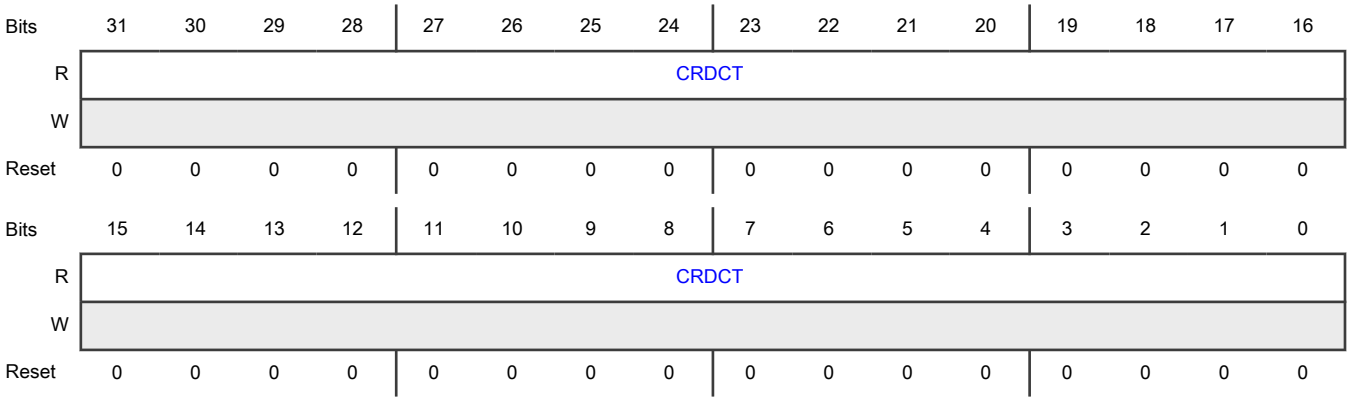
Offset

Register	Offset
CQCRDCT	148h

Function

This register is used for passing the response of a DCMD task to software.

Diagram



Fields

Field	Function
31-0 CRDCT	Direct command last response This register contains the response of the command generated by the last direct-command (DCMD) task which was sent. CQE updates this register when it receives the response for a DCMD task. This register is considered valid only after bit 31 of CQTDBR register is cleared by CQE.

40.6.1.51 Command Queuing Response Mode Error Mask (CQRMEM)

Offset

Register	Offset
CQRMEM	150h

Function

This register controls the generation of Response Error Detection (RED) interrupt.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	1	0	1	0	0	0	0	0	1	0	0	0	0	0	0	0

Fields

Field	Function
31-0 RMEM	Response mode error mask This bit is used as in interrupt mask on the device status filed which is received in R1/R1b responses. The reset value of this register is set to trigger an interrupt on all “Error” type bits in the device status, as defined in 6.13. **NOTE** Responses to CMD13 (SQS) encode the QSR, so they are ignored by this logic. 0000_0000_0000_0000_0000_0000_0000_0000b - When a R1/R1b response is received, bit i in the device status is ignored 0000_0000_0000_0000_0000_0000_0000_0001b - When a R1/R1b response is received, with bit i in the device status set, a RED interrupt is generated

40.6.1.52 Command Queuing Task Error Information (CQTERRI)

Offset

Register	Offset
CQTERRI	154h

Function

This register is updated by CQE when an error occurs on data or command related to a task activity.

When such error is detected by CQE or indicated by the eMMC controller CQE stores in CQTERRI the task IDs and the command indices of the commands which were executed on the command line and data lines when the error occurred.

Software is expected to use this information in the error recovery procedure. See B.2.8 for more details.

Initiators access XSPI via M-bus[2]	CPU0 system bus, eDMA0, eDMA1, ELS, PKC, ETR	CPU0 code bus, eDMA0, eDMA1, ELS, PKC, ETR	No

Table continues on the next page...

Table 325. Module instance features (continued)

Features	XSPI0	XSPI1	XSPI2
Initiators access XSPI via NIC_NEDIA1	JPEGDEC, PNGDEC, VGPU, LCDIF, EZH-V and DAP via NIC_MEDIA0: USB0-1, uSDHC0-1	JPEGDEC, PNGDEC, VGPU, LCDIF, EZH-V and DAP via NIC_MEDIA0: USB0-1, uSDHC0-1	JPEGDEC, PNGDEC, VGPU, LCDIF, EZH-V and DAP via NIC_MEDIA0: USB0-1, uSDHC0-1 via NIC_DSP: HiFi4 via M-bus: CPU0 system bus, eDMA0, eDMA1, ELS, PKC, ETR via S-bus: CPU1 system bus, eDMA2, eDMA3
Initiators access XSPI via NIC_DSP	HiFi4	HiFi4	N/A
Prince CTR/GCM	Yes	Yes	No
Prince XEX	No	Yes	No
x16 mode	No (8 bidirectional data lines)	Yes (16 bidirectional data lines)	Yes (16 bidirectional data lines)
Dummy pad loopback	No	No	No

1. See System memory map for more details.
2. The initiators access XSPI via M-bus also via cache.

41.1.2 IPED XEX write limitation

When IPED XEX is used in this chip, CPU0, eDMA0 and eDMA1 are the only managers that should write the memory, and the CACHE64_CTRL must be used with writeback mode enabled for the IPED XEX region(s). Other managers can be used to read the IPED XEX region, but they cannot write.

41.1.3 Stop request

In this chip, SLEEPCON modules can be used to send Stop request to the XSPI modules.

Table 326. Stop request to XSPI instances

Send stop request to	Control register in SLEEPCON
XSPI0	SYSCON0.PRIVATE_TCTRL2[XSPI0_STOP]
XSPI1	SYSCON0.PRIVATE_TCTRL2[XSPI1_STOP]
XSPI2	SYSCON0.SHA_MED_TCTRL0[XSPI2_STOP] or SYSCON1.SHA_MED_TCTRL0[XSPI2_STOP]

41.1.4 Configure XSPI to boot from XSPI NOR

In order to boot from XSPI NOR, configure XSPI depending on XSPI boot configuration.

41.1.5 Hard reset

In this chip, you can use the following register bits to reset XSPI modules:

Table 327. Reset XSPI modules

XSPI modules	Reset by
XSPI0	Write 1b to RSTCTL0.PRSTCTL2[XSPI0] or RSTCTL0.PRSTCTL2_SET[XSPI0]
XSPI1	Write 1b to RSTCTL0.PRSTCTL2[XSPI1] or RSTCTL0.PRSTCTL2_SET[XSPI1]
XSPI2	Write 1b to RSTCTL4.PRSTCTL0[XSPI2] or RSTCTL4.PRSTCTL0_SET[XSPI2]

41.1.6 SOC configuration register (SOCCR)

In this chip, the SOCCR[23:0] is not connected.

41.1.7 Manager ID allocation

In this chip, the AHB manager ID (MSTRID) is allocated as below.

Table 328. Manager ID allocations

Manager ID	Module	Manager ID	Module
xxxx_xxxx_xxx0_0000b	CPU0 system	xxxx_xxxx_xxx1_0000b	CPU0 code
xxxx_xxxx_xxx0_0001b	eDMA0	xxxx_xxxx_xxx1_0001b	Reserved
xxxx_xxxx_xxx0_0010b	eDMA1	xxxx_xxxx_xxx1_0010b	Reserved
xxxx_xxxx_xxx0_0011b	ELS	xxxx_xxxx_xxx1_0011b	Reserved
xxxx_xxxx_xxx0_0100b	HiFi4	xxxx_xxxx_xxx1_0100b	Reserved
xxxx_xxxx_xxx0_0101b	CPU1 system	xxxx_xxxx_xxx1_0101b	CPU1 code
xxxx_xxxx_xxx0_0110b	eDMA2	xxxx_xxxx_xxx1_0110b	JPEGDEC
xxxx_xxxx_xxx0_0111b	eDMA3	xxxx_xxxx_xxx1_0111b	PNG
xxxx_xxxx_xxx0_1000b	HiFi1	xxxx_xxxx_xxx1_1000b	Reserved
xxxx_xxxx_xxx0_1001b	EZH-V	xxxx_xxxx_xxx1_1001b	Reserved

41.1.8 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

41.2 Overview

XSPI is a memory controller IP, designed to support serial flash or RAM memories. The controller includes a programmable sequence engine providing flexibility to support existing and future memory devices. XSPI supports single, dual, quad modes of operation. Also this supports high performance x16 mode of operation in Octal mode.

NOTE

The terminology in this chapter has been updated to align with NXP's inclusive language standards, as shown in the table below.

Table 329. Updated terms

Updated term	Deprecated term
Initiator	Master
Target	Slave

41.2.1 Features

XSPI supports the following features:

- Programmable sequence engine for memory device commands and operations to support all existing and future memory devices, with support for all types of addressing. For example sequences, see Serial flash memory devices.
- Single, dual, and quad modes of operation supported for Quad flash memories
- Serial NAND device support for NOR-compatible command through the IPS interface
- Octal and single IO operation supported for Octal flash memories
- Double Data Rate (DDR)/Double Transfer Rate (DTR) mode that generates data on every edge of the memory clock
- Flash memory data strobe signal to support data sampling in DDR and Single Data Rate (SDR) mode
- HyperRAM support
- TX buffer fill via IPS register space (32-bit access) or AHB (64-bit width interface)
- IPS initiator to read the RX data buffer through the IPS register space (32-bit access).
- Multi-initiator AHB accesses with priority
- Flexible and configurable buffer for each initiator, with total available buffer size of 4096 bytes.
- Direct memory mapping of all AHB memory accesses to the chip system memory space.
- x16 operation with EIGHT PAD support.
- Programmable bit skewing adjustment for dual DQS.
- Enable or disable encryption of data written to external memories.
- Encryption or decryption for random reads or writes based on the data block size or boundaries as expected by IPED PRINCE algorithm with certain limitations.

41.2.2 Block diagram

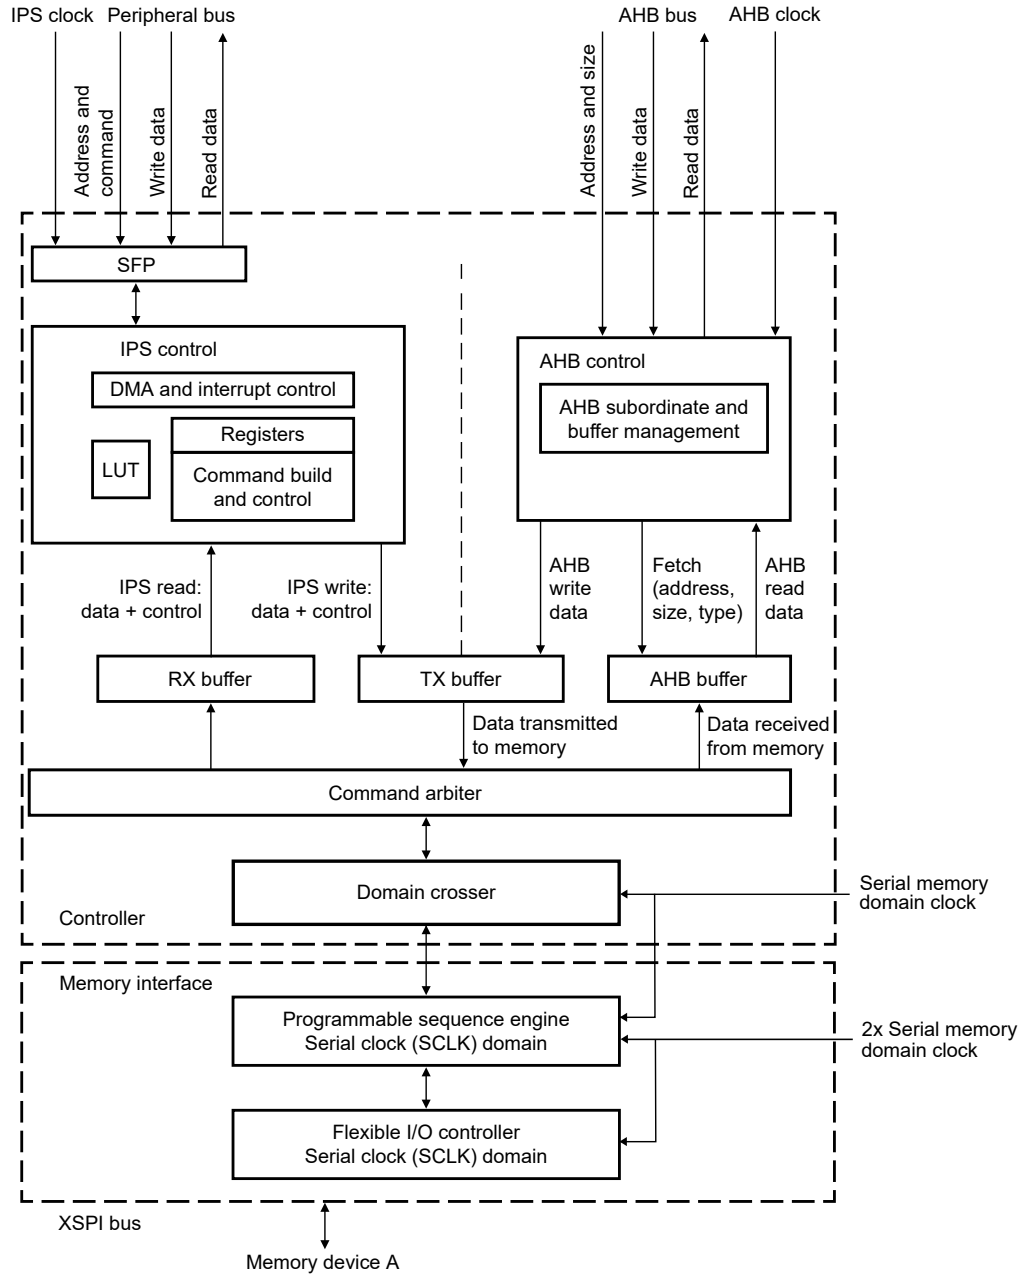

Figure 143. XSPI block diagram

41.3 Functional description

This section provides a functional description of the XSPI module.

41.3.1 Behavior of XSPI in chip modes

Chip mode	XSPI behavior
Normal	For write and read access to an external memory device. See Normal mode overview. • Serial flash memory write: Program data into memory through the IP interface or AHB interface. See Flash memory programming using IP command. • Serial flash memory read: Read the contents of memory through one of two separate read channels: the RX buffer and the AHB buffer. See Flash memory read using IP command for details.
Module disable	Use to disable the serial flash memory clock and AHB commands. Module disable mode stops the clock to XSPI main logic. XSPI enters module disable mode if an external controller asserts stop when Doze mode is enabled (MCR[DOZE] = 1) or when you write 1 to MCR[MDIS].

41.3.2 Serial flash memory access schemes

In the individual flash memory mode, all supported commands are available.

41.3.3 Normal mode overview

In normal mode, XSPI communicates with an external serial flash memory device through 16 high-data rate bidirectional data lines. It uses the programmable sequence engine to send sequences of instructions, along with optional address, mode, dummy, and data operands, to the memory device. You program these sequences in the lookup table (LUT). Together, the engine and the LUT provide the flexibility to support memory devices from various flash memory vendors by being able to accommodate a wide variety of command protocols.

For additional information, see:

- Programmable sequence engine
- Programmable sequence engine instructions
- Lookup table (LUT)

41.3.3.1 Programmable sequence engine

The programmable sequence engine uses sequences of instruction-operand pairs stored in the LUT. As its name implies, the engine executes the instructions in sequence.

The programmable sequence engine allows you to configure the XSPI module according to the serial flash memory connected on board. This flexible structure is compatible with new command or protocol changes from different vendors.

41.3.3.2 Programmable sequence engine instructions

This tables lists and describes the instructions supported by the programmable sequence engine and their operands.

Table 330. Programmable sequence engine instructions

Command	Instruction (INSTR*n*)	Pads (PAD*n*)	Operand (OPRND*n*)	Action
CMD	000001b (1h)	00b = 1 pad 01b = 2 pads 10b = 4 pads	8-bit command value	Provide the SFM command operand (encoded) on the specified number of pads in Single transfer rate (STR) mode.

Table continues on the next page...

Table 330. Programmable sequence engine instructions (continued)

Command	Instruction (INSTR*n*)	Pads (PAD*n*)	Operand (OPRND*n*)	Action
ADDR	000010b (2h)	11b = 8 pads[1]	Number of address bits	Provide the address of the transaction, using the necessary number of address cycles based on the operand value and the specified number of pads. For example, 24 bits on 4 pads takes 6 cycles in SDR mode or 3 cycles in DDR mode. For AHB-initiated transactions, the address is the actual address of the incoming transaction. For IPS-initiated transactions, the address comes from SFAR. If you specify a column address space value (SFACR[CAS] > 0), then XSPI takes CAS into consideration.
DUMMY	000011b (03h)		Number of dummy clock cycles (from 2 to 64)	Provide the specified number of dummy cycles. PAD*n* defines the number of pads in input mode. For example, 00b (1 pad) means that pad 1 is not driven, but all the rest are driven. See Dummy cycles generation. **NOTE** If DLL is enabled (DLLCR*x*[DLLEN] = 1) and you need *n* dummy cycles, you must program two back-to-back (split) DUMMY instructions: DUMMY with *n* – 2 cycles, followed by DUMMY with 2 cycles.
MODE	000100b (04h)		8-bit mode value	Provide an 8-bit operand on the specified number of pads.
MODE2	000101b (05h)	00b = 1 pad 01b = 2 pads	2-bit mode value	Provide a 2-bit operand on the specified number of pads.[2]
MODE4	000110b (06h)	00b = 1 pad 01b = 2 pads 10b = 4 pads	4-bit mode value	Provide a 4-bit operand on the specified number of pads. [3]

Table continues on the next page...

Table 330. Programmable sequence engine instructions (continued)

Command	Instruction (INSTR*n*)	Pads (PAD*n*)	Operand (OPRND*n*)	Action
READ	000111b (07h)	00b = 1 pad 01b = 2 pads 10b = 4 pads 11b = 8 pads	Number of data bytes to read. This value must be a multiple of 8.	Read the specified number of bytes on the specified number of pads. You can overwrite the data size: • AHB-initiated transactions: BUF*n*CR[ADATSZ] • IPS-initiated transactions: IPCR[IDATSZ]
WRITE	001000b (08h)		Number of data bytes to write	Write the specified number of bytes on the specified number of pads. You can overwrite the data size (IPCR[IDATSZ]).
JMP_ON_CS[4]	001001b (09h)	NA	Instruction number	Every time CS deasserts, jump to the sequence instruction pointed to by the operand. This instruction allows you to specify XSPI behavior on initiation of a new read transaction following a CS deassertion. **NOTE** If DLL is enabled (DLLCR*x*[DLLEN] = 1), XSPI does not support this instruction.
ADDR_DDR	001010b (0Ah)	00b = 1 pad 01b = 2 pads 10b = 4 pads 11b = 8 pads	Number of address bits to send	Provide the address of the transaction of the specified width using on the specified number of pads using each clock edge of the memory clock. For example: a 24-bit address on 4 pads requires 3 cycles. For AHB-initiated transactions, the address is the actual address of the incoming transaction. For IPS-initiated transactions, the address comes from SFAR. If you specify a column address space value (SFACR[CAS] > 0), then XSPI takes CAS into consideration.
MODE_DDR	001011b (0Bh)		8-bit mode value	Provide the 8-bit operand on the specified number of pads using each clock edge of the memory clock. For example: with 4 pads, an 8-bit operand requires 1 cycle; with 2 pads, an 8-bit operand takes 2 cycles.

Table continues on the next page...

Table 330. Programmable sequence engine instructions (continued)

Command	Instruction (INSTR*n*)	Pads (PAD*n*)	Operand (OPRND*n*)	Action
MODE2_DDR	001100b (0Ch)	00b = 1 pad	2-bit mode value	Provide the 2-bit operand on the specified number of pads using each clock edge of the memory clock.[5]
MODE4_DDR	001101b (0Dh)	00b = 1 pad 01b = 2 pads	4-bit mode value	Provide the 4-bit operand on the specified number of pads using each clock edge of the memory clock.[6].
READ_DDR	001110b (0Eh)	00b = 1 pad 01b = 2 pads 10b = 4 pads 11b = 8 pads	Number of data bytes to read. This value must be a multiple of 8.	Read the specified number of bytes on the specified number of pads using each clock edge of the memory clock. You can overwrite the data size: • AHB-initiated transactions: BUF*n*CR[ADATSZ] • IPS-initiated transactions: IPCR[IDATSZ][7]
WRITE_DDR	001111b (0Fh)		Number of data bytes to write. This value must be a multiple of 8.	Write the specified number of bytes on the specified number of pads using each clock edge of the memory clock. You can overwrite the data size (IPCR[IDATSZ][7]).
DATA_LEARN	010000b (10h)	00b = 1 pad 01b = 2 pads 10b = 4 pads 11b = 8 pads	8-bit data learning pattern Operand bits 6–0: • Number of bits to use for the data learning pattern. For example, if operand is 16 then a 16-bit data learning pattern is read and compared.	Find the correct sampling point with the data learning pattern. See Data learning This instruction causes XSPI to ignore the sampling configuration (SMPR) and find the correct sampling point by sampling the data learning pattern.[8]
CMD_DDR	010001b (11h)	00b = 1 pad 01b = 2 pads 10b = 4 pads 11b = 8 pads	8-bit command value	Provide the SFM command operand (encoded) to memory with the SFM command operand (ncoded) on the specified number of pads using each clock edge of the memory clock (DTR mode).
CADDR	010010b (12h)		Number of column address bits to send	Provide the specified number of column address bits on the specified number of pads. The actual address depends on SFACR[CAS]. For example, if SFACR[CAS] is 3, then the address to memory is bits 2–0 of the incoming address for AHB-initiated transactions and SFAR for IP-initiated transactions. XSPI appends 0

Table continues on the next page...

Table 330. Programmable sequence engine instructions (continued)

Command	Instruction (INSTR*n*)	Pads (PAD*n*)	Operand (OPRND*n*)	Action
				if SFACR[CAS] is less than the specified number of pads.
CADDR_DDR	010011b (13h)		Number of column address bits to be sent	Provide the specified number of column address bits on the specified number of pads using each clock edge of the memory clock. The actual address to be provided to memory depends on the value of SFACR[CAS]. For example, if CAS is 3, then the address to memory is [2:0] of the incoming address for AHB and the value of SFAR for IP. This is appended with 0 if CAS is less than the number of pads for memory.
JMP_TO_SEQ[4]	010100b (14h)	NA	Sequence number	After CS deassertion of initial sequence, jump to the LUT sequence pointed to by the operand. This instruction allows the programmer to join two sequences and initiates the second flash memory transaction automatically. It can be used to join write-enables with flash memory write or data learn with read. **NOTE** If DLL is enabled (DLLCR*x*[DLLEN] = 1), XSPI does not support this instruction.
STOP[4]	000000b (00h)	NA	NA	Stop execution; deassert CS. **NOTE** Unused LUT locations need to be filled with STOP instruction.

1. For x16 mode same 8 pads configuration is used.
2. For a one-pad instruction, MODE2 takes two cycles on the memory device interface.
3. For a one-pad instruction, MODE4 takes four cycles on the memory interface. For a four-pad instruction, MODE4 takes one cycle on the memory interface.
4. A sequence ending with this instruction must have all remaining bits as 0s after it.
5. For a one-pad instruction, MODE2_DDR takes one memory clock cycle on the memory interface.
6. For a one-pad instruction, MODE4_DDR takes two memory clock cycles on the memory interface. For a four-pad instruction, MODE4_DDR takes half a cycle on the memory interface.
7. In DDR mode, XSPI supports a minimum IDATSZ of 2 bytes. Specifying IDATSZ as 1 byte imposes a half-cycle sampling limitation, that causes assertion of the CS.
8. Do not use 0h or FFh as the data learning pattern.

41.3.3.3 Lookup table (LUT)

The LUT contains storage for 16 program sequences. Each sequence can have a maximum of 5 instruction-operand pairs (10 instruction-operands), which when executed sequentially by the programmable sequence engine, generate valid memory transactions. You program these instruction sequences into their corresponding LUT*n* registers. See LUT and sequence structure.

At reset, sequence 0 (LUT0–LUT4) contains the basic read sequence described in Basic read sequence. After reset, you can reprogram the complete LUT to support the on-board memory device or devices. To protect its contents in the event of a code run over, you can lock the LUT, which prevents writing to the LUT until it has been unlocked again.

For additional information, see:

- Locking the LUT
- Unlocking the LUT
- Example LUT sequences

41.3.3.4 LUT and sequence structure

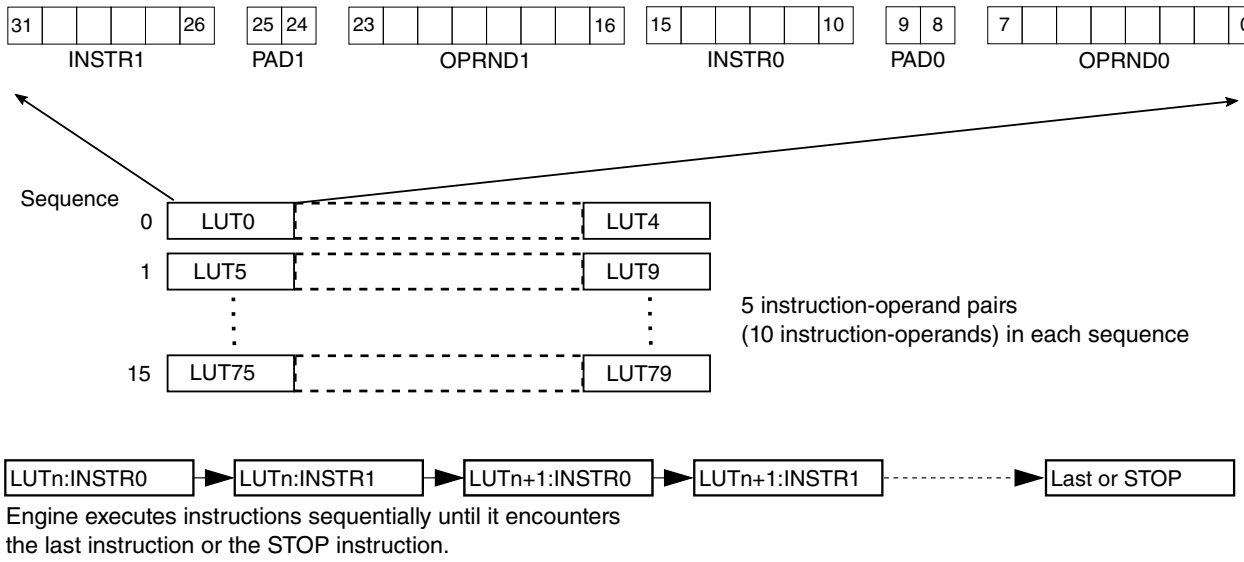

Figure 144. LUT and sequence structure

NOTE

For AHB and IPS transactions, the LUT OPRNDn value for WRITE, WRITE_DDR, READ, and READ_DDR instructions must be 0000_1000b (8 bytes).

41.3.3.5 Basic read sequence

After reset, instruction sequence 0 contains this default read sequence.

Table 331. Basic read sequence

Sequence	Instruction	Pads	Operand	Description
LUT0 0	CMD	00b	0000_0011 b (03h)	Read data byte command on one pad.

Table continues on the next page...

Table 331. Basic read sequence (continued)

Sequence	Instruction	Pads	Operand	Description
LUT0 1	ADDR	00b	0001_1000 b (18h)	Send 24 address bits on one pad.
LUT1 0	READ	00b	0000_1000 b (8h)	Read 64 bits.
LUT1 1	JMP_ON_CS	00b	0000_0000 b (0h)	Jump to instruction 0 (CMD).

41.3.3.6 Locking the LUT

The key for locking or unlocking the LUT is 5AF05AF0h. To lock the LUT:

Table 332. Locking the LUT

Step	Purpose	Programming	Notes
1	Insert the key.	Write 5AF05AF0h to LUTKEY[KEY].	
2	Lock the LUT. You must perform this step immediately after step 1. If any IPS transaction occurs between these steps, the lock action fails.	Write 01b to LCKCR.	A successful write to this register locks the LUT. Write access to LCKCR is disabled when the global configuration lock is enabled (MGC[GCLCK] != 00b).
3	Check the lock status.	Read LCKCR[LOCK].	If LCKCR[LOCK] is 1, LUT is locked.

41.3.3.7 Unlocking the LUT

The key for locking or unlocking the LUT is 5AF05AF0h. To unlock the LUT:

Table 333. Unlocking the LUT

Step	Purpose	Programming	Notes
1	Insert the key.	Write 5AF05AF0h to LUTKEY[KEY].	
2	Unlock the LUT. You must perform this step immediately after step 1. If any IPS transaction occurs between these steps, the lock action fails.	Write 10b to LCKCR.	A successful write to this register unlocks the LUT. Write access to LCKCR is disabled when the global configuration lock is enabled (MGC[GCLCK] != 00b).
3	Check the unlock status.	Read LCKCR[UNLOCK].	If LCKCR[UNLOCK] is 1, LUT is unlocked.

41.3.3.8 Issuing SFM commands

Each access to the external device follows this sequence:

1. You must pre-populate the LUT with the serial flash memory command sequences that are required for the flash memory device being used.
2. The module executes the instructions in this sequence one by one. The transaction starts and the module sets the value of SR[BUSY].

3. Communication with the external serial flash memory device starts and the transaction executes.
4. After the transaction is complete (all transmit and receive operations with the external serial flash memory device are complete), the module resets SR[BUSY]. In case of an IP command, FR[TFF] is asserted.

You can trigger the processing of SFM commands in the XSPI module in one of the following ways:

Using IP commands

For details, see Flash memory programming using IP command and Flash memory read using IP command.

Using AHB commands

For details, see AHB read and AHB write.

41.3.3.9 Flash memory programming using IP command

In all NOR Flash devices memory sector to be written needs to be erased first. The programming sequence is then initiated in the following way:

1. When SFP block is present, the IP command has to be targeted for a specific queue (TG) and based on this the registers have to be selected.
2. Check that TG queue that is selected for transfer is empty (TGSFARS[VLD] or TGSFARS_SUB_1[VLD] is 0).
3. Write the serial flash memory address to the Serial Flash Memory Address (SFP_TG_SFAR) or Serial Flash Memory Address (SFP_TG_SUB_1_SFAR) for that specific queue. For IP commands not related to specific addresses, the base address of the related flash memory needs to be programmed.
4. Write the sequence ID and data size details in the IP Configuration (SFP_TG_IPCR) or IP Configuration (SFP_TG_SUB_1_IPCR) depending on the queue selected. Maximum value of IPCR[IDATSZ(data size) is equal to the TX buffer size (1 KB) of XSPI.
5. After writing the SFP_TG_IPCR[SEQID] and SFP_TG_SUB_1_IPCR[SEQID], the queue is locked and if SFP checks are passed then transfer request is send to XSPI arbiter.
6. Wait for arbitration to be granted. In case of flash memory write transfers after the arbitration has been granted - clear the TX buffer, if it has older data present by writing 1 to MCR[CLR_TXF] field. Then program the correct TBCT[WMRK] and fill the TX data for the program command into the circular buffer through the TBDR.
7. After the TX data has been filled and TBCT[WMRK] is triggered, the SR[TXWA] flag goes low and transaction is triggered to XSPI which starts executing it.
8. The TBDR register access remains enabled for the queue which has the arbitration granted.
9. SR[TXFULL] and TBSR[TRBFL] can be used to check if the buffer is ready to receive more data. There will be few-cycle's latency before the status is reflected in TBSR[TRBFL] and SR[TXFULL]. TBSR[TRCTR] can be read to check how many words have been written into the TX buffer.
10. SR[BUSY] flag, SR[ARB_STATE] and TGSFARS[VLD] or TGSFARS_SUB_1[VLD] can be checked to know when the transfer is completed.

The software ensures that the correct sequence is programmed into the LUT in accordance with the flash memory connected to the module. The data is fetched from the TX buffer. It consists of 256 entries of 32-bit sizes and is organized as a circular FIFO, the read pointer for which is incremented after each fetch. When all the data is transmitted, the XSPI module returns from the busy state to the idle state. However, this is not true for the external device because the internal programming is still ongoing. You may monitor the relevant status information available from the serial flash memory device and ensure that the programming is done appropriately.

The application must define the IDATSZ value in alignment with the data programming requirements of the TBDR register, which is 4-byte aligned. Initiating a configuration write transaction on flash memory with a data size less than 32 bits results in the removal of one data entry from the TX buffer. In such cases, only the valid bits are utilized, while the remaining bits are discarded.

NOTE

See Secure flash protection for details on TG queues and related registers.

41.3.3.9.1 TX buffer operation

The TX buffer provides the data used for page programming through IP command or AHB interface. When TBCT[WMRK] is greater than or equal to the payload size, for proper operation it is required to write the entire payload data in TX buffer prior to starting execution of the page programming command. When TBCT[WMRK] is less than payload size, it is required to provide at least one entry in the TX buffer prior to starting the execution of the page programming command. The application must ensure that the required number of data bytes is written into the TX buffer fast enough as long as the command is executed without a TX buffer overflow or underrun.

The XSPI module sets the FR[TBFF] field as long as the TX buffer is not full and can accept more data. At the end of write through TX buffer, you must clear FR[TBFF] to avoid unnecessary last TX buffer fill interrupt. However, there would always be a pending request asserted from XSPI controller at the end of any DMA transfer. When external DMA finishes transfer iteration, this request from XSPI is kept asserted for the next iteration loop.

NOTE

Even if the generation of DMA requests for filling the TX buffer is disabled by using RSER[TBFDE], the TX buffer still accepts a DMA transfer because of the last asserted pending request.

Disabling of DMA transfer should be controlled by an external DMA initiator.

When the XSPI module tries to pull data out of an empty TX buffer, FR[TBUF] signals the TX buffer underrun. The current IP command leading to the underrun condition is aborted after the available data has been programmed and SW needs to re-execute the entire transaction. SR[TXFULL] and TBSR[TRBFL] can be used to check if the buffer is not full and can receive more data. When this sequence command is complete, FR[TBFF] is asserted, indicating that the TX buffer is ready to be written again. In case of underrun, application needs to execute the transaction again.

The TX buffer overflow is not signaled explicitly, but SR[TXFULL] and TBSR[TRBFL] can be used to monitor if the buffer is not full and can receive more data.

For more information, see TX Buffer Status (TBSR) and Flag (FR).

41.3.3.9.2 TX underrun handling by hardware

1. When underrun event is detected at flash side due to slow data rate feeding or incorrect watermark setting, hardware flushes the residue data towards flash by initiating another transaction for residue data.
2. Set AWRCR[PPW_WR_DIS] = 1b for flash devices that require program wait period to enable the auto RDSR mechanism. See Page program wait handling for configuration details.
3. When transaction detects underrun event, hardware stops the current transfer and initiates a new transfer to flush the residue data either immediately (PSRAM/HyperRAM devices) or after waiting for Tpp (NOR flash devices).
4. Step 4 is repeated until all the residue data is transferred until SFP timeout.
5. FR[TBUF] is generated in case the required data is not received from the application within SFP timeout period.

41.3.3.10 Flash memory read using IP command

Host access to the data stored in the external serial flash memory device is performed in two steps. First, the data must be read into the internal buffers and in the second step, these internal buffers can be read by the host.

Reading serial flash memory data into the XSPI module internal buffers

A read access to the external serial flash memory device can be triggered through IP command as given below:

1. For reading flash memory data into the RX buffer select the TG queue through which transfer has to be started.
2. Check that TG queue that is selected for transfer is empty (TGSFARS[VLD] or TGSFARS_SUB_1[VLD] field is 0).
3. Write the serial flash memory address to the Serial Flash Memory Address (SFP_TG_SFAR) or Serial Flash Memory Address (SFP_TG_SUB_1_SFAR) for that specific queue.

4. Write the sequence ID and data size details in the IP Configuration (SFP_TG_IPCR) or IP Configuration (SFP_TG_SUB_1_IPCR) depending on the queue selected. Read data size shall be limited to the RX Buffer size. You must provide the correct sequence ID in SFP_TG_IPCR[SEQID]. The sequence ID points to a sequence in the LUT. The software needs to ensure that a correct read sequence is programmed in the LUT in accordance with the serial flash memory device connected on board.
5. After writing the IPCR[SEQID], the queue is locked and transfer request is sent to the XSPI arbiter. Wait for arbitration to be granted.

All available read commands supported by the external serial flash memory are possible. Processing of AHB buffer — hit scenario is parallel to ongoing IP read command. AHB read request is served from buffered data based on buffer hit scenario.

Optionally, it is possible to clear the RX buffer pointer prior to triggering the IP command by writing a 1 to MCR[CLR_RXF]. This invalidates the data currently present in the RX buffer and any new read data overwrites the old data. The transaction is not triggered to XSPI if there is some older data pending in the RX buffer. Using these inputs, the complete transaction is built when arbitration is granted for this queue. The transaction related to the read access starts and the requested number of bytes is fetched from the external serial flash memory device into the RX buffer. As the read access is triggered by an IP command, the value of both SR[IP_ACC] and SR[BUSY] is set to 1. A count of the number of entries currently in the Rx buffer can be obtained from RBSR[RDBFL].

NOTE

See Secure flash protection for details on TG queues and related registers.

Communication with the external serial flash memory stops if the specified number of bytes are read (on successful completion of the transaction).

NOTE

In case of external DQS strobe based sampling, read data size (IDATSZ or LUT size) must be in multiples of 8 bytes.

41.3.3.10.1 RX buffer push event

RX buffer push event is generated automatically whenever there is data available in RX Async FIFO and space available in RX buffer.

By default, each buffer push event adds two entries to the RX buffer because the interface to the serial clock domain is 64 bits in width. Depending on the number of bytes read from the serial flash memory device, it is possible for the very last buffer push event that only one entry is added.

RBSR[RDBFL] is incremented by the number of entries added to the RX buffer.

41.3.3.10.2 RX buffer POP event

RX buffer pop event needs to be generated after reading RBCT[WMRK] + 1 entries through RBDR0 - RBDR63.

Each buffer POP event removes (RBCT[WMRK] + 1) valid entries from the buffer. RBSR[RDBFL] is decremented by the same number and RBSR[RDCTR] is incremented accordingly.

41.3.3.10.3 Data transfer from the XSPI module internal buffers

The data read out from the external serial flash memory device by the XSPI module is stored in the internal buffers. The means of accessing the data from the buffer differs depending on which buffer the data is loaded to. See Block diagram for details on the two available buffers, the RX buffer and the AHB buffer, in this module. The buffer appears transparent to you and is non-memory mapped. See the "Flexible AHB Buffer" section for details.

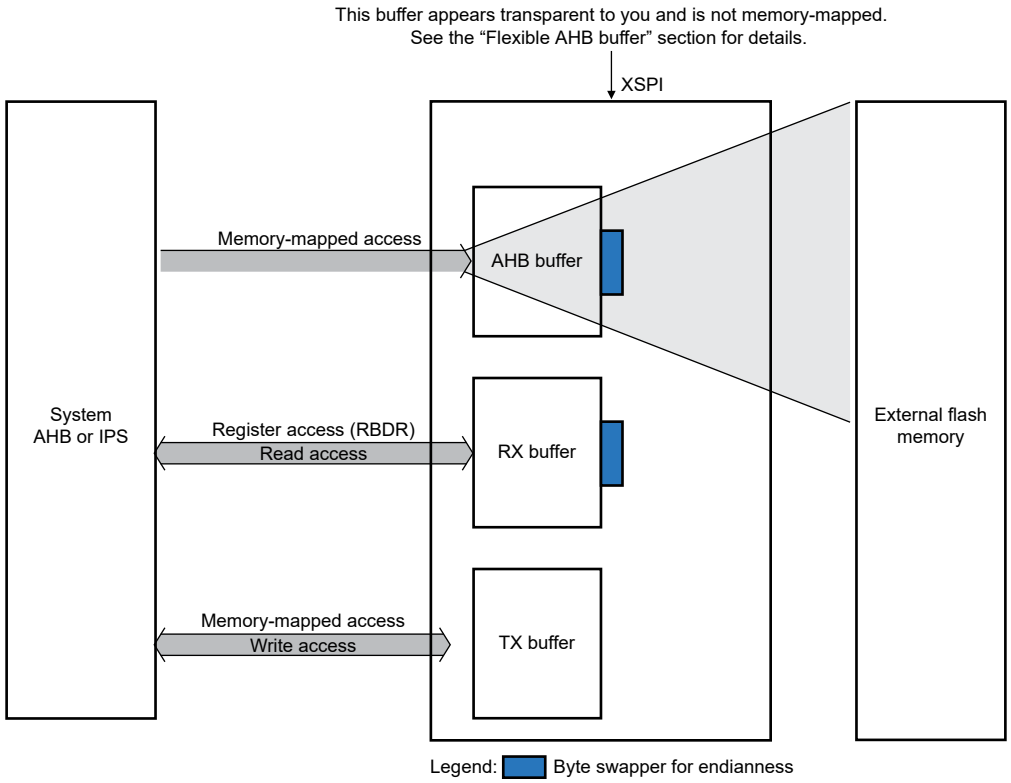

Figure 145. XSPI memory map

The RX buffer is implemented as FIFO of 32-bits width. Its content is accessible in the IPS address space in the area associated with RX Buffer Data (RBDR0 - RBDR63).

The RX buffer operation can be summarized as follows:

- RBCT[WMRK] determines at which fill level SR[RXWE] is asserted and how many entries are removed from the RX buffer on each buffer POP operation.
- SR[RXWE] indicates that the configured number of data entries is available in the RX buffer and RBSR[RDBFL] indicates how many valid entries are available in total.
- The first entry (RBDR0) always corresponds to the first valid entry in the RX buffer.

For details, see RX Buffer Data (RBDR0 - RBDR63).

- Flag-based data read of the RX buffer is performed by polling SR[RXWE]. When it is asserted, the valid entries can be read via the IPS address space (RBDRn). A buffer POP operation must be triggered by the application by writing a 1 to FR[RBDF]. This automatically updates the FIFO to point to the next entry as defined by RBCT[WMRK]. For example, if WMRK is set to 3, then the buffer discards 16 bytes of data.
- Internal DMA-controlled data read of the RX buffer is performed by using the DMA module. The application must ensure that the DMA controller of the related chip is programmed appropriately, as described in DMA.
- Internal DMA-controlled read out is triggered fully automatically by the assertion of SR[RXWE]. The related buffer POP operation is also handled completely inside the XSPI module. As in the case explained here, accessing the RX buffer content on RBDRn related addresses is equivalent.
- AHB buffer data read via memory-mapped access: This kind of access is performed by reading one of the addresses assigned to the external serial flash memory device(s) within the range specified in Table 406. If this is not the case, a memory-mapped AHB command read is triggered as described above. If the requested data is already available in the AHB buffer, it is provided directly to the host.

41.3.3.11 ARDB read

41.3.3.11.1 RX buffer read through ARDB registers

41.3.3.12 AHB read

For reading flash memory data into the AHB buffer, you must:

- Set up a read access by a initiator to the address range in the system memory map, which the external serial flash memory devices are mapped to.
- Write a desired value to SFACR[CAS], if required, or write 0 to the field.
- Program the buffer registers corresponding to the AHB initiator initiating the request.
- Provide the correct sequence ID in the BFGENCR. The software ensures that a correct read sequence is programmed in the LUT in accordance with the serial flash memory device connected on board. Flash memory device selection and access mode are determined by the address accessed in the AHB address space associated with the XSPI module (see Memory-mapped serial flash memory data—individual flash memory mode on flash memory A

On each AHB read access to the memory mapped area, the valid data in the AHB buffer is checked against the address requested in the actual read. When the AHB read request cannot be served (buffer-miss) from the content of the AHB buffer, the buffer is flushed and the controller executes the sequence pointed to by the sequence ID. The requested number of buffer entries defined in BUFxCR[ADATSZ] is then fetched from the external serial flash memory device into the internal AHB buffer. As the read access is triggered through the AHB miss condition, the value of SR[AHB_ACC] is set, driving SR[BUSY] in turn, until the transaction is complete. Communication with the external serial flash memory stops when the specified number of entries is filled.

When an AHB access is made to the flash memory mapped address, the data is fetched and returned to the AHB interface. The AHB interface is stalled (HREADY low) until the data is fetched. As soon as the data from the requested address is read by the XSPI module, the AHB read access is served. Therefore, it is possible to run sequential reads from the AHB buffer at arbitrary speed without the need to monitor any information about the availability of the data. Nevertheless, this access scheme stalls the AHB bus for the time required to read the data from the serial flash memory device. If you know that the access is sequential, a better way is to have a prefetch enabled by programming the value of BUFxCR[ADATSZ] so that the data is fetched into the buffer before the next sequential AHB access.

As long as the host restricts its accesses to the data present in the buffer and to the data currently fetched from the serial flash memory, it is possible to run the host read from the AHB buffer simultaneously with the serial flash memory read into the AHB buffer.

NOTE

AHB HRESP error is generated in case the AHB read address received is out of the valid flash address range programmed with XSPI. To avoid the timeout in this case of illegal access, software abort should be done by using the SPTRCLR[ABRT_CLR] bit.

41.3.3.12.1 Flexible read xAHB buffers

To reduce the latency of the reads for AHB initiators, the data read from serial flash memory is buffered in flexible AHB buffers. There are four such flexible buffers. The size of each of these buffers is configurable with the minimum size being 0 bytes and maximum size being the size of the complete buffer instantiated (4096 bytes). Each 1st–level buffer size can be configured in range of 0 KB, 512 B, 1 KB, 2 KB, 4 KB. Each of these buffers can be further sub-divided into 4 sub-buffers.

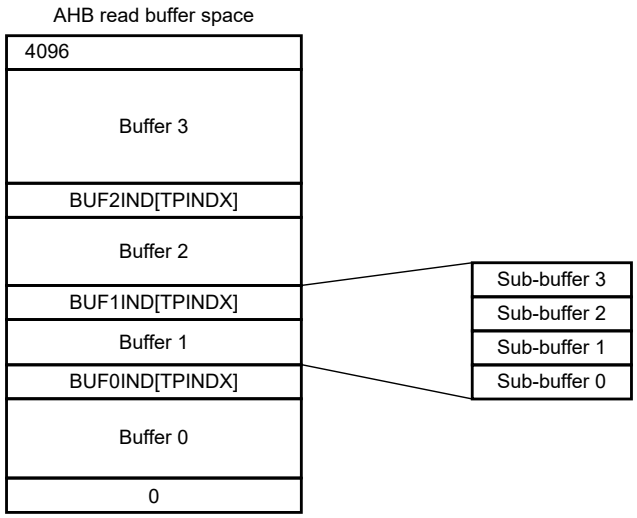

Figure 146. Flexible read AHB buffers

For any AHB access, the sequence pointed to by BFGENCR[SEQID] is used for the initiated flash memory transaction. BFGENCR[SEQID] points to an index of the LUT. See LUT for details.

Each 1st–level buffer size can be configured in range of 0 KB, 512 B, 1 KB, 2 KB, 4 KB. The size of buffer 0 is the difference between Buffer 0 Top Index (Buffer n Top Index (BUF0IND - BUF2IND)) and 0. The size of buffer 1 is the difference between Buffer 1 Top Index (Buffer n Top Index (BUF0IND - BUF2IND)) and Buffer 0 Top Index (Buffer n Top Index (BUF0IND - BUF2IND)). The size of buffer2 is the difference between Buffer 2 Top Index (Buffer n Top Index (BUF0IND - BUF2IND)) and Buffer 1 Top Index (Buffer n Top Index (BUF0IND - BUF2IND)), buffer 3 is the difference between the size of the complete buffer (4096 bytes and Buffer 2 Top Index (Buffer n Top Index (BUF0IND - BUF2IND)).

NOTE

AHB initiator assignment is strictly prohibited for the AHB buffers those are allocated with a depth of zero, as this constitutes an invalid AHB buffer configuration.

The sub-buffer division for each buffer can be enabled by writing '1' to the respective BUFnCR[SUB_DIV_EN] field. Size of sub-buffer is decided based on the division factor from total buffer size. This division factor is programmed using respective BUFnCR[SUBBUF0_DIV], BUFnCR[SUBBUF1_DIV], and BUFnCR[SUBBUF2_DIV] fields. XSPI supports division factors of /2, /4, /8 and /16. Size of Sub-buffer 3 is decided based on the left over space from three sub-buffers (0-2).

For example: if TPINDX0 field in BUF0IND register is programmed as 8. Then the size of buffer 0 becomes 8*64 bits. Then size of sub buffer can be decided based on division factors programmed as given in table below:

Table 334. Sub-buffer division factors

Sub-buffer number	SUBBUF*n*_DIV	Sub-Buffer division factor	Sub-buffer size
Sub Buffer 0	001	/2	4*64 bits
Sub Buffer 1	010	/4	2*64 bits
Sub Buffer 2	011	/8	1*64 bits
Sub Buffer 3	-	Remaining size	1*64 bits

Ensure that buffer size is always programmed in multiples of 2 when sub-buffer division is enabled.

Each flexible AHB buffer is associated with the following:

- An AHB initiator: A single AHB initiator can be assigned to a buffer by programming the respective BUFnCR[MSTRID] field. Buffer3 may be configured as an "all initiator" buffer by writing 1 to BUF3CR[ALLMST]. When buffer3 is configured in such a way, any access from a initiator not associated with any other buffers (0-2) is routed to buffer3.
- A data size field representing the amount of data to be fetched from the flash memory on every missed access.

The initiator ID of every incoming AHB request is checked and the data is returned or fetched into the corresponding buffer. If the address being requested by AHB initiator is already present inside the buffer/sub-buffer it is called as buffer-hit. If the address is not already present or not same as the address currently being read/prefetched from flash it is called as buffer-miss. In case of buffer hit the data is returned from the buffer and no access is generated towards the serial flash memory. Every missed access to the buffer causes the controller to clear the buffer and fetch the BUFxCR[ADATSZ] amount of data from the serial flash memory. As such, you need not configure the buffer size to be greater than BUFxCR[ADATSZ] because the locations greater than BUFxCR[ADATSZ] are never used. The data is returned to the initiator as soon as the requested address is read from the serial flash memory. The controller, however, continues to prefetch the rest of the data in anticipation of a next consecutive request.

In case BUF3CR[ALLMST] field is set to '0' and incoming AHB read request initiator ID is not mapped to any of the programmed buffers, then controller will keep the AHB HREADY low and will provide pre-defined AHB error payload (AHB Error Payload High (AHB_ERR_PAYLOAD_HI)and AHB Error Payload Low (AHB_ERR_PAYLOAD_LO)) on the read data bus when the HREADY timeout counter expires and FR[AITEF] flag is set.

41.3.3.12.1.1 Buffer function with sub-buffer division enabled

When sub-buffer division is also enabled for a buffer it places additional constraints for incoming AHB transaction to be mapped to a sub-buffer. Each sub-buffer is associated with an address range which can be programmed in AHB Buffer n Sub Buffer m Start and End Address Range (AHB Buffer n Sub Buffer m Start and End Address Range (BUF0_0_ADDR_RANGE - BUF3_3_ADDR_RANGE)) registers. Address ranges will be aligned in unit of 64 KB. When an AHB read access comes it is assigned to a buffer based on its initiator ID. Then it is further assigned to a sub-buffer based on which sub-buffer address range this transaction lies into. When sub-buffer division is enabled for a buffer the ADATSZ field is ignored. In case of a buffer miss controller will fetch the data equal to the size of that sub-buffer. This address range mapping constraint is not applicable when sub-buffer division is disabled for a buffer. Buffer overflow will happen and FR[ABOF] flag is set, due to incorrect programming of the End address, and the next buffer contents are modified.

It should be ensured while programming that no two address range of sub-buffers within same buffer are overlapping. The required configuration registers for AHB buffer programming should be programmed before the transaction starts and should not be changed during runtime.

In case the incoming address from an AHB initiator does not lie within any of the sub-buffer's address range of that buffer or matches within multiple sub-buffer address ranges of that buffer, an error field (FR[RDADDR]) is set and interrupt is generated if enabled for that error field. The address and AHB initiator ID which generated this AHB transfer is latched in AHB Read Error Address (AHB Read Error Address (AHB_RD_ERR_ADDR)) and AHB Read Error Initiator ID (AHB Read Error Initiator ID (AHB_RD_ERR_MID)) fields respectively. On AHB interface no error response is generated for this transaction. And the AHB error payload (AHB Error Payload High (AHB_ERR_PAYLOAD_HI) , AHB Error Payload Low (AHB_ERR_PAYLOAD_LO)) is sent as the read data for that transaction. In case of multiple errors the error status registers will keep the first error information latched unless the error field (FR[RDADDR]) is cleared in Flag register by writing '1' to this field.

41.3.3.12.2 Abort mechanism during AHB read

When sub-buffer division is disabled the buffer hit/miss condition is checked at individual buffer level. When sub-buffer division is enabled for a buffer the hit/miss check is done at sub-buffer level.

Any ongoing read transaction (prefetch) on flash is aborted if a request from the same initiator (which started the pre-fetch) comes and results in a buffer miss. The abort can happen at any point of time. After the abort completes, the controller generates a new read transfer to flash with the address currently being requested by the AHB initiator. All the data prefetched in the buffer is discarded and new prefetch is started with the current AHB address.

In case sub-buffer division is enabled the prefetch takes place for individual sub-buffers. If the AHB initiators requests an address which is already present inside the sub-buffer, the controller gives the data from this sub-buffer. In case the data for requested address is not present inside the sub-buffer and it results in a buffer-miss, In this case if the prefetch was in progress on the same sub-buffer on which the requested address lies then the prefetch is aborted. Once the abort completes the data inside that

sub-buffer is discarded and new data starting from the current AHB address is prefetched. The content of other sub-buffers are not changed.

If the prefetch was in progress for some sub-buffer and AHB initiator requests an address which results in buffer-miss on some other sub-buffer of the same initiator then the controller will wait for prefetch to complete first. Once the prefetch for this sub-buffer completes a new read transaction will be generated on flash with current AHB address being requested and the data will be written into the other sub-buffer on which buffer-miss occurred.

An ongoing prefetch is also aborted in case the start address + data prefetched so far reaches the end-address boundary set for that sub-buffer. It ensures that two sub-buffers of a single buffer do not contain the data for same address.

These abort conditions are not treated as error and no flag/status is set for these aborts.

The ongoing prefetch transaction can be aborted in case software abort is requested by using the SPTRCLR[ABRT_CLR] bit. It will stop the ongoing read/prefetch from flash and invalidates all the data already present inside the buffers. The software abort during AHB read may result in FR[AITEF] flag generation, if the read is not initiated towards flash controller. This software abort may also result in FR[AAEF] flag being set in case any AHB read transfer was ongoing during software abort. Any ongoing prefetch is also aborted in case any AHB write request arrives while the prefetch is ongoing. But in this case the data already present inside the buffers is not invalidated when prefetch is enabled and no error flag is set. Any ongoing prefetch is also aborted in case any AHB write request arrives while the prefetch is ongoing.

41.3.3.12.3 Suspend-resume mechanism

AHB initiators are categorized into high priority or normal priority categories. Any low-priority AHB read access (prefetch) can be suspended by a high-priority AHB initiator request which results in a buffer miss. In case a higher priority initiator request results in a buffer-hit the data is provided from the buffer and it will not suspend any ongoing prefetch. The ongoing transaction is always suspended at 64-bit boundary. The suspended transaction is resumed after the high priority initiator is served and the high priority transaction including data prefetch is completed.

Buffer0 or Buffer 1 can be configured to be a high-priority initiator by writing 1 to BUF0CR[HP_EN] and BUF1CR[HP_EN] bits. There can be only one suspended transaction at a time. The status of suspended transaction can be read from Sequence Suspend Status (SPNDST). Suspended address is stored in Sequence Suspend Status (SPNDST). If the prefetch was in progress in any high priority buffer and AHB read request arrives for another high priority buffer with a buffer miss, it will wait for the prefetch to complete first. High priority initiator can not suspend the ongoing prefetch of another high priority initiator. After the high priority requests are served, suspended requests are given a priority over other AHB read requests from non-high priority initiators. Controller will first complete the suspended transfer and then service the prefetch request from non-high priority initiators. In case of buffer hit requests, the data is provided from the buffer and it does not affect any ongoing prefetch.

While a transaction is in suspended state, it might get aborted if a read request by the same suspended initiator arrives on same sub-buffer and results in a buffer-miss. In this case the SPNDST[STATE] will change from 01b to 00b without going to 11b. A suspended/resumed prefetch will also be aborted in case of software abort request or if any AHB write request arrives.

A prefetch by a non-high priority initiator can be suspended multiple times in case higher priority requests keep arriving in between with buffer miss. A high priority initiator request can’t suspend the prefetch of another high-priority initiator or prefetch of same initiator on any other sub-buffer.

SPTRCLR[PREFETCH_DIS] field should be set to 0 while using the suspend resume functionality else it may lead to read data mismatch.

41.3.3.12.4 HBURST support with AHB read

XSPI controller supports HBURST and HSIZE as part of AMBA AHB standard interface. HBURST indicates if the transfer forms part of a burst. Four, eight, and sixteen beat bursts are supported and the bursts might either be incrementing or wrapping. Undefined length incremental burst is also supported by XSPI. HSIZE indicates the size of the transfer, and supports 8-, 16-, 32-, and 64-bit data sizes. In case of WRAP accesses, XSPI generates aligned accesses to serial flash memory if there is no buffer hit for any incoming, non-sequential AHB read access. In case there is a buffer hit, the incoming AHB address is latched as it is. If the total burst size is more than the data prefetch size, an error response is generated on the bus and the value of FR[AIBSEF] is set as 1. The data prefetch size can be defined by BUFnCR[ADATSZ] or data size mentioned in the sequence pointed to by the SEQID field when ADATSZ is programmed as 0. In case sub-buffer division is enabled the data prefetch size is defined as

the size of sub-buffer. In case of wrap burst, data prefetch size must be greater than or equal to the wrap burst size + 32 bytes. A few examples are shown in the figure below:

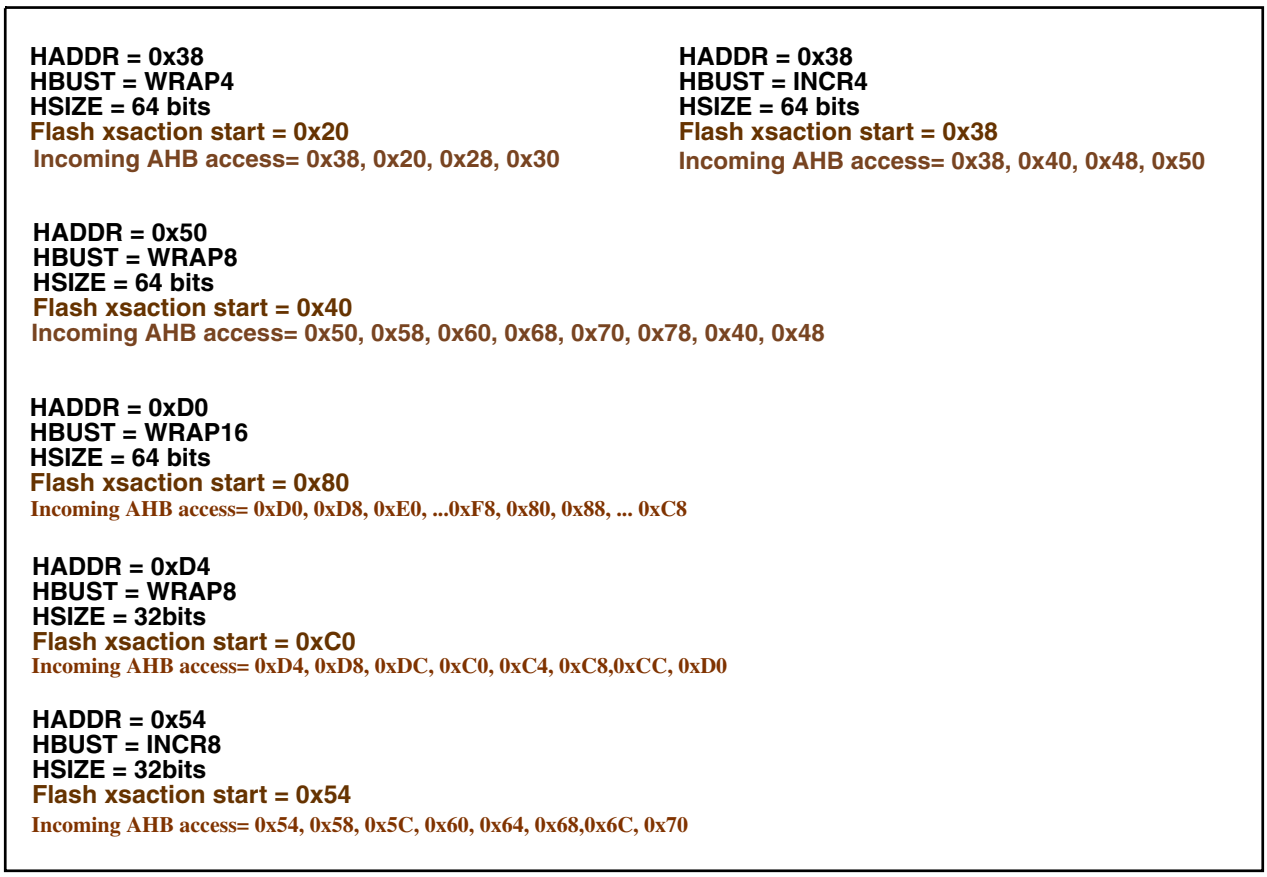

Figure 147. XSPI HBURST support

NOTE

The software must take care that the prefetch size should never be set less than the minimum data needed by any external interface to start processing.

NOTE

Whenever a core accesses XSPI memory with cache enabled, the prefetch size must be configured as equal or more than the cache line size; otherwise, FR[AIBSEF] error appears.

41.3.3.12.5 AHB read buffer status

The status of AHB sub-buffers is captured in AHB Buffer Status Register (AHB Buffer Status (AHB_BUF_STATUS)). Each of the sub-buffer status can take three values depending on which level the buffer is filled after the data prefetch. 00b – Sub-buffer is empty, 01b – Sub-buffer is full or 10b- Sub-buffer is partially full.

Sub-buffer can be empty in case no data prefetch has been started on that buffer since operation start or after clearing of buffers. It can be partially full in case prefetch is ongoing in that sub-buffer or prefetch was aborted in between or if the prefetch is suspended.

Status register fields SR[AHB0FUL, AHB1FUL, AHB2FUL, and AHB3FUL] also shows the individual buffers status as Full or not-empty. In case the sub-buffer division is disabled for that buffer these bits show the full or not-empty status for that buffer. In case sub-buffer division is enabled the buffer full status register bit get set to '1' if any of its sub-buffer is full.

41.3.3.12.6 AHB read performance monitors

XSPI provides a mechanism to track the hit and miss performance of AHB read transfers at every sub-buffer level. AHB Buffer Hit/Miss Performance Monitor Control Register (AHB Buffer Hit/Miss Performance Monitor Control (AHB_PERF_CTRL)) is used for controlling this performance monitoring. XSPI has four 16-bit Hit counters and four 16-bit miss counters which can be used for performance monitoring. Each set of counters is associated with a single AHB buffer partition and can be enabled by writing AHB_PERF_CTRL[BUFn_EN] fields. It can be further selected which sub-buffer the performance counters are restricted to, by using AHB_PERF_CTRL[SUB_BUF_SELn] fields. If the sub-buffer division is not enabled for that buffer irrespective of SUB_BUF_SEL programming it will monitor the accesses for complete buffer. After performing the required configuration in AHB_PERF_CTRL[CNTSTART] field can be written as '1' to start the performance monitoring. These counters work at system (AHB) clock.

Performance monitors have two 16-bit counters one for buffer hit (AHB read request address is found within the AHB buffer and no new read transfer is generated towards the flash or the incoming read request data is already part of prefetch ongoing on flash) and another for buffer miss (AHB read address is not present in the AHB buffers and is not equal to the address currently being prefetched from flash. It will cause a new read transaction to be generated towards flash).

After starting the performance counters the monitoring stops on any of the below conditions:

- If '1' is written to AHB_PERF_CTRL[CNTSTP] bit.
- If any of the buffer hit/miss counters overflow and corresponding overflow bit is set in AHB Buffer Hit/Miss Performance Monitor Control (AHB_PERF_CTRL).
- If the performance time counter overflows.

In case of overflow FR[PERFOVF] field is set in flag register and an interrupt can be generated if enabled in RSER register. The overflow bits in AHB Buffer Hit/Miss Performance Monitor Control (AHB_PERF_CTRL) remain latched unless this flag register bit is cleared by writing '1'. After the monitoring is stopped the values of the counters are updated in AHB Buffer n Performance Monitor (AHB Buffer n Performance Monitor (AHB_PERF_BUF0 - AHB_PERF_BUF3)) registers. In case of overflow the counter value may be shown as 0. The time period for which the performance monitoring is run is latched in AHB Performance Monitor Time Counter (AHB Performance Monitor Time Counter (AHB_PERF_TIME_CNT)). This is a 32-bit counter which is running on AHB clock frequency. These performance counters and time counter are cleared when new monitoring is started.

41.3.3.12.7 Stale data prevention inside AHB RX buffer

When AHB prefetch is enabled the AHB RX buffer is used to prefetch data as per size configured in BUFnCR[ADATSZ]. This can lead to stale data being present inside the AHB buffer in case any AHB or IP command is used to over write the address which is already prefetched inside the AHB buffer. To prevent stale data being read there are two options.

- Use SPTRCLR[PREFETCH_DIS] bit programming as '1' this will ensure that every time a new AHB read transaction starts it reads new data from external memory instead of reading the data already stored in AHB buffer. This method invalidates all the prefetched data in AHB buffers when a new AHB read transfer is started hence making sure that every new AHB transaction results in a buffer miss and new data is read in buffer.
- Use BFGENCR[WR_FLUSH_EN] bit. When this bit is programmed as '1' during IP command write or AHB write, XSPI checks for the address at which the data is being currently written. If the data for that corresponding address is already prefetched and present inside any of the AHB buffer/sub-buffer then it invalidates all data entries of that specific buffer/sub-buffer. The data present in rest of the buffers/sub-buffers is not changed.

41.3.3.13 AHB write

This module supports a single initiator AHB write with these burst types — INCR4, INCR8, INCR16, and INCR unspecified 4n bytes and single 4n bytes — and these burst types are supported with all HSIZE's. An AHB write transaction size can be expressed in multiples of 4 bytes, and a single transaction must have a minimum of 4 bytes. In case of HyperRAM ,this limitation of minimum 4 bytes is not present. Also unspecified INCR and single transactions are supported without the limitation of 4n bytes in case of HyperRAM. In case of RAM devices, this limitation of minimum 4 bytes is not present and also unspecified INCR and single transactions are supported without the limitation of 4 bytes. XSPI controller changes to the RAM mode in which, the write data mask can be done using DQS when MCR[DQS_OUT_EN] = 1. See OctalRAM support for more details.

The following restrictions apply to the XSPI module with respect to AHB write transactions:

- AHB transactions of WRAP* types are not supported. For these unsupported access types, the controller returns an AHB error response (HRESP) and does not initiate any flash memory transaction.
- Back to back, fixed address AHB write is not supported.
- Early burst termination is not supported for AHB transactions.

The XSPI controller queues back-to-back AHB writes with continuous address and sends them in a single flash memory transaction. However, in case the AHB address of a burst is not in continuous addressing sequence to previous write burst, a new flash memory transaction is initiated. Supports random read and Write operations for PSRAM devices.

Following is the programming sequence for an AHB write:

1. Check that SR[BUSY] is deasserted or is 0 and check that the TX buffer is empty. If there is any residue data present in the TX buffer (SR[TXNE]), the buffer must be cleared by writing '1' to MCR[CLR_TXF].
2. If the memory device used is a flash and based on the type of flash, AWRCR[PPW_WR_DIS] and AWRCR[PPW_RD_DIS] need to be programmed.

   The default reset value for both the fields is 0 and allows writing to flash memory device assuming a very low T_{pp} (page program wait time) period. This period is very high for most of the flash memory devices. After any write to a flash memory device, XSPI waits for the T_{pp} period to finish automatically before proceeding further when AWRCR[PPW_WR_DIS] = 1.

   This is controlled by the AWRCR[PPW_WR_DIS] and AWRCR[PPW_RD_DIS] field configurations.
3. Program the BFGENCR[SEQID] or BFGENCR[SEQID_WR] (if BFGENCR[SEQID_WR_EN] = 1) to point to the LUT where flash memory write sequence is stored.
4. AHB write initiator can now enable the transactions to be written to the flash memory.
5. When a flash memory write completes and flash memory CS is deasserted, the software must poll SR[BUSY] for the deasserted value, which is 0. This indicates that the AHB write is complete.
6. Whenever flash memory CS is deasserted after an AHB write sequence, FR[PPWF] is set if any of AWRCR[PPW_RD_DIS/PPW_WR_DIS] is enabled. FR[PPWF] disables any further flash memory read/write based on AWRCR[PPW_RD_DIS/PPW_WR_DIS]. After FR[PPWF] is set, any AHB transfer pending on bus remains in waiting state with HREADY low unless this flag is cleared.
7. On the expiry of wait period required for flash memory, FR[PPWF] is cleared by hardware or Software, depending on the BFGENCR[PPWF_CLR] bit. See Page program wait handling for details. After this flag is cleared, XSPI automatically generates another transfer for flushing the residue data in TX buffer, if any.
8. The software must ensure that the correct write LUT sequences are selected corresponding to the AHB write transactions. XSPI would malfunction if flash memory read sequence is selected during AHB write or vice versa.
9. SW should ensure that for NOR flash or other flashes where page program wait period is applicable after flash page programming (AWRCR[PPW_WR_DIS]=1), the AHB burst is broken at the page boundary crossing of flash. A new NON SEQ transaction should start after the page boundary crossing. XSPI generates AHB HRESP error if this condition is not met. For NOR flash devices this address should be 4 bytes aligned. Sequence-Abort scenario is generated to stop the ongoing TX in case of buffer underrun and No bus error will be generated. Another transaction will be generated with new calculated start address to send the residual TX data.

NOTE

- In case any IPS write transfer results in an under-run because of which some residue data is left in TX buffer and FR[TBUF] flag is set, the AHB write transfer will remain pending unless this flag is cleared by SW.
- In case of early abort (having residue data in TX FIFO) during an AHB write, all other requests are gated in arbitration till the residue data in TX buffer is flushed completely.

41.3.3.13.1 OctalRAM support

XSPI supports OctalRAM memories, and by virtue of this protocol, XSPI supports the following functionalities:

- Bidirectional data strobe/read write data strobe (RWDS)

- During command and address phase, to support normal/initial latency, the byte wise RWDS pad should be pulled down

- Variable refresh latency
  - If the value of MCR[VAR_LAT_EN] is 1, based on the status of RWDS from the memory device during the command/address phase, XSPI includes an additional initial access latency. If RWDS is high, XSPI includes twice the latency mentioned in the dummy phase. If RWDS is low, latency mentioned in the dummy phase is not included.
  - In XSPI, MCR is not part of LUT programming, so, if MCR[VAR_LAT_EN] = 0, then the RWDS status is not considered by the XSPI for dummy cycle latency.
  - If the value of MCR[VAR_LAT_EN] is not set, fixed latency mentioned in the dummy phase is included.
- Read data strobe to latch data from memory device
- Programming considerations:
  - Data masking during the AHB write is enabled when MCR[DQS_OUT_EN] is programmed as 1.

41.3.3.13.2 Page program size

In some of the external flash devices there is a restriction that data can be written only for a defined page size in a single flash program cycle. To adhere to this restriction for AHB write transfers, SFACR[PPWB] field can be programmed. This page program boundary size should be programmed in Log2 (size in bytes) format. If the AHB transfer is crossing this defined page boundary then XSPI breaks the transfer at page boundary and waits for flash programming to complete. Then it generates a new flash programming transfer from next page boundary.

Software should ensure that starting AHB address is 32 bit aligned so that at page boundary the limitation of AHB transaction in multiple of 4 bytes is maintained wherever required.

41.3.3.13.3 Timeout in case of AHB write

In case of AHB write if the AHB interface is not served and HREADY is kept low then timeout occurs and FR[AITEF] is set. If no AHB data has been accepted by XSPI (TX buffer is empty assuming no IPS transfer is currently ongoing) then after timeout remaining beats of the AHB write burst are given AHB HRESP error and AHB state machine recovers. But in case the data is accepted in the TX buffer (TX buffer not empty) for multiple beats but no transfer has been generated towards the flash. This situation may occur because of wrong SEQID programming or some other reason. If a timeout occurs in this situation then a SW reset (MCR[SWRSTHD]) will be required to clear the TX buffer and reset the AHB state machine.

41.3.3.14 Byte ordering of serial flash memory read data

The basic scheme is that the first byte read out of the serial flash memory device, which is addressed by SFAR[SFADR], corresponds to RBDR0[31–24] for IP command read. Similarly, to send a single byte it should be positioned in TBDR[7–0]. In contrast to that for AHB command read, the bytes are always positioned according to the byte ordering of the AHB bus.

- Byte ordering in individual flash memory mode

  The following table provides the byte ordering scheme of how the byte oriented data space of the serial flash memory device is mapped into one single 32-bit entry of the RX buffer or the AHB buffer. The table is valid within the following context:
  - Flash memory A in individual flash memory mode
  - All AHB data read commands with 32-bit access size

Table 335. Byte ordering in individual flash memory mode

Serial flash memory byte numbering	3	2	1	0
Buffer entry bit position [31–0] (32-bit data width)	[31–24]	[23–16]	[15–8]	[7–0]

NOTE

For IP commands, the read size can be specified as number of bytes. If this number is not a multiple of four, then the last buffer entry is not completely filled with the missing higher numbered bytes at undefined values.

For AHB commands and reads, starting from an address not aligned to 32-bit boundaries, the requested bytes are given at the appropriate positions according to the AMBA AHB specification.

- Buffer entry ordering for 64-bit read access

  For read access via the AHB interface, a 64-bit access is possible. Each 64-bit access reads two 32-bit entries, simultaneously. The ordering of these 32-bit entries within the 64-bit word is provided in the following table.

Table 336. 64-bit read access buffer entry ordering

AHB read data bit position [63–0]	[63–32]	[31–0]
Buffer entry #	Even (0, 2, 4, ...)	Odd (1, 3, 5, ...)

41.3.3.15 Normal mode interrupt and DMA requests

XSPI module has different flags that can only generate interrupt requests and one flag that can generate an interrupt as well as DMA requests. The following table lists the eight conditions. Note that the flags mentioned in the table are associated with the Flag (FR).

Table 337. Interrupt and DMA request conditions

Condition	Flag (FR)	DMA
Data learn pattern failure	DLPFF	-
TX buffer fill	TBFF	-
TX buffer underrun	TBUF	X
Illegal instruction error	ILLINE	-
RX buffer drain	RBDF	X
RX buffer overflow	RBOF	-
AHB buffer overflow	ABOF	-
AHB sequence error	ABSEF	-
AHB illegal transaction error	AITEF	-
AHB illegal burst size error	AIBSEF	-
IP command trigger could not be executed error	IPIEF	-
IP command related transaction finished	TFF	-

Each condition has a corresponding field in Flag (FR) and a request enable field in Interrupt and DMA Request Enable (RSER). FR[RBDF] has separate enable fields for generating IRQ and DMA requests. Note that not all the fields have an individual IRQ line. See the chip's Interrupt Vector table for details.

- Transmit buffer fill interrupt request

  This indicates that the TX buffer can accept new data. The buffer fill interrupt is asserted if FR[TBFF] is asserted and if the value of the corresponding enable field, RSER[TBFIE], is 1. See TX buffer Operation for details on the assertion of FR[TBFF].

  Apart from IRQ, it is possible to handle the TX buffer fill by using the DMA. If the value of RSER[TBFDE] is 1, a DMA request is triggered when the number of available space in the TX buffer is more than the TBCT[WMRK] valid entries and value of

SR[TXWA] is set. The application must configure the environment appropriately (for example, the DMA controller) for the DMA transfer.

In SFP Enabled configurations, program RSER[TBFDE] bit to 1 only when arbitration is won and TBDR access is unlocked after checking STATE field of FSMSTAT register. After TBDR programming is completed by DMA, reset this bit otherwise, XSPI SFM state will remain busy and no further IPS accesses can be served by that Target queue.

- Receive buffer drain interrupt or DMA request

  This is derived from FR[RBDF], indicating that the RX buffer of the XSPI module has data available from the serial flash memory device to be read by the host. It remains set as long as SR[RXWE] is configured. Also, RSER[RBDIE] enables the related IRQ.

  Apart from the IRQ, it is possible to handle the RX buffer drain by using the DMA. If the value of RSER[RBDDE] is 1, a DMA request is triggered when the RX buffer contains more than RBCT[WMRK] valid entries. The application must set the environment appropriately (for example, the DMA controller) for the DMA transfers.

- Buffer overflow/underrun interrupt request

  This is a combination of the following fields (all located in the Flag (FR) with the related enable bits in the Interrupt and DMA Request Enable (RSER)):

  — TBUF - TX buffer underrun, enabled by TBUIE

  — RBOF - RX buffer overflow, enabled by RBOIE

  — ABOF - AHB buffer overflow, enabled by ABOIE

  — The transmit buffer underrun indicates that an underrun condition in the TX buffer has occurred. It is generated when a write instruction is triggered whilst the TX buffer is empty and the value of RSER[TBUIE] is 1.

  — The receive buffer overflow indicates that an overflow condition in the RX buffer has occurred. It is generated when the RX buffer is full, an additional read transfer attempts to write into the RX buffer, and the value of RSER[RBOIE] is 1.

  — The AHB buffer overflow indicates that an overflow condition in the AHB buffer has occurred. It is generated when the AHB buffer is full, an additional read transfer attempts to write into the AHB buffer and the value of RSER[ABOIE] is 1.

  — The data from the transfers that generated the individual overflow conditions is ignored.

- Serial flash memory command error interrupt request
- Transaction finished interrupt request

  The IP command transaction finished IRQ indicates the completion of the current IP command. It is triggered by FR[TFF] and is masked by RSER[TFIE].

IPED decryption error interrupt is generated in case the IPED module generates an error during data decryption. It can be enabled using RSER[IPEDIE].

AHB read address error interrupt is generated in case the read address given by AHB interface does not lie in any of the sub-buffer address ranges or lies within multiple sub-buffers address range of a single buffer. It is triggered by FR[RDADDR] and can be enabled using RSER[RDADDRIE].

Performance monitors overflow interrupts are triggered by FR[PERFOVF] and can be enabled by RSER[PERFOVIE] bit. these are generated when any of the performance monitor counter overflows.

Arbitration lock timeout interrupt is triggered by ERRSTAT[ARB_LOCK_TO] and is generated when arbitration lock requested by any SFP queue is not cleared and results in timeout counter expiring. It can be enabled by INT_EN[ARB_TO_IE].

Arbitration win interrupt is generated when any TG queue which has requested the transfer is granted. It can be enabled by INT_EN[ARB_WIN_IE] and is triggered by ERRSTAT[ARB_WIN].

41.3.3.16 Address schemes

Earlier, serial flash memories supported only a 24-bit address space, restricting the maximum memory size of the serial flash memory to 16 MB. The new memory specification supports two types of 32-bit addressing mode in addition to the legacy 24-bit address mode. It also supports segregation of address programmed into Row address and Column address of the flash memory.

Extended address mode

In this mode, the legacy 24-bit commands are converted to accept 32-bit address commands. The memory will default to the legacy 24-bit mode (only the first 16 MB of the memory can be accessed while in this mode), and the memory must be configured for 32-bit address mode to access the entire memory. Also, while programming the LUT sequence in XSPI for 32-bit mode, the ADDR and ADDR_DDR commands should be programmed with 32d as the operand value with SFACR[CAS] programmed to 0. If a flash memory needs some bits of the address as its column address, then it must be considered that a total of 12 bits are required by the flash memory; however, the number of bits should not exceed 32 because the maximum address supported by XSPI is 32 bits.. Each of the memory vendors have a different way of enabling this mode (see the memory specification from memory vendors). For example, the command B7h sent to the Macronix flash memory enables it for the 32-bit address mode.

Extended address register mode in external memory device

In this mode, the upper 8 bits of the 32-bit address are provided by the Extended address register in the memory. This effectively converts the legacy 24-bit address command into 32-bit address commands. The memories greater in size than 16 MB consist of banks of 16 MB each. The 8 bits occupied in the extended address register effectively enable a bank. For example, in Spansion memory, when the extended address register is updated with a value of 1h, with the help of the 17h command, it opens Bank1 of the memory. The consequent 24-bit address commands access Bank1. The extended address register needs to be updated with the respective value for access to other banks.

Separation of address into rows and columns

This mode has been introduced for flash memories that need addresses segregated into rows and columns. The value in SFACR[CAS] defines the width of the column address required by a flash memory. The actual address to be provided is derived from the incoming address in case of AHB-initiated transactions and the value of SFAR in case of IPS-initiated transactions, if the value of SFACR[CAS] is 0. Otherwise, the actual address takes CAS into consideration. If the value of SFACR[CAS] is 3, then bits 26-3 of the programmed address are sent to the flash memory as its page/row address and bits 2-0 are sent as its column address. If a flash memory requirement for column address is less than the number of pads in which address has to be sent, then XSPI appends the remaining bits by 0. You must program the operand value in CADDR and CADDR_DDR command accordingly. The total number of address bits in the column and row address must be 32-bits or less.

Word addressable mode for flash memory

This mode has been introduced for flash memories, which have a word-addressable memory. This means, each address of the flash memory contains one word (two bytes) of data. The value of SFACR[WA] is configured to 1 to enter this mode. If the address of flash memory contains two-words (4 bytes) of data, set the XSPI's SFACR[WA_4B_EN]. XSPI internally divides the incoming address in the AHB bus or the address in the SFAR to map it to a valid flash memory location. For example, if the incoming address is 2004h, the controller re-maps this address to access the flash memory location 1002h.

41.3.3.17 AHB alignment

XSPI module can define the AHB transaction (read/write) address boundary using BFGENCR[ALIGN]. Any continuous AHB write transfer is broken into smaller sub-accesses at the address boundary specified using the BFGENCR[ALIGN] field setting.

For AHB read transactions, XSPI checks the start address and end address (start address + ADATSZ programmed in BUFnCR registers) to see if it is crossing the address boundary specified by ALIGN. If the transaction crosses the address boundary, then it reduces the transaction size such that the data pre-fetch is stopped before the address boundary. Now, if the AHB initiator is reading the data sequentially it will get buffer hits up to the ALIGN boundary. When it reaches the next address boundary it will get a buffer miss and a new data pre-fetch will be launched towards the external memory device.

For AHB write transfers, XSPI keeps track of the start address and then compares it with the address of subsequent transaction received on the AHB bus. When the boundary programmed in BFGENCR[ALIGN] field is reached, XSPI negates AHB HREADY to block new accesses. This signal will be kept low until all the previous received write data is written to external memory and chip select is de-asserted. After that it allows next AHB write data to be received by making HREADY high thus ensuring that transaction is split at address boundary on external memory.

41.3.3.18 AHB transaction split

41.3.3.18.1 Write split

When this feature is enabled (BFGENCR[SPLITEN]=1), HW will split one single AHB write burst into smaller bursts on flash side, based on BFGENCR[AHBSSIZE] setting.

Assumptions:

When IPED GCM is enabled, Split size should be N*32B and the split happens on 40B/80B so that the Header/authentication is included with every block.

NOTE

When split is enabled, as the alignment logic will work before the split, both will work parallel and needed. When IPED is enabled alignment logic is used to handle the context boundary crossing(GCM and CTR) in a single transaction.

41.3.3.18.2 Read split

When this feature is enabled (BFGENCR[SPLITEN]=1), HW will realign the prefetch size to split size and in that way splits a single read burst into smaller bursts, based on BFGENCR[AHBSSIZE] setting.

Assumptions:

WRAP bursts will not work if the total burst size exceeds the split size.

When IPED GCM is enabled, the split size should be 32B/64B. HW will the split the bursts into 40/80 Bytes to include Header/authentication tag for each block.

41.3.4 Stop and module disable modes

41.3.4.1 Stop mode

XSPI supports the Stop mode protocol using the Stop request and Stop request acknowledgement handshake. By default, Stop request acknowledgement signal is de-asserted. When a request is made to enter Stop mode, the XSPI block acknowledges the request by asserting Stop request acknowledgement when it is ready to have its clocks shut off.

XSPI will return the Stop request acknowledgement handshake when all the conditions below are fulfilled:

- SR[BUSY] = 0
- SR[AHBTRN] = 0
- RBSR[RDBFL] = 0
- SR[RXDMA] = 0
- SR[TXDMA] = 0
- No pending interrupts (none of the flags in Flag (FR) that are enabled as interrupts is set).

The conditions mentioned above ensures the following:

- There is no SFM command currently being executed.
- All the data read into the RX buffer from the serial flash memory have been fetched by the application.
- There is no current AHB access.
- There is no active DMA request.
- There is no enabled interrupt that is pending.

While the clocks are shut off, the XSPI memory-mapped logic is not accessible. In Stop mode, write to XSPI registers is disabled and does not have any effect.

NOTE

It is illegal to issue a new SFM command starting two clock cycles prior to raising the request of entering Stop mode until the XSPI stays in this mode. Software must ensure that there are no pending transactions in SFP queues before requesting Stop or Module Disable mode.

41.3.4.2 Module Disable mode

Module Disable mode is a block-specific mode that the XSPI can enter to disable serial flash memory clock and AHB command. This mode can be entered by:

- The host software: by asserting MCR[MDIS].
- The hardware: by asserting the ipg_doze signal while MCR[DOZE] is asserted.

Below are the conditions that are checked by hardware before asserting acknowledgment as part of stop request/acknowledgment handshake to enter Module Disable mode:

- SR[BUSY] = 0
- SR[AHBTRN] = 0
- RBSR[RDBFL] = 0
- SR[RXDMA] = 0
- SR[TXDMA] = 0
- None of the flags in Flag (FR) are enabled as interrupts is set.

The conditions mentioned above ensures the following:

- There is no SFM command currently being executed.
- All the data read into the RX buffer from the serial flash memory have been fetched by the application.
- There is no current AHB access.
- There is no active DMA request.
- There is no enabled interrupt that is pending. SFP interrupts are not checked here so software needs to handle those.

In Module Disable mode, few configuration fields (mentioned in MCR and SMPR register function) of XSPI can only be written.

NOTE

It is illegal to issue a new SFM command starting two clock cycles prior to raising the request of entering the Module Disable mode until the XSPI stays in this mode. Software should follow stop acknowledgment handshake to ensure that there are no pending transactions in SFP queues while requesting stop or module disable mode.

41.3.4.3 Leaving Stop mode and Module Disable mode

After XSPI has returned to Normal mode, the execution of the first SFM command is deferred until the clock to drive that part of the module related to the serial flash memory device is available.

41.3.5 Dummy cycles generation

The operand value for a DUMMY instruction (LUT*n*[OPRND*n*]) controls the dummy cycle operation as described in the following table.

- Bit 7 of the operand value controls split DUMMY operation. That is, if bit 7 is 1 (OPRND*n* > 80h), XPSI performs a split DUMMY operation.
- Bits 6–0 specify the number of cycles for the DUMMY operation, with modification resulting from the split DUMMY, RWDS, and variable latency settings.

For example sequences that use the dummy cycle capability, see Example LUT sequences.

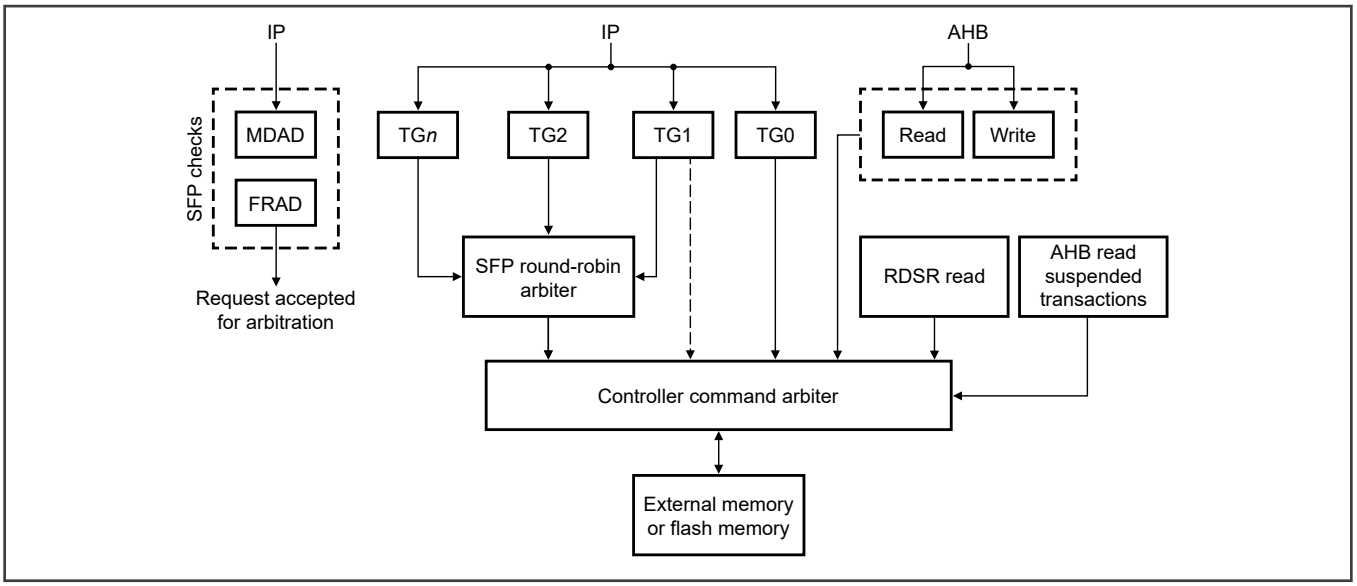
Table 338. Dummy cycles generation

Operand		RWDS[1]	Variable latency [2]	Dummy cycles	Notes
Bit 7	Bits 6–0 (*m*)				
1	> 1[3]	Asserted	1	2*m* + 1	This scenario requires one extra cycle to achieve 2x cycle latency. You accomplish this by inserting a MODE instruction (which adds 1 cycle) before the DUMMY instruction. With RAM devices, for *m* cycles, specify *m* – 1 in the operand.
0	> 1[3]	Asserted	1	2*m* + 2	—
1 or 0	> 1[3]	—	0	*m* + 1	—
1	0[4]	Asserted	1	3	—
0	0[4]	Asserted	1	4	—
0	0[4]	—	0	2	Two is the minimum number of dummy cycles.

1. Read Write Data Strobe
2. MCR[VAR_LAT_EN]
3. All pads act as inputs.
4. All pads act as outputs.

41.3.6 IP and AHB command arbitration

XSPI controller supports arbitration between the flash accesses coming from IP interface and AHB interfaces. The arbitration scheme is shown in figure below:



NOTE

Above figures shows 'n' number of TG queues but only 2 TG queues exist. Also SFP round-robin arbiter is not present and TG1 request directly goes to Controller command arbiter.

Arbitration priority between different requests coming to controller command arbiter block is given in table below with 1 being highest priority order.

Transaction request	Priority order
TG0 (IP command)	1
AHB write	2
AHB Read	3
Suspended AHB Read transaction	4
TG 1 (IP command)	5
Reserved	6
RDSR read	7

On IP command interface the incoming access requests can be filled in multiple TG queues based on the access criteria being set in SFP block. They are presented for arbitration only after they have passed through the MDAD and FRAD checks of SFP.

On AHB interface only one transaction from read and write can come at a time. AHB Read transaction is presented for arbitration only in case of buffer miss (when data is not present inside AHB buffer and has to be read from the external memory device). The suspended AHB Read prefetch requests are generated as a part of AHB Read requests when no high priority AHB Read initiators are pending on the bus. In case any AHB Write transfer comes, it may abort any ongoing read-prefetch or any suspended read transfers. For AHB Write, the requests generated after an early abort (data left in TX Buffer and CS de-asserted) are taken at highest priority level (even higher than TG0) as the data is already present inside the TX Buffer or is part of ongoing AHB Write transfers. Early abort in AHB Write is treated as pending AHB Write transfer which is in continuation of last AHB Write request. The RDSR read requests are generated when Page program wait period is ongoing after an AHB Write transfer has completed. This is not a software generated request; it is automatically generated by XSPI as part of page program period handling. See AHB command page program wait handling for details.

The arbitration state machine remains in IDLE state and then moves on to ARB state after the requests have arrived for arbitration. It remains in ARB state for one clock cycle then moves on to the state which has been granted arbitration, for example, AHB write, AHB Read, or SFP IPS TG state. After the flash transfer is completed the state machine goes to PROC_FIN state and waits for other blocks to finish the processing before going for next arbitration. The current state can be checked by reading Status Register (SR[ARB_STATE]).

Please refer the below tables for some of the examples of arbitration scenarios:

Table 339. Arbitration scenarios for handling AHB and IPS requests

Arbitration category	Environment-1 operation (Ongoing)	Environment-2 operation (New Request)	Scenarios
AHB-AHB	AHB Read	AHB Read	**Scenario 1: Normal Read** AHB Read from Environment-2 will wait till AHB Read from Environment-1 (ongoing) completes. **Scenario 2: High priority based suspend transaction** AHB Read prefetch is ongoing for low priority AHB initiator from Environment-1. Higher priority AHB Read request from Environment-2 will suspend the ongoing prefetch and arbitration will be granted to Environment-2.
	AHB Read	AHB Write	**Scenario 1: Contention for grant**

Table continues on the next page...

Table 339. Arbitration scenarios for handling AHB and IPS requests (continued)

Arbitration category	Environment-1 operation (Ongoing)	Environment-2 operation (New Request)	Scenarios
			AHB Read request (Environment-1)and AHB Write request (Environment-2) are present at arbiter for contention. As per Arbitration Priority (AHB Write is having greater priority than AHB Read) - Environment-2 will be given grant. **Scenario 2: Write terminate enabled (BFGENCR[WRTER_EN] = 1b)** AHB Read prefetch for Environment-1 is ongoing. AHB Write comes for Environment-2 and aborts the ongoing read prefetch and takes the grant. **Scenario 3: Write terminate disabled (BFGENCR[WRTER_EN] = 0b)** AHB Read prefetch for Environment-1 is ongoing. AHB Write comes for Environment-2. Grant to AHB Write is given after completion of AHB Read prefetch.
	AHB Write	AHB Read	**Scenario 1: Normal write before Read** AHB Read request (Environment-2) is granted after the completion of AHB Write (Environment-1). **Scenario 2: Wait period with Read While Write (RWW) NOR Flash** AHB Write from Environment-1 is completed (SR[BUSY] = 0b), FR[PPWF] is set, AWRCR[PPW_WR_DIS] is set, AWRCR[PPW_RD_DIS] is not set. AHB Read from Environment-2 comes on top. RWW flash, AHB Read is allowed during wait period, hence the arbitration will be given to the AHB Read from Environment-2. **Scenario 3: Wait period with non-RWW NOR Flash** AHB Write is completed (SR[BUSY] = 0b), FR[PPWF] is set, AWRCR[PPW_WR_DIS] is set, and AWRCR[PPW_RD_DIS] is set. Non-RWW flash, AHB Read is not allowed during wait period, hence the arbitration will not be given to the AHB Read (Environment-2) till PPW period is over. **Scenario 4: No wait period with PSRAM** There is no PPW (wait period) for PSRAM. AHB Read request (Environment-2) is granted after the completion of AHB Write (Environment-1).
	AHB Write	AHB Write	**Scenario 1: Continuous address - no PPW**

Table continues on the next page...

Table 339. Arbitration scenarios for handling AHB and IPS requests (continued)

Arbitration category	Environment-1 operation (Ongoing)	Environment-2 operation (New Request)	Scenarios
			Due to continuous address both AHB Write will be executed in the same grant. First AHB Write from Environment-1 followed by AHB Write from Environment-2. **Scenario 2: Random address - PPW** Due to random address, HREADY is pulled low to not allow AHB Write from Environment-2. Flushing mechanism is used to flush the data for AHB Write from Environment-1. Once the AHB Write from Environment-1 is completed, FR[PPWF] is set. During FR[PPWF], AHB Write request from Environment-2 is stalled till FR[PPWF] is over.
AHB-IPS	AHB Read	IPS Read	**Scenario 1: Normal operation** AHB transaction is ongoing, IPS transaction request is put on stall till the AHB transaction is completed (SR[BUSY] = 0b). **Scenario 2: AHB Read with HREADY timeout** User environment went dormant at Environment-1 causing FR[AITEF] flag to be set (HREADY timeout). IPS Read will be stalled. **Recovery mechanism:** On applying soft reset simultaneously on AHB and flash side, will release the AHB grant. Arbitration goes to IDLE as SR[BUSY] = 0b (due to chip select deassertion). Arbitration is given according to priority for the pending requests. In this case IPS is given grant **Cost:** Software needs to re-initiate the AHB transaction for Environment-1 from the address reported by XSPI during soft reset. Due to this pending IPS request from Environment-2 gets the grant and AHB transaction will be delayed.
	AHB Read	IPS Write/Erase	
	AHB Write	IPS Write/Read	**Scenario 1: Underrun - Residue data in TX path** No issue as early abort flag is set and auto flushing mechanism will be executed for flushing the residue data. The arbitration is blocked for IPS transaction (Environment-2). **Scenario 2: PPW for Non-RWW flash** AHB Write is completed (SR[BUSY] = 0b), FR[PPWF] is set, AWRCR[PPW_WR_DIS] is set, and AWRCR[PPW_RD_DIS] is set. IPS comes on top: Due to FR[PPWF] set, IPS transaction is stalled. Due to AWRCR[PPW_WR_DIS] and AWRCR[PPW_RD_DIS] is set, AHB Write and AHB Read are also blocked.

Table continues on the next page...

Table 339. Arbitration scenarios for handling AHB and IPS requests (continued)

Arbitration category	Environment-1 operation (Ongoing)	Environment-2 operation (New Request)	Scenarios
			Scenario 3: PPWF with HREADY timeout AHB Write is completed, FR[PPWF] flag is set, HREADY timeout happens. Due to FR[PPWF] flag Arbitration is blocked for IPS and arbitration lock timer will start. To clear the hang scenario software reset is used. Software reset does not clear the FR[PPWF] flag. After software deassert, as PPW is there, IPS will be blocked,only RDSR request will be given grant. **Scenario 4: PPWF with HREADY timeout and Arbitration Lock timeout** AHB Write is completed, FR[PPWF] flag is set, HREADY timeout happens, Arbitration lock timeout also occurred. Due to FR[PPWF] flag Arbitration is blocked for IPS and arbitration lock timer will start and arbitration lock timeout is generated on reaching arbitration counter max value. To clear the hang scenario software reset is used. Software reset does not clear the FR[PPWF] flag. After software deassertion, as PPW is there, IPS will be blocked, only RDSR request will be given grant.
IPS-AHB	IPS Read	AHB Read/Write	**Scenario 1:** IPS Read is ongoing, AHB will wait till the IPS is completed (SR[BUSY] = 0b). **Scenario 2:** While reading data through IPS, User became dormant, MTO came. IPS grant is release. AHB Grant is gated until MTO is cleared by Main environment.
IPS-IPS	IPS Read	IPS Write/Erase	**Scenario 1: If any ongoing queue becomes dormant and it has not taken arbitration lock** SW: 1. Main environment needs to clear the TX Buffer, once MTO happens and SR[TXNE] flag is set. 2. After clearing the TX Buffer, Main environment needs to clear the corresponding interrupt flags (for FR[TBUF]) by writing W1C (XSPI HW will clear the interrupt for User environment, once the Main environment acknowledges them). 3. Main environment needs to clear it's own timeout flag.
	IPS Write/Erase	IPS Write/Erase	

Table continues on the next page...

Table 339. Arbitration scenarios for handling AHB and IPS requests (continued)

Arbitration category	Environment-1 operation (Ongoing)	Environment-2 operation (New Request)	Scenarios
			New environment which got grant has to wait for these steps and FSMSTAT[STATE] will remain 00b until then. **Scenario 2: If any ongoing queue becomes dormant and it has taken arbitration lock** SW: • Main environment needs to clear the TX Buffer, once MTO happens and SR[TXNE] flag is set. • After clearing the TX Buffer, Main environment needs to clear the corresponding interrupt flags (for FR[TBUF]) by writing W1C (XSPI HW will clear the interrupt for User environment, once the Main environment acknowledges them). • Main environment needs to clear it's own timeout flag. • Main environment to release arbitration lock through W1C field of ERRSTAT register after arbitration timeout error happens. **Scenario 3: SFP transaction has been arbitrated with arbitration lock and TBDR is being filled and User environment became dormant** • Main environment needs to clear TX Buffer/RX Buffer once MTO happens. • Main environment needs to clear it's own timeout flag. Arbitration stays with that TG queue until Arbitration lock timeout error comes and is acknowledged by the Main environment. **Scenario 4: SFP transaction has been arbitrated with arbitration lock and User environment was reading data and became dormant** 1. Main environment needs to clear the TX Buffer/RX Buffer once MTO happens. 2. After clearing the RX Buffer, Main environment needs to clear the corresponding interrupt flags (for FR fields: RFDF if set) by writing W1C (XSPI HW will clear the interrupt for User environment, once the Main environment acknowledges them). 3. The Main environment needs to clear it's own timeout flag. Arbitration stays with that TG queue until Arbitration lock timeout error comes and is acknowledged by the Main environment.

Table continues on the next page...

Table 339. Arbitration scenarios for handling AHB and IPS requests (continued)

Arbitration category	Environment-1 operation (Ongoing)	Environment-2 operation (New Request)	Scenarios
			Scenario 5: TBDR is filled above threshold. XSPI is triggered with SFAR and IPCR and user became dormant and underrun came (watermark is wrongly programmed) **Situation:**Flash will request data, since User environment became dormant, underrun will happen (FR[TBUF] = 1b). SW: 1. Main environment needs to clear the TX Buffer, once MTO happens and SR[TXNE] flag is set. 2. After clearing the TX Buffer, Main environment needs to clear the corresponding interrupt flags (for FR[TBUF]) by writing W1C (XSPI HW will clear the interrupt for User environment, once the Main environment acknowledges them). 3. Main environment needs to clear it's own timeout flag. New environment which got grant has to wait for these steps and FSMSTAT[STATE] will remain 00b until then. **Scenario 6: Arbitration lock is requested and TBDR is filled above threshold. XSPI is triggered with SFAR and IPCR and MTO happened (too much time due to wrong MTO programming)** **Situation:**Flash will request data, since User environment became dormant, underrun will happen (FR[TBUF] = 1b) 1. Main environment needs to clear the TX Buffer, once MTO happens and SR[TXNE] flag is set. 2. After clearing the TX Buffer, Main environment needs to clear the corresponding interrupt flags (for FR[TBUF]) by writing W1C (XSPI HW will clear the interrupt for User environment, once the Main environment acknowledges them). 3. Main environment needs to clear it's own timeout flag. 4. Main environment to release arbitration lock through W1C field of ERRSTAT register after arbitration timeout error happens.
Semaphore	IPS Write/Erase	AHB Read	**Scenario:** Initiator (with domain ID) is given semaphore lock, IPS Transaction is ongoing, AHB Read request from the same initiator (domain ID) comes, then it will be given grant only after IPS is finished. Any AHB request from any other AHB initiator is given error.

Table 340. SFP round-robin arbitration scenarios for handling multiple IPS requests

Scenario	FSM State	MTO error	Arbitration lock requested	Arbitration lock counter	SW workaround
TG Queue has been granted but XSPI is busy	0	No	Yes	Not started (Since FSM state is 00)	TG will wait for XSPI to be idle. See XSPI IDLE conditions section
SFP transaction has been arbitrated and TBDR is being filled and User environment became dormant.	1	Yes (User environment became dormant)	Yes	Started (As soon as MTO error happens)	1. Main environment needs to clear the TX Buffer/RX Buffer pointers once MTO happens. 2. Main environment needs to clear its own timeout (MTO) flag ERRSTAT[TO_ERR] by W1C. 3. Status of TX Buffer register (TBSR) and RX Buffer register (RBSR) for that User environment queue is not updated unless the queue wins the arbitration again (keeping the last value). Arbitration stays with that TG queue until Arbitration lock timeout error comes and is acknowledged by the Main environment.
SFP transaction has been arbitrated and TBDR is filled above threshold. XSPI is triggered with SFAR and IPCR and MTO error happened	10	Yes	Yes	Started (As soon as MTO error happens)	
SFP transaction has been arbitrated and User environment was reading data and became dormant	11	Yes (User environment became dormant)	Yes	Started (As soon as MTO error happens)	1. Main environment needs to clear the TX Buffer/RX Buffer pointers once MTO happens. 2. Main environment needs to clear its own timeout (MTO) flag ERRSTAT[TO_ERR] by W1C. 3. Status of TX Buffer register (TBSR) and RX Buffer register (RBSR) for that User environment queue is not updated unless the queue wins the arbitration again (keeping the last value). 4. After clearing TX/RX Buffer, Main environment needs to clear the corresponding interrupt flags (for FR field: RBDF if set) by writing W1C. Arbitration stays with that TG queue until Arbitration lock timeout error comes and is acknowledged by the Main environment.

41.3.6.1 Page program wait handling

In many of the external flash memories there is a limitation of page program wait. After programming the flash no other access can be forwarded to the flash for some time duration.

41.3.6.1.1 IP command page program wait handling

In case of IP command when flash programming is done, arbitration can be locked by the TG queue which will not allow any other access request to go through unless this arbitration is unlocked by the same TG queue. This makes sure that the duration for which arbitration was locked no other request from AHB/IPS interface can go through except the transfer requests from TG queue which locked the arbitration. So effectively the arbitration remains granted for only the TG queue which has locked the arbitration. Software needs to ensure that after arbitration is locked it does not generate any transfers on that TG queue which can conflict with the page program requirements of flash. It can use this TG queue to read the status register of flash to check if page program wait period has finished, and then it can unlock the arbitration. If it is a RWW type of flash which allows read transactions even during page program wait period, then it can send flash read transfers also through during this arbitration lock period. These read transfers should be targeted on separate Flash block/FRAD region.

For details, see Arbitration lock.

In GCM mode, if a page boundary is crossed, the hardware automatically handles the page program wait period before initiating the next page program for the remaining data.

41.3.6.1.2 AHB command page program wait handling

In case of AHB transaction, based on the type of flash memory device that is used for page programming, software should configure AWRCR[PPW_WR_DIS] and AWRCR[PPW_RD_DIS] fields. The default reset value for both the fields is 0 and allows writing to flash memory device assuming a very low T_{pp}(page program wait time) period. This period is very high for most of the flash memory devices.

Whenever flash memory CS is de-asserted after an AHB write sequence completes, FR[PPWF] is set either of AWRCR[PPW_RD_DIS/PPW_WR_DIS] is set. If both the bits are set (AWRCR[PPW_RD_DIS] and AWRCR[PPW_WR_DIS]) then XSPI locks the arbitration and all accesses to the external memory are blocked. During this period if any AHB read access comes which results in buffer-hit the data is provided after reading from AHB buffer. If AHB read results in buffer miss, it will be kept in waiting state by the XSPI arbiter by keeping HREADY low. An AHB bus error (if SOCCFG[HRESP_ERR_MASK] is 0) is generated for all AHB write transfers. During this period all IP commands are blocked, so there is no mechanism by software to trigger a status register read towards the external memory device.

If only AWRCR[PPW_WR_DIS] is '1' but AWRCR[PPW_RD_DIS] is programmed as '0' then it means that flash is a RWW type and it can handle read transactions during this page program wait period. In this case all IP commands and any AHB write command is blocked from arbitration but any AHB read command will go through to external memory.

It should be ensured that correct programming is done for these bits based on the external memory/flash being used. Also ensure that in case of RWW flash, where AWRCR[PPW_RD_DIS] is '0', software ensures that any additional requirement on read transfer is met. For example, in some cases of RWW the read transaction is allowed during page program wait period but on different sector. It is the application's responsibility to ensure AHB read commands are launched to different sectors/pages from the AHB write that is completing. XSPI controller can’t check/handle these kind of limitations.

41.3.6.1.2.1 RDSR status read

When FR[PPWF] flag is set an internal counter starts within XSPI. After this counter reaches the value programmed in Page Program Wait Time Counter (PPWF_TCNT), a read is triggered by the XSPI module using the SEQID programmed in BFGENCR[SEQID_RDSR]. This counter is working on AHB clock frequency. It is required that this location in LUT is programmed with the required commands for reading the flash status register. After the time period programmed in this counter is reached and status register is read from the flash its value is updated in PPW_RDSR[RDSR] field and PPW_RDSR[VALID] field is set to '1'. The counter is reset to 0 and it again starts incrementing. This PPW_RDSR[31] field will remain set to '1' unless FR[PPWF] flag is cleared and PPW_RSDR[RSDR] bits will keep on updating its value as and when this counter reaches its programmed value. Software needs to ensure correct programming of the register fields in Page Program Wait Read Status (PPW_RDSR) register and correct LUT programming sequence for reading the flash status register as per BFGENCR[SEQID_RDSR]. Now there are two mechanisms to clear this FR[PPWF] flag once the page program wait period is over.

1. Automatic clear by XSPI – This mode is used when BFGENCR[PPWF_CLR]=1'. PPW_RDSR[LOC] needs to be programmed with the location of the field which is to be checked in PPW_RDSR[RDSR] field to know that page program wait period is over or not. When this field is read back as value programmed in PPW_RDSR[RDSR_VAL_CHK] field, XSPI automatically clears the FR[PPWF] flag and unlocks the arbitration for other requests.

2. Clearing by Software – This mode is used when BFGENCR[PPWF_CLR]=0. In this case XSPI depends on software to read PPW_RDSR[RDSR] and clear FR[PPWF] after the page program wait period is over. After the software clears FR[PPWF], it unlocks the arbitration for other requests.

The SFP arbitration lock timeout counter also starts when FR[PPWF] sets. If PPWF is not cleared within the time period specified by SFP_ARB_TIMEOUT[SFP_ARB_TOC] the arbitration lock timeout error (ERRSTAT[ARB_LOCK_TO]) is generated along with interrupt if enabled. Once this ERRSTAT[ARB_LOCK_TO] field is set, the FR[PPWF] flag can not be cleared by automatic mode or by software. Software must clear the arbitration lock timeout flag (ERRSTAT[ARB_LOCK_TO]) first and then needs to clear the FR[PPWF] flag manually to restart normal XSPI operation.

41.3.7 Byte ordering – endianness

XSPI provides support for swapping the flash memory read/write data based on the configuration of MCR[END_CFG]. By default, the data is always returned in a 64-bit LE format on the AHB bus and in a 32-bit LE format on the IPS interface when read through the RX buffer and written in a 32-bit LE format when written through the TX buffer.

The following table shows the complete bit ordering. BE specifies that the high-order bits of the associated data vectors are associated with low-order address positions, and LE specifies that the lower-order bits of the associated data vectors are associated with low-order address positions. See Figure 145.

Table 341. MCR[END_CFG]

00	64-bit BE
01	32-bit LE
10	32-bit BE
11	64-bit LE

The following tables show how this configuration is implemented in XSPI AHB and IPS interfaces, respectively. B in the table signifies byte and the index 1-8 refers to the byte position, which means 1 refers to bits[7:0], and 8 refers to bits[63:56].

Table 342. Byte ordering configuration in AHB

64-bit BE	B1	B2	B3	B4	B5	B6	B7	B8
64-bit LE	B8	B7	B6	B5	B4	B3	B2	B1
32-bit BE	B5	B6	B7	B8	B1	B2	B3	B4
32-bit LE	B4	B3	B2	B1	B8	B7	B6	B5

Table 343. Byte ordering configuration in IPS

32-bit BE	B1	B2	B3	B4
32-bit LE	B4	B3	B2	B1

The following topics show the byte ordering in 64-bit BE configuration for AHB buffer and 32-bit BE for TX/RX buffer.

41.3.7.1 Programming flash memory data

CPU writes configuration data to the TBDR register, such as:

- Write TBDR: 01_02_03_04h
- Write TBDR: 05_06_07_08h

The following table shows the content against each TX buffer entry.

Table 344. Example of XSPI TX buffer

TX buffer entry	Content
0	01_02_03_04h
1	05_06_07_08h

Programming the TX buffer into the external serial flash memory device results in the following byte order to be sent to the serial flash memory:

- 01...02...03...04...05...06...07...08

41.3.7.2 Reading flash memory data into the RX buffer

Reading the content from the same address provides the following sequence of bytes, identical to the write case:

- 01...02...03...04...05...06...07...08

The following table shows the content against each RX buffer entry.

Table 345. Resulting RX buffer content

RX buffer entry	Content
0	01_02_03_04h
1	05_06_07_08h

41.3.7.2.1 Readout of the RX buffer through RBDRn

The RX buffer content appears at CPU read access through the peripheral bus interface in the following order:

- Read RBDR0: 01_02_03_04h
- Read RBDR1: 05_06_07_08h

41.3.7.3 Reading flash memory data into the AHB buffer

Reading the content from the same address as it was written to provides the following sequence of bytes, identical to the write case:

- 01...02...03...04...05...06...07...08

The following table shows the content against each AHB buffer entry.

Table 346. Resulting AHB buffer content

AHB buffer entry	Content
0	01_02_03_04_05_06_07_08h

41.3.7.3.1 Readout of the AHB buffer through memory-mapped read

The AHB buffer content appears at read access on the AMBA AHB interface at the XSPI module boundary:

- 32-bit read access: 1_02_03_04h
- 32-bit read access: 5_06_07_08h
- 64-bit read access: 1_02_03_04_05_06_07_08h

41.3.8 Driving flash memory control signals in single and dual modes

In single and dual modes, the serial flash memory devices that can connect to the XSPI module expect additional control signals on the inputs, which are connected to IOFA[3]and IOFA[2] in the quad mode. For easy interfacing, the outputs IOFA[3:2] for flash memory A are driven to the logic state selected by configuration fields MCR[ISD3FA]and MCR[ISD2FA].

These outputs are driven all the time to the logic level programmed in the MCR except the time when quad commands of the serial flash memory are executed. See the specifications of the related serial flash memory device for details about the inactive level.

41.3.9 Serial flash memory devices

Several different vendors make flash memory devices with a XSPI interface. At present, there is no set standard for the XSPI instruction set. The most common commands currently have the same instruction code for all vendors; however, some commands are unique to specific vendors. For example sequences for selected memory devices, see Example LUT sequences.

41.3.9.1 Dual-die flash memories

Certain serial flash memory vendors provide dual-die packages that are essentially two devices (dies) stacked within the same package to increase the memory capacity of a single package. These two devices within a package share the same data and clock pins, but have individual chip selects. The following figure shows the dual-die package and the naming conventions used in this document. For simplicity, the data pins are shown to be unidirectional.

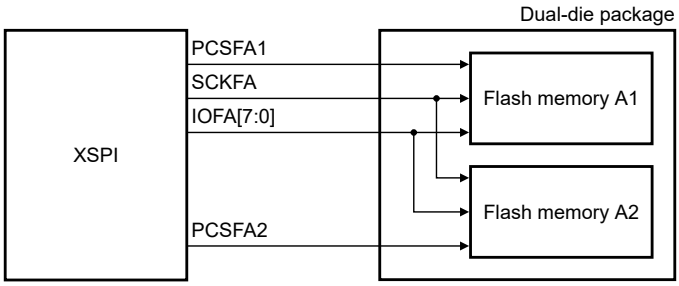


Figure 148. Generic configuration for dual-die support

Because the two devices within a package share the same I/O pads, they cannot function in the parallel mode.

41.3.10 Sampling of serial flash memory input data

41.3.10.1 Basic description

XSPI is used to read data from the serial flash memory device. Depending on the actual implementation, there is a delay between the internal clocking in the XSPI module and the external serial flash memory device. See the following figure for an overview of this scheme.

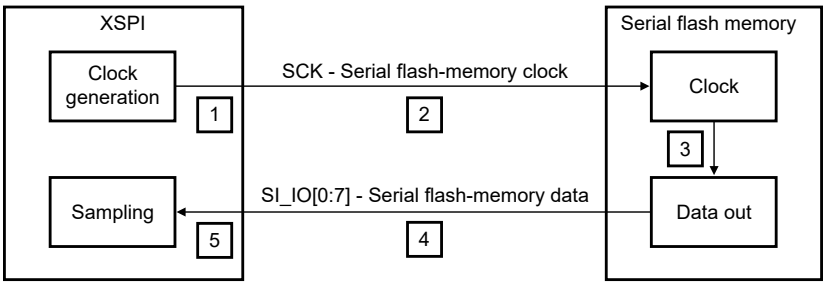

Figure 149. Serial flash memory sampling clock overview

The rising edge of the internal reference clock is taken as timing reference for the data output of the serial flash memory. After a time of t_{total_delay} the data arrives at the internal sampling stage of the XSPI module. Considering the figure provided here, the following parts of the delay chain contribute to t_{total_delay}:

1. Output delay of the serial flash memory clock for the device containing the XSPI module
2. Wire delay of PCB from the device containing the XSPI module to the external serial flash memory device
3. Clock to data out delay of the external serial flash memory device, including input and output delays
4. Wire delay of PCB from the external serial flash memory device to the device containing the XSPI module
5. Device delay corresponding to the input data

NOTE

The t_{total_delay} is specific to the characteristics of the actual implementation.

41.3.10.2 DQS sampling method

41.3.10.2.1 Basic description

In the DQS mode, the data strobe signal (DQS/RWDS) is used to sample the read data. Here, both DQS and the data sent by the flash memory move in the same direction; therefore, it is relatively easier to achieve at higher frequencies.

When using DQS for SDR reads, XSPI internally samples the incoming data on the rising edge of the strobe signal. FSPHS=0 only.

The next figure shows the sampling read data in the SDR mode using the DQS.

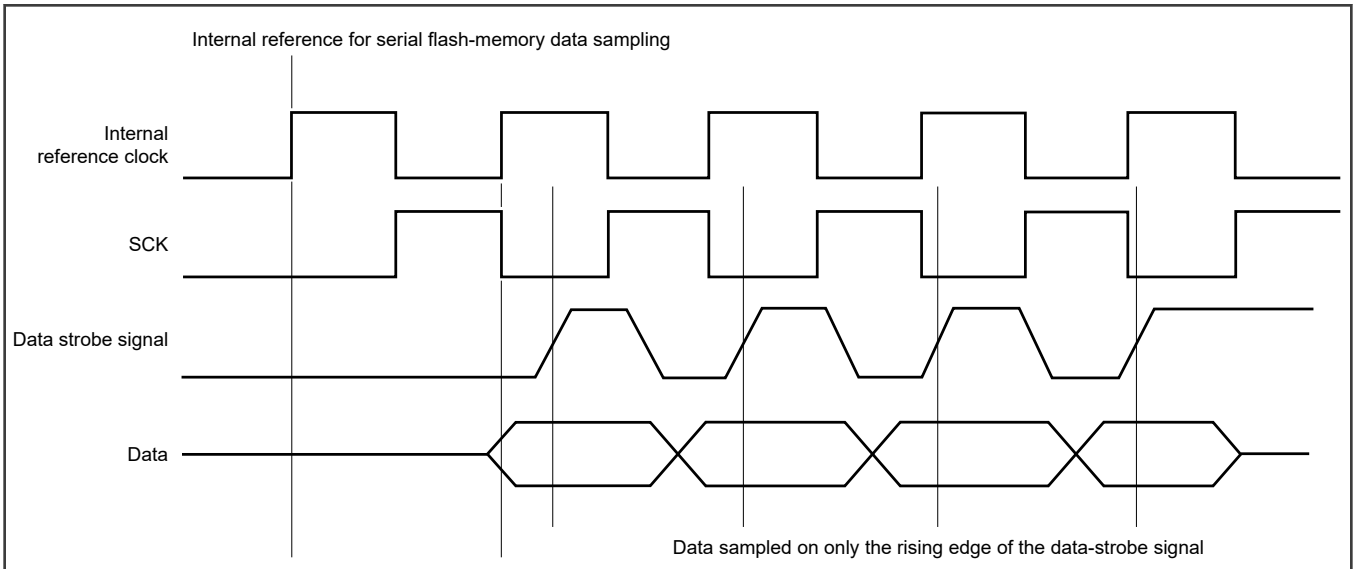

Figure 150. Data strobe functionality in SDR mode for read operation

NOTE

Consider "Data Strobe Signal" as "Data Strobe Signal driven by memory" and "Data" as "Data from memory".

NOTE

Refer to the Datasheet for specific timing waveforms of XSPI

When using the DQS for DDR reads, XSPI internally samples the incoming data on both the edges of the strobe signal. See the next figure for details.

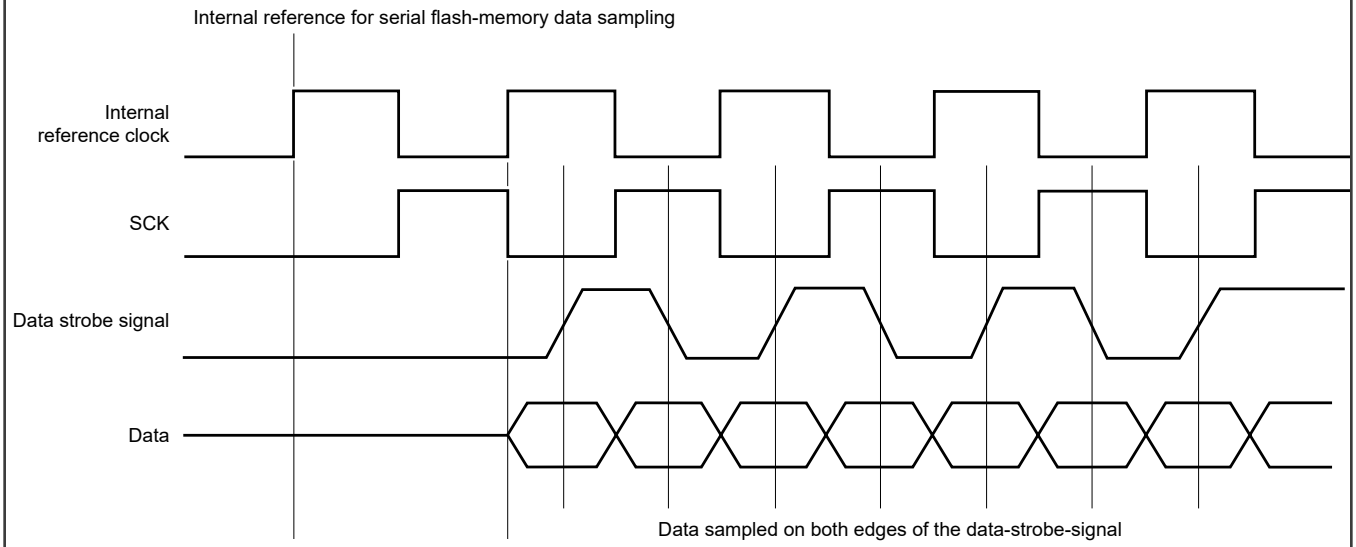

Figure 151. Data strobe functionality in DDR mode for read operation

NOTE

Consider "Data Strobe Signal" as "Data Strobe Signal driven by memory" and "Data" as "Data from memory".

NOTE

For Specific details - Refer to the Data Sheet specification of XSPI module.

41.3.10.2.2 External DQS

In serial flash memories supporting DQS, the data strobe signal is an output from the flash memory device that indicates when data is being transferred from the flash memory to the host controller. The data is then captured by the controller on:

- Only one edge (either rising or falling edge) of DQS signal in SDR mode
- Both rising/falling edges of the DQS signal in DDR mode

Some serial flash memories (for example, HyperFlash) provide the data strobe output (RWDS) with latency cycles included in between the ongoing read transactions. The data is sampled on both the edges of this signal taking into consideration that when no signal is provided by the flash memory between ongoing transactions, data is not sampled then, and at the end of the transaction, the required number of data to be fetched remains the same. See the next figure for details.

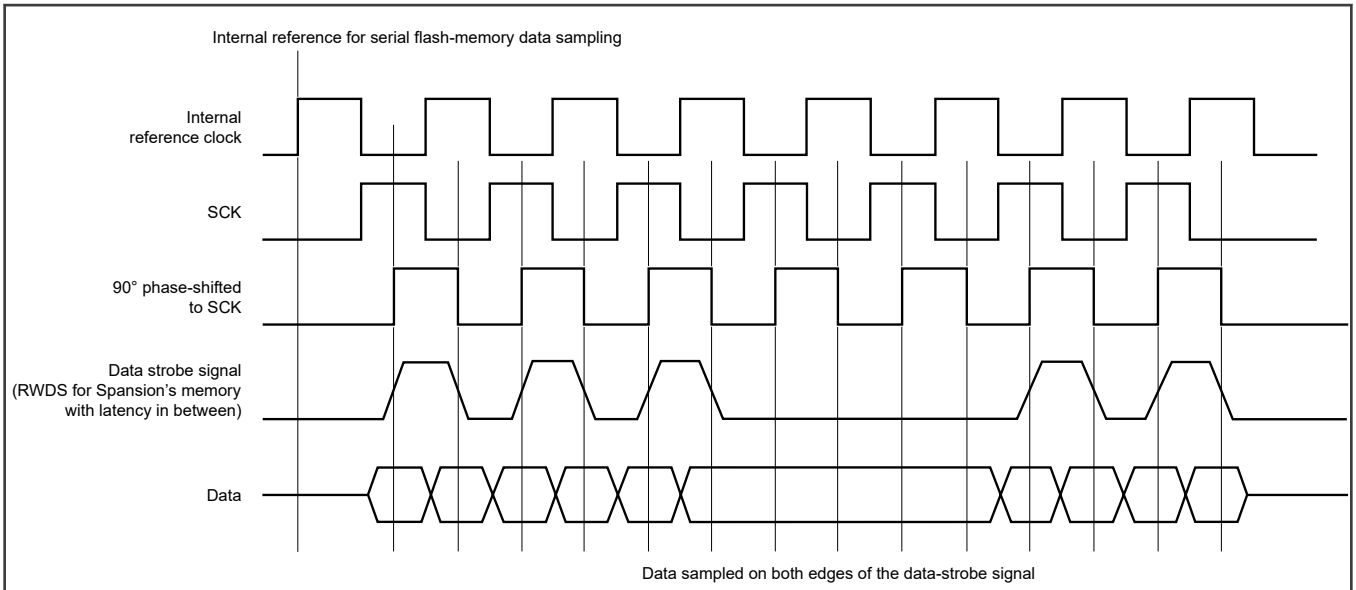

Figure 152. Data strobe functionality with latency included

External DQS sampling mode can be enabled by programming MCR[DQS_FA_SEL] = "11" for flash memory A. This mode supports the following configurations:

- Both high/low frequency delay chain manual programming using DLLCRA[SLV_DLY_COARSE] and DLLCRA[SLV_FLINE_OFFSET]
- DLL-assisted sampling only using DLLCRA[DLLEN]
- DLL-assisted auto data learning using DLLCRA[DLLEN] along with MCR[DLPEN]

41.3.10.2.3 Dummy Pad loopback

In this mode, the internal clock is loop-backed from a dummy internal pad to compensate data pad delays. This can be enabled by configuring the value of MCR[DQS_FA_SEL] as "01" for flash memory A. This mode can be used with the following configuration:

- High/low frequency delay chain manual programming in bypass mode using DLLCRA[SLV_DLY_COARSE] and DLLCR[FREQEN].
- DLL-assisted sampling only using DLLCRA[DLLEN]

NOTE

Refer to DS or "Chip-specific section" of XSPI for Fixed sampling Tap specific settings/details with or without DLL (in bypass mode)

- DLL-assisted auto data learning using DLLCRA[DLLEN] and along with MCR[DLPEN]

NOTE

Refer to Data learning with DLL for further details.

41.3.10.2.4 DQS pad loopback

This mode is similar to internal DQS but the internal clock is loop-backed through the DQS pad to compensate data pad delays. This can be enabled by configuring the value of MCR[DQS_FA_SEL] as "10" for flash memory A. This mode can be used with the following configuration:

- High/low frequency delay chain manual programming using DLLCRA[SLV_DLY_COARSE] and DLLCR[FREQEN].
- DLL-assisted sampling only using DLLCRA[DLLEN]

- DLL-assisted auto data learning using DLLCRA[DLLEN] and along with MCR[DLPEN]

NOTE

- To support DQS pad loopback scenario, if any External DQS pad is used instead of Dummy pad, then that External DQS pad should not be connected to the board (left floating) to avoid any electrical interference.

41.3.11 DLL and delay chain usage

The DLL is a general-purpose, dynamically adaptive clock delay module. It provides the ability to select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage, and temperature (PVT). The DLL is suitable for applications where accurate delay adjustment is required, such as in case of DDR/SDR (with Data-Learning) and support for "DLL based fixed Tap sampling" etc.

41.3.11.1 DLL working concept

The DLL control loop consists of a counter, reference delay line, and phase detector which operate on the reference clock (ref_clk) input. The reference clock (ref_clk) is fed into the reference delay line. After reset, a single delay tap is selected for individual delay line or reference delay chain. A phase detector is used to detect the condition where a half shift of reference clock has occurred. In addition to this, signals are generated internally to either increment or decrement the counter, which controls the delay of reference delay line to identify the half-phase detection of reference clock. Any changes in the delay of the individual elements of the delay chain (because of PVT) automatically cause the phase detector logic to determine if a change in the counter value is required. After the half-phase shift is detected, an internal lock signal is generated, status is captured in DLLSR[DLLA_LOCK] and after a lock event occurs, the target delay chain is ready to be updated based on a triggering event.

41.3.11.2 DLL configuration

NOTE

See AC specifications in chip data sheet for individual functional modes like DDR, SDR, QUAD, OCTAL, etc.

Programmability	Description	Values
MCR[DDR_EN]	Enables DDR mode.	See "XSPI configurations" table in chip data sheet.
MCR[DQS_FA_SEL]	Selects the DQS clock for sampling read data at the flash memory A XSPI port.	See "XSPI configurations" table in chip data sheet.
MCR[DLPEN]	Enables the data learning mechanism.	See "XSPI configurations" table in chip data sheet.
FLSHCR[TDH]	Specifies which clock to use for data alignment.	See "XSPI configurations" table in chip data sheet.
FLSHCR[TCSH]	Specifies the CS hold time in serial flash memory clock cycles.	See "XSPI configurations" table in chip data sheet.
FLSHCR[TCSS]	Specifies the CS setup time in serial flash memory clock cycles.	See "XSPI configurations" table in chip data sheet.
DLLCRA registers:		
DLLCRA[DLLEN]	IO timing closure with DLL or without DLL.	See "XSPI configurations" table in chip data sheet.
DLLCRA[FREQEN]	IO timing closure with low or high DLL.	See "XSPI configurations" table in chip data sheet.

Table continues on the next page...

Table continued from the previous page...

Programmability	Description	Values
DLLCRA[DLL_CDL8]	Support up to 2x/3x PVT variation.	See "XSPI configurations" table in chip data sheet.
DLLCRA[DLL_REFCNTR]	DLL Reference Counter	See "XSPI configurations" table in chip data sheet.
DLLCRA[DLLRES]	Resolution margin	See "XSPI configurations" table in chip data sheet.
DLLCRA[SLV_FINE_OFFSET]	Fine Offset Delay Elements	See "XSPI configurations" table in chip data sheet.
DLLCRA[SLV_DLY_OFFSET]	T/16 Offset Delay Elements	See "XSPI configurations" table in chip data sheet.
DLLCRA[SLV_DLY_COARSE]	Delay Elements in Delay Tap. Usage: DLLCRA[SLV_DLL_BYPASS] = 1	See "XSPI configurations" table in chip data sheet.
DLLCRA[SLV_DLY_FINE]	Fine Adjustment Delay Elements Usage: DLLCRA[SLV_DLL_BYPASS] = 1	See "XSPI configurations" table in chip data sheet.
DLLCRA[SLAVE_AUTO_UPDT]	Subordinate Chain Auto-Update Enable	See "XSPI configurations" table in chip data sheet.
DLLCRA[SLV_EN]	Subordinate Enable	See "XSPI configurations" table in chip data sheet.
DLLCRA[SLV_DLL_BYPASS]	Subordinate DLL Bypass	See "XSPI configurations" table in chip data sheet.
DLLCRA[SLV_UPD]	Subordinate Update	See "XSPI configurations" table in chip data sheet.
SMPR[DLLFSMPFA]	DLL Nth Tap selection for Data sampling	See "XSPI configurations" table in chip data sheet.
SMPR[FSDLY]	Selects the delay for full-speed commands for loopback DQS.	See "XSPI configurations" table in chip data sheet.
SMPR[FSPHS]	Selects the edge of the sampling clock valid for full-speed commands.	See "XSPI configurations" table in chip data sheet.

41.3.11.3 Target delay chain programming sequence

Programming sequence of Target delay chain for DLL Bypass mode and DLL Auto Update mode is explain in sub-sections.

41.3.11.3.1 DLL Bypass mode

Following is the programming sequence for DLL Bypass mode:

NOTE

For DLL minimum frequency support value, see the AC specifications in chip data sheet. Any low frequency application with respect to DLL minimum frequency support condition need to be closed in DLL bypass mode (DLL disable).

1. Program DLLCRA[SLV_EN]=1, DLLCRA[SLV_DLL_BYPASS]=1, and DLLCRA[SLAVE_AUTO_UPDT]=0.
2. Program the following fields to provide the desired DQS delay for sampling: DLLCRA[SLV_FINE_OFFSET], DLLCRA[SLV_DLY_COARSE], DLLCRA[SLV_DLY_FINE], and DLLCRA[FREQEN]. See the AC specifications (XSPI configurations) in chip data sheet for supported frequency/DLL functional mode.
3. Program DLLCRA[SLV_UPD]=1 to load these values in the target delay chain.
4. Check the target delay chain update status by polling DLLSR[SLVA_LOCK]=1.
5. Clear DLLCRA[SLV_UPD] after confirming the update state.

41.3.11.3.2 DLL Auto Update mode

Following is the programming sequence for DLL Auto Update mode:

NOTE

For DLL minimum frequency support value, see the AC specifications in chip data sheet. Any high frequency application with respect to DLL minimum frequency support condition need to be closed in DLL Auto Update mode (DLL enable).

1. Program DLLCRA[SLV_EN]=1, DLLCRA[SLV_DLL_BYPASS]=0, and DLLCRA[SLAVE_AUTO_UPDT]=1.
2. Program the DLL configuration by using DLLCRA[DLL_REFCNTR] and DLLCRA[DLLRES]. See the AC specifications (XSPI configurations) in chip data sheet for supported frequency/DLL functional mode.
3. Program the target settings to delay DQS by using these fields: DLLCRA[SLV_FINE_OFFSET], DLLCRA[SLV_DLY_OFFSET], and DLLCRA[FREQEN]. See the AC specifications (XSPI configurations) in chip data sheet for supported frequency/DLL functional mode.
4. If offset delay needs to be updated on the target chain, program DLLCRA[SLV_UPD]=1.
5. Enable DLL by programming DLLCRA[DLLEN]=1 and reset DLLCRA[SLV_UPD]=0. Target delay chain is updated automatically and can be checked by polling DLLSR[SLVA_LOCK]=1

41.3.12 Data learning

Auto Data learning is used to manage minimum data valid windows (t_{DVW}) from the flash memory as well as skew variations in the chip based on PVT conditions for both SDR and DDR modes. XSPI provides this feature via the DATA_LEARN instruction for all flash memories, irrespective of whether the flash memory supports it. The DATA_LEARN instruction accepts an operand that defines the number of bits of the known pattern for which the data learning has to be done. The known pattern is provided in the DLPR register. Data learning feature is supported for both SDR and DDR modes with PAD loopback DQS (MCR[DQS_FA_SEL] = 01b or 10b).

NOTE

Data learning feature is not supported if sampling clock source is flash provided External DQS (MCR[DQS_FA_SEL] = 11b).

During DATA_LEARN instruction, XSPI will compare the sampled data bits with internal data learn pattern (DLPR) and determine the correct sampling clock phase. The phase selection is automatically updated after executing DATA_LEARN instruction and applied to following Read instructions or sequences.

XSPI controller generates both 08 posedge clock phases (Phase 0 ~ Phase 7) and 08 negedge clock phases (Phase 0 ~ Phase 7) by DLL Target delay line for the selected sample clock (MCR[DQS_FA_SEL]: PAD loopback DQS). Clock Phase 0 is actually the input sample clock (DQS_IN) with or without any static delay based on DLLCRx configuration.

There are 16 sampling flops implemented (8 for each clock edge) for each Data IO line in one sampling unit based on below skew assumptions.

- Skew on each Data IO line need to be balanced to each sampling flop[i]
- Skew on DQS tap[i] to be balanced with each other to sample flop[i]
- DQS tap[i] : i^{th} tap to be balanced for all 8/16 Data IO lines

To accommodate pessimistic data skew between the different IO lines, you must program a different learning pattern on each of the data pins IO1 and IO3 through DLPR[DLPV] and (DLCR[DLP_SEL_FA] = 1b or 11b).

If DLL-assisted auto data learning using DLLCRA[DLLEN] along with MCR[DLPEN] is enabled, DATA_LEARN instruction causes XSPI to ignore the sampling configuration (SMPR) and find the correct sampling point (clock phase) by comparing the data learning pattern. The sample clock phase selected could be polled by register field DLSR_FA[POS_EDGE] and DLSR_FA[NEG_EDGE]. If data learning failed, there will be a status flag (DLSR_FA[DLPFF]) and interrupt bit set (FR[DLPFF]).

Auto data learning is supported with PAD loopback DQS only through MCR[DQS_FA_SEL] register settings. To start data learning, follow the below sequence:

1. Configure a known pattern in the Data Learn register (if programmable) inside flash memories that support data learning Preamble pattern. The pattern should be selected to have multiple low and high transitions in the data bus.
2. Set up XSPI DDR data read sequence, inserting a DATA_LEARN instruction before the READ_DDR instruction. The flash memory returns the data learning pattern in between dummy cycles and subsequent read command.

   Example sequence:

   CMD -> ADDR_DDR -> DUMMY -> DATA_LEARN -> READ_DDR -> STOP

   NOTE

   Set DATA_LEARN instruction operand bit[7] =1 to select DDR mode

   - 1 - DDR mode
   - 0 - SDR mode

   NOTE

   For flash memories that does not support data learning Preamble pattern:

   a. Configure a known location[fixed address] in flash memory with a known pattern. The pattern should be selected to have multiple low and high transitions in the data bus.
   b. Configure the known pattern in DLPR[DLPV].
   c. Set up a DATA_LEARN sequence with fixed address (memory) where Preamble data pattern is stored.
   d. Set up a XSPI DDR data read sequence by utilizing JMP_TO_SEQ command after executing the DATA_LEARN sequence.

      Example sequence:

      CMD -> CMD[fixed Address] -> DUMMY -> DATA_LEARN -> JMP_TO_SEQ[Index]

      [index]: CMD -> ADDR_DDR -> DUMMY -> READ_DDR -> STOP

   e. See Programming the data learning pattern in flash memory for details on how the Preamble pattern has to be ordered in memory for correct operation.
3. Initiate a read operation either through AHB or IPS interface.
4. XSPI reads the data from the flash memory. It then encounters the DATA_LEARN instruction and samples the incoming data on both edges (rising and falling) of the DQS.

   NOTE

   If the data from the flash memory does not match the data learning pattern, the FR[DLPFF] flag is set.

5. Hardware algorithm will select the best-suited sampling point based on the incoming data learning pattern using (03) three-tap algorithm.

This feature might be used to auto-calibrate the sampling point for DDR reads, and auto-calibration might be triggered depending on a change in PVT conditions. In case the sampling point (clock phase) needs to be changed based on initiating options (such as DLL lock status or software forced interrupt), data learn instruction has to be re-initiated.

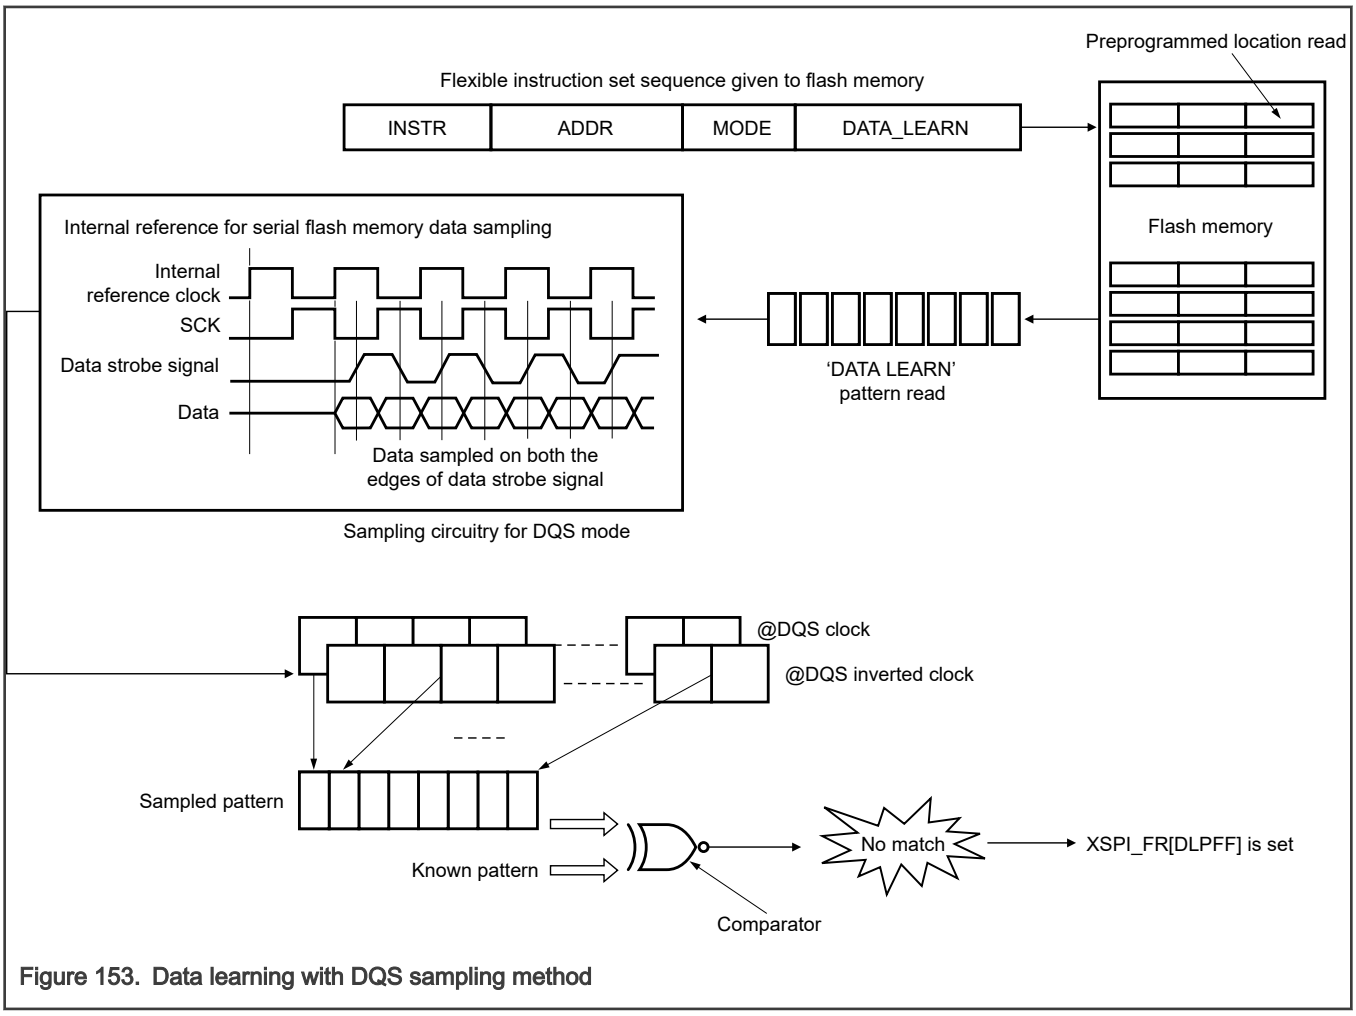

Figure 153. Data learning with DQS sampling method

41.3.12.1 Programming the data learning pattern in flash memory

Example scenario: If the value of DLPR[DLPV] is 43h, XSPI tries to match this sample on every incoming data line for single, dual, quad, or octal configurations. The following table shows the data programmed in flash memory with endianness taken into consideration.

Table 347. Programming the data learning pattern in flash memory

Endianness	Single IO	Dual IO	Quad IO	Octal IO
BE	43h	300Fh	0F0000FFh	00FF00000000FFFFh
LE	43h	0F30h	FF00000Fh	FFFF0000000000FFh

41.3.13 Data input hold requirement of flash memory

In DDR mode, the data is valid only for half clock cycle. It is difficult to meet the data input hold time requirement for flash memory. XSPI internally delays the data sent to flash memory so that it becomes easy to meet the hold requirement. The FLSHCR[TDH] is

used for this purpose. If FLSHCR[TDH] is configured to 0, then the data sent to flash memory is aligned with the internal reference clock of XSPI. If it is 1, then the data is aligned to 2x internal reference half clock.

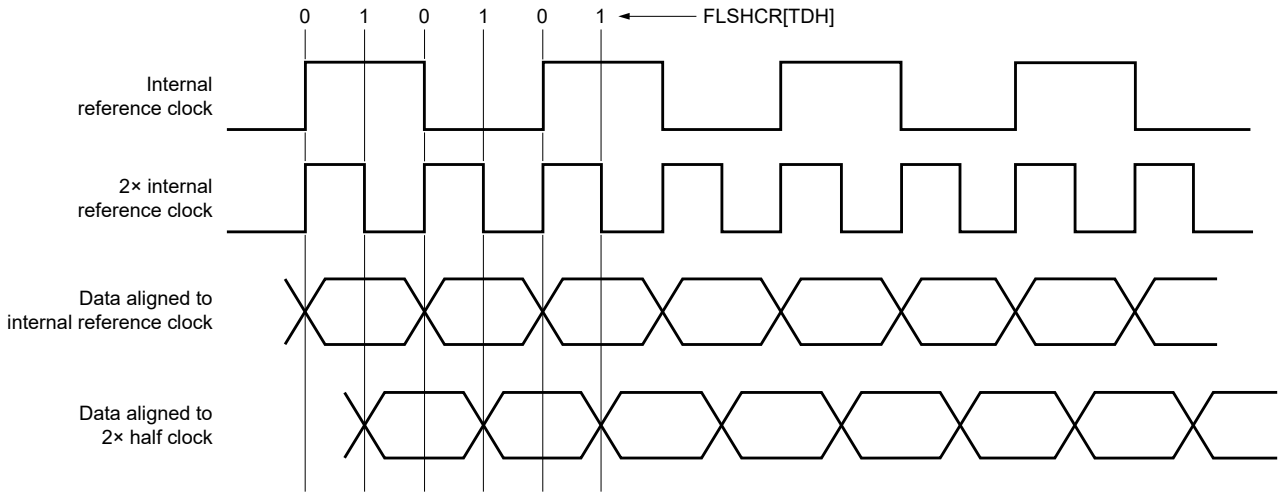

Figure 154. Data hold

41.3.14 Inline PRINCE encryption and decryption (IPED) CTR

IPED is a PRINCE-based encryption-decryption IP with a 64-bit block cipher and 128-bit key. XSPI supports automatic encryption on IP and AHB write commands, and automatic decryption on AHB read commands.

NOTE

- Read/write sends to IPED.i_data should always be 64 bits (8 byte).
- For AHB based read, start address will always be 8 bytes aligned by hardware and BUFnCR[ADATSZ] should be N*8 Byte aligned by application.
- For write, start address will always be 8 bytes aligned and should be handled by software.

Changing the register setting of IPEDCTRL changes the behavior of IPED.

Below register setting should be applied to use IPED feature:

- BFGENCR[ALIGN]: This configuration is needed to stop the AHB prefetch at the given boundary crossing 01-256 B, 10-512 B, and 11-1 KB

There are maximal sixteen contexts supported by XSPI to use different 64bits IPED.i_iv to encrypt/decrypt data. The sixteen ranges are controlled by IPEDCTX*START and IPEDCTX*END registers. There should be no overlap between these sixteen ranges; otherwise, the behavior of IP is undefined. Any single one read/write request to flash should not cross one context boundary. For AHB read/write it can be kept by hardware automatically by setting BFGENCR[ALIGN]. The IP command write boundary should be maintained by software. Any read/write across context boundary will lead to wrong data to/from external device.

Context 15 is reserved for OTA based region, and it is accessible by IPS transactions.

The write ability of IPEDCTX*n*START and IPEDCTX*n*END is controlled by IPEDCTXCTRL0 and IPEDCTXCTRL1. By default, after power on reset, IPEDCTX*n*START and IPEDCTX*n*END cannot be modified. For details see the truth table below:

Table 348. IPEDCTX*n*START and IPEDCTX*n*END write ability

IPEDCTXCTRL0[CTX*n*_FREEZE0]	IPEDCTXCTRL1[CTX*n*_FREEZE1]	CTX*n*_FREEZE0 and CTX*n*_FREEZE1 writable	IPEDCTX*n*START and IPEDCTX*n*END writable
10b	10b	Yes	Yes
01b (default)	01b (default)	Yes	No
don't care	not 10b?	No	No
00b or 11b?	don't care	No	No

41.3.15 IPED - Bypass mode specific data-size limitations

1. IPED - Bypass mode is enabled through static software programming by disabling the IPEDCTRL[IPED_EN], IPEDCTRL[IPED_XEX_EN], IPEDCTRL[IPWR_EN], and IPEDCTRL[AHBWR_EN]: 4 B data size restriction applied on non-encrypted regions based on IPED.
2. IPED - Bypass mode is targeted based on dynamic switching between GCM/CTR(XEX)/Bypass context regions: 8 B data size restriction applied on non-encrypted regions based on IPED.

41.3.16 PRINCE IP GCM function support

Now there are 8/16 region of PRINCE which have separated IV/AAD that are defined by start and end addresses. Each region's read write control is defined by IPEDCTXCTRL0 and IPEDCTXCTRL1 similar as before.

Ctx 15 is reserved for OTA based region and it is accessible by IPS transactions only when IP_WR_OTA is enabled.

41.3.16.1 GCM READ

Every AHB read request from SOC will be aligned to 32 Bytes boundary automatically by IP, and ADATSZ should be N*32 Byte aligned.

Software must guarantee that the RX buffer size for initiator that will issue GCM region read must be multiple times of 32 Bytes.

It is because PRINCE IP's authentication check is based on 32 Bytes of data. So any valid read must be the unit of 32 Bytes.

IP will trigger the converted read address and read size based on the rule that every 32 Bytes of raw data = 32 Bytes of encrypted data + 8 Bytes tag.

NOTE

In GCM AHB read transactions, for wrap bursts with the unaligned start address, the burst size should be 32 Bytes.

Below is key software setting and sequences to conduct correct AHB GCM read:

- Set

  IPEDCTRL[AHBGCMRD] = 1

  IPEDCTRL[IPED_EN] = 1

  IPEDCTRL[CONFIG] = 1/0 depends on test vectors
- Write IPEDCTX0IV0 = lower 32 bits of IV

  Write IPEDCTX0IV1 = higher 32 bits of IV
- Write IPEDCTX0START = start address and IPEDCTX0START[GCM] = 1
- Write IPEDCTX0END = end address
- Write IPEDCTX0AAD0 lower 32 bits of AAD
- Write IPEDCTX0AAD1 higher 32 bits of AAD

If current external device has boundary limitation (like pSRAM has 1 KB limitation) below additional setting is needed

- BFGENCR[ALIGN]: This configuration is needed to stop the AHB prefetch at the given boundary crossing 01-256B, 10-512B, and 11-1KB.

If PRINCE IP indicates there is an authentication check fail, the entire 32 Bytes will be discarded, and error defined value will be put on to AHB bus. Also FR[IPEDERR] interrupt will be set.

41.3.16.2 GCM AHB Write

IP also supports AHB GCM write. But write start address should be 32 bytes aligned, and size should be multiple times of 32 bytes, it is not maintained by IP.

Any GCM write request violating this request will lead to undefined behavior.

All software setting are the same as GCM AHB read except IPEDCTRL[AHBGCMWR] = 1.

If the current external device has a boundary limitation (such as pSRAM has 1KB limitation) then below additional setting is needed:

- BFGENCR[ALIGN]: This configuration is needed to stop the AHB prefetch at the given boundary crossing 01-256B, 10-512B, and 11-1KB

41.3.16.3 GCM IP command write

IP support IP command write with PRINCE IP GCM.

Application needs to align Payload size to 32B boundary with the IPED-GCM block.

Software sequence: (program size = 256 bytes as example)

- Set

  IPEDCTRL[IPED_EN] = 1

  Set IPEDCTRL[CONFIG] = 1/0 depends on test vectors
- Write IPEDCTX0IV0 = lower 32 bits of IV

  Write IPEDCTX0IV1 = higher 32 bits of IV
- Write IPEDCTX0START = start address and IPEDCTX0START[GCM] = 1
- Write IPEDCTX0END = end address
- Write IPEDCTX0AAD0 lower 32 bits of AAD

  Write IPEDCTX0AAD1 higher 32 bits of AAD
- Set IPEDCTRL[IPGCMWR] = 1

NOTE

1. AHB frequency must be greater than flash frequency to avoid underrun with PSRAM devices, when x16 mode and DDR mode with IPS IPED is present.
2. Flash programming should be done before enabling static bits of IPEDCTRL.
3. Watermark should be defined by considering TAG, that is:

$$TBCT[WMRK] = TX_FIFO_DEPTH - (\frac{IPCR[IDATSZ]x1.25}{4} - 1)$$

Equation 4. Watermark calculation

   Watermark is programmed by polling IPEDCTRL[IPS_GCM], to check the GCM context region.
4. Application needs to follow the below configuration sequence when the page boundary crosses on physical address in the case of IPS GCM:
   a. Set AWRCR[PPW_WR_DIS] = 1b for flash devices that require program wait period, to enable the auto RDSR mechanism. See Page program wait handling for more configuration details.
   b. Initiate a locked transfer by setting SFP_TG_IPCR[ARB_LOCK].
   c. When the transaction crosses the page boundary, hardware will stop the current transfer and initiate a new transfer to flush the residue data either immediately (PSRAM/HyperRAM devices) or after waiting for T_{pp}(NOR Flash devices).
   d. Poll FSMSTAT[STATE] = 00b to confirm that the write transfer is completed.
   e. Software needs to wait for T_{pp} (NOR Flash devices) after residue data transfer and release the ARB Lock.

In IPS GCM mode, application must guarantee that IPCR[IDATSZ] should be in multiple of 32 Bytes, if application is unable to maintain this, XSPI will not generate trigger to flash even if correct Watermark Programming TBCT[WMRK]) is done and initiator timeout (MTO) will occur and ERRSTAT[TO_ERR] is set to 1b. Once ERRSTAT[TO_ERR] is set to 1b, it indicates that incorrect programming is done, as XSPI is unable to generate trigger to flash, so to allow external IPED to come in IDLE state, main environment needs to clear the IPED through IPEDCTRL[IPED_SWRESET] and needs to release IPEDCTRL[IPED_SWRESET] before any environment gets grant. This will prevent unwanted hang situation in XSPI.

Early abort does not arise if we follow the below assumptions:

Assumptions:

1. Transaction max size = TX buffer size (1KB) of XSPI (IPS payload data + GCM tag). Software can write 128B of data in TX buffer in a single shot. For payload size of more than 128B, XSPI needs a waiting period after writing 128B to avoid the IPED GCM Encryption buffer overflow condition.
2. Water mark = IPS payload data + GCM tag.

NOTE

If IPCR[IDATSZ] is more than TBCT[WMRK] (256 is programmed in TBCT[WMRK]) then it waits for the threshold to cross before writing SFAR and IPCR registers to XSPI to avoid TX async FIFO underrun.

41.3.16.4 IPED XEX

IPED XEX is an XEX-based memory encryption block with several configuration options.

Read/write sends to IPED.i_data should always be 64 bits(8 byte).

For read, start address will always be 8 bytes aligned and fetch size is also 8 bytes aligned.

For write, start address will always be 8 bytes aligned and should be handled by software.

XEX logic is controlled by parameter IP_XEX_EN, when IP_XEX_EN will be there only then XEX based encryption will be enabled.

Software setting:

- IPED function control IPEDCTRL[IPED_XEX_EN] - Drive IPED XEX interface i_enable

NOTE

Rest of the programming will be same as CTR based encryption.

Configuration supported:

Data Prince 12 Rounds

Tweak Prince 8 Rounds

Configurable Pipeline

Enhanced Timing for Data

i_rnd shall be tied to logic zero by integration team

41.3.16.5 Context Register Programming

CTR and XEX Context Register settings

Context region size = N * Page size

GCM Context Register setting

Context region should be define in such a way that after defining context_n range start and end address, 20% for TAG data should be kept as holes. Rest of the configuration is defined above.

NOTE

- Context comparison is done with application address.
- Any encrypted area should be defined after 1K boundary to avoid encryption of the flash configuration register data.

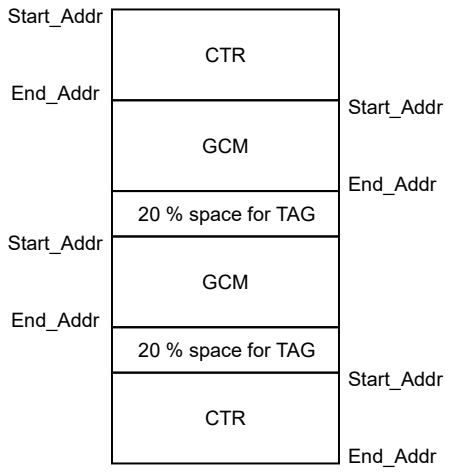

Figure 155. Context programming

41.3.16.6 Reset sequence with IPED

1. XSPI should be enabled (MCR[MDIS] = 0), when asserting MCR[SWRSTHD] and MCR[SWRSTSD].
2. Write 1 to MCR[SWRSTHD], MCR[SWRSTSD], and MCR[IPS_TG_RST] to assert the resets.
3. Assert IPEDCTRL[IPED_SWRESET].

NOTE

Assert IPEDCTRL[IPED_SWRESET], only when MCR[SWRSTHD], MCR[SWRSTSD], and MCR[IPS_TG_RST] are already asserted.

4. Wait for MCR[IPS_TG_RST] to be 0 which means software reset for IPS target queue is completed.
5. Wait until IPEDCTRL[IPED_SWRESET] is completed.
6. Disable XSPI with writing 1 to MCR[MDIS] before de-asserting MCR[SWRSTHD] and MCR[SWRSTSD].
7. Clear MCR[SWRSTHD] and MCR[SWRSTSD]. Clear IPEDCTRL[IPED_SWRESET].
8. Enable XSPI with writing 0 to MCR[MDIS].

41.3.17 Secure flash protection

This secure flash module enforces access control policies based on the ID, privilege and secure attributes of the command transactions. All accesses throughout the flash device need to be monitored to determine their validity. If a transaction from a given IPS initiator has appropriate access rights, it is forwarded to flash, else the access is denied and an error is generated.

There are two levels of checks present in this module, based on MDAD and FRAD descriptors programmed. First level checks the input transactions based on secure attributes and ID associated with that transaction, which are checked according to MDAD. Second level check selects the appropriate FRAD based on address range of transaction. Each FRAD allows the transaction to pass through only when secure, privilege and ID related attributes are matching the criteria set. If either check level fails, the transaction is not forwarded and IPS bus error/interrupt is generated. Flash regions can be programmed to cover the entire address space to provide a default set of access permissions. For flash read transactions only first level of MDAD check is enabled.

Software can bypass both or anyone of these checks by writing to MGC[GVLDFRAD], MGC[GVLDMDAD], or MGC[GVLD] fields.

The IPS initiators must write on SFP register (SFP_TG_SFAR, SFP_TG_IPCR, SFP_TG_SUB_n_SFAR, and SFP_TG_SUB_n_IPCR registers) addresses for generating transfers to flash based on the TG queue that is being targeted for transfer. If the transaction passes both MDAD and FRAD checks then it is passed through to XSPI, otherwise a bus error or interrupt is generated. There is only a single IPS target interface which can be used for XSPI IPS register access and SFP IPS register access.

XSPI SFP related register sets are present here.

41.3.17.1 MDAD

These descriptors form the first level of checks. There are 2'd2 target group queues present in SFP block and each of these queues can be programmed with different set of MDAD descriptor checks in TG*n*MDAD registers. These registers are under access control and can only be programmed by initiators with privilege attributes. These descriptors must be programmed prior to the start of any flash transaction else any IP command initiated flash transaction will generate an IPS bus error.

Multiple transactions can be queued in target groups in parallel, and one of them is launched towards XSPI after the arbitration.

41.3.17.1.1 MDAD checks

- Secure check – This is decided by the TG*n*MDAD[SA] field of the MDAD descriptor. If TG*n*MDAD[SA] = 01b then the queue is reserved for only non-secure transactions. If TG*n*MDAD[SA] = 10b then the queue is reserved for only secure transactions. If TG*n*MDAD[SA] = 11b then this check is bypassed.
- Initiator ID check – This check compares the initiator ID of the transaction with the MID match value set in the TG*n*MDAD[MIDMATCH] field and allows only matching transactions inside the queue. There are 6 mask fields (TG*n*MDAD[MASK]) inside the descriptor. If the mask type (TG*n*MDAD[MASKTYPE]) is set to 0 then the input transactions initiator ID is ANDed with the mask bits before comparing with the MID match value. If the mask type is set to 1 then the input initiator ID is ORed with the masks bits and then compared with the MID match bits. Multiple initiator IDs can be allowed inside the queue using this mask.

When an IPS write is done to TG queue SFAR and IPCR registers (Serial Flash Memory Address (SFP_TG_SFAR), IP Configuration (SFP_TG_IPCR),) then SFP block checks the attributes with MDAD descriptor of that queue. If the attributes match with the descriptor checks it is written inside that queue, else an IPS transfer error is generated and that entry is discarded. The

queue is considered locked once the IPCR SEQID fields are written. So, software should ensure that IPCR SEQID bits are written only after SFAR and other IPCR bits like DATSZ are written in that queue. The queue will be unlocked when flash transfer is completed for that transaction.

Once a initiator ID is assigned to a queue then transactions with only that initiator ID are allowed inside the queue. The data in the queue is cleared once the flash transaction is finally completed by the XSPI.

The data path for initiating IP-command transaction with SFP is shown in the following figure.

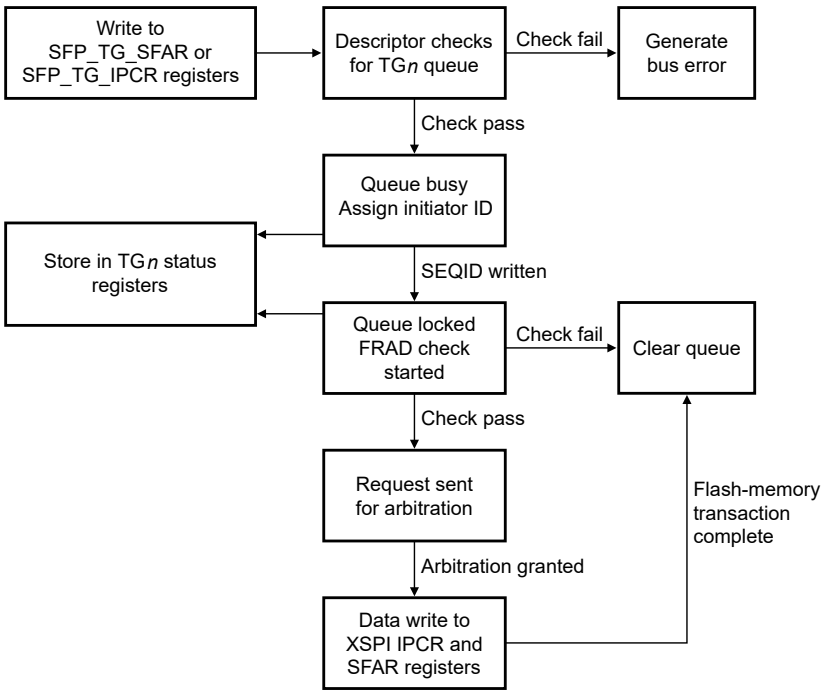

Figure 156. Data path for initiating IP- command flash transaction through SFP

If the SFAR write passes first level of MDAD checks then the value is written in SFP register TG*n*SFAR, valid bit is set in TG*n*SFARS register and queue is considered as busy. Similarly when IPCR write passes the checks, its value is written into TG*n*IPRCS register, TG*n*IPRCS[VLD] field is set to 1 and queue is considered as locked. It is mandatory that IPCR is written only after SFAR has been written for a queue and queue is busy. If IPCR is written before SFAR then it will result in IPS transfer error. As soon as queue is locked (IPCR SEQID written) and passes FRAD checks, the transaction is sent for arbitration. See IP and AHB command arbitration for more details.

NOTE

TBDR register write is not allowed until the SFP_TG_SFAR and SFP_TG_IPCR entries of that TG queue have passed MDAD and FRAD checks and the transaction is granted the arbitration. If TBDR registers are written before arbitration win, transfer error will be generated. IPS initiator can read FSMSTAT register to check the status of their transaction. TBDR access is allowed when FSMSTAT[VLD] field is set and for the initiator whose initiator ID matches with bits [13:8] of this register, and bits [1:0] are set to 01 or 10.

41.3.17.1.2 MDAD error conditions

The error conditions for first level of MDAD checks and the response is given in table below. These error conditions can occur when SFP_TG_SFAR, SFP_TG_IPCR or TBDR registers are being written.

NOTE

Queue is considered busy if it has been written successfully one time with any of the values SFAR, IDATSZ or PAR. Queue is considered locked when SEQID has been written successfully by passing MDAD checks.

Table 349. MDAD check error conditions

Error condition	Response	Common/Queue error
Queue descriptor SFP_TG_MDAD is not programmed	IPS transfer error is generated	Common error
Target group queue is locked and SFAR/IPCR written again	IPS transfer error is generated	Common error
Queue busy and same IPS initiator writes SFAR or IPCR registers with wrong security attribute	IPS transfer error is generated and queue is cleared (SFAR and IPCR needs to be written again for transfer to start).	Queue error
Queue is locked and any IPS initiator writes	IPS transfer error is generated	Common error
If initiator ID of transaction does not qualify MID check or fails the attribute checks of the queues	IPS transfer error is generated	Common error
TBDR register is written before SFAR and IPCR SEQID qualifies MDAD checks	IPS transfer error is generated	-
If none of FRAD descriptors are programmed	IPS transfer error is generated	Common error
IPCR is written before SFAR	IPS transfer error is generated	Common Error - If the transaction doesn't matches the security attribute check or MID check of any MDAD. Queue error - If it matches security and MID attribute of the queue.

When a common error is generated its details are latched in IPS Error (IPSERROR) or register and corresponding error field is set to 1. This register will keep the last error transaction latched unless cleared by writing 1 to CLR field of this register. In case a queue is busy and same IPS initiator writes IPCR or SFAR with wrong security attributes the queue is cleared, the Target Group SFAR Status (TGSFARS) valid field goes low. In this case the IPS initiator should write the SFAR an IPCR again for proper transaction to start.

In case of queue error the details are latched in Target Group IP Configuration Status (TGIPCRS) or Target Group SFAR Status (TGSFARS) registers. These registers will also keep the error status latched until cleared by writing 1 to CLR field of respective registers.

41.3.17.2 FRAD

These descriptors form the second level check for IPS flash transactions. IPS read transaction are not processed by this level of check and are passed through after MDAD checks. There are 8 FRADs which can be programmed by initiators with privilege attributes. So the access checks can be programmed for up to 8 unique address ranges. Each of the address range is equipped with different access attribute checks and based on this write access can be controlled for the flash region. These descriptors must be programmed before starting transactions on flash.

After programming the FRAD*n*_WORD0, FRAD*n*_WORD1, FRAD*n*_WORD2 and FRAD*n*_WORD3, registers, FRAD*n*_WORD3[VLD] field should be written 1. SFP block doesn't consider the FRAD descriptors which are not valid (FRAD*n*_WORD3[VLD] field is not set).

There is a descriptor lock feature to prevent spurious changes to the FRAD. FRAD*n*_WORD3[LOCK] can be programmed to make all FRAD*n* registers as read only or to allow write access to all or some initiators with specific initiator ID.

41.3.17.2.1 FRAD checks

- Address range checks – Start and end address for FRAD region are programmed in FRAD*n*_WORD0 and FRAD*n*_WORD1 registers. Start address of IPS flash transaction written in SFP_TG_SFAR register and data size programmed in SFP_TG_IPCR register are used to check if the transaction lies within any of the FRAD address ranges. This address range match will be used to select the corresponding FRAD from which other access checks will be done. The start and end address are programmed around 64 KB boundary so 16 MSB are only used for range check.

  The data size should not be programmed as 0 in SFP_TG_IPCR register for normal data transfers to flash and actual size should be programmed. In the cases where only flash instruction has to be sent and no data has to be written in TBDR register, this DATSZ can be programmed as 0. If DATSZ is programmed as 0 in SFP_TG_IPCR, SFP module blocks the write access to TBDR register, and generates IPS transfer error.

- Exclusive access lock – Exclusive IPS initiator access lock can be enabled over any flash address defined under a FRAD. The initiator ID of the IPS initiator which enables/owns the exclusive access is captured in FRAD*n*_WORD2[EALO] fields. Once enabled, the exclusive lock can be released only by the same IPS initiator which enabled the lock by writing the FRAD*n*_WORD3[EAL] field. The exclusive write access permissions of a flash region are decided as given in table below:

Table 350. Exclusive access lock

FRAD*n*_WORD3[EAL]	Write permissions
00	No lock. The write permissions are decided as set in FRAD*n*_WORD2[MDnACP] fields for respective IPS initiator domain.
10	Write permissions are revoked for all IPS initiators. Any write transaction coming to this flash address region will not be forwarded through and will result in an error.
11	Write permissions are revoked for all IPS initiators except the initiator ID matching the ID specified by FRAD*n*_WORD2[EALO] fields.

- Flash region privilege checks – If the FRAD*n*_WORD3[EAL] fields are set to 00 then flash write permissions for any IPS initiator is decided based on the settings done in FRAD*n*_WORD2[MDnACP] fields as given in table below. One of the FRAD*n*_WORD2[MDnACP] is selected for permission checks based on which target group queue the transaction arrives from.

Table 351. Flash region privilege checks

MDxACP value	Privilege access	Secure access	Write access
111	No	No	Not allowed
	No	Yes	Not allowed
	Yes	No	Allowed
	Yes	Yes	Allowed
110	No	No	Allowed
	No	Yes	Allowed
	Yes	No	Allowed
	Yes	Yes	Allowed
101	No	No	Not allowed
	No	Yes	Not allowed
	Yes	No	Not allowed
	Yes	Yes	Allowed

Table continues on the next page...

Table 351. Flash region privilege checks (continued)

MDxACP value	Privilege access	Secure access	Write access
100	No	No	Not allowed
	No	Yes	Allowed
	Yes	No	Not allowed
	Yes	Yes	Allowed
0xx	-	-	Not allowed

If any transaction fails FRAD check then error interrupt is generated if enabled.

FRAD status registers keep the details of last transaction which lie within the address range of that respective FRAD and will be updated only when a new transaction comes which corresponds to same FRAD address range.

Flash Region Compare Address Status register stores the flash start address that was compared and Flash Region Compare Status Data contains the initiator ID, privilege and secure attributes of the transaction. The transaction details are stored in FRAD register for which the address compare check passed. These status registers are not updated in case of read transfers or when FRAD check is disabled. For example, if the transaction address lies in the range set in FRAD2_WORD0 and FRAD2_WORD1 then the transaction details will be stored in FRAD2_WORD4 and FRAD2_WORD5 registers and FRAD2_WORD5[CMPVALID] will be set. If transaction fails the security or privilege attribute check for the corresponding FRAD, then FRAD*n*_WORD5[CMP_ERR]. This bit and other transaction details will remain latched unless cleared by writing '1' to ERRSTAT[FRAD*n*ACC].

If transaction address does not match any of the FRAD address range then also error interrupt is generated but the details will not be stored in any of the FRAD status registers.

FRAD checks are done only for flash write transactions, flash read transactions are passed through to XSPI if MDAD checks are passed. At least one FRAD region must be made valid (if the FRAD check is enabled from MGC register) for flash read instructions to go through even though FRAD check is not done for read instructions. SFP module identifies the transfer as read/write based on the command programmed in Initiator Read Command (MRC) register. If the sequence selected in LUT for IP transfer has any one of the command from MRC register the whole sequence is considered as read, else it is considered as write. There are two command codes which are predefined READ_DDR and READ commands. Software can program two other command code as per its convenience by writing into fields [21:16] or [29:24] and then writing respective valid bit as 1.

For any type of Flash Read command in which payload size is not required, that transaction will be treated as 'Write' transaction by SFP block. In this case MRC register can't be used to define it as a 'Read' instruction. Certain examples for these type of commands are - In SNAND Flash, PAGE READ (‘h13), PAGE READ CACHE RANDOM (‘h30) etc.

41.3.17.2.2 Error conditions

Any transaction passing the MDAD checks will be checked for FRAD checks and can lead to following error scenarios.

Table 352. Error conditions

Error condition	Response
None of the FRAD are programmed	IPS transfer error will be generated and status will be latched in IPS_ERROR register
Transaction address doesn’t fall within any of the FRAD address range	Error interrupt will be generated if enabled
Transaction match with multiple FRAD address range	Error interrupt will be generated if enabled. Error bit will be set, and status will be stored in FRADx_WORD5 status registers for whom the address check passed

Table continues on the next page...

Table 352. Error conditions (continued)

Error condition	Response
Transaction passes FRAD address check but fails MDxACP checks or if SEQID is not allowed to be executed from that FRAD by SFP_LUT_EN register.	Error interrupt will be generated if enabled. Error bit will be set, and status will be stored in FRADx_WORD5 status registers for whom the address check passed
Transaction passes FRAD address check but range was locked by EAL bits	Error interrupt will be generated if enabled. Error bit will be set, and status will be stored in FRADx_WORD5 status registers for whom the address check passed
Read transaction	No FRAD check will be done and no error will be generated for FRAD failure. But if FRAD check is enabled in MGC then at least one FRAD must be valid else it will give error during SFAR/IPCR write

NOTE

There are different error registers corresponding to each TG queue (IPSERROR, IPSERROR_SUB_n, FRAD*_WORD5, FRAD*_WORD5_SUB_n). These registers will be updated according to the TG queue from which transaction entered.

41.3.17.2.3 LUT access enable

SFP block can control which SEQID is executed through which of the target group queues. This gives more control for limiting any crucial security related instructions to some specific target group. These access controls can be defined in LUT Access Enable (SFP_LUT_EN0 - SFP_LUT_EN1). There is one register corresponding to each target group queue. Each register contains 16 bits corresponding to 16 locations of the LUT. Whenever a transaction passes through the MDAD checks and is presented for FRAD checks, the SEQID written in IPCR register is checked with corresponding bit in LUT Access Enable (SFP_LUT_EN0 - SFP_LUT_EN1). If the bit is set to '0' it will pass through FRAD checks if MDxACP permissions are also present. Else it will cause a FRAD access error. This LUT access check is applicable only for write transactions if FRAD checks are enabled in Initiator Global Configuration (MGC).

41.3.17.3 TBDR register write lock

SFP module keeps the TBDR write permissions locked for IPS transactions by default. When a IPS initiator writes SFAR and IPCR transactions and this transaction passes MDAD and FRAD checks then the accesses are unlocked for that initiator ID. Lock and unlock procedure is shown with an example in figure below:

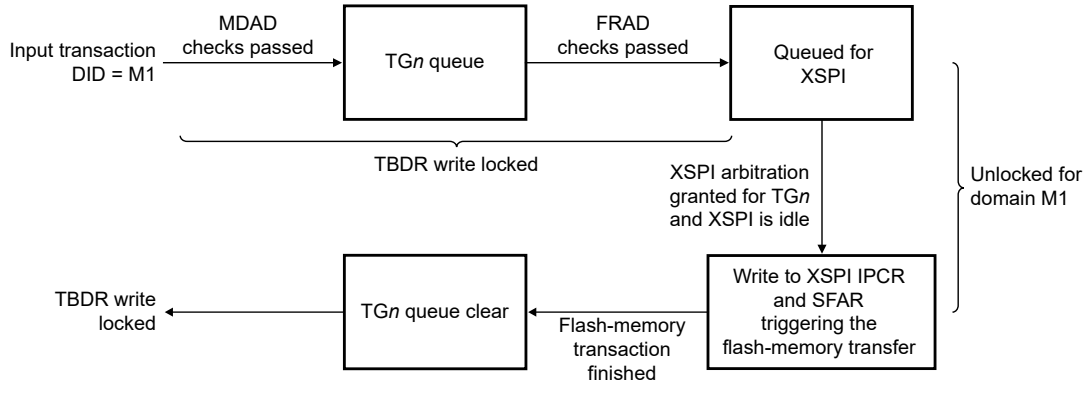

Figure 157. TBDR lock and unlock procedure

If any IPS initiator writes on TBDR register when it is not unlocked for that initiator ID it will result in IPS transfer error. FSMSTAT[MID] indicates which initiator ID is currently active, and if the value of FSMSTAT[STATE] is 01 or 10 and FSMSTAT[VLD] is set as 1, then the TBDR lock is open for write transactions. It is advisable that for write transactions

where IDATSZ is non zero, initiator clears the TX buffer from any residue data and program the TBCT[WMRK] watermark after its request is granted in arbitration (FSMSTAT bit [1:0] are 01). In case of transfers having IDATSZ programmed as 0 the TX Buffer Data (TBDR) register remains locked and data can't be written to this register.

In case DMA is being used to fill the TBDR buffer, program RSER[TBFDE] field to 1 only when write access is granted and TBDR access is unlocked after checking FSMSTAT[STATE] field. Once DMA completes the TBDR write, this field is set back to 0. After this, the SFP will write SFAR and IPCR to XSPI triggering the flash transfer. It should be made sure that the DMA should have same initiator ID as the TG, which won the arbitration.

NOTE

RBCT[WMRK] can only be programmed when no IP command is triggered on XSPI (SR[IPACC] is 0). So It is not possible to program two different RBCT[WMRK] for two different TG queues if both are used in parallel. SFP triggers the read transfers to flash as soon as TG queue gets grant and XSPI is IDLE. So it is recommended to use a common RBCT[WMRK] value for both TG queues or change the value when both the queues are empty.

41.3.17.4 Transaction status registers

SFP module has two registers (FSM Status (FSMSTAT) and Flash Sequence Request (FLSEQREQ)) which show the current and last transaction status. These registers are updated only after MDAD and FRAD check are passed and arbitration is granted for this request. See IP and AHB command arbitration for details.

- FSM Status (FSMSTAT) register shows the request for the target group queue has been granted by the XSPI arbiter and FSMSTAT[VLD] is set. If FSMSTAT[CMD] is set to 1 then it is a non-read instruction sequence and it is set to 0 then it means that this is a read sequence. FSMSTAT[MID] shows the initiator ID from which this transaction is generated. FSMSTAT[STATE] shows the current state of active transaction when valid FSMSTAT[VLD] is set.

  The figure below shows the IPS transaction flow inside SFP block along with various values of bits [1:0]:

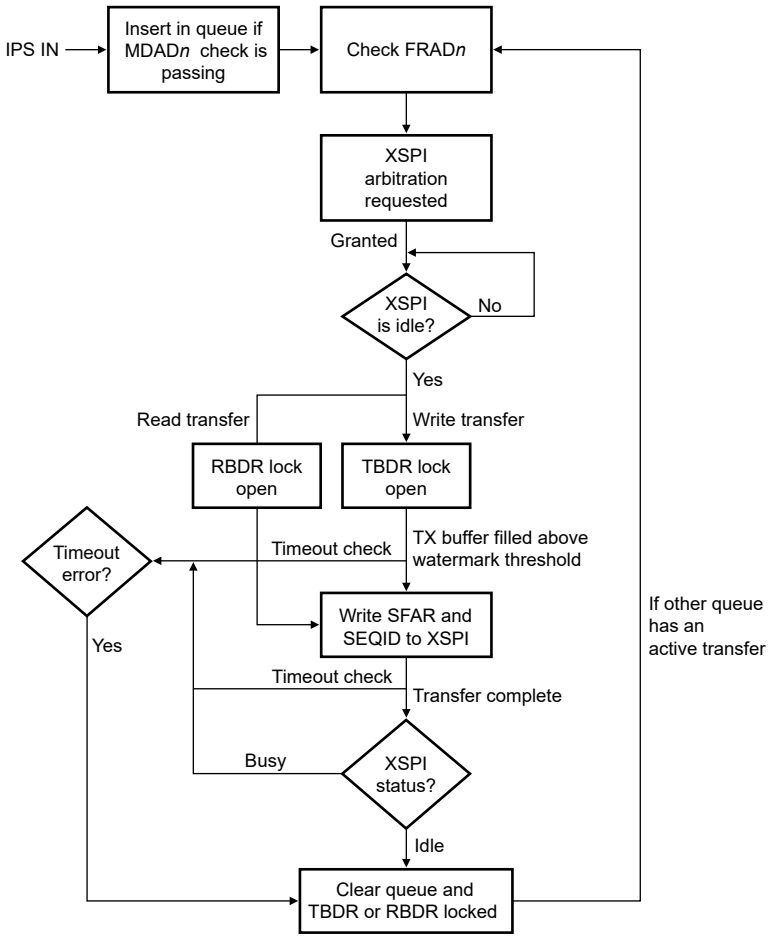

Figure 158. Transaction status

NOTE

1. If IPCR[DATSZ] is more than the TX buffer watermark threshold value (256- Watermark programmed in TBCT) then it waits for threshold to cross before writing the SFAR and IPCR registers to XSPI. Else SFP block waits for one entry to be written to TBDR register and after that it writes the SFAR and IPCR to XSPI thus triggering the transfer. In case of read transfers or if the datasize is zero, SFAR and IPCR are triggered as soon as grant is received.
2. XSPI is considered IDLE if transaction is finished at flash, No DMA and interrupt pending for following FR fields: TBUF, RBDF, IUEF, ILLINE. RX data is completely read.

FSM state values in FSM Status (FSMSTAT) for different states are in the following table:

Table 353. FSMSTAT register field details

FSMSTAT register fields	
FSMSTAT[VLD]	0 - No IPS transfer is present in TG queues or request is send to XSPI arbiter for grant. 1 - IPS transfer is granted by the XSPI arbiter or running in XSPI
FSMSTAT[STATE]	00 - Transaction request is granted but XSPI is not IDLE due to any previous DMA transaction ongoing, any residue data left in RDBFL or if any interrupt is pending (FR[TBUF], FR[RBDF], FR[ILLINE]).

Table continues on the next page...

Table 353. FSMSTAT register field details (continued)

FSMSTAT register fields	
	01 - TBDR lock is open. XSPI considers IPS transfer and IPS initiator can write TBDR. 10 - TX buffer filled above threshold. Write transfer is triggered. SEQID is written to XSPI. 11 - Read transfer is triggered. SEQID is written to XSPI.

For flash write transfers which pass MDAD and FRAD checks and XSPI is not busy with any previous transfer, TBDR lock is opened and FSMSTAT[STATE] shows value of 01. After the IPS initiator fills the TX buffer till the level where free entries in TX buffer are less than the watermark threshold set in TX Buffer Control (TBCT) and SR[TXWA] flag is de-asserted, SFP block writes the SFAR and IPCR entries to XSPI registers and transaction is triggered. To avoid underrun, program the watermark accordingly for size of the data to be transferred. This programming can be done when arbitration is granted. TBCT Watermark can be programmed as 256-(IDATSZ/4-1) in most of the scenarios. If IPCR[IDATSZ] is less such that TX buffer can never be filled till watermark threshold, in such cases SFP block does not wait for the TBCT[WMRK] to trigger and writes the Serial Flash Memory Address (SFAR) and IP Configuration (IPCR) registers as soon as one data entry is written to TX Buffer Data (TBDR) register. In case of flash memory read transfers SFAR and IPCR entries are written to XSPI as soon as XSPI is IDLE and FSMSTAT[STATE] is set to 11. FSMSTAT[VLD] goes to 0 once the IPS transfer is completed and XSPI is IDLE. IPS initiator should clear the TX buffer before writing to TBDR register to ensure that no data from previous transaction is left in TX buffer. Also if any read data is left in the buffer from previous transfer, then it should also be cleared by writing '1' to MCR[CLR_RXF] field.

For any IPS initiated RW transaction which needs two separate transactions at flash interface, like Write-Enable transaction followed by Write-data transaction (Data-Learn flash transaction followed by Read-data transaction) at flash interface must be joined together with JMP_TO_SEQ instruction.

- Flash Sequence Request (FLSEQREQ) register holds the details of transaction which was last sent to XSPI and completed. After a flash transaction is completed this register is updated and its valid field (FLSEQREQ[VLD]) is set to 1. This register holds the command type (read or write), transaction initiator ID (FLSEQREQ[REQ_MID]), target group queue from which this transaction passed in field (FLSEQREQ[REQ_TG]), privilege and secure attributes for the transaction, FLSEQREQ[SEQID] and number of flash descriptor FRAD within whose address range the transaction lies (FLSEQREQ[FRAD]). This flash descriptor number always remains 0 in case of read transfers.

  This register also contains a timeout error field FLSEQREQ[TIMEOUT] which is set when a timeout error occurs, and transaction is aborted. When the error occurs this register keeps the status latched unless it is cleared by writing 1 to ERRSTAT[TO_ERR].

41.3.17.4.1 XSPI IDLE conditions

XSPI is considered IDLE if the following conditions are all true:

- No ongoing AHB/IP transfer.
- No DMA transaction.
- No residue data left in RDBFL after read transfer.
- None of these interrupt types are enabled and pending: FR[TBUF], FR[RBDF], FR[ILLINE]

After the TG queue is granted, SFP waits for XSPI to be in IDLE state before triggering any transfer over to XSPI. Also, once the transaction has finished on external memory, SFP again waits for XSPI to reach IDLE condition before considering the transaction as complete and clearing the queue. If XSPI remains BUSY, it will lead to SFP timeout error generation.

NOTE

Any TG queue which doesn't want to read the complete RX buffer must clear it after the read to avoid timeout error generation and to avoid exposing this data to another TG queue.

41.3.17.5 Timeout error

Initiator Timeout (MTO) register can be programmed with a timeout value above which the transaction should be aborted. When the transaction passes MDAD and FRAD level checks and request is granted by XSPI arbiter and XSPI is IDLE, this counter is started working on IPS/system clock. If the transaction is not completed and XSPI does not become IDLE before this timeout counter reaches the value programmed, the transaction is considered aborted by SFP and an error interrupt is generated, if enabled. The error bit is also set in Flash Sequence Request (FLSEQREQ) register along with the transaction details. After the timeout error, next transaction is requested for arbitration, which was queued in another target group queue once SR[BUSY] flag goes low.

NOTE

Timeout counter doesn't starts in case queue was granted but XSPI was not in IDLE condition. So any environment on TG queue, after receiving the grant should track FSMSTAT[STAT] bits. If they remain in 00 even after receiving the grant then it should take some corrective action to bring XSPI to IDLE state and start the transfer.

41.3.17.6 Arbitration lock

The arbitration lock feature is used to lock the arbitration with a particular queue and can be used for handling the page program wait requirement for some external flashes. This lock can be requested by main environment (EENV0) by writing '1' into SFP_TG_IPCR[ARB_LOCK] field. Once the transaction passes both the checks (MDAD and FRAD), wins the arbitration and transfer is completed, this lock will be granted. If the TG queue had requested the arbitration lock and was granted but TG SW reset came before transfer gets completed, then also the arbitration lock will be granted. After this, the transaction from the other queue or any AHB access will not be granted by driving HREADY=0 and HREADY-timeout counter is started unless the arbitration is unlocked by previous queue. The main environment (EENV0) which locked the arbitration can unlock it by writing '1' to SFP_TG_IPCR[ARB_UNLOCK] field.

NOTE

The user environment always needs to request the arbitration lock.

Example scenario for handling IP commands resulting in page program wait period.

1. Write the Serial Flash Memory Address (SFP_TG_SFAR) with the required address.
2. Write required transaction attributes in IP Configuration (SFP_TG_IPCR) with SFP_TG_IPCR[ARB_LOCK] field set as '1'.
3. Complete the transfer after request is granted by XSPI.
4. Arbitration lock is received on completion of transfer.
5. Wait for approx time required for page program wait period to end.
6. Generate a flash status register read transfer (for checking WIP bit) with SFP_TG_IPCR[ARB_LOCK] set as '1'.
7. If the WIP bit is read back as '0' it means page program wait period is over (this is applicable for NOR Flash, for other devices; respective settings need to be followed).
8. Generate another flash status register read transfer (for checking WIP bit) with SFP_TG_IPCR[ARB_UNLOCK] set as '1'.
9. This will unlock the arbitration.

There is a arbitration lock timeout counter which starts once the transaction has finished and arbitration is locked for a certain queue. Once this counter reaches the value set in SFP Arbitration Lock Timeout Counter (SFP_ARB_TIMEOUT) register it will generate an interrupt and error bit is latched in ERRSTAT[ARB_LOCK_TO] field. Once the arbitration lock timeout is set, the arbitration can not be unlocked using normal process as shown above. Then clearing this error field (ERRSTAT[ARB_LOCK_TO]) will unlock the arbitration.

NOTE

- In case of TX Buffer residue data left (due to wrong programming) by the IPS initiator and AHB write was pending during that time then TX Buffer residue data can interfere with AHB write data. To avoid this interference, the arbitration lock feature should be used for all IPS transactions, so that TX Buffer can be cleared before providing AHB write grant.

41.3.17.7 Error Interrupt Enable

INT_EN allows software to disable or enable the interrupt signal generation in case of any of the listed conditions.

- Time out error (INT_EN[TO_ERR])
- IPCR register write error (INT_EN[TG*n*IPCR])
- SFAR register write error (INT_EN[TG*n*SFAR])
- IPS common error (INT_EN[IPS_ERR])
- FRAD access error (INT_EN[FRAD*n*ACC])
- No FRAD address range match error (INT_EN[FRADMTCH])
- Lock register write error (INT_EN[LCK_ERR_IE])
- Arbitration win interrupt (INT_EN[ARB_WIN_IE])
- Arbitration lock timeout interrupt (INT_EN[ARB_TO_IE])

If the respective field is set to 1 for any of the error conditions, then the interrupt signal is set to 1 when that error occurs and it remains set until the error is cleared by writing 1 to error clear bit as listed in register descriptions.

Other than these interrupts SFP can also generate interrupt on following conditions:

1. Arbitration win interrupt (INT_EN[ARB_WIN_IE]).
2. Arbitration lock timeout interrupt (INT_EN[ARB_TO_IE]).

41.3.17.8 Register lock access error

There are some lock fields present in SFP registers which can lock the write access to some of the registers. When these fields are locked and any write access occurs on these registers error fields is set in ERRSTAT[LOCK_ERR] and interrupt is generated if enabled. The register address which was accessed is captured in SFP_LOCK_ERR_ADDR register. The first address captured will remain latched unless the error bit is cleared by writing '1' to ERRSTAT[LOCK_ERR].

The list of registers and their corresponding lock bit are listed in table below:

Table 354. Lock error details

Register name	Lock fields
FRADn_WORD0, where n = 0 to 7	FRADn_WORD3[LOCK]=01b
FRADn_WORD1, where n = 0 to 7	FRADn_WORD3[LOCK]=01b
FRADn_WORD2 where n = 0 to 7	FRADn_WORD3[LOCK]=01b
TGnMDAD, where n = 0 to 7	TGnMDAD[LCK]=1b
INT_EN	INT_EN[LCK]=1b
LUTn, where n=0 to 79	MGC[GCLCK]=01b,10b,11b
BFGENCR	MGC[GCLCK]=01b,10b,11b
SFP_LUT_ENn, where n=0 to 1	SFP_LUT_ENn[LOCK]=1b or MGC[GCLCK]=01b

Table continues on the next page...

Table 354. Lock error details (continued)

Register name	Lock fields
MGC	MGC[GCLCK]=01
MRC	MGC[GCLCK]=01
MTO	MGC[GCLCK]=01
SFP_ARB_TIMEOUT	MGC[GCLCK]=01

41.3.18 Soft reset considerations

In case the soft reset is being used for XSPI, software should take some considerations so that correct functionality is maintained. MCR[IPS_TG_RST] field can be used to reset all TG queues and their error and status registers. If any TG queue was granted and transaction was ongoing towards the flash then XSPI waits for that transaction to complete on flash and chip-select de-assertion before triggering this IPS TG reset and clearing the TG queues and related logic. If no IP command was executing on the flash then this soft reset is immediately executed. IPS_TG_RST only resets the SFP logic related to TG queues it doesn't affects any XSPI native registers. AHB SW reset (MCR[SWRSTSD]) resets the complete AHB related logic, XSPI internal IP command logic and also clears the TX and RX buffers. It also resets the AHB buffer pointers hence invalidating the data in AHB buffer. AHB soft reset during an ongoing AHB read transaction, may lead to write data corruption or read data mismatch. Flash domain SW reset (MCR[SWRSTHD]) resets the state machine and logic on the flash domain side of XSPI.

NOTE

It is advisable that all three reset are done at same time (IPS_TG_RST, SWRSTHD, and SWRSTSD) to clear the complete XSPI transaction path. Using these resets independently may lead to some side-effects.

The AHB soft reset should be used when no AHB transaction(WRITE/READ) is pending on AHB interface. This is to ensure that data loss/corruption does not happen. The main environment should ensure that the pending AHB transaction needs to be re-issued if AHB soft reset is asserted during a pending AHB transaction. SR[AHBTRN] should be used to check if there is any pending request on the AHB interface. If AHB soft reset is asserted during an ongoing AHB transaction, the main environment should also ensure that the ongoing transaction needs to be re-issued. SR[AWRACC] and SR[AHB_ACC] should be used to check if there is any ongoing Write or Read transaction on the AHB interface. Software should take care of the page program wait period while doing soft reset. Doing IPS or AHB reset doesn't affects the arbitration lock status. Hence if any TG queue has locked the arbitration it will remain locked even after IPS_TG_RST has been asserted. After the soft reset if no IPS transactions are done then there will be a SFP arbitration lock timeout and clearing that timeout error will unlock the arbitration. This is done so that in case any previous transfer done has resulted in page program period on flash then we don't allow any AHB or IPS transfer to go through after the soft reset.

In case of AHB write transfers if the AHB and flash domain soft reset is asserted before the transfer is completed on the flash then it may result in no PPWF flag being set. In this case, SW should ensure that no transaction is done on XSPI if the page program wait period on flash was ongoing. If the soft reset is asserted after the transaction has completed on the flash and the PPWF flag is set then this flag remains set even after soft reset completion. RDSR read will start once the soft reset has been de-asserted.

In case of IPED, IPEDCTRL[IPED_SWRESET] need to be asserted with software reset for AHB (MCR[SWRSTHD]), serial flash memory domain (MCR[SWRSTSD]), and IPS TG queue (MCR[IPS_TG_RST]).

If SR[AW_SWRST] is not set after soft reset, software must use the last HADDR, which was written before soft reset assertion, to determine which write bursts must be re-issued.

NOTE

Software must adhere to IPED address boundary rules while determining which AHB write bursts to re-issue after soft reset de-assertion.

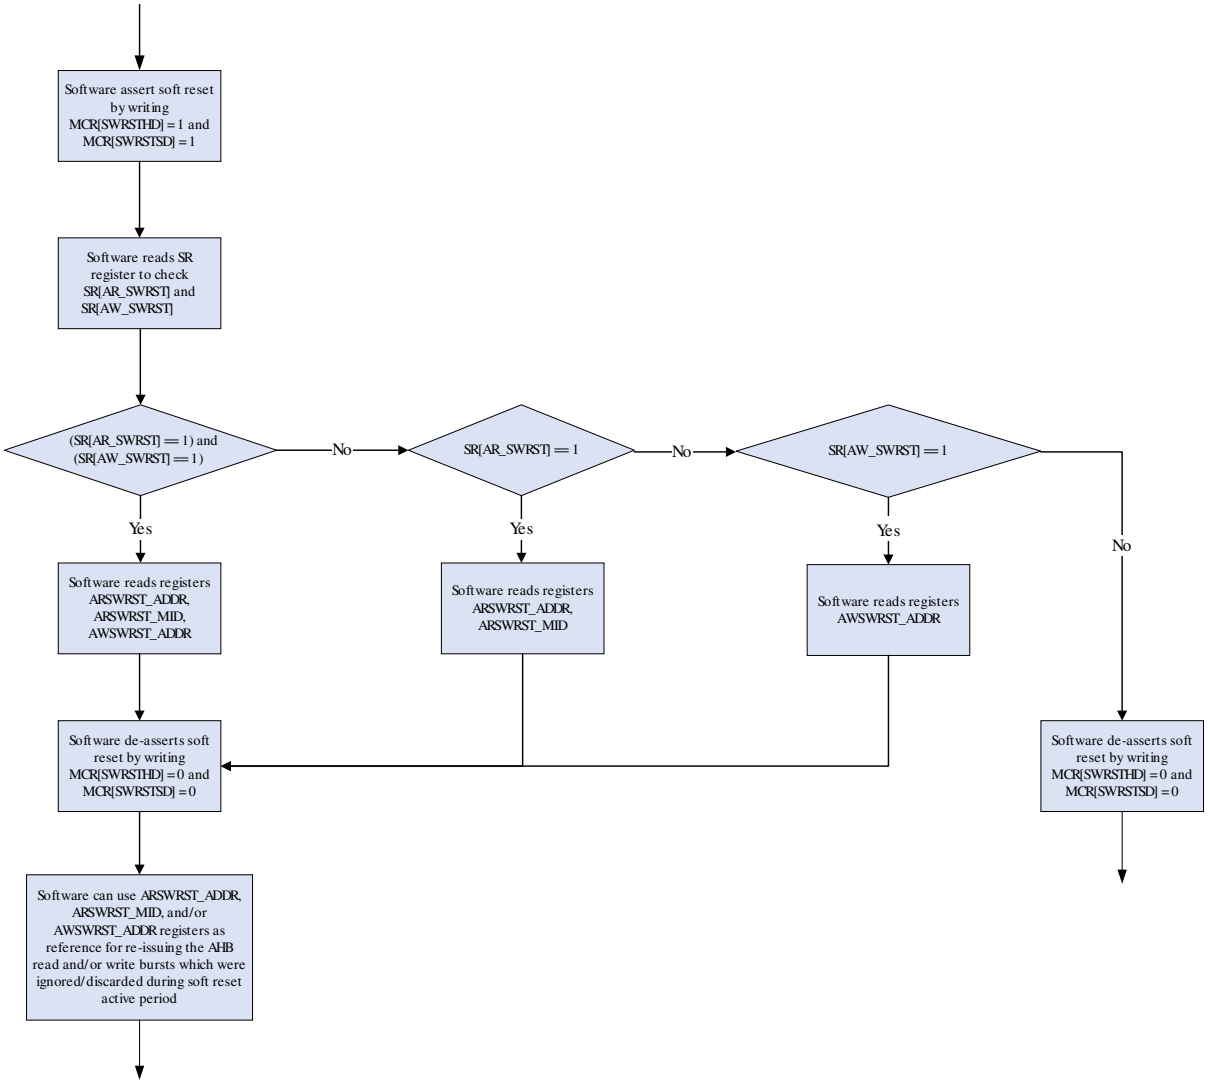

Figure 159. Soft reset programming sequence

41.3.19 Clocking

XSPI has the following clocks.

Table 355. Clocking

XSPI Clock Domain	Input clocks to XSPI-IP	Functional descriptions
Host System clock domain	SoC Internal: AHB clock (ahb_clk)	Input clock for AHB clock domain logic within XSPI-IP. It is used for handling the AHB read and AHB write accesses/operations through AHB interface to the external memory.

Table continues on the next page...

Table 355. Clocking (continued)

XSPI Clock Domain	Input clocks to XSPI-IP	Functional descriptions
		NOTE 1. AHB clock can be gated by ahb_enable_clk signal. 2. Supported AHB : IPS clock ratio == 2:1 or 1:1 only (Edge aligned Synchronous clocks) 3. 2: 1 clock ratio with IPED is restricted with AHB MIN Freq=133Mhz
	SoC Internal: IPS clock (ipg_clk_s)	**In-Direct memory-mapped accesses:** Peripheral clock used for controlling the In-Direct memory-mapped accesses through IPS interface. To allow external logic to stop this clock by writing 1 to MCR[MDIS]. **NOTE** This clock must be running for software reset (MCR[IPS_TG_RST]) to propagate it to the TG queue.
	SoC Internal: IPS clock (ipg_clk)	**Register-mapped accesses:** Peripheral clock used for controlling the register accesses on Control and Configuration registers within XSPI-IP.
Serial Memory (Volatile/ Non-Volatile) domain	SoC External: Free running Serial Memory domain clock (ipg_clk_sfck)	Free running Serial Memory (Volatile/Non-Volatile) domain clock: 1. Source clock for External Memory Device Clock through PAD: SCK 2. Also a source clock for internally generated Dummy/DQS PAD loopback DQS signal for data sampling.
	SoC internal: Gated Serial Memory domain clock (ipg_clk_sfif)	Serial Memory (Volatile/Non-Volatile) domain clock for XSPI-IP logic. It is synchronous to input clock: ipg_clk_sfck. **NOTE** Clock can be gated by "enable_clk_sfif" signal
	SoC internal: Gated 2x Serial Memory domain clock (ipg_clk_2xsfif)	2x Serial Memory (Volatile/Non-Volatile) domain clock for XSPI-IP logic. It is synchronous to input clock: ipg_clk_sfck. **NOTE** Clock can be gated by enable_clk_2xsfif signal in non-DDR mode.
Serial Memory Interface domain	SoC External: DQS (External DQS or Dummy/DQS PAD loopback DQS)	Serial memory device DQS signal. Asynchronous to the other clocks from both Host System bus & Serial Memory (Volatile/Non-Volatile) domains.

41.3.20 Reset

XSPI has the following reset sources.

Table 356. Resets

Reset source	Description
Hard reset	Resets whole XSPI module from external reset signal.
Software reset for serial flash memory domain	MCR[SWRSTSD]
Software reset for AHB domain	MCR[SWRSTHD]
Software reset for IPS target group queue	MCR[IPS_TG_RST]

41.3.21 DMA

This section provides XSPI-specific DMA information. It describes DMA operation in normal mode. For a complete description of the DMA module, see the DMA controller chapter.

41.3.21.1 AHB bus-side read: case 1

The total number of bus cycles for each DMA minor loop completion is added from the following components:

In this use case, DMA needs to read 4 bytes from memory and provide them to XSPI, which takes 4 bus clock cycles. Then, DMA handshake adds an additional 6 cycles, resulting in a total of [6 + 4 * (32/4) = 38] bus clock cycles.

This table provides typical read examples. The data represents an ideal scenario; actual performance depends on the chip-specific integration of XSPI and the DMA controller.

Table 357. Access duration examples for AHB bus-side read: case 1

RBCT[WMRK]	Bytes per DMA minor loop[1]	Bus clock cycles per DMA minor loop	Duration of DMA minor loop at 60 MHz bus clock frequency
3	16	6 + (16/4) * 4 = 22	~366ns
7	32	6 + (32/4) * 4 = 38	~633ns
11	48	6 + (48/4) * 4 = 54	~900ns
15	64	6 + (64/4) * 4 = 70	~1166ns

1. A DMA minor loop is the process of filling the RX buffer to the watermark and then reading the buffer.

41.3.21.2 AHB bus-side read: case 2

The total number of bus cycles for each DMA minor loop completion is added from the following components:

Case 2: DMA needs to read 32 bytes from SRAM and provide to XSPI. DMA handshake takes an additional six bus cycles, with 32 bytes DMA read from SRAM costs (8 + 3) core clock cycles. DMA writes 32 bytes to XSPI, takes 2 * (32/4) = 16 bus cycles with one additional CPU access to XSPI, costing two bus clock cycles. This results in a total 6 + (8+3)/2 + 2 * (32/4) +2 = 30 bus clock cycles.

This table provides typical read examples. The data represents an ideal scenario; actual performance depends on the chip-specific integration of XSPI and the DMA controller.

Table 358. Access duration examples for bus clock side

RBCT[WMRK]	Bytes per DMA minor loop[1]	Bus clock cycles per DMA minor loop	Duration of DMA minor loop at 80 MHz bus clock frequency
3	16	6 + (4+3) /2 + (16/4)*2 + 2 = 20	~333ns
7	32	6 + (8+3) /2 + (32/4)*2 + 2 = 30	~500ns
11	48	6 + (4+3)/2*3 + (48/4)*2 + 2 = 44	~733ns
15	64	6 + (8+3) + (64/4)*2 + 2 = 51	~810ns

1. A DMA minor loop is the process of filling the RX buffer to the watermark and then reading the buffer.

41.3.21.3 Memory device-side read

For the memory device-side read data flow, the duration in bus clock cycles for a DMA minor loop completion is the sum of the following components:

- Clock cycles to read 4 bytes, corresponding to one RX buffer entry (not counting setup of command and address):
  - Octal DDR mode in the individual flash memory mode: 2
  - Quad SDR mode instructions in individual flash memory mode: 8

  and so on.
- Overhead due to clock domain crossing: 1 cycle

This table lists the clock cycles required to read data from memory depending on typical RX buffer watermark (RBCT[WMRK]) values. The data represents an ideal scenario; actual performance depends on the chip-specific integration of XSPI and the DMA controller.

Table 359. Access duration examples for serial flash memory side

RBCT[WMRK]	Bytes per DMA minor loop[1]	SCKFx clock cycles at 60 MHz		Duration of flash memory data readout at 80 MHz SCKFx (~12.5 ns period)	
		IFM [2] quad	IFM quad DDR	IFM quad	IFM quad DDR
0	4	8	4	~100 ns	~50 ns
1	8	16	8	~200 ns	~100 ns
3	16	32	16	~400 ns	~200 ns
7	32	64	32	~800 ns	~400 ns

1. A DMA minor loop is the process of filling the RX buffer to the watermark and then reading the buffer.
2. Individual flash memory mode

A complementary example is when the watermark is set to be too high. In such a case, the time taken by the DMA to read out the RX buffer entries should be lesser than the time taken by the controller to push in the remaining entries in the buffer.

41.3.21.4 IPS bus-side write

For the IP bus-side write data flow, the duration in bus clock cycles for a DMA minor loop completion is the sum of the following components:

- Overhead for each minor loop, as determined by DMA controller: assume 10 cycles

- Overhead resulting from clock domain crossing: assume 2 cycles
- Number of cycles required for 16 bytes (128-bit write size): assume 4 cycles (read/write sequence of DMA controller)

The TX buffer watermark (TBCT[WMRK]) determines the size of the DMA minor loop. Therefore, XSPI distributes the DMA controller overhead across (TBCT[WMRK] + 1) write accesses of 32 bits each.

This table provides typical write examples. The data represents an ideal scenario; actual performance depends on the chip-specific integration of XSPI and the DMA controller.

Table 360. Access duration examples for IP bus-side write

TBCT[WMRK]	Bytes per DMA minor loop[1]	Bus clock cycles per DMA minor loop	Duration of DMA minor loop at 80 MHz bus clock frequency
3	16	12 + 4 = 16	~200 ns
7	32	12 + 8 = 20	~250 ns

1. A DMA minor loop is the process of filling the RX buffer to the watermark and then reading the buffer.

41.3.21.5 Memory device-side write

For the memory device-side write data flow, the duration in bus clock cycles for a DMA minor loop completion is the sum of the following components:

- Memory clock cycles required to write 16 bytes, corresponding to four TX buffer entries (not counting setup of command and address):
  - Octal DDR mode instructions in individual flash memory mode: 8
  - Quad SDR writes in individual flash memory mode: 32
- Overhead due to clock domain crossing: 1

The TX buffer watermark (TBCT[WMRK]) determines the size of the DMA minor loop. This table provides typical write examples. The data represents an ideal scenario; actual performance depends on the chip-specific integration of XSPI and the DMA controller.

This table provides typical write examples. The data represents an ideal scenario; actual performance depends on the chip-specific integration of XSPI and the DMA controller.

Table 361. Access duration examples for serial flash memory side

TBCT[WMRK]	Bytes per DMA minor loop[1]	SCKFx clock cycles per DMA minor loop		Duration for consuming data on memory interface at 100 MHz SCKFx (10 ns period)[2]		Duration for emptying FIFO buffer[3]	
		IFM [4] quad	IFM octal DDR	IFM quad	IFM octal DDR	IFM quad	IFM octal DDR
3	16	32	8	320 ns	80 ns	2240 ns	560 ns
7	32	64	16	640 ns	160 ns	1920 ns	480 ns

1. A DMA minor loop is the process of filling the RX buffer to the watermark and then reading the buffer.
2. Not all flash memory devices support writes at 100 MHz. For the actual page program frequency supported, see the flash memory data sheet.
3. These timings assume that the TX buffer is full when the transaction is initiated.
4. Individual flash memory mode

Considering the examples provided in the two tables above for TX FIFO, it is evident that depending on the relationship between the bus clock and serial flash memory clock frequencies, there are settings possible where the serial flash memory consumes

data faster than the IPS bus can write data in TX buffer. In these cases, a TX buffer underrun situation occurs. To avoid TX buffer underrun, the data transaction size should be large enough.

41.4 External signals

Table 362. External signals

Signal name	Function	Direction	Description
PCSFA1	Peripheral chip select flash memory A1	O	Chip select for the serial flash memory device A1, the first device in a dual-die package flash memory A or the first of two flash memory devices that share IOFA. See Dual-die flash memories.
PCSFA2	Peripheral chip select flash memory A2	O	Chip select for the serial flash memory device A2, the second device in a dual-die package flash memory A or the second of two flash memory devices that share IOFA. See Dual-die flash memories.
SCKFA	Serial clock flash memory A	O	Serial clock output to serial flash memory device A.
SLCKFA_N	Serial loopback clock flash memory A	O	Inverted serial clock output to serial flash memory device A.
IOFA[7:0]	Serial I/O flash memory A	I/O	Data I/O lines to and from serial flash memory device A. For information about signal drive and timing behavior, see Driving external signals. The function of signal pins of the serial flash memory device may change according to the SFM command executed, leaving them as control inputs when executing single and dual instructions. XSPI supports driving these inputs to dedicated values. In single I/O mode, XSPI drives data on IOFA[0] and expects data on IOFA[1].
IOFA_x16[7:0]	x16 Serial I/O Flash memory A	I/O	x16 data I/O lines to and from memory device A. For signal drive and timing behavior, see Driving external signals. The signal pins of the memory device may change function depending on the SFM command being executed, acting as control inputs when executing single and dual instructions. XSPI supports driving these inputs to dedicated values.
DQSFA	Data strobe signal flash memory A	I/O	Data strobe signal for port A. Some flash memory vendors provide the Data Read Strobe (DQS) signal to which the read data is aligned in DDR mode. It also functions as an output signal during the write data phase.
DQS1FA	x16 data strobe signal flash memory A	I/O	x16 data strobe signal for port A. Some flash memory vendors provide the x16 Data Read Strobe (DQS1) signal to which the read data is aligned in DDR mode. It also functions as an output signal during write data phase.

NOTE

See the chip-specific information to confirm the XSPI signals that are available.

41.4.1 Driving external signals

Single/dual/quad/octal/x16 instructions

Depending on the serial flash memory device connected to XSPI, there are instructions that use different numbers of data lines:

- Single pad: Single line I/O with one data out and one data in line to/from the serial flash memory device
- Dual pad: Dual line I/O with two bidirectional I/O lines, driven alternatively by the serial flash memory device or the XSPI module

- Quad pad: Quad line I/O with four bidirectional I/O lines, driven alternatively by the serial flash memory device or the XSPI module
- Octal pad: Octal line I/O with eight bidirectional I/O lines, driven alternatively by the serial flash memory device or the XSPI module

The different phases of the serial flash memory access scheme are shown in the following figure.

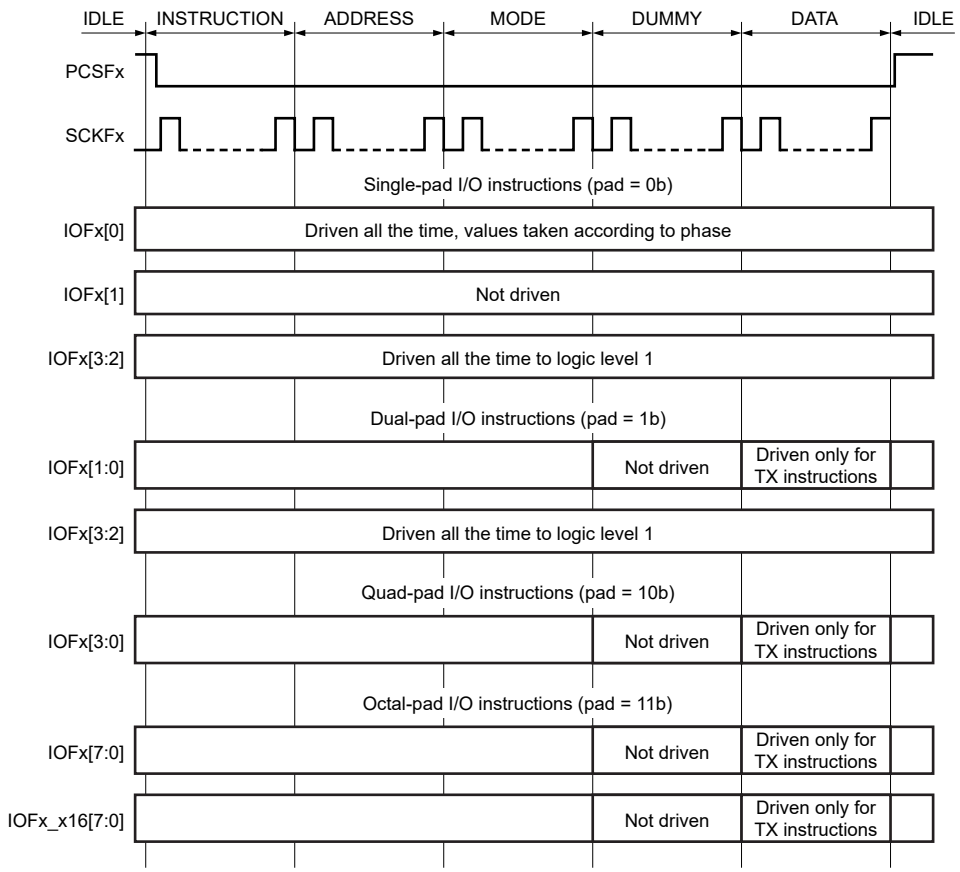

Figure 160. Serial flash memory access scheme

Note1:The IOs are driven from XSPI as per the number of pads configured for ongoing phase.

Note:The lines status will change based on command mode in case of instruction, address and mode phases. It can be either 1,2 or 4 lines

Following are the different phases and the I/O driving characteristics of the XSPI module:

- Idle: Serial flash memory device not selected – no interaction with the serial flash memory device and the IOFx signals are driven.
- Instruction: Serial flash memory device selected – the instruction is sent to the serial device and all the IOFx signals are driven.
- Address: Serial flash memory address is sent to the device – all the IOFx signals are driven and this phase is not applicable for all SFM commands.
- Mode: Mode bytes are sent to the serial flash memory device – all the IOFx signals are driven and this phase is not applicable for all SFM commands.
- Dummy: Dummy clocks are provided to the serial flash memory device. See Figure 160 for the IOFx signals driven. The actual data lines required for the SFM command executed are not driven for data read commands.

NOTE

— This phase is not applicable for all the SFM commands.

— All read commands in Dual pad, Quad pad /or Octal pad modes must use dummy phase before read phase. Note that this restriction is not applicable to Single-pad mode.

- Data: Serial flash memory data are sent to or received from the serial flash memory device. See the preceding figure for the IOFx signals driven. The actual data lines required for the SFM command executed are not driven for data read commands.

NOTE

This phase is not applicable for all the SFM commands.

The PCSFx and SCKFx signals are driven permanently throughout all the phases. In the individual flash memory mode, this applies to the selected flash memory device.

Access to a single, individual serial flash memory device

See Serial flash memory access schemes for details.

Read access to two serial flash memory devices attached to the XSPI module in parallel. See Serial flash memory access schemes for details.

41.5 Initialization

41.5.1 Power up and reset

This is an example sequence for resetting flash memory device A:

You must ensure:

- The inputs of a memory device connected to XSPI meet the required special voltage characteristics for that device during power up or reset.
- The memory device supports reset when CS*n* is high and IOFA[3] is low.

CAUTION

To avoid corrupted flash pages, all erase or program commands must complete before you issue a reset or power cycle. To enable recovery from corrupted flash pages, your application must ensure there is a backup of critical data stored at a different location.

Step	Purpose	Programming
1	Initiate software reset and hardware reset.	• Write 1 to MCR[SWRSTSD]. • Write 1 to MCR[SWRSTHD].
2	End software reset and hardware reset.	• Write 0 to MCR[SWRSTSD]. • Write 0 to MCR[SWRSTHD].
3	Reset the SFP TG queues.	Write 1 to MCR[IPS_TG_RST] .
4	Disable XSPI.	Write 1 to MCR[MDIS].
5	Deassert the idle signal for flash memory A (IOFA[3]).	Write 0 to MCR[ISD3FA].
6	Enable XSPI.	Write 0 to MCR[MDIS].
7	Disable XSPI.	Write 1 to MCR[MDIS].

Table continues on the next page...

Table continued from the previous page...

Step	Purpose	Programming
8	Assert the idle signal for flash memory A (IOFA[3]).	Write 1 to MCR[ISD3FA].
9	Enable XSPI.	Write 0 to MCR[MDIS].

41.5.2 Available status/flag information

This section provides an overview of the different flags and statuses available, and their interdependencies for different use cases. The SR and FR are the related registers. SR[ARB_STATE] can be checked to know which state the arbitration state machine is presently in.

41.5.2.1 IP commands

See IP Configuration (IPCR) for additional details not explicitly covered in this paragraph.

- IP commands — normal operation

  Once the IP command is triggered, after arbitration is granted the SFAR and IPCR registers are written to XSPI. Given that this is a legal command, SR[IPACC] and SR[BUSY] are asserted simultaneously, immediately after the execution starts.

  XSPI IPCR[SEQID] is written only after SFP related checks have been cleared by that TG queue and arbitration is won. See Secure flash protection for details.

  After the instruction on the serial flash memory device is complete, these fields deassert and FR[TFF] is configured.

- IP commands — error situations

  See FR error flags overview .

41.5.2.2 AHB commands

See the "Reading serial flash memory data into the XSPI module internal buffers" topic in the Flash Memory Read section for details.

- AHB commands - normal operation

  Memory-mapped read access to a serial flash memory address not contained in the AHB buffer triggers the execution of an AHB command. Given that this is a legal command, SR[AHB_ACC] and SR[BUSY] are asserted simultaneously, immediately after the execution starts. After the instruction on the serial flash memory device is complete, these fields are deasserted.

- AHB commands - error situations

  See FR error flags overview.

41.5.2.3 SFM commands

An SFM command consists of an instruction code and all other parameters (for example, size or mode bytes) needed for that specific instruction code. Triggering a command either initiates a transaction on the external serial flash memory or results in an error. See FR error flags overview.

41.5.2.4 FR error flags overview

This table provides an overview of the flags in FR, as well as additional error-related details.

Table 363. FR error flags overview

Error	Flag	Description	Command execution on serial flash memory device FR[TFF] behavior (in case of IP commands only and AHB behavior)
AHB Buffer Overflow	ABOF	Indicates an attempt to push too much data into the AHB buffer. Occurs only as a result of an incorrect value in BUF*n*CR[ADATSZ].	Flash memory transaction continues until completion. No AHB error response.
AHB Illegal Burst Size	AIBSEF	Indicates that the total burst size (size x beat) of an AHB transaction is greater than the specified prefetch data size (BUF*n*CR[ADATSZ]).	XSPI terminates the flash memory transaction and rejects incoming AHB read transactions with an AHB error response (HRESP). If the HRESP error mask is asserted (SOCCFG[HRESP_ERR_MASK] = 1) then XSPI does not return an AHB error but instead provides the AHB error payload on the AHB read data bus and processes the next transaction regardless of this flag.
AHB Illegal Transaction Error	AITEF	Indicates that XSPI has not generated a response to the AHB bus due to an illegal transaction and expiration of the watchdog timer.	XSPI terminates the memory transaction and provides the error payload to the AHB read data bus for the beat where the timeout error occurred. It executes subsequent AHB read transactions. While this flag is set, XSPI generates the AHB error response (HRESP) for all AHB write transfers. If the AHB Illegal Transaction Error interrupt is enabled (RSER[AITIE] = 1) and the interrupt is not cleared, XSPI blocks the SFP/IP interface.
Data Learning Pattern Failure	DLPFF	Indicates that XSPI encountered a DATA_LEARN instruction in a sequence, but no sampling point is found for the data learning pattern.	The memory transaction continues until completion. While this flag is set, XSPI generates the AHB error response (HRESP). If the HRESP error mask is asserted (SOCCFG[HRESP_ERR_MASK] = 1) then XSPI does not return an AHB error but instead provides the AHB error payload on the AHB read data bus and processes the next transaction regardless of this flag.
Illegal Instruction Error	ILLINE	Indicates that XSPI encountered an illegal instruction in any sequence.	XSPI terminates the memory transaction. When this error occurs, you must reconfigure the correct sequence instruction and assert software reset for both the serial flash memory and AHB domains (see FR[ILLINE]).
IP Command Trigger Fail Error	IPIEF	Indicates when one of several conditions occur. For details, see the field description.	XSPI ignores any command that causes assertion of this error. XSPI does not assert IP Command Transaction Finished (TFF) for the triggering command.
RX Buffer Overflow[1]	RBOF	Indicates when the RX buffer cannot receive any more data from the serial flash memory device.	XSPI asserts IP Command Transaction Finished (TFF) for the triggering command. If the RX Buffer Drain Interrupt is enabled (RSER[RBDIE] = 1), then you must clear the interrupt for completion of the IP command; otherwise, you may encounter an SFP timeout error. XSPI executes the next SFP TG transaction only after you clear this interrupt.

Table continues on the next page...

Table 363. FR error flags overview (continued)

Error	Flag	Description	Command execution on serial flash memory device FR[TFF] behavior (in case of IP commands only and AHB behavior)
TX Buffer Underrun[1]	TBUF	Indicates that XSPI has attempted to pull data when the TX buffer is empty.	XSPI asserts IP Command Transaction Finished (TFF) for the triggering command. If the TX Buffer Underrun Interrupt is enabled (RSER[TBUIE] = 1), then you must clear the interrupt for completion of the IP command; otherwise, you may encounter an SFP timeout error. XSPI executes the next SFP TG transaction only after you clear this interrupt. The AHB write transfer remains waiting until this flag is cleared.

1. Only the buffer-related errors are associated with a transaction on the external memory.

41.5.3 Flash memory device selection

Regardless of the SFM command (IP or AHB), the access mode (access to serial flash memory A1 or A2) is selected by specifying the 32-bit address value for the following SFM command.

For IP commands, the access mode is selected with the address programmed into the SFAR register. See Serial Flash Memory Address (SFAR) for details. SFAR register is read-only if SFP block is present. When SFP is present the address is programmed in Serial Flash Memory Address (SFP_TG_SFAR) registers. See Secure flash protection for details.

For AHB commands, the access mode is determined by the memory-mapped address. See Flash memory mapped AMBA bus for details.

41.5.4 Flash memory devices address mapping

XSPI is configured in Single mode for the supported flash memory port A

The sizes of the flash memory devices are mapped with the system memory space based on the configurations of the following registers:

- SFA1AD
- SFA2AD

The total memory region for the flash memory devices is mapped between XSPI_AMBA_BASE and TOP_ADDR_MEMA2 such that the corresponding CS is asserted based on SFA1AD and SFA2AD register configurations.

41.5.4.1 Single mode

For single-die flash memories, you must write the same value to SFA2AD register that you write to the SFA1AD register.

Following is a programming example for single mode single-die flash memory:

- XSPI_AMBA_BASE - 1000_0000h
- SFA1AD[TPADA1] - 2000_0000h
- SFA2AD[TPADA2] - 2000_0000h

The following figure illustrates the memory mapping for single mode XSPI configuration.

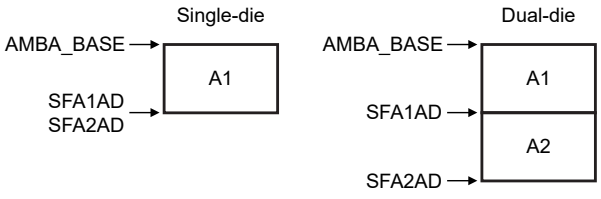

Figure 161. Memory map for Single mode

41.6 Application information

41.6.1 Configuration for x8 and x16 operation

x8 and x16 operation requires the following configuration:

- In x16 operation, the PAD*n* value should be 11b (eight pads).
- To enable x16 mode, write 1 to MCR[X16_EN].
- Based on the requirements of the target device:
  - To enable 16-bit WORD addressable mode, write 1 to SFACR[WA].
  - To enable 32-bit WORD addressable mode, write 1 to SFACR[WAWA_4B_EN].
- To send address and command information on a x16 IO databus, write 1 to MCR[X16_DB_CA_EN].
- To enable variable latency, write 1 to MCR[VAR_LAT_EN].
- PSRAM (such as APMEM) does not support variable latency.
- XSPI does not support wrap burst transactions.
- For dummy cycle operation configuration, see Dummy cycles generation.

41.6.2 Example LUT sequences

The following sections provide example sequences for use with various memory brands and types.

- Sequence: Exit 4 x IO read enhance performance mode (XIP) and read status—Macronix
- Sequence: Read command—HYPERFLASH/HyperRAM
- Sequence: Read status register—HYPERFLASH/HyperRAM
- Sequence: Word program—HYPERFLASH/HyperRAM
- Sequence: Fast read—Macronix, Numonyx, Spansion, Winbond
- Sequence: Fast dual IO DT read—Macronix
- Sequence: Fast read quad output—Winbond
- Sequence: 4 x IO read in enhanced performance mode (XIP)—Macronix
- Sequence: Dual command page program—Numonyx
- Sequence: Sector erase—Macronix, Numonyx, Spansion
- Sequence: Read status register—Macronix, Numonyx, Spansion, Winbond
- Sequence: Data learn instruction for 4 x IO memory
- Sequence: Data learn instruction for 8 x IO memory
- Sequence: x8 and x16 WRITE with DUMMY split and 16-bit word addressing

- Sequence: x8 or x16 READ with DUMMY split and 16-bit word addressing
- Sequence: x8 and x16 WRITE with DUMMY split, variable latency, RWDS = 1
- Sequence: x8 and x16 READ with DUMMY split, variable latency, RWDS = 1
- Sequence: x8 and x16 WRITE with DUMMY split, variable latency, RWDS = 0
- Sequence: x8 and x16 READ with DUMMY split, variable latency, RWDS = 0
- Sequence: x8 and x16 WRITE without DUMMY split, variable latency
- Sequence: x8 and x16 READ without DUMMY split, variable latency
- Sequence: x8 and x16 WRITE with DUMMY split, fixed latency
- Sequence: x8 and x16 READ with DUMMY split, fixed latency
- Sequence: x8 and x16 WRITE without DUMMY split, fixed latency
- Sequence: x8 and x16 READ without DUMMY split, fixed latency

For all x8 and x16 sequences, see also Configuration for x8 and x16 operation.

41.6.2.1 Sequence: Exit 4 x IO read enhance performance mode (XIP) and read status—Macronix

Table 364. Sequence: Exit 4 x IO read enhance performance mode (XIP) and read status

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 0	CMD	00b	EBh	4 x I/O read command.
LUT0 1	ADDR	10b	18h	Send 24 address bits on four pads.
LUT1 0	MODE	10b	00h	Execute two mode cycles (exit XIP).
LUT1 1	DUMMY	00b	04h	Execute four dummy cycles.
LUT2 0	READ	10b	08h	Read 8 bytes (64 bits) on four pads.
LUT2 1	CMD	00b	05h	Read status register command.
LUT3 0	READ	00b	01h	Read status register data.
LUT3 1	STOP	00b	00h	Stop, sequence completed.

1. Sequence numbering assumes the use of LUT sequence 0 for demonstration purposes. You can program this example into any available LUT sequence.
2. For instruction descriptions, see Programmable sequence engine instructions.

41.6.2.2 Sequence: Read command—HYPERFLASH/HyperRAM

HYPERFLASH/HyperRAM memory is word-addressable memory. Each address accesses a word-wide (two-byte) data value. When connecting HyperFLASH/HyperRAM memory to the controller, you must configure that memory as word-addressable (write 1 to SFACR[WA]), which causes XSPI to remap a byte access to a word access.

Table 365. Sequence: Read command—HYPERFLASH/HyperRAM

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 0	CMD_DDR	11b	A0h	Read command with continuous burst type.
LUT0 1	ADDR_DDR	11b	18h	Send 24-bit row address.
LUT1 0	CADDR_DDR	11b	10h	Send 16-bit column address with lower 3 bits valid and the rest 0.

Table continues on the next page...

Table 365. Sequence: Read command—HYPERFLASH/HyperRAM (continued)

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT1 1	DUMMY	11b	0Fh	Execute 15 dummy cycles.
LUT2 0	READ_DDR	11b	04h	Read 32 bits of data on 8 pads.
LUT2 1	STOP	11b	00h	Stop, sequence completed.

1. Sequence numbering assumes the use of LUT sequence 0 for demonstration purposes. You can program this example into any available LUT sequence.
2. For instruction descriptions, see Programmable sequence engine instructions.

41.6.2.3 Sequence: Read status register—HYPERFLASH/HyperRAM

Table 366. Sequence: Read status register—HYPERFLASH/HyperRAM

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
Sequence: Read Pre Command				
LUT0 0	CMD_DDR	11b	00h	Write command with wrapped burst type.
LUT0 1	ADDR_DDR	11b	18h	Send 24-bit row address (0000AAh) in DDR mode.
LUT1 0	CADDR_DDR	11b	10h	16-bit column address with lower 3 bits valid and the rest 0 (0005h) treated as command.
LUT1 1	CMD_DDR	11b	00h	Write command with wrapped burst type.
LUT2 0	CMD_DDR	11b	70h	Write data to memory as pre-command.
Sequence: Command phase (fourth/final chip select phase)				
LUT2 1	CMD_DDR	11b	A0h	Read command with continuous burst type.
LUT3 0	ADDR_DDR	11b	18h	Send 24-bit row address.
LUT3 1	CADDR_DDR	11b	10h	Send 16-bit column address with lower 3 bits as valid and the rest 0.
LUT4 0	DUMMY	11b	0Fh	Execute 15 dummy cycles
LUT4 1	READ_DDR	11b	04h	Read 4 bytes (32 bits) on 8 pads.
LUT5 0	STOP	11b	00h	Stop, sequence completed.

1. Sequence numbering assumes the use of LUT sequence 0 for demonstration purposes. You can program this example into any available LUT sequence.
2. For instruction descriptions, see Programmable sequence engine instructions.

41.6.2.4 Sequence: Word program—HYPERFLASH/HyperRAM

Table 367. Sequence: Word program—HYPERFLASH/HyperRAM

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
Unlock sequence 1 (first chip select phase)				
LUT0 0	CMD_DDR	11b	00h	Write command with wrapped burst type.
LUT0 1	CMD_DDR	11b	00h	Treat 8-bit address 00h as command.

Table continues on the next page...

Table 367. Sequence: Word program—HYPERFLASH/HyperRAM (continued)

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT1 0	CMD_DDR	11b	00h	Treat 8-bit address 00h as command.
LUT1 1	CMD_DDR	11b	AAh	Treat 8-bit address AAh as command.
LUT2 0	CADDR_DDR	11b	10h	Treat 16-bit column address with lower 3 bits valid and the rest 0 (0005h) as command
LUT2 1	CMD_DDR	11b	00h	Write command with wrapped burst type.
LUT3 0	CMD_DDR	11b	AAh	Write data to memory as pre-command.
Unlock sequence 2 (second chip select phase)				
LUT3 1	CMD_DDR	11b	00h	Write command with wrapped burst type.
LUT4 0	CMD_DDR	11b	00h	Treat 8-bit address 00h as command
LUT4 1	JMP_TO_SEQ	11b	01h	Jump to sequence 1 (which begins with LUT5).
LUT5 0	CMD_DDR	11b	00h	Treat 8-bit address 00h as command.
LUT5 1	CMD_DDR	11b	55h	Treat 8-bit address 55h as command.
LUT6 0	CADDR_DDR	11b	10h	Treat 16-bit column address with lower 3-bits valid and the rest 0 (0002h) as command.
LUT6 1	CMD_DDR	11b	00h	Write command with wrapped burst type.
LUT7 0	CMD_DDR	11b	55h	Write data to memory as pre-command
Program setup phase (third chip select phase)				
LUT7 1	CMD_DDR	11b	00h	Write command with wrapped burst type.
LUT8 0	CMD_DDR	11b	00h	Treat 8-bit address 00h as command.
LUT8 1	CMD_DDR	11b	00h	Treat 8-bit address 00h as command.
LUT9 0	CMD_DDR	11b	AAh	Treat 8-bit address AAh as command.
LUT9 1	JMP_TO_SEQ	11b	02h	Jump to sequence 2 (which begins with LUT10).
LUT10 0	CADDR_DDR	11b	10h	Treat 16-bit column address with lower 3 bits valid and the rest 0 (0005h) as command.
LUT10 1	CMD_DDR	11b	00h	Write command with wrapped burst type.
LUT11 0	CMD_DDR	11b	A0h	Write data to memory as pre-command.
Command phase (fourth/final chip select phase)				
LUT11 1	CMD_DDR	11b	00h	Write command with wrapped burst type.
LUT12 0	ADDR_DDR	11b	18h	Send 24-bit row address in DDR mode.
LUT12 1	CADDR_DDR	11b	10h	Send 16-bit column address with lower 3 bits as valid and the rest 0.
LUT13 0	WRITE_DDR	11b	02h	Write 2 bytes (16 bits) on 8 pads (D1D2).
LUT13 1	STOP	11b	00h	Stop, sequence completed.

1. For demonstration purposes, sequence numbering assumes a sequence depth of five instruction-operand pairs and the use of LUT sequences 0-2, with JMP_TO_SEQ commands to bridge the sequences. You can program this example into any available LUT sequences.

2. For instruction descriptions, see Programmable sequence engine instructions.

41.6.2.5 Sequence: Fast read—Macronix, Numonyx, Spansion, Winbond

Table 368. Sequence: Fast read

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 0	CMD	00b	0Bh	Perform a fast read.
LUT0 1	ADDR	00b	18h	Send 24 address bits on one pad.
LUT1 0	DUMMY	00b	08h	Execute eight dummy cycles.
LUT1 1	READ	00b	04h	Read 32 bits on one pad.
LUT2 0	JMP_ON_CS[3]	00b	00h	Jump to instruction 0 (LUT0 0: CMD).

1. Sequence numbering assumes the use of LUT sequence 0 for demonstration purposes. You can program this example into any available LUT sequence.
2. For instruction descriptions, see Programmable sequence engine instructions.
3. If DLL is enabled (DLLCR*x*[DLLEN] = 1), you must use a STOP instruction.

41.6.2.6 Sequence: Fast dual IO DT read—Macronix

Table 369. Sequence: Fast dual IO DT read

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT	CMD	00b	BDh	Fast dual IO DT read command.
LUT0 0	ADDR_DDR	01b	18h	Send 24 address bits on two pads in DDR mode.
LUT0 1	MODE4_DDR	01b	00h	P2 = P0 or P3 = P1 is necessary. See the Macronix data sheet for details. One clock cycle for mode.
LUT1 0	DUMMY	00b	06h	Execute six dummy cycles.
LUT1 1	READ_DDR	01b	04h	Read 32 bits on two pads in DDR mode.
LUT2 0	JMP_ON_CS[3]	00b	00h	Jump to instruction 0 (LUT0 0: CMD).

1. Sequence numbering assumes the use of LUT sequence 0 for demonstration purposes. You can program this example into any available LUT sequence.
2. For instruction descriptions, see Programmable sequence engine instructions.
3. If DLL is enabled (DLLCR*x*[DLLEN] = 1), you must use a STOP instruction.

NOTE

If DLL is enabled (DLLCRx[DLLEN] = 1), then we should use only STOP and if DLL is disabled, then we can use either STOP or JMP_ON_CS as per requirement.

41.6.2.7 Sequence: Fast read quad output—Winbond

Table 370. Sequence: Fast read quad output

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 0	CMD	00b	6Bh	Fast read quad output command.
LUT0 1	ADDR	00b	18h	Send 24 address bits on one pad.

Table continues on the next page...

Table 370. Sequence: Fast read quad output (continued)

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT1 0	DUMMY	00b	08h	Execute eight dummy cycles.
LUT1 1	READ	10b	04h	Read 32 bits on four pads.
LUT2 0	JMP_ON_CS[3]	00b	00h	Jump to instruction 0 (LUT0 0: CMD).

1. Sequence numbering assumes the use of LUT sequence 0 for demonstration purposes. You can program this example into any available LUT sequence.
2. For instruction descriptions, see Programmable sequence engine instructions.
3. If DLL is enabled (DLLCR*x*[DLLEN] = 1), you must use a STOP instruction.

41.6.2.8 Sequence: 4 x IO read in enhanced performance mode (XIP)—Macronix

In XIP mode, you must ensure that all flash memories connected to XSPI are in this mode. As part of initialization, all the flash memories might be enabled with XIP by carrying out dummy reads.

NOTE

When using XIP mode, you must request arbitration lock for the queue executing the XIP transfer. Otherwise, after the first transfer completes another high priority manager may acquire the grant.

Table 371. Sequence: 4 x IO read in enhanced performance mode (XIP)

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 0	CMD	00b	EBh	4 x IO read command.
LUT0 1	ADDR	10b	18h	Send 24 address bits on four pads.
LUT1 0	MODE	10b	A5h	Two mode cycles.
LUT1 1	DUMMY	00b	04h	Execute four dummy cycles.
LUT2 0	READ	10b	04h	Read 32 bits on four pads,
LUT2 1	JMP_ON_CS	00b	01h	Jump to instruction 1 (LUT0 1: ADDR).

1. Sequence numbering assumes the use of LUT sequence 0 for demonstration purposes. You can program this example into any available LUT sequence.
2. For instruction descriptions, see Programmable sequence engine instructions.

41.6.2.9 Sequence: Dual command page program—Numonyx

Table 372. Sequence: Dual command page program

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 0	CMD	01b	02h	Dual command page program.
LUT0 1	ADDR	01b	18h	Send 24 address bits on two pads.
LUT1 0	WRITE	01b	20h	Write 32 bytes on two pads.
LUT1 1	STOP	00b	00h	Stop, sequence completed.

1. Sequence numbering assumes the use of LUT sequence 0 for demonstration purposes. You can program this example into any available LUT sequence.
2. For instruction descriptions, see Programmable sequence engine instructions.

41.6.2.10 Sequence: Sector erase—Macronix, Numonyx, Spansion

Table 373. Sequence: Sector erase

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 0	CMD	00b	20h	Sector erase command.
LUT0 1	ADDR	00b	18h	Send 24 address bits on one pad.
LUT1 0	STOP	00b	00h	Stop, sequence completed.

1. Sequence numbering assumes the use of LUT sequence 0 for demonstration purposes. You can program this example into any available LUT sequence.
2. For instruction descriptions, see Programmable sequence engine instructions.

41.6.2.11 Sequence: Read status register—Macronix, Numonyx, Spansion, Winbond

Table 374. Sequence: Read status register

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 0	CMD	00b	05h	Read status register command.
LUT0 1	READ	00b	01h	Read status register data.
LUT1 0	STOP	00b	00h	Stop, sequence completed.

1. Sequence numbering assumes the use of LUT sequence 0 for demonstration purposes. You can program this example into any available LUT sequence.
2. For instruction descriptions, see Programmable sequence engine instructions.

41.6.2.12 Sequence: Data learn instruction for 4 x IO memory

Table 375. Sequence: Data learn instruction for 4 x IO memory

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 0	CMD	00b	6Bh	Fast read quad command.
LUT0 1	ADDR_DDR	00b	18h	Send 24 address bits on four pads in DDR mode.
LUT1 0	DUMMY	10b	08h	Execute eight dummy cycles.
LUT1 1	DATA_LEARN	10b	01h	Send 1-byte data learn pattern.
LUT2 0	READ_DDR	10b	06h	Read 6 bytes on 4 pads.[3]
LUT2 1	JMP_ON_CS[4]	00b	00h	Jump to instruction 0 (LUT0 0: CMD).

1. Sequence numbering assumes the use of LUT sequence 0 for demonstration purposes. You can program this example into any available LUT sequence.
2. For instruction descriptions, see Programmable sequence engine instructions.
3. For 4 x IO mode, you must follow the DATA_LEARN instruction with a READ_DDR instruction of a minimum of eight bytes.
4. If DLL is enabled (DLLCR*x*[DLLEN] = 1), you must use a STOP instruction.

41.6.2.13 Sequence: Data learn instruction for 8 x IO memory

Table 376. Sequence: Data learn instruction for 8 x IO memory

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 0	CMD_DDR	11b	A0h	Read command for hyperflash memory.

Table continues on the next page...

Table 376. Sequence: Data learn instruction for 8 x IO memory (continued)

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 1	ADDR_DDR	11b	18h	Send 24-bit row address on eight pads in DDR mode. [3]
LUT1 0	CADDR_DDR	11b	10h	Send 16-bit column address on eight pads in DDR mode.
LUT1 1	DUMMY	11b	0Fh	Execute 15 dummy cycles.
LUT2 0	DATA_LEARN	11b	01h	Send 1-byte data learn pattern.
LUT2 1	READ_DDR	11b	0Ch	Read 12 bytes on 8 pads in DDR mode.
LUT3 0	STOP	11b	00h	Stop, sequence completed.

1. Sequence numbering assumes the use of LUT sequence 0 for demonstration purposes. You can program this example into any available LUT sequence.
2. For instruction descriptions, see Programmable sequence engine instructions.
3. The address must be aligned to prevent latency between the RWDS edges.

41.6.2.14 Sequence: x8 and x16 WRITE with DUMMY split and 16-bit word addressing

See Configuration for x8 and x16 operation.

Table 377. Sequence: x8 and x16 WRITE with DUMMY split and 16-bit word addressing

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 0	CMD_DDR	11b	A0h	Write command at positive edge of the clock.
LUT0 1	CMD_DDR	11b	A0h	Write command at negative edge of the clock.
LUT1 0	ADDR_DDR	11b	20h	Send 32-bit address on eight pads in DDR mode.
LUT1 1	DUMMY	11b	84h	First DUMMY instruction: Execute four dummy cycles.[3]
LUT2 0	DUMMY	11b	82h	Second DUMMY instruction: Execute two dummy cycles.[3]
LUT2 1	WRITE_DDR	11b	FFh	Read the specified number of bytes on eight pads in DDR mode (FFh is the maximum).
LUT3 0	STOP	11b	00h	Stop, sequence completed.

1. Sequence numbering assumes the use of LUT sequence 0 for demonstration purposes. You can program this example into any available LUT sequence.
2. For instruction descriptions, see Programmable sequence engine instructions.
3. For *n* dummy cycles, the first DUUMY instruction must specify *n* – 2 – 1 cycles. The second DUMMY instruction then specifies two dummy cycles.

41.6.2.15 Sequence: x8 or x16 READ with DUMMY split and 16-bit word addressing

See Configuration for x8 and x16 operation.

Table 378. Sequence: x8 and x16 READ with DUMMY split and 16-bit word addressing

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 0	CMD_DDR	11b	20h	Read command at positive edge of the clock.
LUT0 1	CMD_DDR	11b	20h	Read command at negative edge of the clock.
LUT1 0	ADDR_DDR	11b	20h	Send 32-bit address on eight pads in DDR mode.

Table continues on the next page...

Table 378. Sequence: x8 and x16 READ with DUMMY split and 16-bit word addressing (continued)

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT1 1	DUMMY	11b	8Ch	First DUMMY instruction: Execute twelve dummy cycles.[3]
LUT2 0	DUMMY	11b	82h	Second DUMMY instruction: Execute two dummy cycles.[3]
LUT2 1	READ_DDR	11b	FFh	Read the specified number of bytes on eight pads in DDR mode (FFh is the maximum).
LUT3 0	STOP	11b	00h	Stop, sequence completed.

1. Sequence numbering assumes the use of LUT sequence 0 for demonstration purposes. You can program this example into any available LUT sequence.
2. For instruction descriptions, see Programmable sequence engine instructions.
3. For *n* dummy cycles, the first DUUMY instruction must specify *n* – 2 – 1 cycles. The second DUMMY instruction then specifies two dummy cycles.

41.6.2.16 Sequence: x8 and x16 WRITE with DUMMY split, variable latency, RWDS = 1

See Configuration for x8 and x16 operation.

Table 379. Sequence: x8 and x16 WRITE with DUMMY split, variable latency, RWDS = 1

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 0	CMD_DDR	11b	20h	Write command at positive edge of the clock.
LUT0 1	ADDR_DDR	11b	18h	Send 24-bit row address on eight pads in DDR mode.
LUT1 0	CADDR_DDR	11b	10h	Send 16-bit column address on eight pads in DDR mode.
LUT1 1	MODE	11b	00h	Single cycle mode.
LUT2 0	DUMMY	11b	84h	First split DUMMY instruction: For a total of 7 dummy cycles, specify 4 in this first instruction.[3]
LUT2 1	DUMMY	11b	82h	Second split DUMMY instruction: Execute two dummy cycles.[3]
LUT3 0	WRITE_DDR	11b	FFh	Write the specified number of bytes on eight pads in DDR mode (FFh is the maximum).
LUT3 1	STOP	11b	00h	Stop, sequence completed.

1. Sequence numbering assumes the use of LUT sequence 0 for demonstration purposes. You can program this example into any available LUT sequence.
2. For instruction descriptions, see Programmable sequence engine instructions.
3. For *n* dummy cycles, the first DUMMY instruction must specify *n* – 2 – 1 cycles. The second DUMMY instruction then specifies two dummy cycles.

41.6.2.17 Sequence: x8 and x16 READ with DUMMY split, variable latency, RWDS = 1

See Configuration for x8 and x16 operation.

Table 380. Sequence: x8 and x16 READ with DUMMY split, variable latency, RWDS = 1

Instruction sequence [1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 0	CMD_DDR	11b	A0h	Read command at positive edge of the clock.

Table continues on the next page...

Table 380. Sequence: x8 and x16 READ with DUMMY split, variable latency, RWDS = 1 (continued)

Instruction sequence [1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 1	ADDR_DDR	11b	18h	Send 24-bit row address on eight pads in DDR mode.
LUT1 0	CADDR_DDR	11b	10h	Send 16-bit column address on eight pads in DDR mode.
LUT1 1	MODE	11b	00h	Single cycle mode.
LUT2 0	DUMMY	11b	84h	First split DUMMY instruction: For a total of 7 dummy cycles, specify 4 in this first instruction.[3]
LUT2 1	DUMMY	11b	82h	Second split DUMMY instruction: Execute two dummy cycles.[3]
LUT3 0	READ_DDR	11b	FFh	Read the specified number of bytes on eight pads in DDR mode (FFh is the maximum).
LUT3 1	STOP	11b	00h	Stop, sequence completed.

1. Sequence numbering assumes the use of LUT sequence 0 for demonstration purposes. You can program this example into any available LUT sequence.
2. For instruction descriptions, see Programmable sequence engine instructions.
3. For *n* dummy cycles, the first DUUMY instruction must specify *n* – 2 – 1 cycles. The second DUMMY instruction then specifies two dummy cycles.

41.6.2.18 Sequence: x8 and x16 WRITE with DUMMY split, variable latency, RWDS = 0

See Configuration for x8 and x16 operation.

Table 381. Sequence: x8 and x16 WRITE with DUMMY split, variable latency, RWDS = 0

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 0	CMD_DDR	11b	20h	Write command at positive edge of the clock.
LUT0 1	ADDR_DDR	11b	18h	Send 24-bit row address on eight pads in DDR mode.
LUT1 0	CADDR_DDR	11b	10h	Send 16-bit column address on eight pads in DDR mode.
LUT1 1	DUMMY	11b	84h	First split DUMMY instruction: For a total of 7 dummy cycles, specify 4 in this first instruction.[3]
LUT2 0	DUMMY	11b	82h	Second split DUMMY instruction: Execute two dummy cycles.[3]
LUT2 1	WRITE_DDR	11b	FFh	Write the specified number of bytes on eight pads in DDR mode (FFh is the maximum).
LUT3 0	STOP	11b	00h	Stop, sequence completed.

1. Sequence numbering assumes the use of LUT sequence 0 for demonstration purposes. You can program this example into any available LUT sequence.
2. For instruction descriptions, see Programmable sequence engine instructions.
3. For *n* dummy cycles, the first DUUMY instruction must specify *n* – 2 – 1 cycles. The second DUMMY instruction then specifies two dummy cycles.

41.6.2.19 Sequence: x8 and x16 READ with DUMMY split, variable latency, RWDS = 0

See Configuration for x8 and x16 operation.

Table 382. Sequence: x8 and x16 READ with DUMMY split, variable latency, RWDS = 0

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 0	CMD_DDR	11b	A0h	Read command at positive edge of the clock.
LUT0 1	ADDR_DDR	11b	18h	Send 24-bit row address on eight pads in DDR mode.
LUT1 0	CADDR_DDR	11b	10h	Send 16-bit column address on eight pads in DDR mode.
LUT1 1	DUMMY	11b	84h	First split DUMMY instruction: For a total of 7 dummy cycles, specify 4 in this first instruction.[3]
LUT2 0	DUMMY	11b	82h	Second split DUMMY instruction: Execute two dummy cycles.[3]
LUT2 1	READ_DDR	11b	FFh	Read the specified number of bytes on eight pads in DDR mode (FFh is the maximum).
LUT3 0	STOP	11b	00h	Stop, sequence completed.

1. Sequence numbering assumes the use of LUT sequence 0 for demonstration purposes. You can program this example into any available LUT sequence.
2. For instruction descriptions, see Programmable sequence engine instructions.
3. For *n* dummy cycles, the first DUUMY instruction must specify *n* – 2 – 1 cycles. The second DUMMY instruction then specifies two dummy cycles.

41.6.2.20 Sequence: x8 and x16 WRITE without DUMMY split, variable latency

See Configuration for x8 and x16 operation.

Table 383. Sequence: x8 and x16 WRITE without DUMMY split, variable latency

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 0	CMD_DDR	11b	20h	Write command at positive edge of the clock.
LUT0 1	ADDR_DDR	11b	18h	Send 24-bit row address on eight pads in DDR mode.
LUT1 0	CADDR_DDR	11b	10h	Send 16-bit column address on eight pads in DDR mode.
LUT1 1	DUMMY	11b	0Dh	For a total of 7 dummy cycles, specify 13 for this instruction.[3]
LUT2 0	WRITE_DDR	11b	FFh	Write the specified number of bytes on eight pads in DDR mode (FFh is the maximum).
LUT2 1	STOP	11b	00h	Stop, sequence completed.

1. Sequence numbering assumes the use of LUT sequence 0 for demonstration purposes. You can program this example into any available LUT sequence.
2. For instruction descriptions, see Programmable sequence engine instructions.
3. For *n* dummy cycles, the DUMMY instruction must specify 2**n* – 1 cycles.

41.6.2.21 Sequence: x8 and x16 READ without DUMMY split, variable latency

See Configuration for x8 and x16 operation.

Table 384. Sequence: x8 and x16 READ without DUMMY split, variable latency

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 0	CMD_DDR	11b	A0h	Read command at positive edge of the clock.

Table continues on the next page...

Table 384. Sequence: x8 and x16 READ without DUMMY split, variable latency (continued)

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 1	ADDR_DDR	11b	18h	Send 24-bit row address on eight pads in DDR mode.
LUT1 0	CADDR_DDR	11b	10h	Send 16-bit column address on eight pads in DDR mode.
LUT1 1	DUMMY	11b	0Dh	For a total of 7 dummy cycles, specify 13 for this instruction.[3]
LUT2 0	READ_DDR	11b	FFh	Read the specified number of bytes on eight pads in DDR mode (FFh is the maximum).
LUT2 1	STOP	11b	00h	Stop, sequence completed.

1. Sequence numbering assumes the use of LUT sequence 0 for demonstration purposes. You can program this example into any available LUT sequence.
2. For instruction descriptions, see Programmable sequence engine instructions.
3. For *n* dummy cycles, the DUMMY instruction must specify 2**n* – 1 cycles.

41.6.2.22 Sequence: x8 and x16 WRITE with DUMMY split, fixed latency

See Configuration for x8 and x16 operation.

Table 385. Sequence: x8 and x16 WRITE with DUMMY split, fixed latency

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 0	CMD_DDR	11b	20h	Write command at positive edge of the clock.
LUT0 1	ADDR_DDR	11b	18h	Send 24-bit row address on eight pads in DDR mode.
LUT1 0	CADDR_DDR	11b	10h	Send 16-bit column address on eight pads in DDR mode.
LUT1 1	DUMMY	11b	8Bh	First split DUMMY instruction: For a total of 13 dummy cycles, specify 11 in this first instruction.[3]
LUT2 0	DUMMY	11b	82h	Second split DUMMY instruction: Execute two dummy cycles.[3]
LUT2 1	WRITE_DDR	11b	FFh	Write the specified number of bytes on eight pads in DDR mode (FFh is the maximum).
LUT3 0	STOP	11b	00h	Stop, sequence completed.

1. Sequence numbering assumes the use of LUT sequence 0 for demonstration purposes. You can program this example into any available LUT sequence.
2. For instruction descriptions, see Programmable sequence engine instructions.
3. For *n* dummy cycles, the first DUUMY instruction must specify *n* – 2 cycles. The second DUMMY instruction then specifies two dummy cycles.

41.6.2.23 Sequence: x8 and x16 READ with DUMMY split, fixed latency

See Configuration for x8 and x16 operation.

Table 386. Sequence: x8 and x16 READ with DUMMY split, fixed latency

Sequence [1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 0	CMD_DDR	11b	A0h	Send command at positive edge of the clock.
LUT0 1	ADDR_DDR	11b	18h	Send 24-bit row address on eight pads in DDR mode.

Table continues on the next page...

Table 386. Sequence: x8 and x16 READ with DUMMY split, fixed latency (continued)

Sequence [1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT1 0	CADDR_DDR	11b	10h	Send 16-bit column address on eight pads in DDR mode.
LUT1 1	DUMMY	11b	8Bh	First split DUMMY instruction: For a total of 13 dummy cycles, specify 11 in this first instruction.[3]
LUT2 0	DUMMY	11b	82h	Second split DUMMY instruction: Execute two dummy cycles.[3]
LUT2 1	READ_DDR	11b	FFh	Read the specified number of bytes on eight pads in DDR mode (FFh is the maximum).
LUT3 0	STOP	11b	00h	Stop, sequence completed.

1. Sequence numbering assumes the use of LUT sequence 0 for demonstration purposes. You can program this example into any available LUT sequence.
2. For instruction descriptions, see Programmable sequence engine instructions.
3. For *n* dummy cycles, the first DUUMY instruction must specify *n* – 2 cycles. The second DUMMY instruction then specifies two dummy cycles.

41.6.2.24 Sequence: x8 and x16 WRITE without DUMMY split, fixed latency

See Configuration for x8 and x16 operation.

Table 387. Sequence: x8 and x16 WRITE without DUMMY split, fixed latency

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 0	CMD_DDR	11b	20h	Write command at positive edge of the clock.
LUT0 1	ADDR_DDR	11b	18h	Send 24-bit row address on eight pads in DDR mode.
LUT1 0	CADDR_DDR	11b	10h	Send 16-bit column address on eight pads in DDR mode.
LUT1 1	DUMMY	11b	8Bh	First split DUMMY instruction: For a total of 7 dummy cycles, specify 13 for this instruction.[3]
LUT2 0	DUMMY	11b	82h	Second split DUMMY instruction: Execute two dummy cycles.[3]
LUT2 1	WRITE_DDR	11b	FFh	Write the specified number of bytes on eight pads in DDR mode (FFh is the maximum).
LUT3 0	STOP	11b	00h	Stop, sequence completed.

1. Sequence numbering assumes the use of LUT sequence 0 for demonstration purposes. You can program this example into any available LUT sequence.
2. For instruction descriptions, see Programmable sequence engine instructions.
3. For *n* dummy cycles, the DUMMY instruction must specify 2**n* – 1 cycles. The second DUMMY instruction then specifies two dummy cycles.

41.6.2.25 Sequence: x8 and x16 READ without DUMMY split, fixed latency

See Configuration for x8 and x16 operation.

Table 388. Sequence: x8 and x16 READ without DUMMY split, fixed latency

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 0	CMD_DDR	11b	A0h	Write command at positive edge of the clock.

Table continues on the next page...

Table 388. Sequence: x8 and x16 READ without DUMMY split, fixed latency (continued)

Sequence[1]	INSTR*n*[2]	PAD*n*	OPRND*n*	Description
LUT0 1	ADDR_DDR	11b	18h	Send 24-bit row address on eight pads in DDR mode.
LUT1 0	CADDR_DDR	11b	10h	Send 16-bit column address on eight pads in DDR mode.
LUT1 1	DUMMY	11b	8Bh	First split DUMMY instruction: For a total of 7 dummy cycles, specify 13 for this instruction.[3]
LUT2 0	DUMMY	11b	82h	Second split DUMMY instruction: Execute two dummy cycles.[3]
LUT2 1	READ_DDR	11b	FFh	READ the specified number of bytes on eight pads in DDR mode (FFh is the maximum).
LUT3 0	STOP	11b	00h	Stop, sequence completed.

1. Sequence numbering assumes the use of LUT sequence 0 for demonstration purposes. You can program this example into any available LUT sequence.
2. For instruction descriptions, see Programmable sequence engine instructions.
3. For *n* dummy cycles, the DUMMY instruction must specify 2**n* – 1 cycles. The second DUMMY instruction then specifies two dummy cycles.

41.6.2.26 SNAND sequences (IPS write and IPS read)

This section contains example sequences for accessing SNAND flash devices in NAND and NOR modes. Before generating read commands, appropriate modes such as QUAD, NAND/NOR are required to be enabled. You need to read the DLP pattern for the selection of proper DLL data sampling point.

41.6.2.26.1 NAND mode

ENPGM = 1

Table 389. CMD_WRITE_STATUS, Addr: 10h (through SFAR send this address), status: 01h

Instruction	Pad	Operand	Comment
CMD	00b	1Fh	Command for Set Feature
ADDR	00b	8d	8-bit write address
WRITE	00b	1d	Write 1 byte of data on single PAD
STOP	00b	0d	Stop, instruction over

Write QE = 1

Table 390. CMD_WRITE_STATUS, Addr: B0h (through SFAR send this address), status: 01h

Instruction	Pad	Operand	Comment
CMD	00b	1Fh	Command for Set Feature
ADDR	00b	8d	8-bit write address
WRITE	00b	1d	Write 1 byte of data on single PAD
STOP	00b	0d	Stop, instruction over

Read QE = 1

Table 391. CMD_READ_STATUS, Addr: B0h (through SFAR send this address)

Instruction	Pad	Operand	Comment
CMD	00b	05h	Command for Read Status
ADDR	00b	8d	8-bit read address
READ	00b	2d	Read 2 byte of data on single PAD
STOP	00b	0d	Stop, instruction over

NOTE

ENPGM is Enable Program, QE is Quad Enable, are configuration bits from SNAND Device configuration register.

DLP Read

Table 392. CMD_READ_DATA, Addr: 8h (through SFAR send this address)

Instruction	Pad	Operand	Comment
CMD	00b	05h	Command for Read Status
ADDR	00b	8d	8-bit read address
READ	00b	2d	Read 2 byte of data on single PAD
STOP	00b	0d	Stop, instruction over

Read status

Table 393. CMD_READ_STATUS, Addr: C0h (through SFAR send this address)

Instruction	Pad	Operand	Comment
CMD	00b	05h	Command for Read Status
ADDR	00b	8d	8-bit read address
READ	00b	2d	Read 2 byte of data on single PAD
STOP	00b	0d	Stop, instruction over

NOTE

SNAND flash require read commands to happen in two steps. Step one to open a page and next command to read number of bytes. IPS interface is used for transactions.

Page selection

Table 402. CMD_FAST_READ, Addr: 100h (through SFAR send this address), size: 192 (continued)

Instruction	Pad	Operand	Comment
Read	10b	size	This is the total size of the data transfer in READ mode. Based on the requirement, this operand value may vary
STOP	00b	0d	Stop, instruction over

41.7 Memory map and register definition

This section provides the memory map and register definitions for the XSPI module

41.7.1 Register write access

Following are the write access restriction terms that apply to all the registers:

- Register write access restriction

  For each register field, the write access conditions are specified in the detailed register description.

  The following table provides a description of the write access conditions. If, for a specific register bit or field, none of the given write access conditions is fulfilled, any write attempt to this register bit or field is ignored without any notification. The values of the bits or fields are not changed.

  The condition term [A or B] indicates that the register or field can be written to if at least one of the conditions is fulfilled.

Table 403. Register write access restrictions

Condition	Description
Anytime mode	No write access restriction
Disabled mode	Write access only if MCR[MDIS] = 1
Normal mode	Write access only if the module is in normal mode

- Register write access requirements

  You can access all registers using 8-bit, 16-bit, and 32-bit wide operations. For some of the registers, at least a 16-bit or 32-bit wide write access is required to ensure correct operation. This write access requirement is stated in the detailed register description for each affected register.

41.7.2 XSPI register descriptions

Attempts to access the following addresses do not result in transfer errors:

- 4h
- 64h
- 138h
- 188h
- 18Ch
- 198h

41.7.2.1 XSPI memory map

XSPI0 base address: 4018_4000h

XSPI1 base address: 4018_5000h

XSPI2 base address: 4041_1000h

Offset	Register	Width (In bits)	Access	Reset value

41.7.2.2 Module Configuration (MCR)

Offset

Register	Offset
MCR	0h

Function

Configures XSPI operation.

NOTE

Coming out of reset and after the initial write to MCR, when XSPI exits module disable mode (MDIS is 0), you must write 1 to SWRSTSD and release it.

Special write access is permitted in different modes:

- Disabled mode: CKN_FA_EN, DQS_FA_SEL, ISD3FA, ISD2FA,
- Anytime mode: All other fields

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Logic low 1b - Logic high
15 DOZE	Doze Enable Enables the Module Disable mode mechanism. See Module Disable mode for details. 0b - Disables 1b - Enables
14 MDIS	Module Disable Allows external logic to stop the clock to XSPI non-memory mapped logic. 0b - Enables clocks 1b - Allows external logic to disable clocks
13 —	Reserved
12 DLPEN	Data Learning Pattern Enable Enables the data learning mechanism. See Data learning. 0b - Disables 1b - Enables
11 CLR_TXF	Clear TX FIFO Clears (invalidates) the TX FIFO buffer by resetting the buffer read and write pointers to 0 and returning the transmit counter (TBSR[TRCTR]) to 0. When clearing is complete, the bit returns to 0. **NOTE** You must wait at least five system cycles and three flash cycles after writing 1 to this field. 0b - No action. Always reads 0. 1b - Clears buffer and returns pointers to 0
10 CLR_RXF	Clear RX FIFO Clears (invalidates) the RX FIFO buffer by resetting the buffer read and write pointers to 0 and returning the RX buffer fill level (RBSR[RDBFL]) to 0. When clearing is complete, the bit returns to 0. 0b - No action. Always reads 0. 1b - Clears buffer and returns pointers to 0
9 IPS_TG_RST	Software Reset for IPS Target Group Queue Resets the IPS TG queue. It clears the transaction currently present in the queue along with its status and error registers. If the transaction was already triggered towards external flash (SR[IP_ACC] = 1), then XSPI waits for the CS to deassert to be sure the transaction has finished on external flash. When the transaction

Table continues on the next page...

Table continued from the previous page...

Field	Function
	completes (CS deasserts), XSPI initiates the software reset. IPS_TG_RST remains 1 until software reset completes, then toggles to 0. XSPI also clears the error register for the queue. This field does not reset SFP or XSPI configuration registers. **NOTE** The IPG clock must be running for the software reset to propagate to the queue. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No action 1b - Reset of IPS TG queue is in progress if is having TG Grant When writing 0b - No action 1b - Resets
8 VAR_LAT_EN	Variable Latency Enable Enables variable latency. Where data strobe acts as an output from memory during the command and address (CA) cycles of a read or write transaction. Enable variable latency when dynamic memory refresh operations require additional initial access latency. See OctalRAM support. **NOTE** If enabled, the serial flash memory CS setup time (FLSHCR[TCSS]) must be >= 2. 0b - Fixed latency 1b - Additional initial latency. "Once" the initial latency based on data strobe during the CA phase.
7 DDR_EN	DDR Mode Enable Enables DDR mode. 0b - 2x clock disabled. Only SDR instructions processed 1b - 2x clock enabled. Both SDR and DDR instructions processed
6 DQS_EN	DQS Enable Enables DQS strobe. This field is valid for both the SDR and DDR modes. See DQS sampling method. When DDR is enabled (DDR_EN = 1), XSPI samples the incoming data on both edges of the DQS input. Otherwise, it samples only on one edge. **NOTE** Do not write 0 to this field. 0b - Reserved 1b - Enables

Table continues on the next page...

Table continued from the previous page...

Field	Function
5 DQS_LAT_EN	DQS Latency Enable Enables latency between read accesses from flash memory in DQS sampling. See DQS sampling method. 0b - Disables 1b - Enables
4 DQS_OUT_EN	DQS Output Enable Enables DQS for output operation. This field is valid when data strobe is also used as an output from the controller during the write data phase. This field is valid for HyperRAM where the data strobe acts as a Read Write Data Strobe (RWDS). See OctalRAM support. **NOTE** DQS Output Enable feature not available for X4 and X1 RAM devices. 0b - Disables 1b - Enables
3-2 END_CFG	Byte Order Selects the byte order for XSPI operation. See Byte ordering – endianness. 00b - 64-bit BE 01b - 32-bit LE 10b - 32-bit BE 11b - 64-bit LE
1 SWRSTHD	Software Reset for AHB Domain Resets the AHB domain. Resetting only the serial flash memory domain or the AHB domain may cause undesirable side effects, so you should reset both domains at the same time. This field does not reset configuration registers. **NOTE** • XSPI must be enabled (MDIS = 0) when you reset the domains. Also, before you deassert the software reset (write 0 to this field), you should disable XSPI (write 1 to MDIS). After you deassert the software resets, you can restart XSPI (write 0 to MDIS). • You must wait for at least three system cycles and three flash cycles after changing the value of this field. 0b - Deasserts reset 1b - Resets
0 SWRSTSD	Software Reset for Serial Flash Memory Domain Resets the serial flash memory domain. Resetting only the serial flash memory domain or the AHB domain may cause undesirable side effects, so you should reset both domains at the same time. This field does not reset configuration registers.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE • XSPI must be enabled (MDIS = 0) when you reset the domains. Also, before you deassert the software reset (write 0 to this field), you should disable XSPI (write 1 to MDIS). After you deassert the software resets, you can restart XSPI (write 0 to MDIS). • You must wait for at least three system cycles and three flash cycles after changing the value of this field. 0b - Deasserts reset 1b - Resets

41.7.2.3 IP Configuration (IPCR)

Offset

Register	Offset
IPCR	8h

Function

This register stores the configured value for an IP-initiated command. It is updated when SFP triggers the IP-initiated command from any target group queue after it passes the required checks and arbitration.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-28 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
27-24 SEQID	LUT Sequence ID Indicates the sequence index of the LUT. See Lookup table (LUT). Each sequence index can accommodate up to 10 instructions (two instructions per register). A write to this field by the SFP triggers a transaction on the serial flash memory interface.
23-17 —	Reserved
16 —	Reserved
15-0 IDATSZ	IP Data Transfer Size Indicates the data transfer size, in bytes, of the IP command. **NOTE** To avoid tCSM timing violation, the IDATSZ needs to be configured during read or prefetch operation with respect to flash frequency. For details, refer to the memory device datasheet about the tCSM period.

41.7.2.4 Flash Memory Configuration (FLSHCR)

Offset

Register	Offset
FLSHCR	Ch

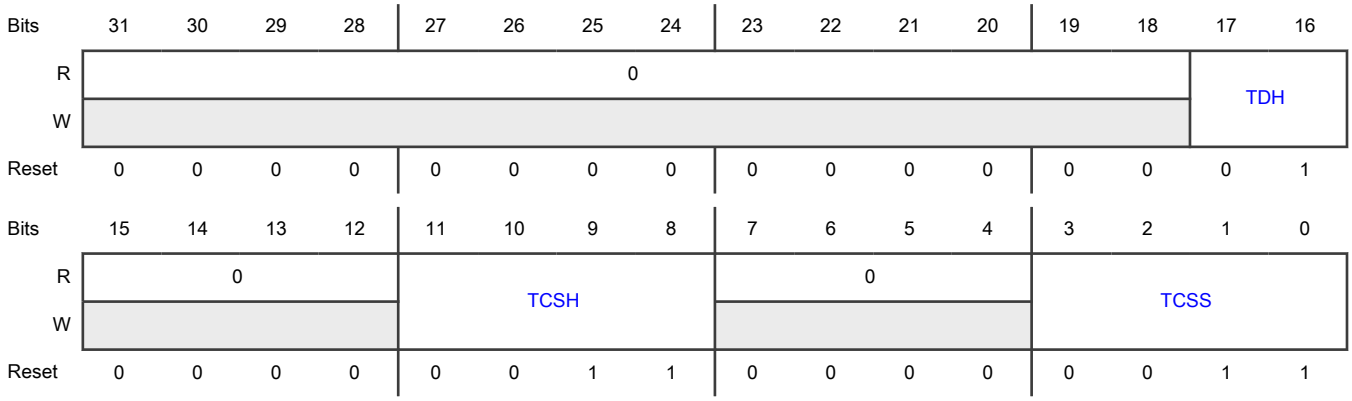
Function

Specifies the timings specific to the flash memory device. XSPI must meet these timings for the device to function correctly.

Special write access is permitted if both:

- AHB read access is not asserted (SR[AHB_ACC] = 0)
- No IP access in progress (SR[IP_ACC] = 0)
- AHB write access is not asserted (SR[AWRACC] = 0)

Diagram



Fields

Field	Function
31-18 —	Reserved
17-16 TDH	Serial Flash Memory Data in Hold Time Specifies which clock to use for data alignment. This field helps meet the data-in-hold-time requirement of a flash memory. This field is valid only in the DDR mode. See Data input hold requirement of flash memory. **NOTE** You must write 0 to this field in SDR mode (MCR[DDR_EN] = 0). 00b - Posedge of XSPI internal reference clock 01b - 2x serial flash memory half clock All other values are reserved.
15-12 —	Reserved
11-8 TCSH	Serial Flash Memory CS Hold Time Specifies the CS hold time in serial flash memory clock cycles. This value must be greater than or equal to two. See the memory Datasheet for the exact value.
7-4 —	Reserved
3-0 TCSS	Serial Flash Memory CS Setup Time Specifies the CS setup time in serial flash memory clock cycles. This value must be greater than or equal to two. See the memory Datasheet for the exact value.

41.7.2.5 Buffer Configuration (BUF0CR)

Offset

Register	Offset
BUF0CR	10h

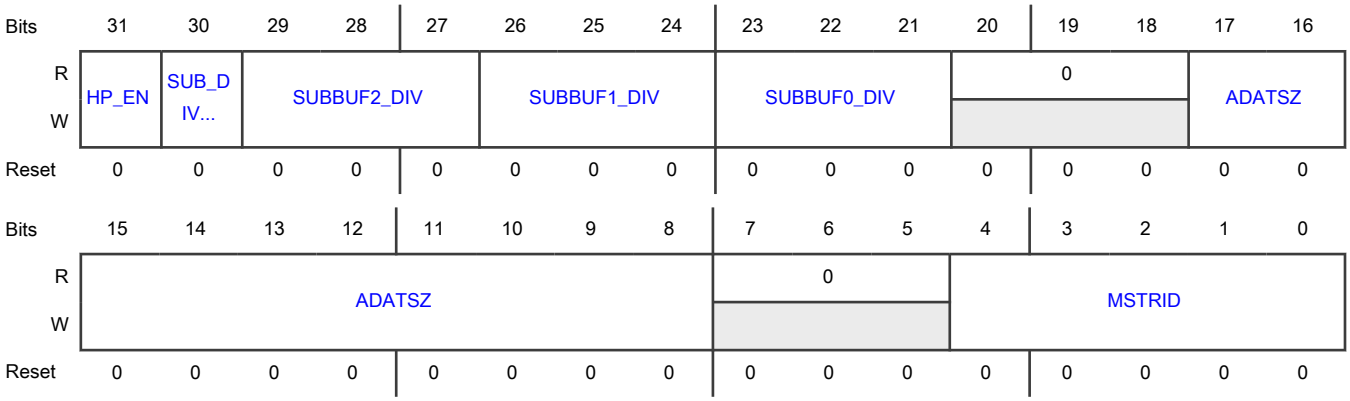
Function

Configures read accesses routed to this AHB buffer, which happens when the initiator ID of the incoming AHB request matches the value in MSTRID. A buffer miss triggers a serial flash memory transaction per the sequence pointed to by BFGENCR[SEQID]. You may also configure the buffer as a high-priority buffer (write 1 to HP_EN).

Special write-access is permitted if both:

- AHB read access is not asserted (SR[AHB_ACC] = 0)
- AHB write access is not asserted (SR[AWRACC] = 0)

Diagram



Fields

Field	Function
31 HP_EN	High Priority Enable Enables high priority for the initiator associated with this buffer by assigning a priority higher than the non-priority initiators. A read access by a high priority initiator suspends any ongoing prefetch by a non-priority AHB initiator and XSPI services the high priority initiator. 0b - Disables 1b - Enables
30 SUB_DIV_EN	Buffer Sub-Division Enable Enables sub-buffer division for this buffer. Also enables the address range-based entry scheme for sub-buffer allocation. See Flexible read xAHB buffers. 0b - Disables 1b - Enables

Table continues on the next page...

Table continued from the previous page...

Field	Function
29-27: SUBBUF2_DIV 26-24: SUBBUF1_DIV 23-21: SUBBUF0_DIV	Sub-Buffer Division Factor Specifies the value (divisor) to be divided into the buffer size to determine the size of the sub-buffer. 001b - 2 010b - 4 011b - 8 100b - 16 All other values are reserved.
20-18 —	Reserved
17-8 ADATSZ	AHB Data Transfer Size Specifies the read data transfer size of an AHB-triggered read access to serial memory targeted to this buffer in multiples of 8 bytes. For example, a value of 2 sets the transfer size to 16 bytes. If you write 0 to this field, the data size specified in the sequence pointed to by SEQID applies. You must ensure that this transfer size is not greater than the size of the buffer or sub-buffer. **NOTE** For IPED CTR, ADATSZ should be N*8 bytes, where N is number of pages in CTR context region. For IPED GCM, ADATSZ Should be N*32 bytes, where N is number of pages in GCM context region. **NOTE** To avoid tCSM timing violation, the ADATSZ needs to be configured during read or prefetch operation with respect to flash frequency. For details, refer to the memory device datasheet about the tCSM period.
7-5 —	Reserved
4-0 MSTRID	Initiator ID Specifies the ID of the AHB initiator to be associated with this buffer. XSPI routes any AHB read access with this initiator ID to this buffer. You must ensure that the initiator ID associated with each buffer is unique.

41.7.2.6 Buffer Configuration (BUF1CR)

Offset

Register	Offset
BUF1CR	14h

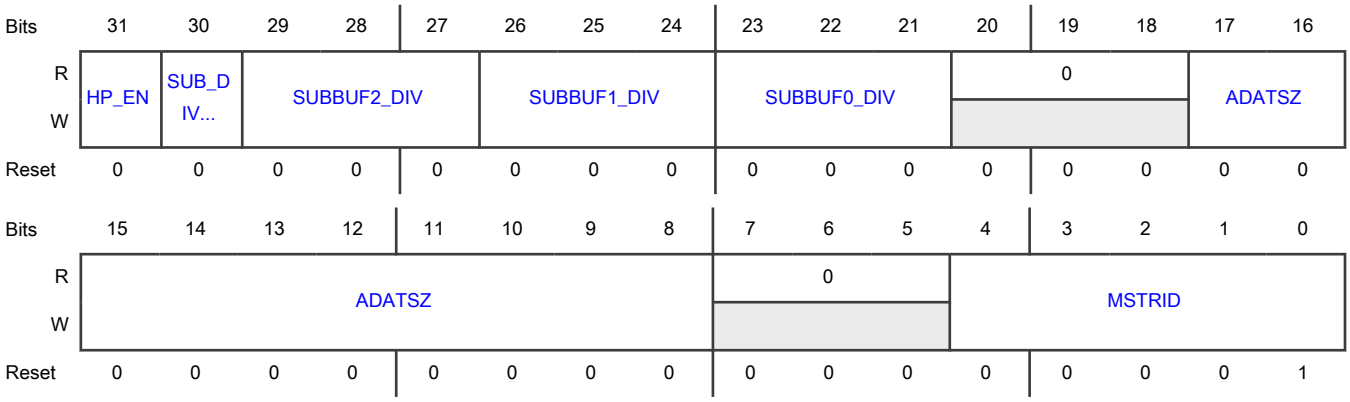
Function

Configures read accesses routed to this AHB buffer, which happens when the initiator ID of the incoming AHB request matches the value in MSTRID. A buffer miss triggers a serial flash memory transaction per the sequence pointed to by BFGENCR[SEQID]. You may also configure the buffer as a high-priority buffer (write 1 to HP_EN).

Special write-access is permitted if both:

- AHB read access is not asserted (SR[AHB_ACC] = 0)
- AHB write access is not asserted (SR[AWRACC] = 0)

Diagram



Fields

Field	Function
31 HP_EN	High Priority Enable Enables high priority for the initiator associated with this buffer by assigning a priority higher than the non-priority initiators. A read access by a high priority initiator suspends any ongoing prefetch by a non-priority AHB initiator and XSPI services the high priority initiator. 0b - Disables 1b - Enables

29-27: SUBBUF2_DIV 26-24: SUBBUF1_DIV 23-21: SUBBUF0_DIV	Sub-Buffer Division Factor Specifies the value (divisor) to be divided into the buffer size to determine the size of the sub-buffer. 001b - 2 010b - 4 011b - 8

Table continues on the next page...

Table continued from the previous page...

Field	Function
	100b - 16 All other values are reserved.
20-18 —	Reserved
17-8 ADATSZ	AHB Data Transfer Size Specifies the read data transfer size of an AHB-triggered read access to serial memory targeted to this buffer in multiples of 8 bytes. For example, a value of 2 sets the transfer size to 16 bytes. If you write 0 to this field, the data size specified in the sequence pointed to by SEQID applies. You must ensure that this transfer size is not greater than the size of the buffer or sub-buffer. **NOTE** For IPED CTR, ADATSZ should be N*8 bytes, where N is number of pages in CTR context region. For IPED GCM, ADATSZ Should be N*32 bytes, where N is number of pages in GCM context region. **NOTE** To avoid tCSM timing violation, the ADATSZ needs to be configured during read or prefetch operation with respect to flash frequency. For details, refer to the memory device datasheet about the tCSM period.
7-5 —	Reserved
4-0 MSTRID	Initiator ID Specifies the ID of the AHB initiator to be associated with this buffer. XSPI routes any AHB read access with this initiator ID to this buffer. You must ensure that the initiator ID associated with each buffer is unique.

41.7.2.7 Buffer Configuration (BUF2CR)

Offset

Register	Offset
BUF2CR	18h

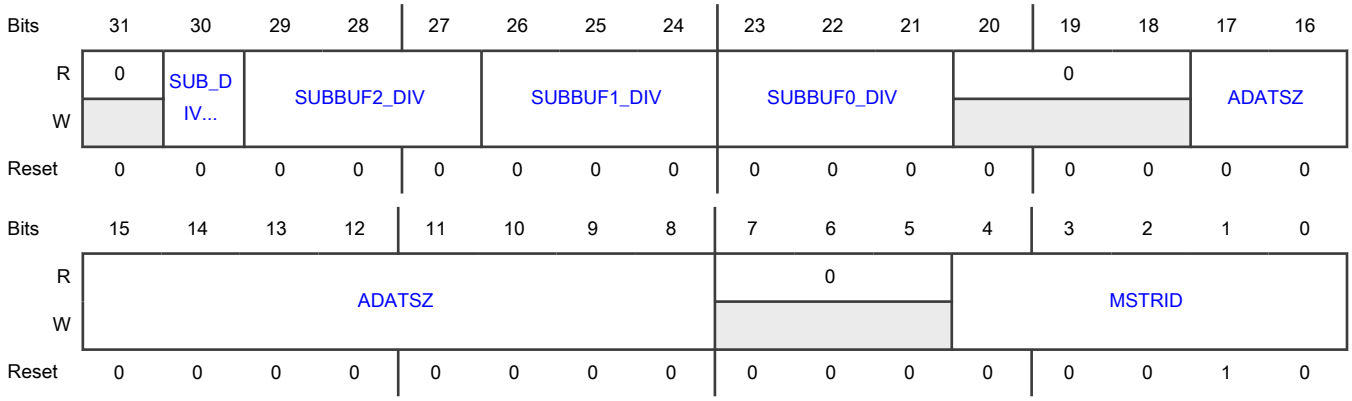
Function

Configures read accesses routed to this AHB buffer, which happens when the initiator ID of the incoming AHB request matches the value in MSTRID. A buffer miss triggers a serial flash memory transaction per the sequence pointed to by BFGENCR[SEQID]. .

Special write-access is permitted if both:

- AHB read access is not asserted (SR[AHB_ACC] = 0)
- AHB write access is not asserted (SR[AWRACC] = 0)

Diagram



Fields

Field	Function
31 —	Reserved
30 SUB_DIV_EN	Buffer Sub-Division Enable Enables sub-buffer division for this buffer. Also enables the address range-based entry scheme for sub-buffer allocation. See Flexible read xAHB buffers. 0b - Disables 1b - Enables
29-27: SUBBUF2_DIV 26-24: SUBBUF1_DIV 23-21: SUBBUF0_DIV	Sub-Buffer Division Factor Specifies the value (divisor) to be divided into the buffer size to determine the size of the sub-buffer. 001b - 2 010b - 4 011b - 8 100b - 16 All other values are reserved.
20-18 —	Reserved
17-8 ADATSZ	AHB Data Transfer Size Specifies the read data transfer size of an AHB-triggered read access to serial memory targeted to this buffer in multiples of 8 bytes. For example, a value of 2 sets the transfer size to 16 bytes. If you write 0 to this field, the data size specified in the sequence pointed to by SEQID applies. You must ensure that this transfer size is not greater than the size of the buffer or sub-buffer.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE For IPED CTR, ADATSZ should be N*8 bytes, where N is number of pages in CTR context region. For IPED GCM, ADATSZ Should be N*32 bytes, where N is number of pages in GCM context region. **NOTE** To avoid tCSM timing violation, the ADATSZ needs to be configured during read or prefetch operation with respect to flash frequency. For details, refer to the memory device datasheet about the tCSM period.
7-5 —	Reserved
4-0 MSTRID	Initiator ID Specifies the ID of the AHB initiator to be associated with this buffer. XSPI routes any AHB read access with this initiator ID to this buffer. You must ensure that the initiator ID associated with each buffer is unique.

41.7.2.8 Buffer Configuration (BUF3CR)

Offset

Register	Offset
BUF3CR	1Ch

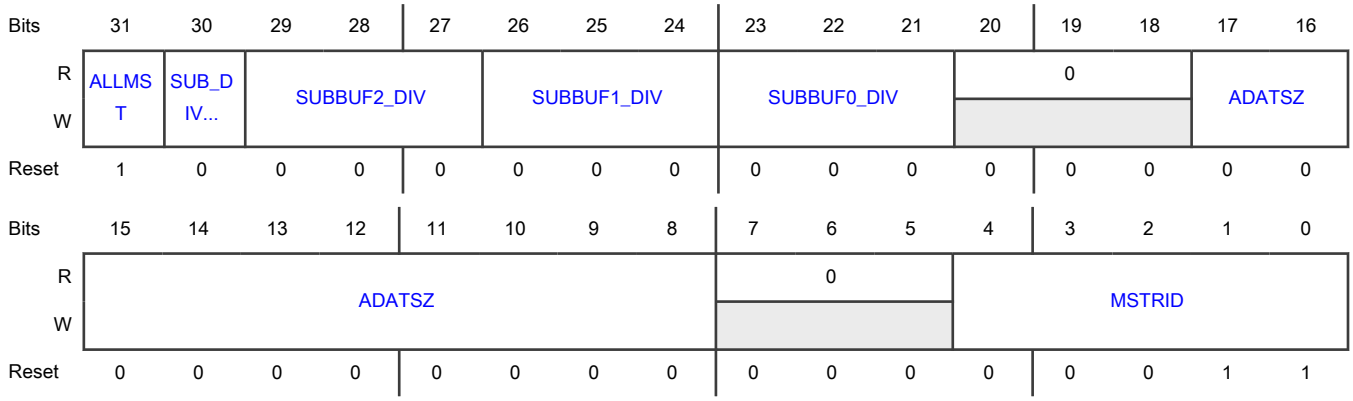
Function

Configures read accesses routed to this AHB buffer, which happens when the initiator ID of the incoming AHB request matches the value in MSTRID. A buffer miss triggers a serial flash memory transaction per the sequence pointed to by BFGENCR[SEQID]. You may also configure the buffer as an all-initiator buffer (write 1 to ALLMST).

Special write-access is permitted if both:

- AHB read access is not asserted (SR[AHB_ACC] = 0)
- AHB write access is not asserted (SR[AWRACC] = 0)

Diagram



Fields

Field	Function
31 ALLMST	All Initiator Enable Enables buffer 3 to act as an all-initiator buffer. Any AHB access with an initiator ID not matching the initiator IDs of buffers 0, 1, or 2 is routed to buffer 3. When enabled, the XSPI ignores the MSTRID field of this register. 0b - Disables 1b - Enables
30 SUB_DIV_EN	Buffer Sub-Division Enable Enables sub-buffer division for this buffer. Also enables the address range-based entry scheme for sub-buffer allocation. See Flexible read xAHB buffers. 0b - Disables 1b - Enables
29-27: SUBBUF2_DIV 26-24: SUBBUF1_DIV 23-21: SUBBUF0_DIV	Sub-Buffer Division Factor Specifies the value (divisor) to be divided into the buffer size to determine the size of the sub-buffer. 001b - 2 010b - 4 011b - 8 100b - 16 All other values are reserved.
20-18 —	Reserved
17-8 ADATSZ	AHB Data Transfer Size Specifies the read data transfer size of an AHB-triggered read access to serial memory targeted to this buffer in multiples of 8 bytes. For example, a value of 2 sets the transfer size to 16 bytes. If you write 0 to this field,

Table continues on the next page...

Table continued from the previous page...

Field	Function
	the data size specified in the sequence pointed to by SEQID applies. You must ensure that this transfer size is not greater than the size of the buffer or sub-buffer. **NOTE** For IPED CTR, ADATSZ should be N*8 bytes, where N is number of pages in CTR context region. For IPED GCM, ADATSZ Should be N*32 bytes, where N is number of pages in GCM context region. **NOTE** To avoid tCSM timing violation, the ADATSZ needs to be configured during read or prefetch operation with respect to flash frequency. For details, refer to the memory device datasheet about the tCSM period.
7-5 —	Reserved
4-0 MSTRID	Initiator ID Specifies the ID of the AHB initiator to be associated with this buffer. XSPI routes any AHB read access with this initiator ID to this buffer. You must ensure that the initiator ID associated with each buffer is unique. If ALLMST is set, XSPI ignores this field.

41.7.2.9 Buffer Generic Configuration (BFGENCR)

Offset

Register	Offset
BFGENCR	20h

Function

Configures the behavior of all buffer accesses. Any buffer miss causes the buffer to be flushed and triggers a serial flash memory transaction per the sequence pointed to by SEQID.

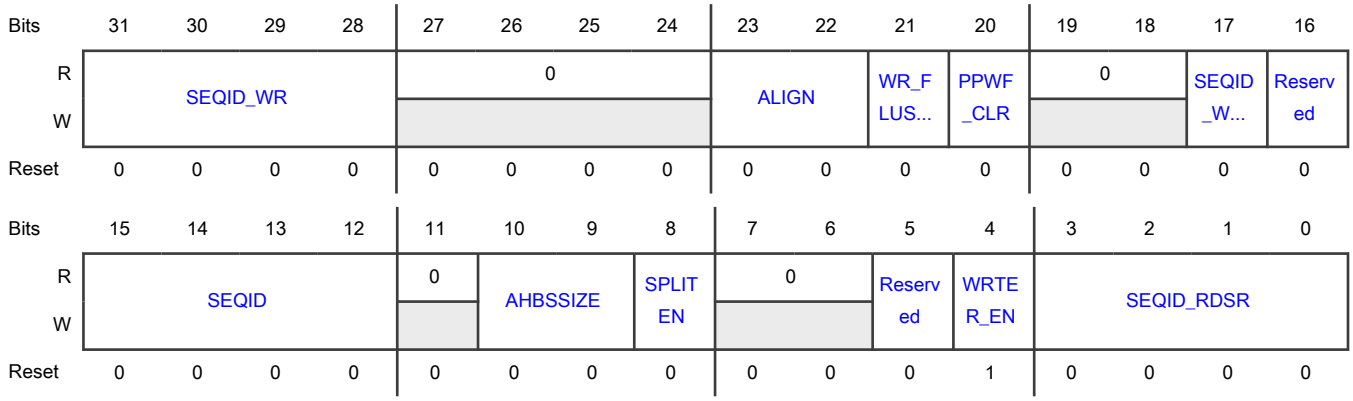
Special write access is permitted if all these conditions apply:

- AHB read access is not asserted (SR[AHB_ACC] = 0)
- AHB write access is not asserted (SR[AWRACC] = 0)
- Global configuration lock is disabled (MGC[GCLCK] = 0)

You can write to this register only if the global configuration lock is disabled (GCLCK = 00b).

Only privilege initiators can write to this register. An attempt to write to it by any other initiator generates a bus transfer error.

Diagram



Fields

Field	Function
31-28 SEQID_WR	Write Sequence ID If you enable write sequence ID (write 1 to SEQID_WR_EN), specifies the write sequence ID of LUT to be selected for an AHB write transaction.
27-24 —	Reserved
23-22 ALIGN	AHB Alignment Specifies the AHB alignment boundary. XSPI breaks the AHB transactions when the below boundary is crossed. **NOTE** This field is not supported in every instance. The following table includes only supported registers. 00b - No limit 01b - 256 bytes 10b - 512 bytes 11b - 1 KB
21 WR_FLUSH_EN	Write Flush Enable Enables the clearing of AHB read prefetch buffers when the same flash address is written by an AHB or IP command.

Instance	Field supported in	Field not supported in
XSPI0	BFGENCR	—
XSPI1	BFGENCR	—
XSPI2	—	BFGENCR

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Not cleared 1b - Cleared
20 PPWF_CLR	Page Program Wait Flag Clear Selects the clearing mechanism for the page program wait flag (FR[PPWF]). See AHB command page program wait handling. 0b - Cleared by software 1b - Cleared by XSPI. No software intervention required.
19-18 —	Reserved
17 SEQID_WR_EN	Enable Write Sequence ID Enables the write sequence ID (SEQID_WR) as the index into the LUT for AHB write transactions. Otherwise, XSPI uses SEQID. 0b - Disables (use SEQID) 1b - Enables
16 —	Reserved
15-12 SEQID	LUT Sequence Pointer Specifies the sequence index of the LUT to be used for an AHB read transaction. If write sequence ID (BFGENCR[SEQID_WR_EN] = 0) is not enabled, it is also used for AHB write transactions. See Lookup table (LUT). **NOTE** If the sequence pointer differs in the new and the previous sequences, you should reset it. For more information, see SPTRCLR.
11 —	Reserved
10-9 AHBSSIZE	AHB Split Size Specifies split size when transaction split is enabled (SPLITEN = 1). See AHB transaction split. **NOTE** When you enable IPED GCM (write 1 to IPEDCTX*n*START[GCM]), you must specify 32 bytes or 64 bytes, and the split happens on 40 bytes or 80 bytes so that the header and authentication is included with every block. 00b - 8 bytes

Table continues on the next page...

Table continued from the previous page...

Field	Function
	01b - 16 bytes 10b - 32 bytes 11b - 64 bytes
8 SPLITEN	AHB Transaction Split Enable Enables the splitting of all AHB read/write bursts into smaller transactions at the flash SPI bus side. You typically use this function for RAM devices with self-refresh limit or when using IPED GCM mode. See AHB transaction split. 0b - Disables 1b - Enables
7-6 —	Reserved
5 —	Reserved
4 WRTER_EN	Write Terminate Enable Specifies whether an AHB write transaction can terminate the ongoing AHB read-prefetch. 0b - Disables 1b - Enables
3-0 SEQID_RDSR	Read Status Register Sequence ID in LUT Specifies the sequence ID in the LUT to be used when reading the status register from flash in the event of a page program wait period. See AHB command page program wait handling.

41.7.2.10 SOC Configuration (SOCCR)

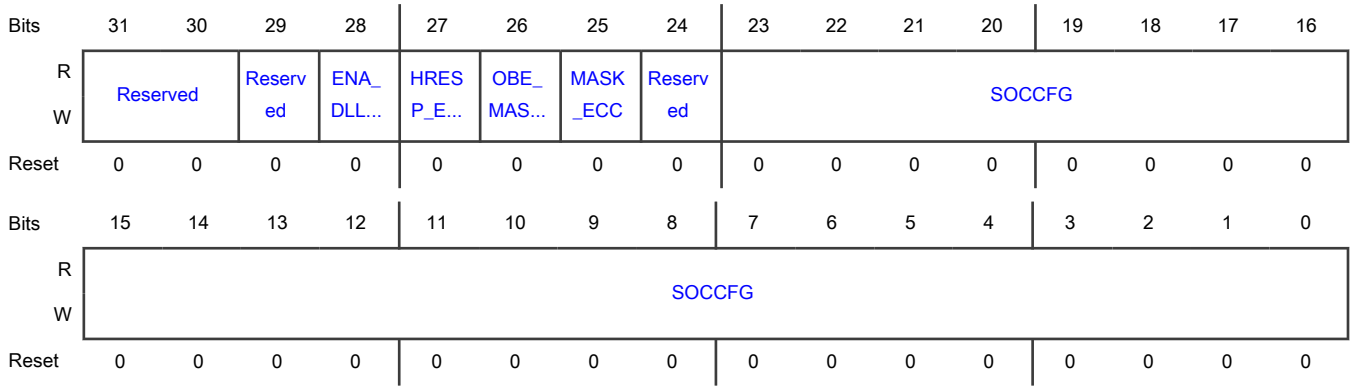
Offset

Register	Offset
SOCCR	24h

Function

Configures XSPI for chip-specific delay chain operation. See chip-specific XSPI information.

Diagram



Fields

Field	Function
31-30 —	Reserved
29 —	Reserved
28 ENA_DLLABRT	DLL Abort Request Status Enable Unmasks the DLL Abort request status on soc_config I/F. 0b - Masks 1b - Unmasks
27 HRESP_ERR_MASK	HRESP Error Mask Masks the AHB HRESP error for some error scenarios. 0b - Allows HRESP error generation 1b - Masks HRESP error generation
26 OBE_MASK_EN	Output Buffer Enable Mask Enable Disable/Enable all OBE in output direction for x8 mode. 0b - Enable all OBE in output direction for x8 mode during write transaction (in a non-Dummy phase) 1b - Normal OBE handling for both read and write operation
25 MASK_ECC	Mask ECC for False AHB Reads Specifies the masking of ECC errors for predicted reads for INCR transfers. This signal can be used outside XSPI to gate ECC error generation in the event of false read scenarios. 0b - Unmask ECC error 1b - Mask ECC error

Table continues on the next page...

Table continued from the previous page...

Field	Function
24 —	Reserved
23-0 SOCCFG	SOC Configuration Specifies chip-specific configuration of XSPI. See the chip-specific XSPI information.

41.7.2.11 Buffer n Top Index (BUF0IND - BUF2IND)

Offset

Register	Offset
BUF0IND	30h
BUF1IND	34h
BUF2IND	38h

Function

Specifies the size of the corresponding AHB buffer. The total size of the AHB buffers is 4 KB. Any left over space is automatically used for buffer 3. See Flexible read xAHB buffers.

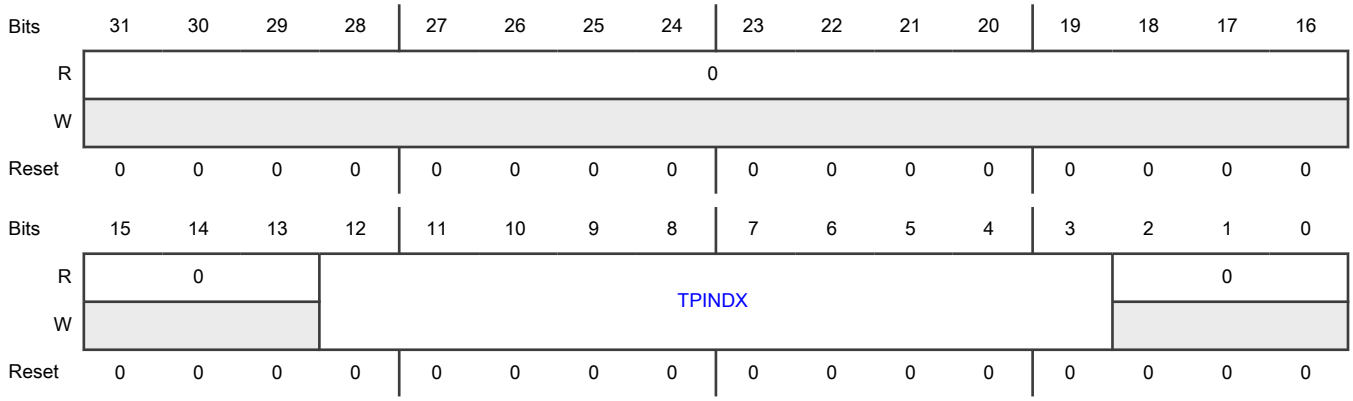
Special write-access is permitted if both:

- AHB read access is not asserted (SR[AHB_ACC] = 0)
- AHB write access is not asserted (SR[AWRACC] = 0)

NOTE

Because each buffer entry is 64-bits (8 bytes) long, the three least-significant bits of this register are 0 to maintain 64-bit alignment.

Diagram



Fields

Field	Function
31-13 —	Reserved
12-3 TPINDX	Top Index Buffer Specifies the top index of buffer 0 in multiples of 8 bytes. For example, a value of 0 equals 0 bytes in the buffer, 1 equals 8 bytes (1 buffer entry), 2 equals 16 bytes (2 buffer entries), and so on. The size of buffer 0 is the difference between BUF0IND and 0. The size of buffer 1 is the difference between BUF1IND and BUF0IND. For example, if BUF0IND[TPINDX] = 20h (BUF0IND = 100h), then writing 26h to BUF1IND[TPINDX] (BUF1IND = 130h) sets the size of buffer 1 to 30h bytes (6 buffer entries). The size of buffer 2 is the difference between BUF2IND and BUF1IND. For example, if BUF1IND[TPINDX] = 26h (BUF1IND = 130h), then writing 30h to BUF2IND[TPINDX] (BUF2IND = 180h) sets the size of buffer 2 to 50h bytes (10 buffer entries).
2-0 —	Reserved

41.7.2.12 AHB Write Configuration (AWRCR)

Offset

Register	Offset
AWRCR	50h

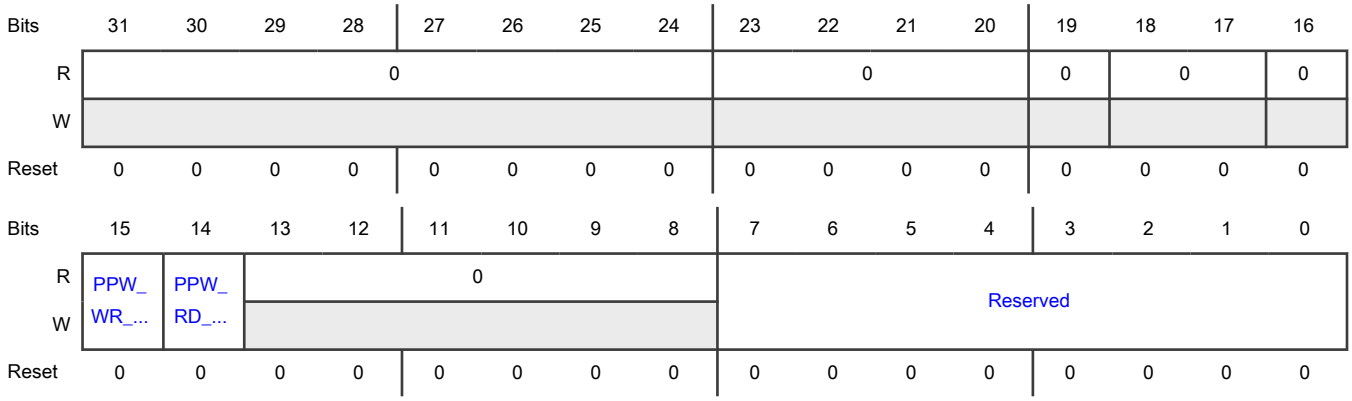
Function

Configures the allowed operations after an AHB write operation. See AHB command page program wait handling.

Special write-access is permitted if:

- AHB read access is not asserted (SR[AHB_ACC] = 0)
- AHB write access is not asserted (SR[AWRACC] = 0)

Diagram



Fields

Field	Function

Fields

Field	Function
31 DLLEN	DLL Enable Enables the DLL logic. Write 1 to this field after you configure the DLL reference settings (FREQEN, DLL_REFCNTR, DLLRES, SLAVE_AUTO_UPDT). 0b - Disables. DLL reference logic remains in reset and should be 0 for at least three flash memory clock cycles for reset. 1b - Enables

Table continues on the next page...

Table continued from the previous page...

Field	Function
30 FREQEN	Frequency Enable Specifies the frequency of delay chain operations. 0b - Low frequency 1b - High frequency
29-28 —	Reserved
27-24 DLL_REFCNTR	DLL Reference Counter Specifies the "n + 1" interval for DLL phase detection and reference delay updating interval (minimum recommended value is 1).
23-20 DLLRES	DLL Resolution Specifies the minimum resolution for the DLL phase detector to remain locked or unlocked based on flash memory clock jitter. The minimum value is 2 but you should specify a more suitable value like 6.
19-16 SLV_FINE_OFFSET	Fine Offset Delay Elements Specifies the number of fine offset delay elements, up to 16, in the incoming DQS. You must specify a minimum of 1 element.
15 —	Reserved
14-12 SLV_DLY_OFFSET	T/16 Offset Delay Elements Specifies the number of T/16 offset delay elements in the incoming DQS. The default is 0.
11-8 SLV_DLY_COARSE	Delay Elements in Delay Tap Specifies the number of delay elements in each delay tap. This value overwrites the DLL-generated delay values and applies when SLV_DLL_BYPASS is 1. See XSPI datasheet for more details.
7-5 SLV_DLY_FINE	Fine Adjustment Delay Elements Specifies the number of fine adjustment delay elements in the total subordinate delay chain. This field is valid only when you enable subordinate DLL bypass (write 1 to SLV_DLL_BYPASS).
4 DLL_CDL8	DLL Course Delay Line 8 Enable Enables CDL8 and specifies the variation range. 0b - DLL is implemented to support up to 2x variation 1b - DLL is implemented to support up to 3x variation (BCS –> WCS)
3	Subordinate Chain Auto-Update Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
SLAVE_AUTO_UPDT	Enables automatic update of the subordinate chain upon DLL lock. 0b - Disables 1b - Enables
2 SLV_EN	Subordinate Enable Enables the DQS subordinate delay chain. You should write 1 to this field before configuring any subordinate settings. 0b - Disables. The DLL subordinate logic remains in reset, and its value should be 0 for at least three flash memory clock cycles for reset. 1b - Enables
1 SLV_DLL_BYPASS	Subordinate DLL Bypass Enables manual selection of the number of delays in each subordinate delay tap. You specify the number of delays in SLV_DLY_COARSE. 0b - Disables 1b - Enables
0 SLV_UPD	Subordinate Update Updates the DQS subordinate delay chain with either the reference delay or the bypass subordinate delay value. You should select this update in the absence of the DQS clock. Write to this field only after you configure the subordinate delay chain. 0b - Disables any further update on the DQS subordinate delay chain. 1b - Updates

41.7.2.14 Serial Flash Memory Address (SFAR)

Offset

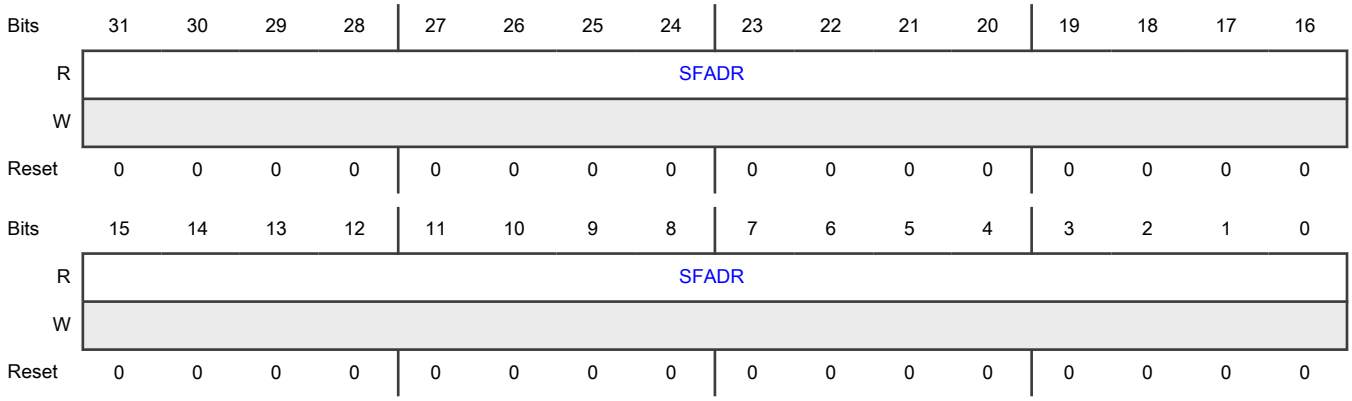
Register	Offset
SFAR	100h

Function

XSPI automatically translates this address in memory to the address in flash memory. When operating in 24-bit mode, only bits 23-0 are sent to the flash memory. In 32-bit mode, bits 27-0 are used with bits 31-28 driven to 0 when the value of SFACR[CAS] is 0. For example, if the value of SFACR[CAS] is 3, then bits 26-3 are sent to the flash memory as its page address in case flash memory is operating in a 24-bit mode. The total number of address bits requested by the flash memory, as its page and column address, must not be more than 32 bits.

XSPI updates this register when SFP triggers an IP-initiated command from any target group queue after it passes required checks and arbitration.

Diagram



Fields

Field	Function
31-0 SFADR	Serial Flash Memory Address Indicates the serial memory address for IP commands. The address is the address of the device without the base address.

41.7.2.15 Serial Flash Memory Address Configuration (SFACR)

Offset

Register	Offset
SFACR	104h

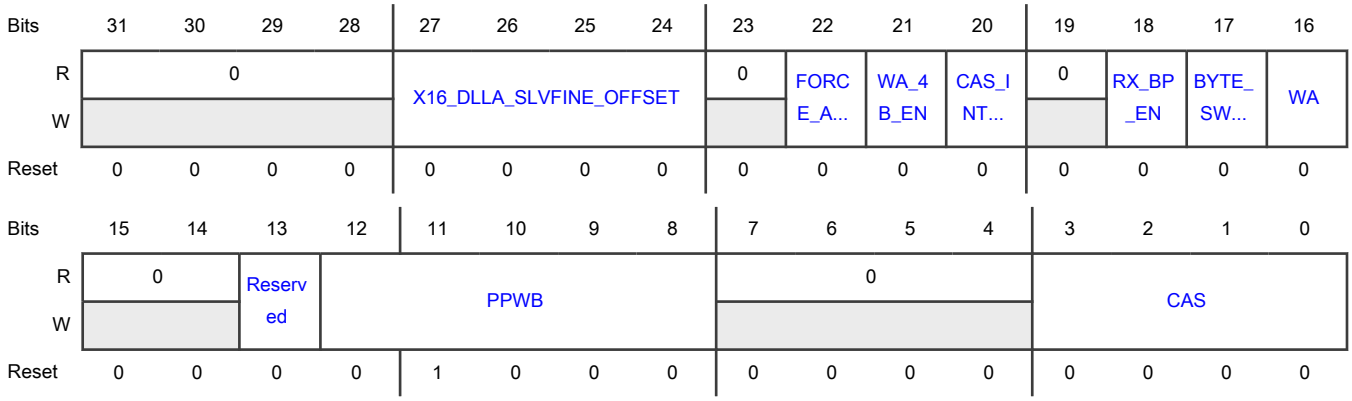
Function

Configures serial flash memory operation. You must program these values for the specific flash memory for XSPI to function correctly. XSPI automatically translates the address in the memory it controls (SFAR) or the incoming address on the AHB bus to the column address of the flash memory. For example, if a flash memory needs 3 bits for its column address, then XSPI sends only the lower three bits of the SFAR or AHB address to the flash memory as its column address. You must ensure that the address in SFAR or the incoming AHB address lies in the valid flash memory address range.

Special write-access is permitted if both:

- IP access is not asserted (SR[IP_ACC] = 0)
- AHB access is not asserted (SR[AHB_ACC] = 0)
- AHB write access is not asserted (SR[AWRACC] = 0)

Diagram



Fields

Field	Function
31-28 —	Reserved
27-24 X16_DLLA_SLVFINE_OFFSET	Fine Offset Delay Elements in Incoming DQS1 Flash Memory A Specifies the number of fine offset delay elements (up to 16) in the incoming DQS1. The default is 1 element. **NOTE** This field is not supported in every instance. The following table includes only supported registers.
23 —	Reserved
22 FORCE_A10	10th Bit Status Specifies whether or not to force bit 10 of the address to 0 during address generation in X16 mode. 0b - Force 1b - Do not force
21 WA_4B_EN	32-Bit Address Mode Enable Enables the 32-bit address mode. Otherwise, XSPI uses the address mode specified in WA.

Instance	Field supported in	Field not supported in
XSPI0	—	SFACR
XSPI1	SFACR	—
XSPI2	SFACR	—

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disables. Use WA-specified mode 1b - 32-bit mode
20 CAS_INTRLVD	CAS Interleaving Enables CAS interleaving. 0b - Disables 1b - Enables
19 —	Reserved
18 RX_BP_EN	RX Backpressure Enable Enables the RX backpressure handling mechanism. 0b - Disables 1b - Enables
17 BYTE_SWAP	Byte Swapping In Octal DDR mode, specifies whether a word unit composed of 2 bytes from the posedge and negedge of a single DQS cycle needs to be swapped. See Page program size. For example; if BYTE_SWAP is enabled and we write 4 bytes (byte 4, byte 3, byte 2, and byte 1) then write data is swapped as byte 3, byte 4, byte 1, and byte2 and written to memory device. 0b - One word of two bytes at addresses [n, n + 1] 1b - One word of two bytes at addresses [n + 1, n]
16 WA	Word Addressable Specifies whether the serial flash memory is a byte-addressable or word-addressable. XSPI uses this specification to remap the address to the flash memory interface. See Address schemes. 0b - Byte addressable 1b - Word (2-byte) addressable mode
15-14 —	Reserved
13 —	Reserved
12-8 PPWB	Page Program Boundary Specifies the flash memory-specific page program boundary size in log base 2 format. For example, to specify a 512-byte page program size, log2(512) = 9. The default value is 8 for a 256-byte page program size.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-4 —	Reserved
3-0 CAS	Column Address Space Specifies the width of the column address. For example, if the column address is contained in bits 2–0 of SFAR or the AHB address, then CAS must be 3. If there is no column address separation in any serial flash memory, you must specify this value as 0. See Address schemes.

41.7.2.16 Sampling (SMPR)

Offset

Register	Offset
SMPR	108h

Function

Configures how XSPI samples the incoming data from external serial flash memory devices.

NOTE

See the chip data sheet for how to configure sampling.

Special write access is permitted if XSPI is disabled (MCR[MDIS] = 0).

Diagram

41.7.2.17 RX Buffer Status (RBSR)

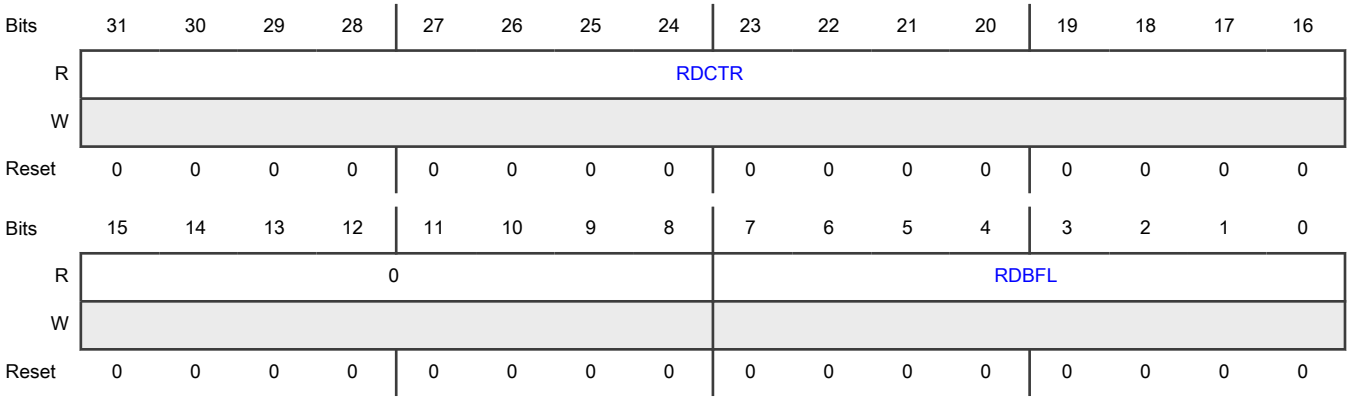
Offset

Register	Offset
RBSR	10Ch

Function

Indicates the status of the receive data buffer.

Diagram



Fields

Field	Function
31-16 RDCTR	Read Counter Indicates the number of 4-byte entries removed from the RX buffer. For example, a value of 2 indicates that 8 bytes have been removed. XPSI increments RDCTR by the value of RBCT[WMRK] + 1 for each RX buffer pop event. You can pop the RX buffer using DMA or by writing 1 to FR[RBDF]; you specify which method to use in RSER[RBDDE]. See RX Buffer Data (RBDR0 - RBDR63) and Data transfer from the XSPI module internal buffers.
15-8 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-0 RDBFL	RX Buffer Fill Level Indicates the number of 4-byte entries available in the RX buffer. For example, a value of 2 indicates 8 bytes are available.

41.7.2.18 RX Buffer Control (RBCT)

Offset

Register	Offset
RBCT	110h

Function

Controls the RX data buffer.

Special write access is permitted if IP access is not asserted (SR[IP_ACC] = 0).

Field	Function
31-28 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
27-24 —	Reserved
23-16 —	Reserved
15 DLLA_LOCK	DLL A Lock Status Indicates that the DDL for flash memory A is locked. 0b - Not locked 1b - Locked
14 SLVA_LOCK	Subordinate High Lock Status - Flash Memory A Indicates that the high-frequency subordinate delay chain is locked. The field is configured when the subordinate decoder is updated with DLLCRA[SLV_UPD] and is reset after you configure SLV_UPD to 0. 0b - Not locked 1b - Locked
13 DLLA_RANGE_ERR	DLL Initiator Delay Chain Range Error - Flash Memory A Indicates that the DLL initiator delay chain for flash memory A is working out of delay range because of incorrect DLL configuration. This is a DLL characterization error and it creates a functional issue related to DLL training. DLL cells need to be re-evaluated with respect to clock period. 0b - In range 1b - Out of range
12 DLLA_FINE_UNDERFLOW	Fine Delay Chain Underflow - Flash Memory A Indicates that fine delay chain underflow has occurred for flash memory A. 0b - No overflow 1b - Overflow
11-8 —	Reserved
7-4 DLLA_SLV_FINE_VAL	Fine Delay Cells in Subordinate Delay Chain Indicates the total number of fine delay cells (1 delay unit) selected in the subordinate delay chain for flash memory A.
3-0 DLLA_SLV_COARSE_VAL	Coarse Delay Cells in Subordinate Delay Chain - Flash Memory A Indicates the total number of coarse delay cells (16 delay units) selected in the subordinate delay chain for flash memory A.

41.7.2.21 Data Learning Configuration (DLCR)

Offset

Register	Offset
DLCR	130h

Function

Configures data learning operation.

To support data learning operation, a flash memory device must provide more than 10 bits of data learn pattern; otherwise, XSPI considers it to be non-DLP Flash. For non-DLP flash devices, you must read at least 16 bits of data learn pattern from a known location. See Data learning.

To accommodate pessimistic data skew between the different IO lines, you must program a different learning pattern on each of the data pins IO1 and IO3.

Special write-access is permitted if both:

- IP access is not asserted (SR[IP_ACC] = 0)
- AHB access is not asserted (SR[AHB_ACC] = 0)

Diagram

Table continued from the previous page...

Field	Function
24 DL_NONDLP_FLSH	DLP Non-DLP Flash Memory Enable Enables data learning for flash memories that do not provide a data learning pattern. For a non-DLP flash memory, execute a one-time data learning through the IPS to select a tap before an AHB read operation. 0b - Disables 1b - Enables
23-16 —	Reserved
15-14 DLP_SEL_FA	DLP Selection Flash Memory A Selects which pad to use for pattern matching IO for flash memory A. 00b - Ignore pattern matching. Use this value only for debugging. 01b - IO1 10b - IO3. Use this value only for debugging. 11b - Both IO1 and IO3
13-8 —	Reserved
7-0 —	Reserved

41.7.2.22 Data Learning Status Flash Memory (DLSR_FA)

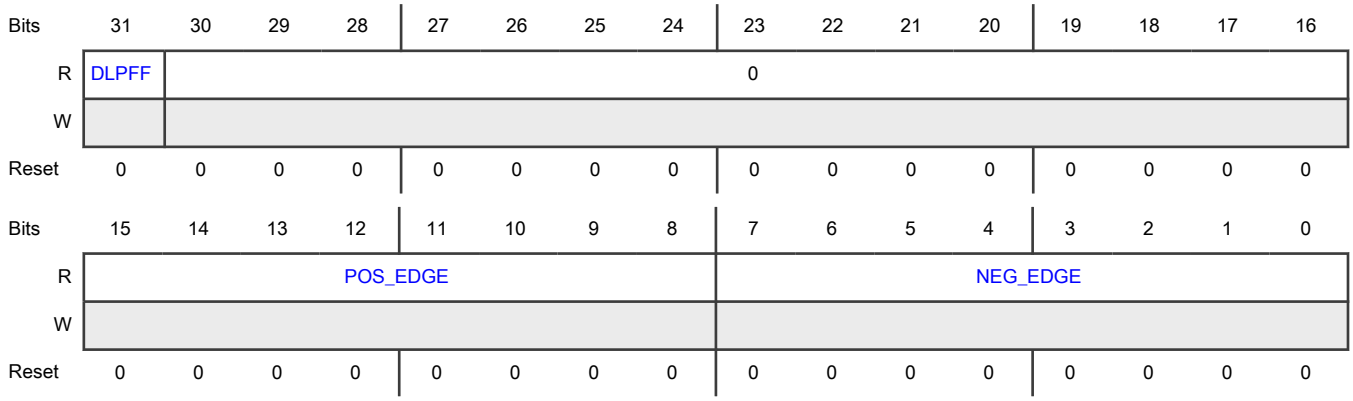
Offset

Register	Offset
DLSR_FA	134h

Function

Indicates the sampling point selected by the data learning algorithm for the corresponding flash memory when data matching is successful (DLPFF = 0). Otherwise, indicates the pattern matching outline.

Diagram



Fields

Field	Function
31 DLPFF	DLP Failure Flag Indicates that data learning has failed. 0b - No failure 1b - Failure
30-16 —	Reserved
15-8 POS_EDGE	DLP Positive Edge Match Indicates the DLP positive edge match signature, which contains the tap number selection (in between 0-7), based on auto data learning scheme.
7-0 NEG_EDGE	DLP Negative Edge Match Indicates the DLP negative edge match signature, which contains the tap number selection (in between 0-7), based on auto data learning scheme.

41.7.2.23 TX Buffer Status (TBSR)

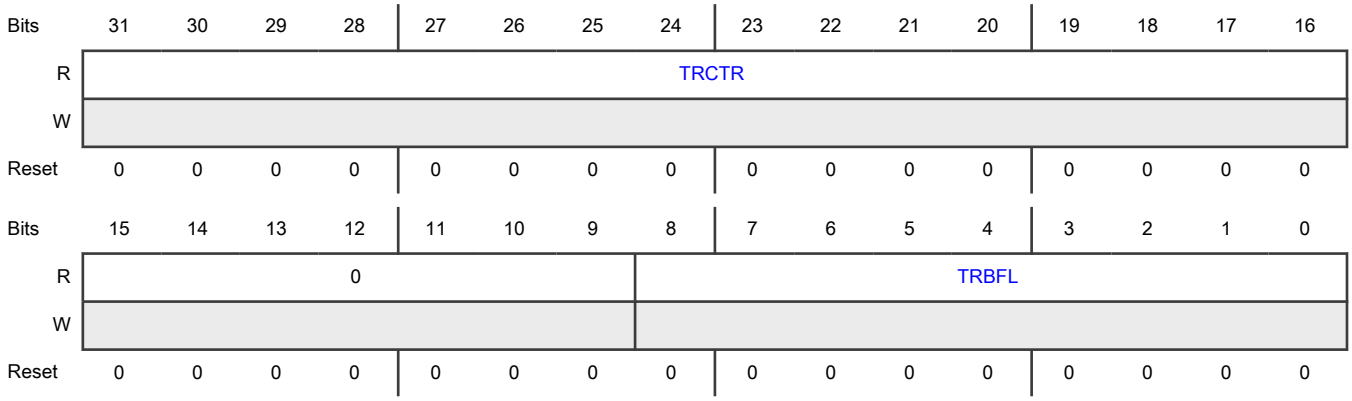
Offset

Register	Offset
TBSR	150h

Function

Indicates the status of the TX data buffer.

Diagram



Fields

Field	Function
31-16 TRCTR	Transmit Counter Indicates how many 4-byte entries have been written to the TX buffer by host accesses. XSPI increments this count on each write to TBDR that results in a push to the TX buffer. To reset this count to 0, write 1 to MCR[CLR_TXF]. If you do not reset the count, it wraps from FFFFh to 0.
15-9 —	Reserved
8-0 TRBFL	TX Buffer Fill Level Indicates the number of 4-byte entries written to the TX buffer for transmitting to the serial flash memory device.

41.7.2.24 TX Buffer Data (TBDR)

Offset

Register	Offset
TBDR	154h

Function

Writes data to the circular TX buffer. The data in the buffer is in turn written to the serial flash memory by the page programming commands.

See Byte ordering – endianness for the byte ordering scheme. A write transaction on the flash memory with data size of less than 32 bits leads to the removal of one data entry from the TX buffer. The valid bits are used and the rest of the bits are discarded.

Special write-access is permitted if the TX buffer is not full (TXFULL = 0).

NOTE

You can write to this register only when write access is granted by the SFP; otherwise, attempting to write to it generates a bus transfer error. See TBDR register write lock.

Diagram

Fields

Field	Function
31-0 TXDATA	TX Data On write, writes the data to the next available entry of the TX buffer. XSPI updates the buffer fill level (TBSR[TRBFL]). On read, returns the last data written to the register.

41.7.2.25 TX Buffer Control (TBCT)

Offset

Register	Offset
TBCT	158h

Function

Controls operation of the TX data buffer.

Special write-access is permitted if:

- IP access is not asserted (SR[IP_ACC] = 0)

Diagram

Field	Function
31 —	Reserved
30 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
29-28 —	Reserved
27 TXFULL	TX Buffer Full Indicates that the TX buffer has the maximum allowed number (256) of 4-byte entries. 0b - Not full 1b - Full
26 TXDMA	TX DMA Indicates that TX buffer fill by DMA is enabled (RSER[TBFDE] = 1) and XSPI has received or is processing a DMA request. 0b - Disabled or not processing the DMA request 1b - Enabled and processing DMA request
25 TXWA	TX Buffer Watermark Available Indicates when the number of available spaces in the TX buffer is greater than or equal to the specified watermark (TBCT[WMRK]). For example, when TBCT[WMRK] = 1, XSPI writes 0 to this field when the TX buffer is full (256 entries). **NOTE** • In case of IPED transaction, once this flag is de-asserted, it will remain low unless application clears buffer pointers after winning arbitration using environment-specific MCR[CLR_TXF]. • In case of timeout (MTO) error, only Main environment-specific MCR[CLR_TXF] is allowed to reset it independent of having arbitration. • In case of arbitration lock timeout, wait for transaction to complete and then release arbitration lock ERRSTAT[ARB_LOCK_TO] by W1C. TX Buffer pointers will retain its previous value and will be cleared using environment-specific MCR[CLR_TXF] after winning arbitration for a new request. 0b - Not available 1b - Available
24 TXNE	TX Buffer Not Empty Indicates when the TX buffer: • Contains data ready for transfer. • Data has been left in the buffer after early termination of a write transaction, which includes the data of the first transfer of an interrupted burst activity when HSIZE is 1 (1 byte) or 2 (2 bytes). 0b - Empty 1b - Not empty
23	RX Buffer DMA

Table continues on the next page...

Table continued from the previous page...

Field	Function
RXDMA	Indicates when RX buffer read out via DMA is active; that is, when DMA is requested or running. 0b - Not active 1b - Active
22-20 ARB_STATE	XSPI Arbitration State Indicates the state of arbitration. 000b - Idle 001b - ARB - Arbitration 010b - AHBWR_PROC - AHB write processing 011b - AHBRD_PROC - AHB read processing 101b - TG_PROC - IP command processing 110b - PROC_FIN - XSPI processing finish wait 111b - RDSR_PROC - RDSR read processing All other values are reserved.
19 RXFULL	RX Buffer Full Indicates that the RX buffer is full; that is, RBSR[RDBFL] equals 128. 0b - Not full 1b - Full
18 —	Reserved
17 —	Reserved
16 RXWE	RX Buffer Watermark Exceeded Indicates that the number of valid entries in the RX buffer exceeds the watermark value (RBCT[WMRK]). 0b - Not exceeded 1b - Exceeded
15 ARB_LCK	Arbitration Lock Status Indicates that arbitration is locked by the AHB page program wait flag (FR[PPWF]) or by the IPS TG queue. 0b - Not locked 1b - Locked
14-11	AHB Buffer n Full

Table continues on the next page...

Table continued from the previous page...

Field	Function
AHBnFUL	Indicates when the corresponding AHB buffer is full. If you enable sub-buffer division (write 1 to BUF*n*CR[SUB_DIV_EN]), indicates that at least one sub-buffer is full. 0b - Not full 1b - Full
10-7 AHBnNE	AHB Buffer n Not Empty Indicates when the corresponding AHB buffer contains data. 0b - Empty 1b - Not empty
6 AHBTRN	AHB Access Transaction Pending Indicates when there is a pending request on the AHB interface. See Flash memory mapped AMBA bus. 0b - No pending request 1b - Request is pending
5 —	Reserved
4 AWRACC	AHB Write Access Indicates when an AHB write access has been requested or is ongoing. 0b - No AHB write access 1b - AHB write access
3 —	Reserved
2 AHB_ACC	AHB Read Access Indicates when an AHB read access has been requested or is ongoing. 0b - Not initiated by AHB bus 1b - Initiated by AHB bus
1 IP_ACC	IP Access Indicates when the currently executing transaction has been initiated by the IP bus. 0b - Not initiated by IP bus 1b - Initiated by IP bus
0 BUSY	Module Busy Indicates when the module is currently busy handling a transaction to an external flash memory device 0b - Not busy

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Busy

41.7.2.27 Flag (FR)

Offset

Register	Offset
FR	160h

Function

Provides all available flags about SFM command execution and arbitration that can serve as sources for the generation of interrupt service requests. The error flags in this register do not relate directly to the execution of the transaction in the serial flash memory device itself but only to the behavior and conditions visible in the XSPI module.

Special write access is permitted in normal mode.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 DLPFF	Data Learning Pattern Failure Flag Indicates that XSPI encountered a DATA_LEARN instruction in a sequence, but no sampling point is found for the data learning pattern. While this flag is set, XSPI returns an AHB bus error for all AHB read transactions. If HRESP_ERR_MASK is 1, then XSPI does not generate the AHB HRESP error. Instead, it returns the AHB error payload for the current AHB burst (AHB_ERR_PAYLOAD_LO, AHB_ERR_PAYLOAD_HI). It then treats the next AHB read burst as a normal AHB read and processes it without regard for the clearing of this flag.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - No failure 1b - Failure When writing 0b - No action 1b - Clears flag
30 —	Reserved
29 —	Reserved
28 DLLABRT	DLL Terminate Indicates that the DLL has unlocked while reading data from the flash memory. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No lock has occurred 1b - DLL unlock occurred When writing 0b - No action 1b - Clears flag
27 TBFF	TX Buffer Fill Flag Indicates that the TX buffer is filling (not yet full). Before writing to the TX buffer, clear this field and then read it. If it is set, the TX buffer has room for more data. If the field remains cleared, the TX buffer is full. See TX buffer operation. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No room in the TX buffer 1b - TX buffer has room When writing

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No action 1b - Clears flag
26 TBUF	TX Buffer Underrun Flag Indicates that XSPI has attempted to pull data when the TX buffer is empty during IPS write transaction. When a TX-buffer underrun occurs (TBUF = 1), the memory interface generates a sequence termination event. In response to an underrun, you must clear the TX buffer (write 1 to CLR_TXF) and re-execute the entire transaction. XSPI does not service pending AHB write transactions (HREADY low) until you clear this flag. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No underrun 1b - Underrun When writing 0b - No action 1b - Clears flag
25 —	Reserved
24 DLLUNLCK	DLL Unlock Indicates the occurrence of a DLL unlock event, regardless of flash memory access. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No unlock event 1b - Unlock event has occurred When writing 0b - No action 1b - Clears the flag
23 ILLINE	Illegal Instruction Error Flag Indicates that XSPI encountered an illegal instruction in any sequence. When this error occurs, you must reconfigure the correct sequence instruction and assert software reset for both the serial flash memory and AHB domains (write 1 to both MCR[SWRSTSD]] and MCR[SWRSTHD]). For a list of legal instructions, see Programmable sequence engine.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No action 1b - Clears error flag
22 —	Reserved
21 —	Reserved
20 —	Reserved
19-18 —	Reserved
17 RBOF	RX Buffer Overflow Flag Indicates when the RX buffer cannot receive any more data from the serial flash memory device. XSPI continues processing the IP command that triggered the overflow until it reads the number of bytes specified by the IP data size (IPCR[IDATSZ]) from the serial flash memory device. The content of the RX buffer remains unchanged. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No overflow 1b - Overflow When writing 0b - No action 1b - Clears flag
16 RBDF	RX Buffer Drain Flag Indicates the RX buffer watermark has been exceeded (SR[RXWE] = 1). If RX buffer drain DMA is enabled (RSER[RBDDE] = 1), XSPI triggers a POP.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If RX buffer drain DMA is not enabled (RSER[RBDDE] = 0), XSPI does not trigger an RX buffer POP event. After the POP event, when you write 1 to this field: • If the RX buffer has less than or up to RBCT[WMRK] valid entries, XSPI clears the flag. • If the RX buffer has more than RBCT[WMRK] valid entries after the POP, XSPI does not clear the flag. For more information, see the "Receive Buffer Drain Interrupt or DMA Request" section in Normal mode interrupt and DMA requests. **NOTE** This field behaves differently for register reads and writes. When reading 0b - RX buffer is not over the watermark 1b - RX buffer is over the watermark When writing 0b - No action 1b - Clears flag if RX buffer is not over the watermark after POP
15 AAEF	AHB Abort Error Flag Indicates that an AHB transaction is in process and any of the following conditions occur that may result in an AHB error response (HRESP): • Data learning pattern failure (FR[DLPFF]) • AHB illegal burst size error during the AHB transfer (FR[AIBSEF]) You should clear this flag and any of these related conditions before initiating any new AHB transfer. If SOCCR[MASK_ECC] is 1, then XSPI does not generate the AHB HRESP error. Instead, it returns the AHB error payload for the current AHB burst. It then treats the next AHB read burst as a normal AHB read and processes it without regard for the clearing of this flag. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No action 1b - Clears error flag
14 AITEF	AHB Illegal Transaction Error Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Indicates that XSPI has not generated a response to the AHB bus due to an illegal transaction and expiration of the watchdog timer. You specify the timer value in AHB HREADY Timeout (AHRDYTO). For an AHB read transaction, if AHB timeout occurs then XSPI returns the AHB error payload as read data and does not generate an HRESP error. If this flag is set, XSPI returns an HRESP error for every AHB write transaction. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No action 1b - Clears error flag
13 AIBSEF	AHB Illegal Burst Size Error Flag Indicates that the total burst size (size x beat) of an AHB transaction is greater than the prefetch data size, as specified by ADATSZ or, if ADATSZ is 1, the data size specified in the sequence pointed to by SEQID. For information about HBURST, see HBURST support with AHB read. Until you clear this flag, XSPI returns AHB read transfers with the HRESP error. If HRESP_ERR_MASK is 1, then XSPI does not generate the AHB HRESP error. Instead, it returns the AHB error payload for the current AHB burst (AHB_ERR_PAYLOAD_LO, AHB_ERR_PAYLOAD_HI). It then treats the next AHB read burst as a normal AHB read and processes it without regard for the clearing of this flag. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No action 1b - Clears error flag
12 ABOF	AHB Buffer Overflow Flag Indicates when the size of the AHB access exceeds the size of the AHB buffer. This condition can occur only if BUF*n*CR[ADATSZ] has the incorrect value. XSPI continues processing the AHB command that triggers this condition until the number of entries specified in BUFxCR[ADATSZ] have been read from the serial flash memory device. The content of the AHB buffer is changed.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - No overflow 1b - Overflow When writing 0b - No action 1b - Clears overflow flag
11 —	Reserved
10 —	Reserved
9 —	Reserved
8 PPWF	Page-Program Wait Flag Indicates assertion of the page-program wait flag after writing to flash memory. When asserted, this flag blocks all SFP or IP transactions. If you disable page program wait writes (write 1 to AWRCR[PPW_WR_DIS]), it also blocks AHB writes. If you disable page program wait reads (write 1 to AWRCR[PPW_RD_DIS]), it also blocks AHB reads. See Page program wait handling. If any AHB transfer is kept waiting by HREADY being held low when this flag is set, it may cause assertion of AITEF. On assertion of PPWF, XSPI starts the SFP arbitration lock timeout counter (SFP_ARB_TIMEOUT). If the counter expires, it triggers an arbitration lock timeout error (writes 1 to ERRSTAT[ARB_LOCK_TO]). If ERRSTAT[ARB_LOCK_TO] is set, you must clear it before you clear PPWF. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No page program wait 1b - Page program wait in effect When writing 0b - No action 1b - Clears flag
7	Reserved

2 PERFOVF	AHB Performance Monitor Overflow Flag Indicates when AHB_PERF_CTRL reports any buffer hit or miss counter overflows. The overflow bits in AHB_PERF_CTRL remain asserted until you clear this flag by writing 1 to this field. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No overflow 1b - Overflow When writing 0b - No action 1b - Clears flags
1 RDADDR	AHB Read Address Error Flag When an AHB buffer is divided into four sub-buffers, indicates one of the following: • The initiator sent an AHB read address to that buffer that is not within the address range of any of its sub-buffers. • The initiator sent an AHB read address to that buffer that is within multiple sub-buffer address ranges because of incorrect programming. The offending transaction causes XSPI to return the AHB error payload (AHB_ERR_PAYLOAD_LO, AHB_ERR_PAYLOAD_HI). See Buffer function with sub-buffer division enabled. This flag is only applicable for a legal AHB read. Clear this flag by writing 1 to this field. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No action 1b - Clears flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 TFF	IP Command Transaction Finished Flag Indicates that XSPI has completed a running IP command. If an error occurs, and the related error flags are valid in the same clock cycle, XSPI asserts TFF. Clear this flag by writing 1 to this field. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not completed 1b - Completed When writing 0b - No action 1b - Clears flag

41.7.2.28 Interrupt and DMA Request Enable (RSER)

Offset

Register	Offset
RSER	164h

Function

Enables the XSPI interrupts and DMA requests.

NOTE

Every enabled interrupt or DMA request prevents the XSPI module from entering stop mode or module disable mode when the flag for that source is set in FR. See Stop mode and Module Disable mode.

Diagram

Fields

Field	Function
31 DLPFIE	Data Learning Pattern Failure Interrupt Enable Enables generation of an interrupt on data learning pattern failure. See FR[DLPFF]. 0b - Disables 1b - Enables
30-29 —	Reserved
28 —	Reserved
27 TBFIE	TX Buffer Fill Interrupt Enable Enables generation of an interrupt on TX buffer fill. See FR[TBFF]. Do not enable this interrupt when using SFP functionality because it causes XSPI BUSY SFM to go high and blocks SFP from generating any transaction over to XSPI. 0b - Disables 1b - Enables
26 TBUIE	TX Buffer Underrun Interrupt Enable Enables generation of an interrupt on TX buffer underrun. See FR[TBUF]. 0b - Disables 1b - Enables
25 TBFDE	TX Buffer Fill DMA Enable Enables generation of a DMA request for TX buffer fill. When enabled, XSPI generates DMA requests as long as the available space in the TX buffer is equal to or greater than the TX watermark (TBCT[WMRK]). 0b - Disables 1b - Enables
24 DLLULIE	DLL unlock interrupt enable Enables generation of an interrupt on a DLL unlock event. See FR[DLLUNLCK]. 0b - Disables 1b - Enables
23 ILLINIE	Illegal Instruction Error Interrupt Enable Enables generation of an interrupt on occurrence of an illegal instruction error. See FR[ILLINE]. 0b - Disables 1b - Enables
22	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
21 RBDDE	RX Buffer Drain DMA Enable Enables generation of a DMA request for RX buffer drain. When enabled, XSPI generates a DMA request when the RX buffer exceeds the watermark (SR[RXWE]). **NOTE** After you enable DMA transfer requests (write 1 to this field). To disable DMA transfers, you must perform a software reset for the AHB domain (write 1 to SWRSTHD). 0b - Disabled 1b - Enables
20 —	Reserved
19 —	Reserved
18 —	Reserved
17 RBOIE	RX Buffer Overflow Interrupt Enable Enables generation of an interrupt on occurrence of RX buffer overflow. See FR[RBOF]. This field indicates the RX buffer overflow interrupt enable flag. 0b - Disables 1b - Enables
16 RBDIE	RX Buffer Drain Interrupt Enable Enables generation of an interrupt on occurrence of RX buffer drain. See FR[RBDF]. 0b - Disables 1b - Enables
15 AAIE	AHB Abort Error Interrupt Enable Enables generation of an interrupt on occurrence of an AHB abort error. See FR[AAEF]. 0b - Disables 1b - Enables
14 AITIE	AHB Illegal Transaction Error Interrupt Enable flag Enables generation of an interrupt on occurrence of an AHB illegal transaction error. See FR[AITEF]. This field indicates the AHB illegal transaction interrupt enable flag.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disables 1b - Enables
13 AIBSIE	AHB Illegal Burst Size Error Interrupt Enable Enables generation of an interrupt on occurrence of an AHB illegal burst size error. See FR[AIBSEF]. 0b - Disables 1b - Enables
12 ABOIE	AHB Buffer Overflow Interrupt Enable Enables generation of an interrupt on occurrence of an AHB buffer overflow. See FR[ABOF]. 0b - Disables 1b - Enables
11 —	Reserved
10 —	Reserved
9 —	Reserved
8 PPWIE	Page-Program Wait Interrupt Enable Enables generation of an interrupt on page-program wait. See FR[PPWF]. 0b - Disables 1b - Enables
7 —	Reserved
6 IPIEIE	IP Command Trigger Fail Error Interrupt Enable Enables generation of an interrupt on occurrence of an IP command trigger fail error. See FR[IPIEF]. 0b - Disables 1b - Enables
5 IPEDIE	IPED RX Decryption Error Interrupt Enable Enables generation of an interrupt on occurrence of an IPED RX decryption error. See FR[IPEDERR]. **NOTE** This field is not supported in every instance. The following table includes only supported registers.

Table continues on the next page...

Table continued from the previous page...

3 —	Reserved
2 PERFOVIE	AHB Performance Monitor Overflow Interrupt Enable Enables generation of an interrupt on a buffer hit or miss counter overflow. See FR[PERFOVF]. 0b - Disables 1b - Enables
1 RDADDRIE	AHB Read Address Error Interrupt Enable Enables generation of an interrupt on occurrence of an AHB read address error. See FR[RDADDR]. 0b - Disables 1b - Enables
0 TFIE	Transaction Finished Interrupt Enable Enables generation of an interrupt when an IP command transaction completes. See FR[TFF]. 0b - Disables 1b - Enables

41.7.2.29 Sequence Suspend Status (SPNDST)

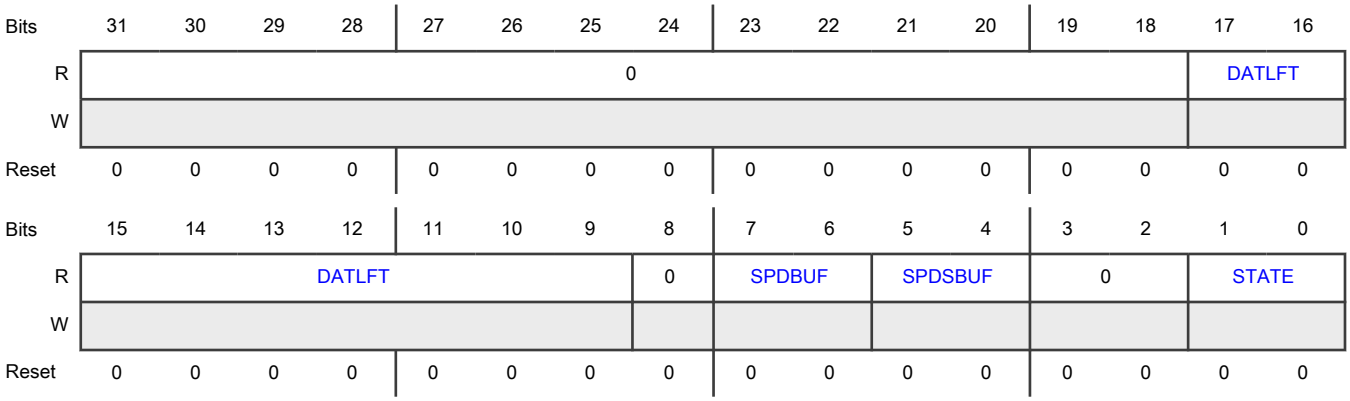
Offset

Register	Offset
SPNDST	168h

Function

Provides information specific to any suspended sequence. An AHB sequence may be suspended when a high priority AHB initiator makes an access before the AHB sequence completes the requested data transfer.

Diagram



Fields

Field	Function
31-18 —	Reserved
17-9 DATLFT	Data Left Indicates the number of 8-byte (64 bits) units of data left to be read in the suspended sequence. This field is valid only when STATE is 01 or 11.
8 —	Reserved
7-6 SPDBUF	Suspended Buffer Indicates the number of the suspended buffer. This field is valid only when STATE is 01 or 11.
5-4 SPDSBUF	Suspended Sub-Buffer Indicates the number of the suspended sub-buffer. This field is valid only when STATE is 01 or 11.
3-2 —	Reserved
1-0 STATE	Suspended Resume State Indicates the state of the suspended transaction. 00b - No suspended transaction pending 01b - Suspended transaction waiting to be resumed 10b - Not applicable 11b - Suspended transaction is resumed

41.7.2.30 Sequence Pointer Clear (SPTRCLR)

Offset

Register	Offset
SPTRCLR	16Ch

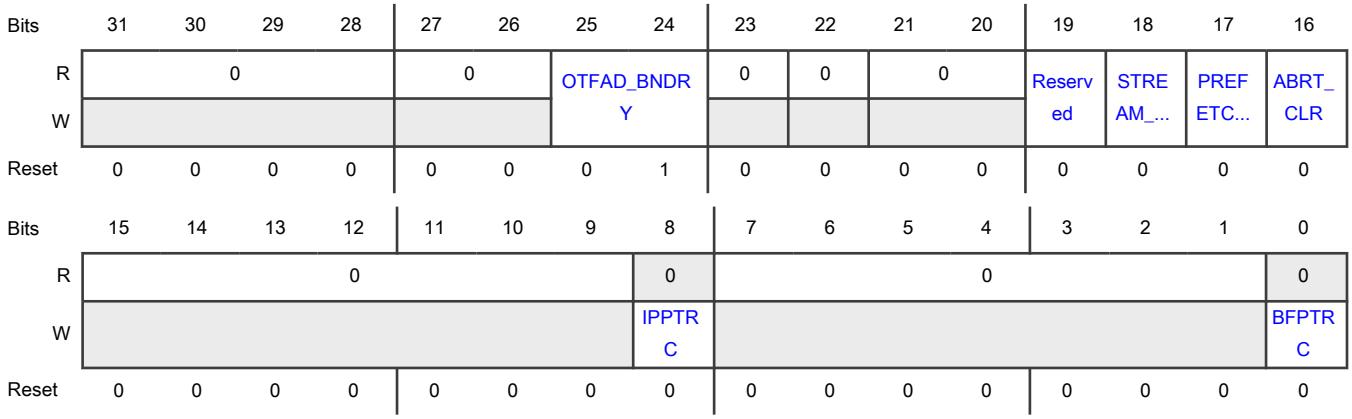
Function

Supports the following controls:

- Clears the IP and buffer sequence pointers.
- Disables prefetch.
- Terminates a flash memory transaction and clears the AHB buffer.
- Enables AHB read as a streaming port.
- Specifies the OTFAD prefetch address boundary.

Sequence pointers specify the index of instructions within the LUT entry that is to be executed next. For example, if the LUT entry ends on a JMP_ON_CS value of 2, the stored index is 2. You should reset the sequence pointers whenever you update the sequence ID (SEQID, SFP_TG_IPCR[SEQID], BFGENCR[SEQID_WR] , SEQID_WR). .

Diagram



Fields

Field	Function
31-28 —	Reserved
27-26 —	Reserved
25-24	OTFAD Prefetch Address Boundary Specifies the OTFAD prefetch boundary.

Table continues on the next page...

Table continued from the previous page...

Field	Function
OTFAD_BNDRY	00b - No prefetch address boundary 01b - Prefetch address boundary is 1K. All other values are reserved.
23 —	Reserved
22 —	Reserved
21-20 —	Reserved
19 —	Reserved
18 STREAM_EN	Enable Streaming Port Enables AHB read as a streaming port with 64K prefetch size. 0b - Enables 1b - Disables
17 PREFETCH_DIS	Prefetch Disable Disables the prefetch mechanism for AHB reads. It is not based on dynamic programming; you should program this field before any other XSPI action. If you enable high priority for either AHB buffer 0 or 1 (HP_EN or HP_EN is 1) then you must write 0 to this field. 0b - Enables 1b - Disables
16 ABRT_CLR	Flash Memory Abort—AHB Buffer Clear Clears the AHB buffer pointers regardless of prefetch disable. It also terminates any current flash memory transaction and rejects any ongoing AHB read with an error. This is a dynamic field; the action takes place immediately. After clearing the AHB buffer pointers, XSPI writes 0 to this field. 0b - No action 1b - Clears pointers and terminates transaction
15-9 —	Reserved
8	IP Pointer Clear

Table continues on the next page...

Table continued from the previous page...

Field	Function
IPPTRC	Clears the sequence pointer for IP accesses (IPCR[SEQID]). This is a self-clearing field; it always reads 0. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Conveys no useful information When writing 0b - No action 1b - Clears the sequence pointer
7-1 —	Reserved
0 BFPTRC	Buffer Pointer Clear Clears the sequence pointer for AHB accesses (BFGENCR[SEQID]). This is a self-clearing field; it always reads 0. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Conveys no useful information When writing 0b - No action 1b - Clears the sequence pointer

41.7.2.31 Serial Flash Memory Top Address (SFA1AD)

Offset

Register	Offset
SFA1AD	180h

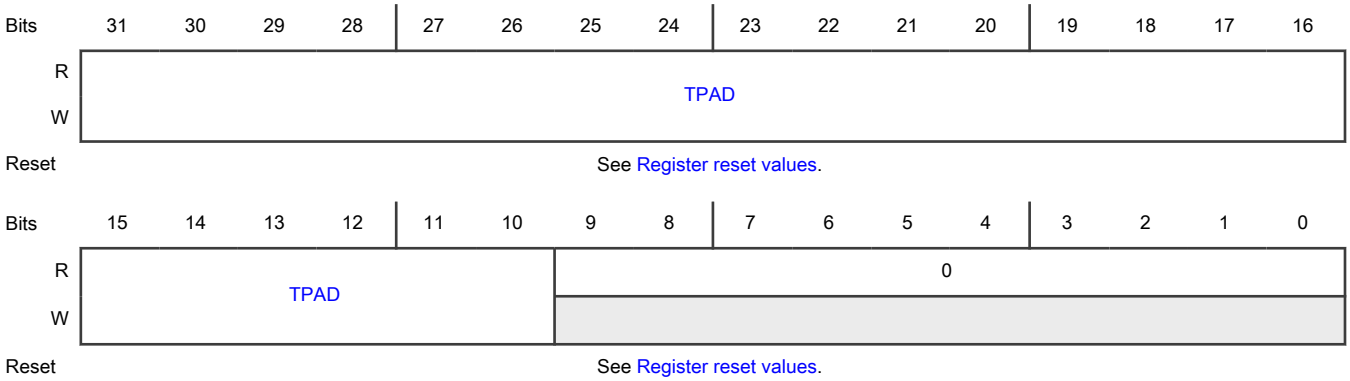
Function

Specifies the top address of the corresponding serial flash memory. See Flash memory device selection.

Special write access is permitted if all these conditions apply:

- IP access is not asserted (SR[IP_ACC] = 0)
- AHB read access is not asserted (SR[AHB_ACC] = 0)
- AHB write access is not asserted (SR[AWRACC] = 0)

Diagram



Register reset values

Register	Reset value
SFA1AD	XSPI0: 2C00_0000h XSPI1: 0C00_0000h XSPI2: 6800_0000h

Fields

Field	Function
31-10 TPAD	Top Address In effect, TPADxn is the first location of the next memory.
9-0 —	Reserved

41.7.2.32 Serial Flash Memory Top Address (SFA2AD)

Offset

Register	Offset
SFA2AD	184h

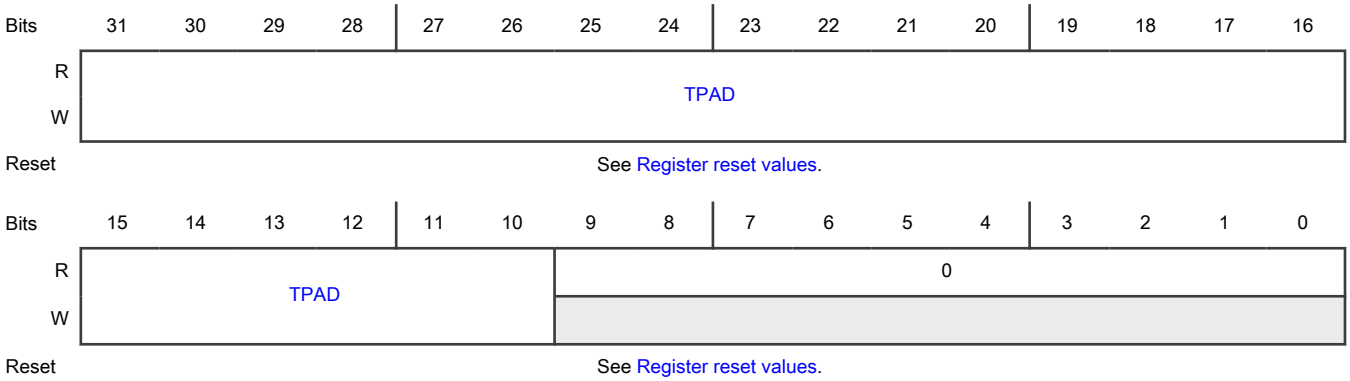
Function

Specifies the top address of the corresponding serial flash memory. See Flash memory device selection.

Special write access is permitted if all these conditions apply:

- IP access is not asserted (SR[IP_ACC] = 0)
- AHB read access is not asserted (SR[AHB_ACC] = 0)
- AHB write access is not asserted (SR[AWRACC] = 0)

Diagram



Register reset values

9-0 —	Reserved

41.7.2.33 Data Learning Pattern (DLPR)

Offset

Register	Offset
DLPR	190h

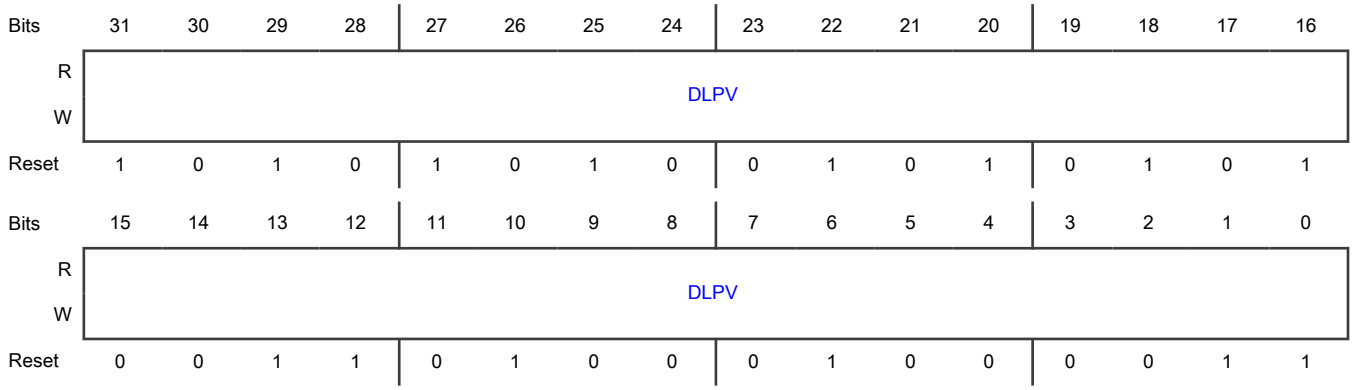
Function

Specifies the data learning pattern for data learning in the DQS modes.

Special write access is permitted if both:

- IP access is not asserted (SR[IP_ACC] = 0)
- AHB read access is not asserted (SR[AHB_ACC] = 0)

Diagram



Fields

Field	Function
31-0 DLPV	Data Learning Pattern Specifies the data learning pattern. XSPI uses this value in the SDR/DDR modes along with the DATA_LEARN instruction. You can specify different patterns for selected IOs. That is, if you select IO1 or IO3 or both (using DLCR[DLP_SEL_FA] , XSPI provides bits 31–16 for the IO3 pattern and 15–0 for the IO1 pattern. You should store the pattern bit-wise in little endian format. See Data learning.

41.7.2.34 Flash Memory A Failing Address Status (FAILA_ADDR)

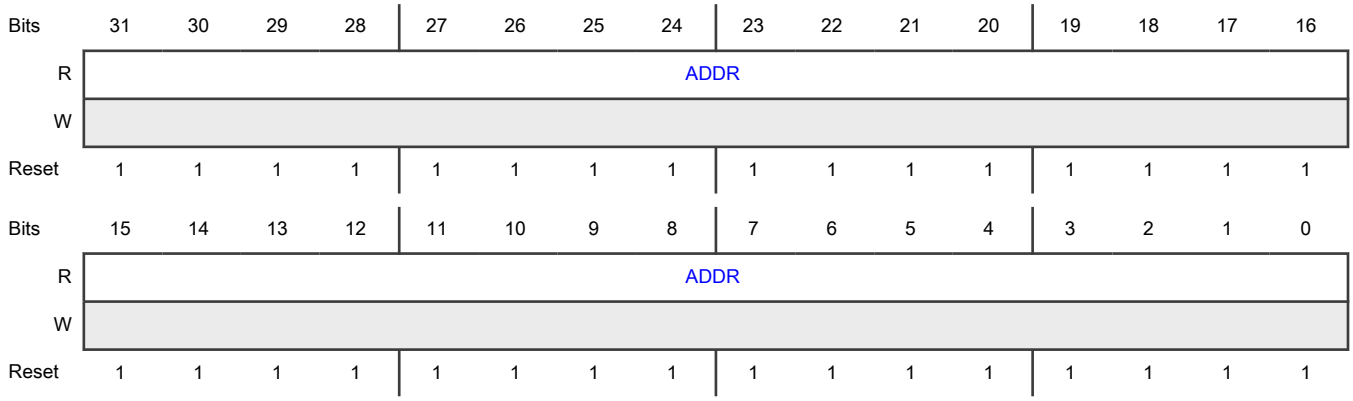
Offset

Register	Offset
FAILA_ADDR	194h

Function

Indicates the flash memory address where a data learning error has occurred.

Diagram



Fields

Field	Function
31-0 ADDR	Failing Address

41.7.2.35 RX Buffer Data (RBDR0 - RBDR63)

Offset

For a = 0 to 63:

Register	Offset
RBDRa	200h + (a × 4h)

Function

Contains the individual entries in the RX buffer. See Byte ordering of serial flash memory read data for the byte ordering scheme.

RBDR0 corresponds to the position of the read pointer within the RX buffer. RBSR[RDBFL] indicates the number of available valid entries that have been written to the RX buffer.

Example 1: The RX buffer is filled completely with 128 words. In this example, the address range for valid read access ranges from RBDR0 to RBDR127.

Example 2: The RX buffer contains five valid words (RBSR[RDBFL] = 5). In this example, RBDR4 points to the last valid entry.

Any access beyond the range of valid RX buffer entries returns undefined results.

NOTE

If the number of valid entries is greater than 64, accessing the buffer data beyond RBDR[63] requires an RX buffer pop event. See RBDF and RX buffer POP event.

41.7.2.37 LUT Lock Configuration (LCKCR)

Offset

Register	Offset
LCKCR	304h

Function

In conjunction with LUTKEY, locks or unlocks the LUT. For a successful lock operation, you must write to LCKCR immediately after writing to LUTKEY. See Locking the LUT and Unlocking the LUT. You cannot write the same value to both LOCK and UNLOCK. In other words, LOCK and UNLOCK cannot both be 00b or both be 11b.

Special write access is permitted after writing to LUTKEY.

31-2 —	Reserved
1 UNLOCK	Unlock LUT Unlocks the LUT. You can write to this field only immediately after writing 5AF05AF0h to LUTKEY. 0b - No action 1b - Unlocks

Table continues on the next page...

Table continued from the previous page...

Field	Function
0 LOCK	Lock LUT Locks or unlocks the LUT. You can write to this field only immediately after writing 5AF05AF0h to LUTKEY. 0b - No action 1b - Locks

41.7.2.38 Lookup Table (LUT0 - LUT79)

Offset

For a = 0 to 79:

Register	Offset
LUTa	310h + (a × 4h)

Function

Specifies instruction-operand pairs. Each LUT register can contain two 16-bit (2-byte) pairs. See Lookup table (LUT).

Special write access is permitted if the LUT is unlocked and the global configuration lock is disabled (MGC[GCLCK] = 00b). See Unlocking the LUT.

Only privilege initiators can access this register. A write attempt by any other initiator generates a bus transfer error. See Programmable sequence engine.

You can write to this register only if the global configuration lock is disabled (GCLCK = 00b).

LUT2–LUT79	XSPI0–XSPI2: 0000_0000h

Fields

Field	Function
31-26 INSTR1	Instruction 1 Specifies instruction 1.
25-24 PAD1	Pads for INSTR1 Specifies the number of pads for instruction 1. 00b - 1 01b - 2 10b - 4 11b - 8
23-16 OPRND1	Operand for INSTR1 Specifies the operand for instruction 1.
15-10 INSTR0	Instruction 0 Specifies instruction 0.
9-8 PAD0	Pads for INSTR0 Specifies the number of pads for instruction 0. 00b - 1 01b - 2 10b - 4 11b - 8
7-0 OPRND0	Operand for INSTR0 Specifies the operand for instruction 0.

41.7.2.39 AHB Buffer n Sub Buffer m Start and End Address Range (BUF0_0_ADDR_RANGE - BUF3_3_ADDR_RANGE)

Offset

For n = 0 to 3; m = 0 to 3:

Register	Offset
BUFn_m_ADDR_RANGE	480h + (n × 10h) + (m × 4h)

Function

Specifies the address range (start and end) for the corresponding AHB buffer when you enable sub-buffer division (write 1 to BUF*n*CR[SUB_DIV_EN]). If the AHB address falls within this address range and results in a buffer miss, then XSPI starts data prefetch in this buffer.

Special write access is permitted if both:

- AHB read access is not asserted (SR[AHB_ACC] = 0)
- AHB write access is not asserted (SR[AWRACC] = 0)

Diagram

Fields

Field	Function
31-16 ENDADR	End Address Specifies the upper 16-bits of the end address range for the associated sub-buffer. Lower 16-address bits are treated as FFFF.
15-0 STARTADR	Start Address Specifies the upper 16-bits of the start address range for the associated sub-buffer. Lower 16-address bits are treated as 0000.

41.7.2.40 AHB Buffer Status (AHB_BUF_STATUS)

Offset

Register	Offset
AHB_BUF_STATUS	4C0h

Function

Indicates the status of pre-fetched data in the AHB buffer.

NOTE

- The AHB buffer asserts a Partial Full status when the difference between the End Address and the Read Address is less than the size of the sub-buffer.
- When sub-buffer division is enabled, the BUFnCR[ADATSZ] field is ignored.

Fields

Field	Function
31-0 PERF_TIME_COUNT	Time Count Indicates, in AHB clock cycles, how long the performance monitor was running. Updated when you stop the performance monitoring or when this counter overflows.

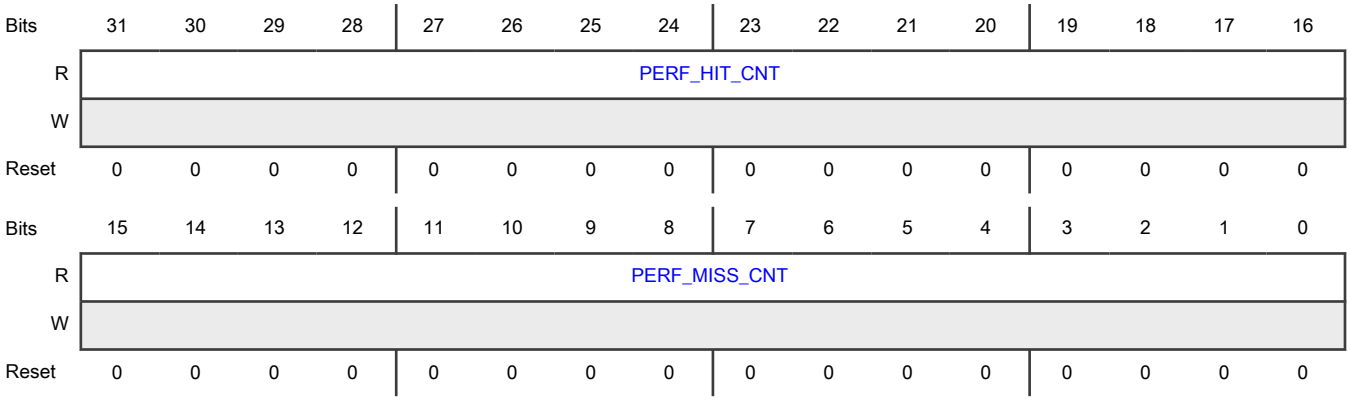
41.7.2.43 AHB Buffer n Performance Monitor (AHB_PERF_BUF0 - AHB_PERF_BUF3)

Offset

Register	Offset
AHB_PERF_BUF0	4CCh
AHB_PERF_BUF1	4D0h
AHB_PERF_BUF2	4D4h
AHB_PERF_BUF3	4D8h

Function
Indicates the hit and miss counts for the corresponding AHB buffer.

Diagram



Fields

Field	Function
31-16 PERF_HIT_CNT	Performance Hit Count Indicates the number of hits that have occurred on the corresponding AHB buffer.
15-0 PERF_MISS_CNT	Performance Miss Count Indicates the number of misses that have occurred on the corresponding AHB buffer and the sub-buffer selected by SUB_BUF_SEL0.

41.7.2.44 AHB HREADY Timeout (AHRDYTO)

Offset

Register	Offset
AHRDYTO	4DCh

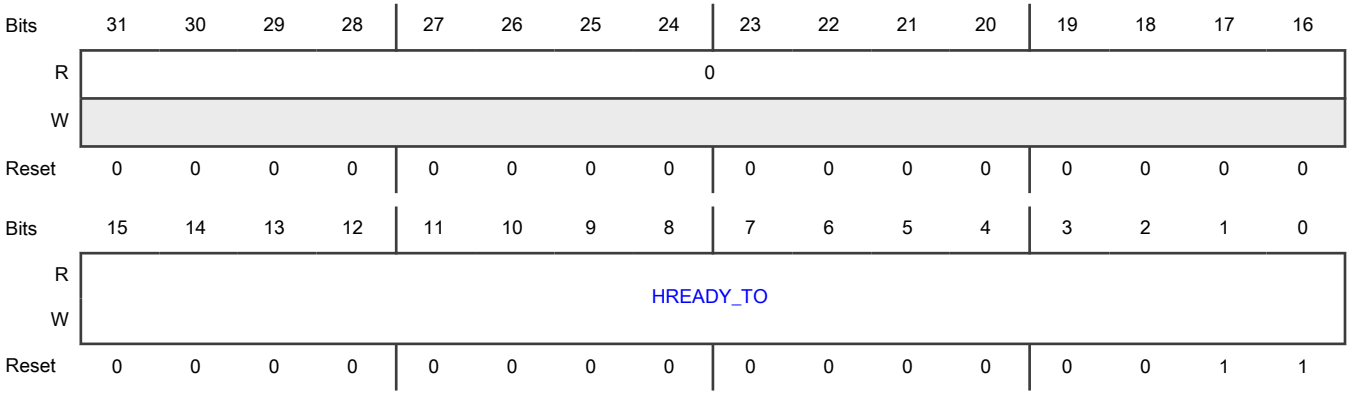
Function

Specifies how long XSPI can hold HREADY low while waiting for response to an AHB transfer.

Special write access is permitted if both:

- AHB read access is not asserted (SR[AHB_ACC] = 0)
- AHB write access is not asserted (SR[AWRACC] = 0)

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 HREADY_TO	AHB HREADY Low Timeout Counter Value Specifies, in multiples of 50000 AHB clock cycles, how long XSPI holds HREADY low before triggering an AHB illegal transaction error (FR[AITEF]).

41.7.2.45 AHB Error Payload High (AHB_ERR_PAYLOAD_HI)

Offset

Register	Offset
AHB_ERR_PAYLOAD_HI	4E0h

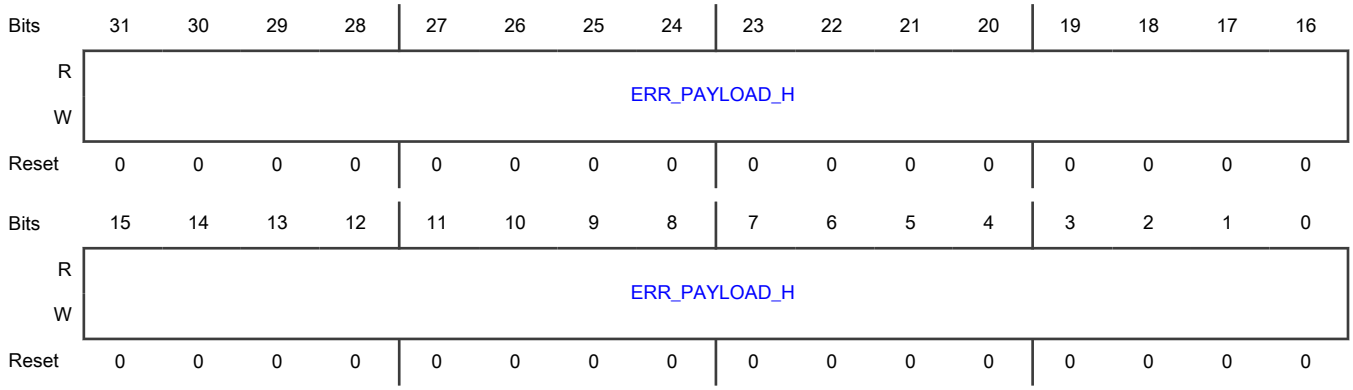
Function

Specifies the data to send on AHB HRDATA[63:32] in the event of certain error situations. Depending on the Error situation, HRESP can be OK or controlled by SOCCR[HRESP_ERR_MASK]). For a list of the error situations, see FR error flags overview.

Special write access is permitted if both:

- AHB read access is not asserted (SR[AHB_ACC] = 0)
- AHB write access is not asserted (SR[AWRACC] = 0)

Diagram



Fields

Field	Function
31-0 ERR_PAYLOAD_H	Error Payload High Specifies the data to send on AHB HRDATA[63:32] in the event of certain error situations.

41.7.2.46 AHB Error Payload Low (AHB_ERR_PAYLOAD_LO)

Offset

Register	Offset
AHB_ERR_PAYLOAD_LO	4E4h

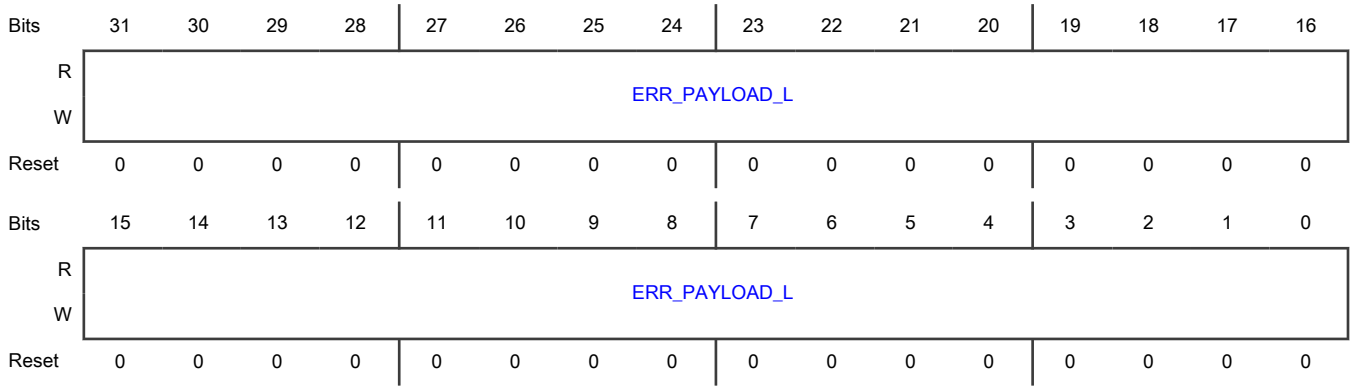
Function

Specifies the data to send on AHB HRDATA[31:0] in the event of certain error situations. HRESP remains OK in such situations. For a list of the error situations, see FR error flags overview.

Special write access is permitted if both:

- AHB read access is not asserted (SR[AHB_ACC] = 0)
- AHB write access is not asserted (SR[AWRACC] = 0)

Diagram



Fields

Field	Function
31-0 ERR_PAYLOAD_L	Error Payload Low Specifies the data to send on AHB HRDATA[31:0] in the event of certain error situations.

41.7.2.47 AHB Read Error Address (AHB_RD_ERR_ADDR)

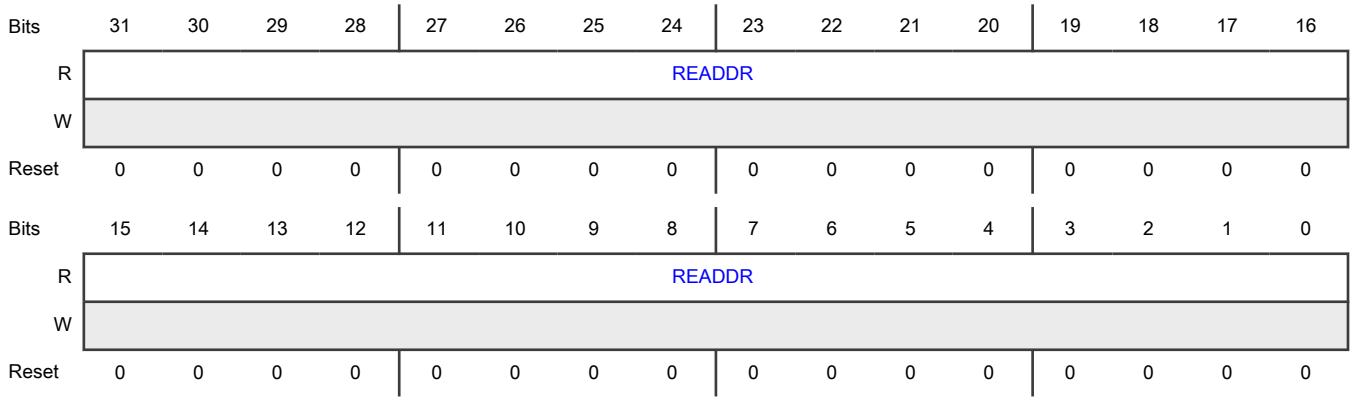
Offset

Register	Offset
AHB_RD_ERR_ADDR	4E8h

Function

Indicates the AHB read error address.

Diagram



Fields

Field	Function
31-0 READDR	Read Error Address Indicates the address of the AHB read transaction that triggered the error flagged in FR[RDADDR]. To clear this field, clear the read error flag (write 1 to FR[RDADDR]).

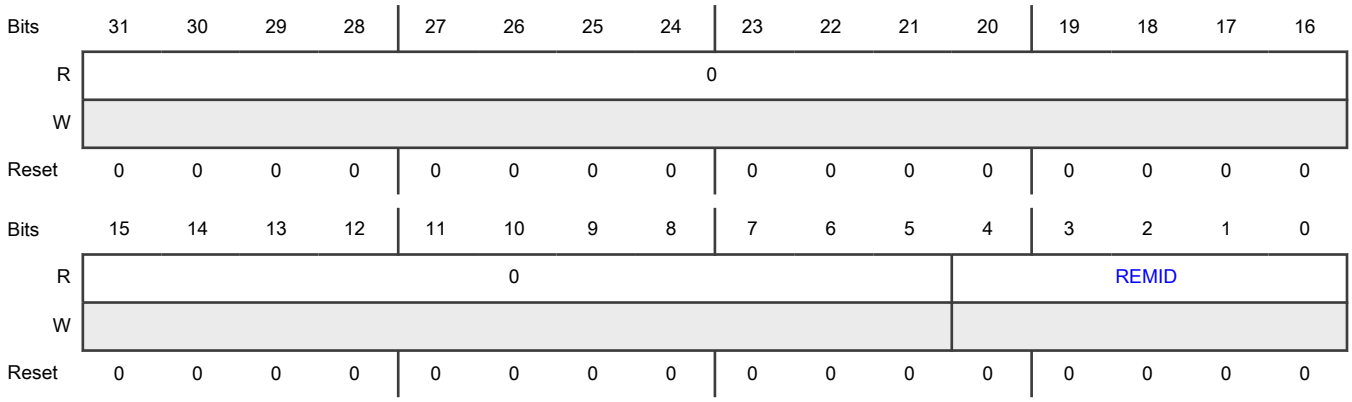
41.7.2.48 AHB Read Error Initiator ID (AHB_RD_ERR_MID)

Offset

Register	Offset
AHB_RD_ERR_MID	4ECh

Function
Indicates the AHB read error initiator ID.

Diagram



Fields

Field	Function
31-5 —	Reserved
4-0 REMID	Read Error Initiator ID Indicates the initiator ID of the AHB read transaction that triggered the error flagged in RDADDR. To clear this field, clear the read error flag (write 1 to FR[RDADDR]). See the chip-specific information for the supported initiator IDs.

41.7.2.49 Suspend Transaction Address (SPNDST_ADDR)

Offset

Register	Offset
SPNDST_ADDR	4F0h

Function

Indicates the suspend transaction address.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	ASAHBR

R	ASAHBR													0		
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-3 ASAHBR	Address of Suspended AHB Read Transaction Indicates the address of the suspended AHB read transaction. This field is valid only when there is a suspended AHB read transaction waiting to be resumed (SPNDST[STATE] = 01b).
2-0 —	Reserved

41.7.2.50 Page Program Wait Time Counter (PPWF_TCNT)

Offset

Register	Offset
PPWF_TCNT	4F4h

Function

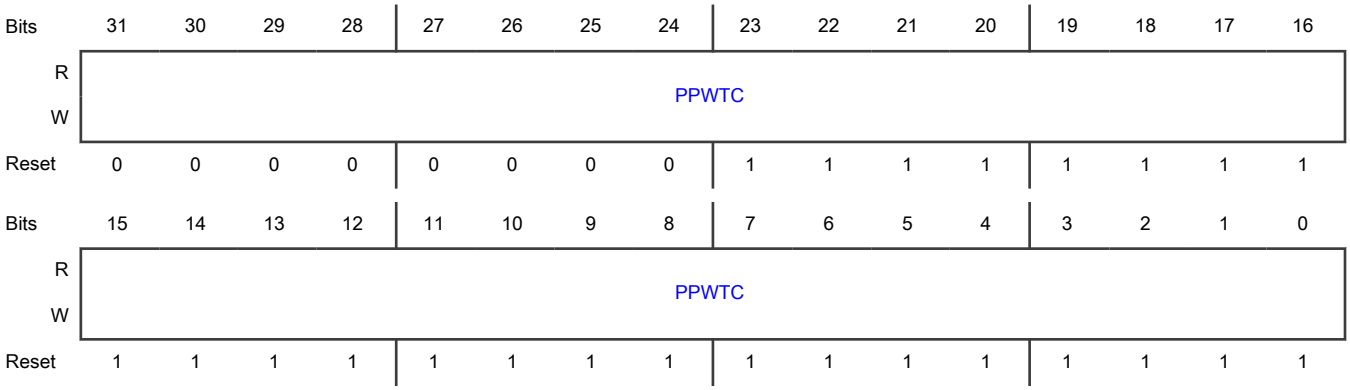
Specifies the page program wait time.

Special write access is permitted if all these conditions apply:

- AHB read access is not asserted (SR[AHB_ACC] = 0)

- AHB write access is not asserted (SR[AWRACC] = 0)
- Page program wait flag is not set (FR[PPWF] = 0)

Diagram



Fields

Field	Function
31-0 PPWTC	Page Program Wait Time Counter Value Specifies, in AHB clock cycles, how long XSPI waits before triggering a read of the flash status register, which is reflected in PPW_RDSR[RDSR]. See Page program wait handling.

41.7.2.51 Page Program Wait Read Status (PPW_RDSR)

Offset

Register	Offset
PPW_RDSR	4F8h

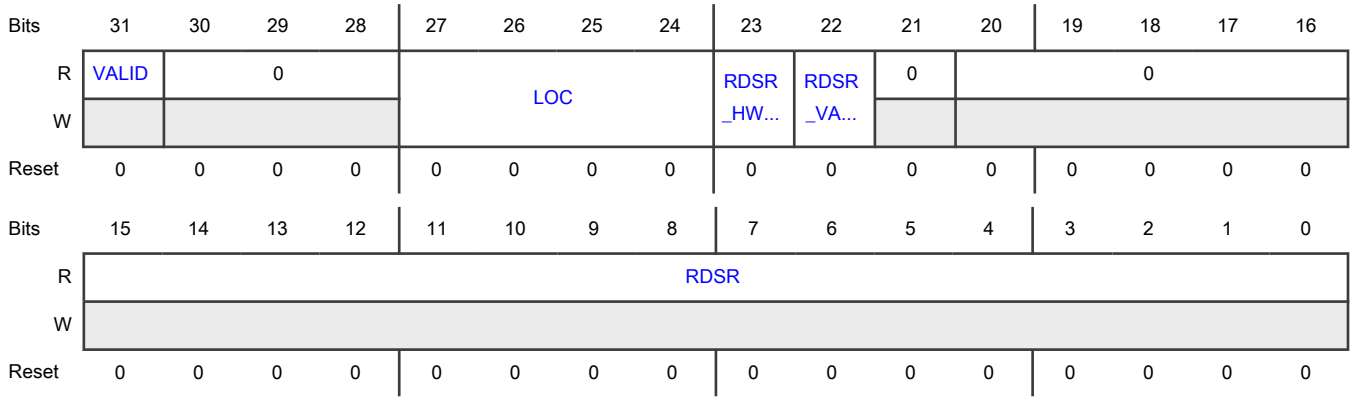
Function

Indicates the page program wait read status.

Special write access is permitted if all these conditions apply:

- AHB read access is not asserted (SR[AHB_ACC] = 0)
- AHB write access is not asserted (SR[AWRACC] = 0)
- Page program wait flag is not set (FR[PPWF] = 0)

Diagram



Fields

Field	Function
31 VALID	Valid Indicates whether the value of RDSR is valid. 0b - Not valid 1b - Valid
30-28 —	Reserved
27-24 LOC	Location of RDSR Specifies the bit in RDSR that indicates the page program wait has expired.
23 RDSR_HWORD_SEL	RDSR Half Word Select Specifies which word (upper or lower) is selected from flash. 0b - RDSR contains 16 least significant bits (15:0) of RDSR read from flash. 1b - RDSR contains 16 most significant bits (31:16) of RDSR read from flash.
22 RDSR_VAL_CHK	RDSR Value Check Specifies the value to be checked on the selected bit location for determining if the page program wait period is expired. 0b - Check for 0 1b - Check for 1
21 —	Reserved
20-16 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-0 RDSR	Value of Flash Status Register Read Indicates the data returned by a flash memory status read.

41.7.2.52 IPED Context Initial Vector (IPEDCTX0IV0 - IPEDCTX15IV1)

Offset

For m = 0 to 15; n = 0 to 1:

Register	Offset
IPEDCTXmIVn	520h + (m × 20h) + (n × 4h)

Function

Specifies the lowest or highest 32 bits of the initial vector for the context region:

- IV 0: lowest 32 bits
- IV 1: highest 32 bits

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
XSPI0	IPEDCTX0IV0–IPEDCTX15IV1	—
XSPI1	IPEDCTX0IV0–IPEDCTX15IV1	—
XSPI2	—	IPEDCTX0IV0–IPEDCTX15IV1

Diagram

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CTX_IV															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 CTX_IV	32 bits of IV for the context region

41.7.2.53 IPED Start Address Region (IPEDCTX0START - IPEDCTX15START)

Offset

For m = 0 to 15:

Register	Offset
IPEDCTXmSTART	528h + (m × 20h)

Function

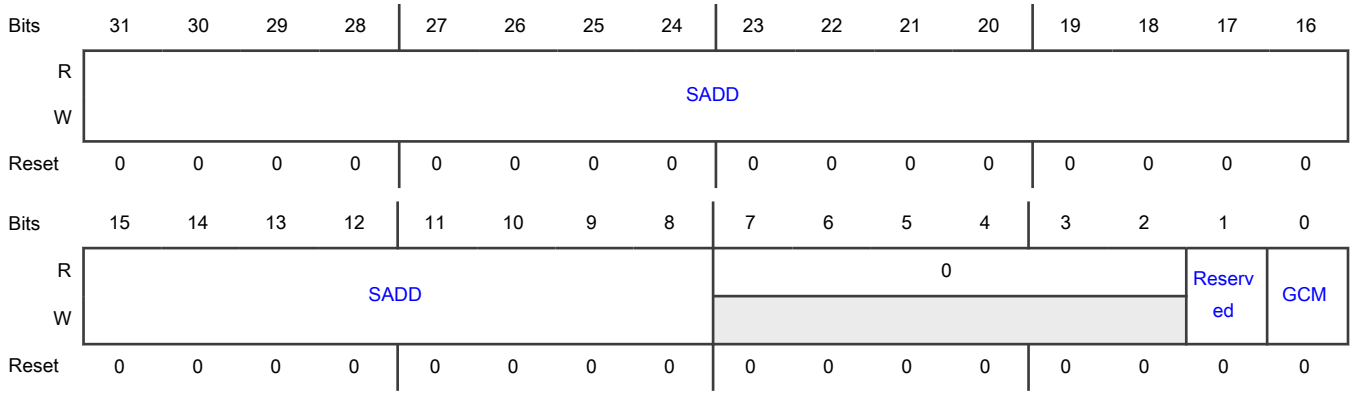
Specifies the lowest address of the IPED region and region operation. If IPEDCTXCTRL0[CTX*n*_FREEZE] is 10b and IPEDCTXCTRL1[CTX*n*_FREEZE] is 10b, then IPEDCTX*n*START is writable.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
XSPI0	IPEDCTX0START–IPEDCTX15START	—
XSPI1	IPEDCTX0START–IPEDCTX15START	—
XSPI2	—	IPEDCTX0START–IPEDCTX15START

Diagram



Fields

Field	Function
31-8 SADD	Start Address Specifies the start address of the corresponding AHB or IPS memory region. This value must be 256-byte aligned.
7-2 —	Reserved
1 —	Reserved
0 GCM	GCM Mode Region Specifies that the corresponding region is a GCM region. 0b - CTR 1b - GCM

41.7.2.54 IPED End Address Region (IPEDCTX0END - IPEDCTX15END)

Offset

For m = 0 to 15:

Register	Offset
IPEDCTXmEND	52Ch + (m × 20h)

Function

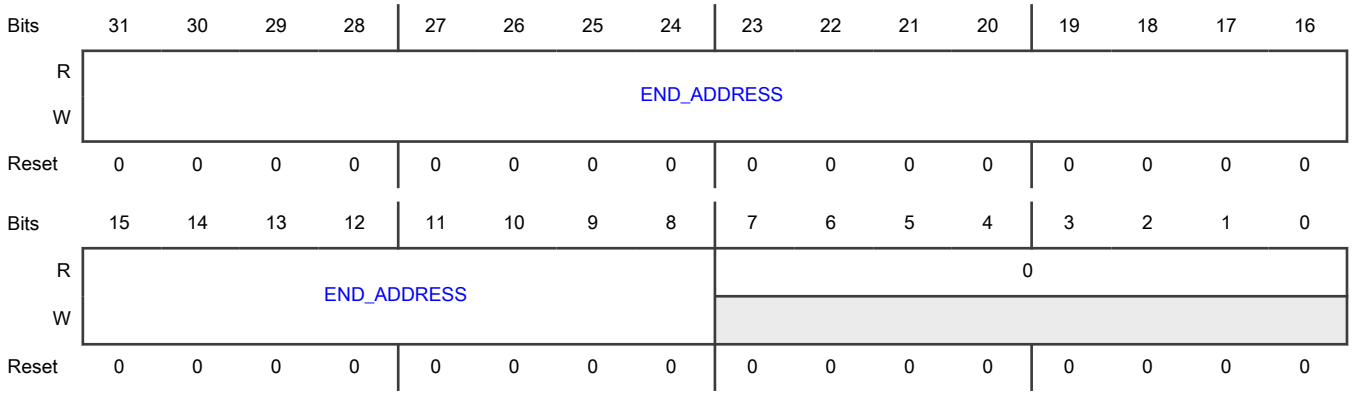
Specifies the highest address of IPED region. If IPEDCTXCTRL0[CTX*n*_FREEZE] is 10b and IPEDCTXCTRL1[CTX*n*_FREEZE] is 10b, then IPEDCTX*n*END is writable.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
XSPI0	IPEDCTX0END–IPEDCTX15END	—
XSPI1	IPEDCTX0END–IPEDCTX15END	—
XSPI2	—	IPEDCTX0END–IPEDCTX15END

Diagram



Fields

Field	Function
31-8 END_ADDRESS	End Address Specifies the end address of the IPED region. This value must be 256-byte aligned. XSPI compares this AHB address with the system bus address. **NOTE** The end address of the context region is defining the upper limit of that region through (END_ADDRESS - 1) value.
7-0 —	Reserved

41.7.2.55 IPED Context Additional Authentication Data (IPEDCTX0AAD0 - IPEDCTX15AAD1)

Offset

For m = 0 to 15; n = 0 to 1:

Register	Offset
IPEDCTXmAADn	530h + (m × 20h) + (n × 4h)

Function

Specifies lowest or highest 32 bits of additional authentication data for the context region:

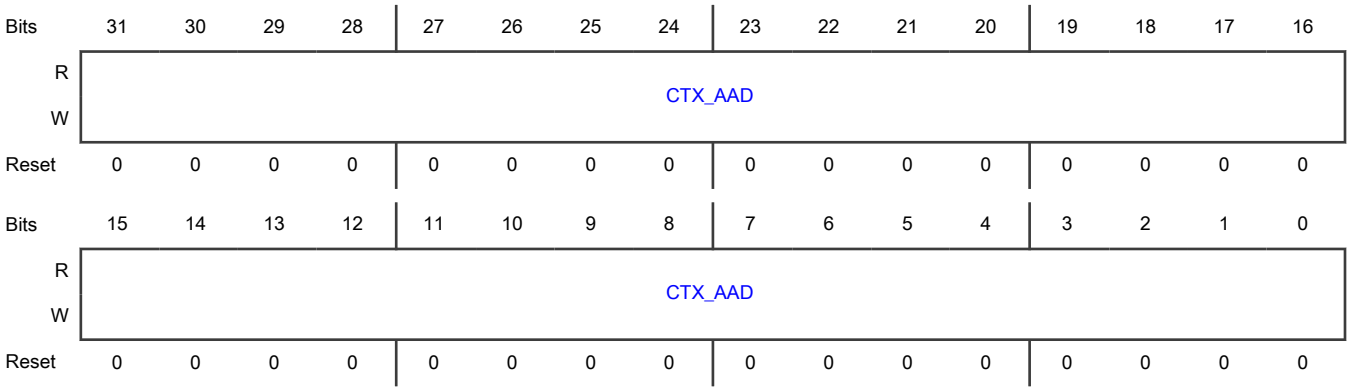
- ADD 0: lowest 32 bits
- ADD 1: highest 32 bits

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
XSPI0	IPEDCTX0AAD0–IPEDCTX15AAD1	—
XSPI1	IPEDCTX0AAD0–IPEDCTX15AAD1	—
XSPI2	—	IPEDCTX0AAD0–IPEDCTX15AAD1

Diagram



Fields

Field	Function
31-0 CTX_AAD	32 bits of AAD for the region

41.7.2.56 IPED Function Control (IPEDCTRL)

Offset

Register	Offset
IPEDCTRL	720h

Function

Specifies the IPED function.

Special write access is permitted if all of these conditions apply:

- IP access is not asserted (IP_ACC = 0)
- AHB read access is not asserted (AHB_ACC = 0)
- AHB write access is not asserted (AWRACC = 0)

NOTE

The following fields should be programmed in isolation: IPEDCTRL[AHBXEXRE], IPEDCTRL[AHBXEXWE], IPEDCTRL[IPSXEXWE].

Additionally, the following fields must also be configured independently: IPEDCTRL[AHBGCMRD], IPEDCTRL[AHBGCMWR], IPEDCTRL[IPSGCMWR], IPEDCTRL[AHBRD_EN], IPEDCTRL[AHBWR_EN], IPEDCTRL[IPSWR_EN].

Dynamic switching between XEX mode and other IPED modes is not supported. XEX mode must operate in isolation.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported

41.7.2.59 Flash Region Word 0 – Start Address (FRAD0_WORD0 - FRAD7_WORD0)

Offset

For n = 0 to 7:

Register	Offset
FRADn_WORD0	800h + (n × 20h)

Function

Specifies the starting address of the flash memory region. Only privilege initiators can write to this register.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	STARTADR															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 STARTADR	Start Address Specifies the most-significant 16 bits of the starting address (64-KB alignment) of the corresponding memory region.
15-0 —	Reserved

41.7.2.60 Flash Region Word 1 – End Address (FRAD0_WORD1 - FRAD7_WORD1)

Offset

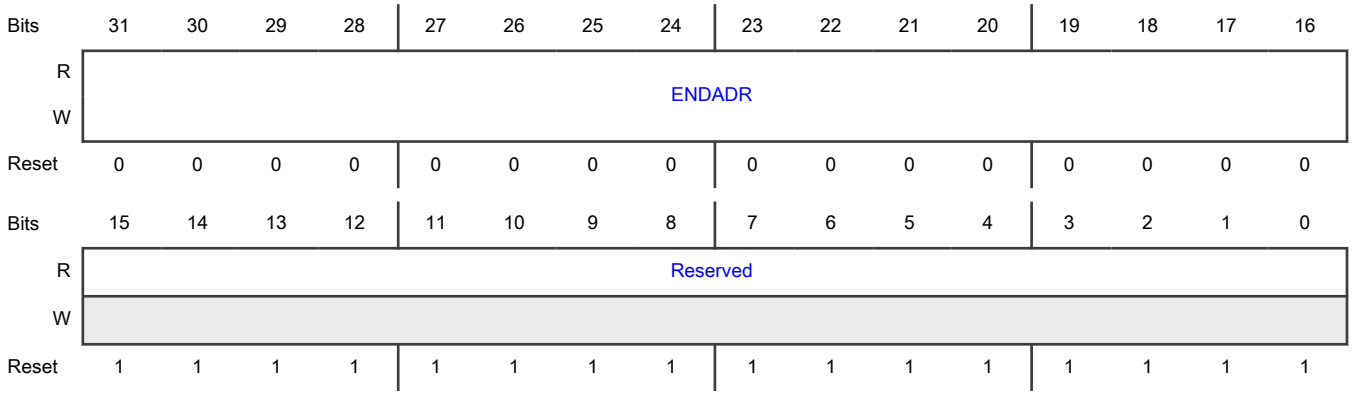
For n = 0 to 7:

Register	Offset
FRADn_WORD1	804h + (n × 20h)

Function

Specifies the ending address of the flash memory region. Only privilege initiators can write to this register.

Diagram



Fields

Field	Function
31-16 ENDADR	End Address Specifies the most-significant 16 bits of the inclusive ending address (64-KB alignment) of the corresponding memory region.
15-0 —	Reserved

41.7.2.61 Flash Region Word 2 – Privileges (FRAD0_WORD2 - FRAD7_WORD2)

Offset

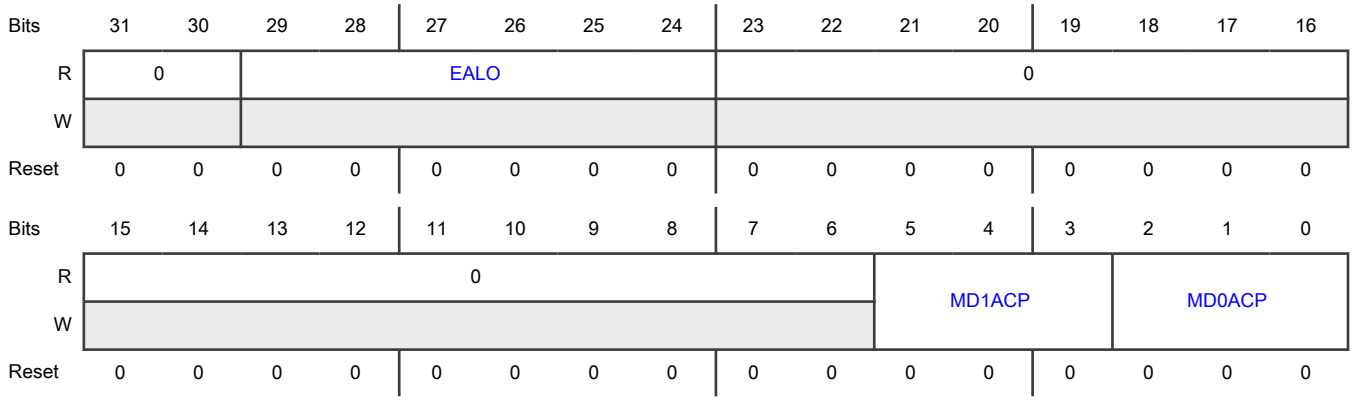
For n = 0 to 7:

Register	Offset
FRADn_WORD2	808h + (n × 20h)

Function

Specifies the access restrictions for the initiator domain and the exclusive access lock owner for the flash memory region. Only privilege initiators can write to this register.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-24 EALO	Exclusive Access Lock Owner If FRAD*n*_WORD3[EAL] = 11b, indicates the initiator ID that owns the exclusive access lock.
23-6 —	Reserved
5-3: MD1ACP 2-0: MD0ACP	Initiator Domain Access Control Policy Specifies the access restrictions for the respective initiator domain/TGn corresponding to this FRAD region. The secure and privilege attributes of the current transaction help to determine the access permissions. Read access is not restricted. You cannot write to this field in any of the following conditions exist: • The MDAD registers are not valid. • FRAD*n* is locked (FRAD*n*_WORD3[LOCK] = 01b). If you lock the descriptor except for initiator write (write 10b to FRADn_WORD3[LOCK]), then you can write to this field only if the initiator ID matches the ID check of the respective MDAD queue. If the MDAD is not valid, then the respective MD*n*ACP register is read-only.

Table 404. Field value mapping

Policy	Secure privilege	Secure user	Non secure privilege	Non secure user
0xxb	Read	Read	Read	Read
100b	Read/Write	Read/Write	Read	Read
101b	Read/Write	Read	Read	Read
110b	Read/Write	Read/Write	Read/Write	Read/Write
111b	Read/Write	Read	Read/Write	Read

Field	Function
	NOTE You must write 101b for a FRAD that has LUT access enabled for all atomic instructions. See LUT access enable.

41.7.2.62 Flash Region Word 3 – Lock Control (FRAD0_WORD3 - FRAD7_WORD3)

Offset

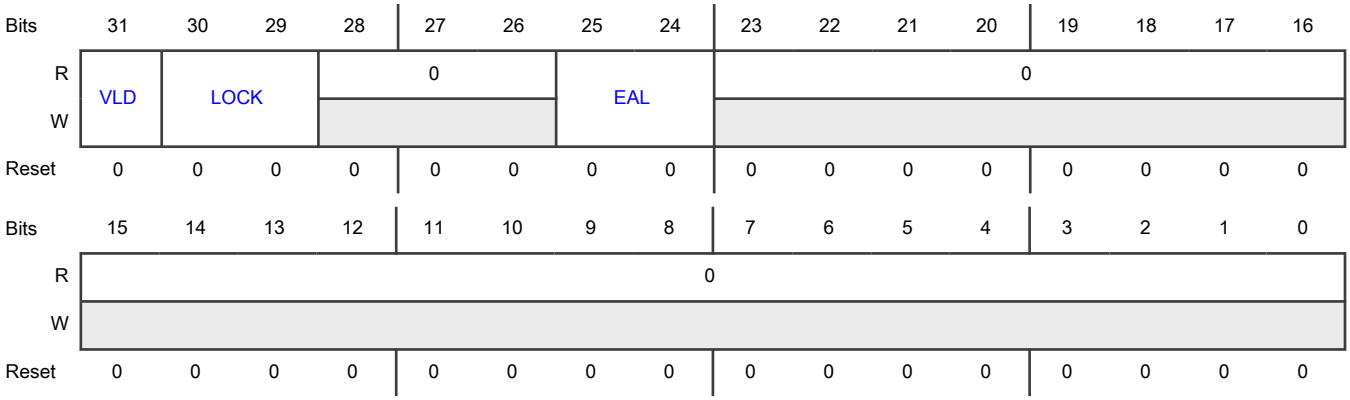
For n = 0 to 7:

Register	Offset
FRADn_WORD3	80Ch + (n × 20h)

Function

Configures exclusive access lock operation. Only privilege initiators can write to this register.

Diagram



Fields

Field	Function
31 VLD	Valid Specifies whether the FRAD descriptor for the flash region is valid. You cannot write this field in the same cycle that you write 10b or 11b to EAL. **NOTE** Write to this field only after you program all of the following: • FRAD*n*_WORD0 • FRAD*n*_WORD1 • FRAD*n*_WORD2

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Invalid 1b - Valid
30-29 LOCK	Descriptor Lock Locks the flash region descriptors (FRAD registers) from accidental writes. Only secure or privileged initiators can lock descriptors. Lock functionality does not affect EAL. 00b - Unlocks. Any initiator can write to the descriptors. 01b - Locks until hard reset. Descriptors are read-only. 10b - Locks except for initiator. Descriptors are read-only. The initiator whose ID matches MID check of the respective target group MDAD can write to the MDnACP fields. If the target group MDAD is not valid, then MDnACP fields are also read-only. 11b - Locks. Descriptors are read-only.
28-26 —	Reserved
25-24 EAL	Exclusive Access Lock Specifies the write lock behavior for the FRAD region based on the initiator domain access control policy (FRAD0_WORD2[MD*n*ACP]). 00b - No lock. Write permission is available for all initiators based on their MD*n*ACP evaluation. 01b - No action 10b - Enables lock. Write permissions revoked for all domains. You can change this field only to 11b; you cannot change it directly to 00b. 11b - Enables exclusive access lock. The initiator with the initiator ID specified as the exclusive access lock owner (FRAD*n*_WORD3[EAL]) has exclusive [read-]write permission based on its MD*n*ACP evaluation. Write access is locked for all other initiators. An initiator can write 11b to this field only if the above condition is met. When it does write 11b to this field, XSPI stores its ID as the exclusive access lock owner (EAL). If the initiator does not satisfy this check, XSPI does not generate a transfer error.
23-0 —	Reserved

41.7.2.63 Flash Region Word 4 – Compare Address Status (FRAD0_WORD4 - FRAD7_WORD4)

Offset

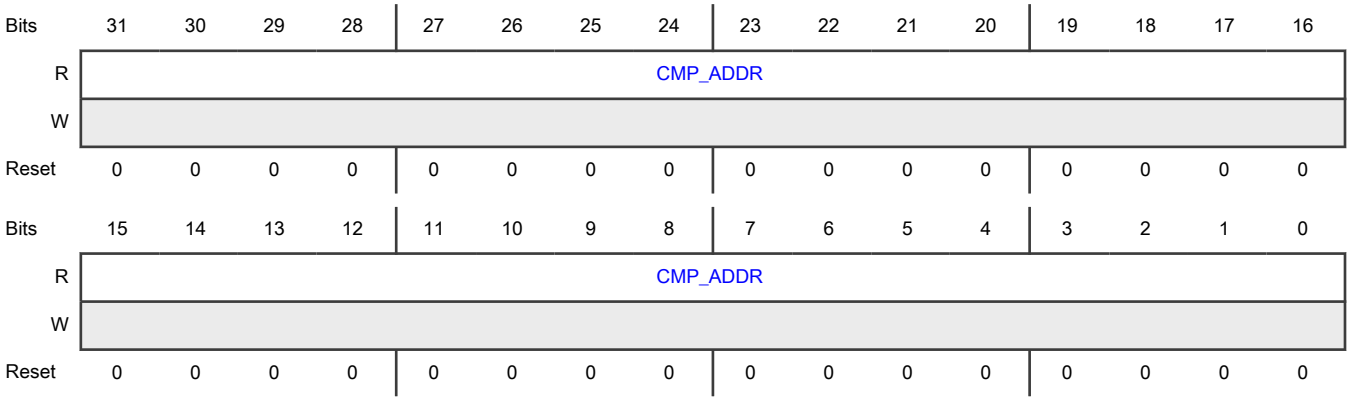
For n = 0 to 7:

Register	Offset
FRADn_WORD4	810h + (n × 20h)

Function

Indicates the 32-bit start address of the last transaction that lies inside the address range of FRAD*n*. Any write to this register generates a bus transfer error.

Diagram



Fields

Field	Function
31-0 CMP_ADDR	Capture Address Indicates the 32-bit start address of the last transaction that lies inside the address range of the FRAD.

41.7.2.64 Flash Region Word 5 – Compare Status Data (FRAD0_WORD5 - FRAD7_WORD5)

Offset

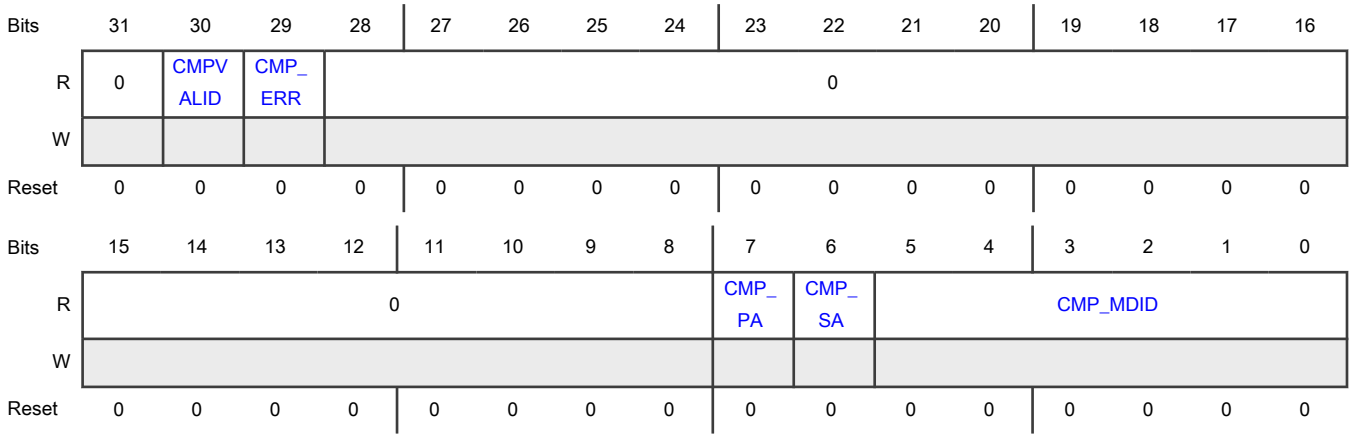
For n = 0 to 7:

Register	Offset
FRADn_WORD5	814h + (n × 20h)

Function

Indicates various aspects of FRAD operation. Any write to this register generates a bus transfer error.

Diagram



Fields

Field	Function
31 —	Reserved
30 CMPVALID	Comparison Valid Indicates availability of the result or status of a flash region-specific comparison check. 0b - Not available 1b - Available
29 CMP_ERR	Comparison Error Indicates the error status (based on MDxACP permissions or exclusive access lock as programmed in FRAD) of the flash region specific comparison check for the last transaction. You clear this error by writing 1 to the corresponding error status field (ERRSTAT[FRAD*n*ACC]). This field updates only after you clear the corresponding error field. 0b - No error 1b - Error
28-8 —	Reserved
7 CMP_PA	Captured Privilege Attribute Indicates the capture Privilege attribute of last transaction that passed the address check for the FRAD. 0b - Non-privileged 1b - Privileged
6 CMP_SA	Captured Secure Attribute Indicates the captured Secure attribute of the last transaction that passed the address check for the FRAD.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Non-secure 1b - Secure
5-0 CMP_MDID	Captured Initiator Value Indicates the captured initiator ID value of the last transaction that passed the address check for the FRAD.

41.7.2.65 SFP Arbitration Lock Timeout Counter (SFP_ARB_TIMEOUT)

Offset

Register	Offset
SFP_ARB_TIMEOUT	8FCh

Function

Specifies the time in clock cycles before an unreleased arbitration triggers a timeout error. Only the initiator with ID 011111b can access this register.

You can write to this register only if the global configuration lock is disabled (GCLCK = 00b).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 SFP_ARB_TOC	SFP Arbitration Timeout Value Specifies the time in IPS clock cycles before an unreleased arbitration triggers a timeout error (ARB_LOCK_TO = 1). See Arbitration lock.

41.7.2.66 Target Group Initiator Domain Access Descriptor (TG0MDAD - TG1MDAD)

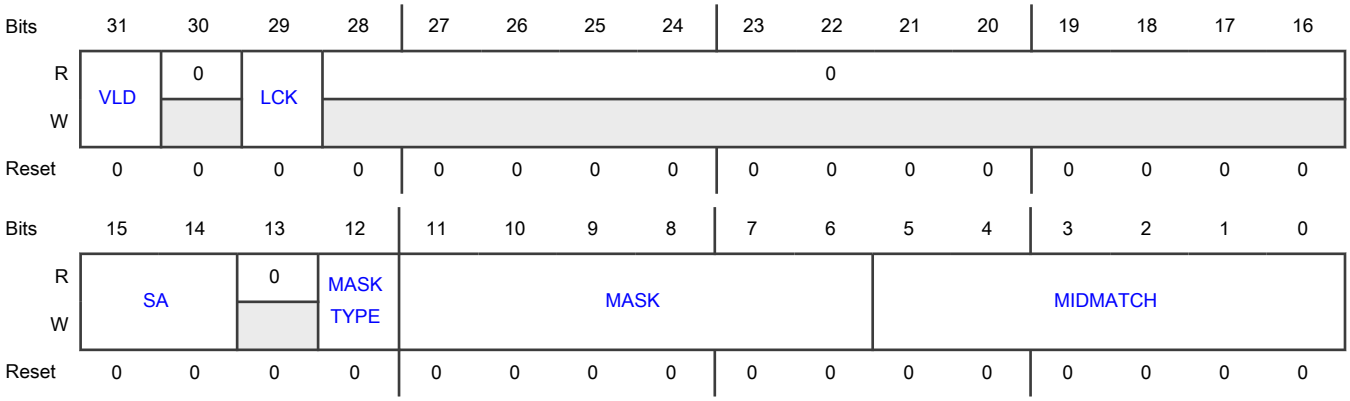
Offset

Register	Offset
TG0MDAD	900h
TG1MDAD	910h

Function

Specifies characteristics of initiator domain access. See MDAD checks. Only privilege initiators can write to this register.

Diagram



Fields

Field	Function
31 VLD	Valid Specifies whether the MDAD for the target group is valid. 0b - Not valid 1b - Valid
30 —	Reserved
29 LCK	Descriptor Lock Locks the MDAD. When locked, the descriptor is read-only. When you lock the descriptor, it remains locked until hard reset. 0b - No action 1b - Locks
28-16 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-14 SA	Secure Attribute Specifies the secure attribute selection criteria for entry into the descriptor queue. 00b - Reserved 01b - Non-secure only 10b - Secure only 11b - Both secure and non-secure
13 —	Reserved
12 MASKTYPE	Mask Type Specifies the mask type. 0b - AND 1b - OR
11-6 MASK	Mask Specifies the 6-bit mask value for the ID Match comparison.
5-0 MIDMATCH	Initiator ID Reference Specifies the reference value of the initiator ID for ID match comparison.

41.7.2.67 Target Group SFAR Address (TGSFAR)

Offset

Register	Offset
TGSFAR	904h

Function

Indicates the flash memory start address of the transaction in the target group queue.

NOTE

Only an initiator that passes the security checks in TG*n*MDAD[SA] can read this register, unless the MDAD is not valid, in which case any initiator can read it. Otherwise, this register reads 0. It also reads 0 if TG*n*MDAD[SA] = 00b.

Diagram

Fields

Field	Function
31-0 SFARADDR	SFAR Address Indicates the flash memory start address of the transaction in the target group queue.

41.7.2.68 Target Group SFAR Status (TGSFARS)

Offset

Register	Offset
TGSFARS	908h

Function

Indicates the status of the target group SFAR.

NOTE

Only an initiator that passes the security checks in TGnMDAD[SA] can read this register, unless the MDAD is not valid, in which case any initiator can read it. Otherwise, this register reads 0. It also reads 0 if TG*n*MDAD[SA] = 00b.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0			PA	0	SA	0						TG_MID			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 VLD	Valid Indicates whether the SFAR address for the target group is valid and the queue is busy. XSPI does not set this bit if ERR is 1. 0b - Not valid 1b - Valid
30 ERR	Error Indicates whether the SFAR address stored by an initiator has the required access attributes for this target group descriptor. 0b - With required attributes 1b - Without required attributes
29 CLR	Clear Clears TGSFAR and TGSFARS. When you write 1 to this field, if there is a valid transaction present in the MDAD queue, XSPI updates TGSFAR and TGSFARS based on that transaction. Otherwise, XSPI clears both registers. Only a secure initiator (TG*n*MDAD[SA] = 10b or 11b) can write to this field. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Conveys no useful information When writing 0b - No action 1b - Clears
28-13 —	Reserved
12 PA	Privileged Attribute Indicates the privilege attribute of the initiator that wrote the SFAR register. 0b - Not privileged 1b - Privileged
11 —	Reserved
10 SA	Secure Attribute Indicates the secure attribute of the initiator that wrote to the SFAR register.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Non-secure 1b - Secure
9-6 —	Reserved
5-0 TG_MID	Transaction Initiator ID Indicates the initiator-ID of a transaction that programmed the SFAR registers with required attributes.

41.7.2.69 Target Group IP Configuration Status (TGIPCRS)

Offset

Register	Offset
TGIPCRS	90Ch

Function

Indicates the status of the target group IPCR.

NOTE

Only an initiator that passes the security checks in TG*n*MDAD[SA] can read this register, unless the MDAD is not valid, in which case any initiator can read it. Otherwise, this register reads 0. It also reads 0 if TG*n*MDAD[SA] = 00b.

Diagram

Fields

Field	Function
31	Valid

Table continues on the next page...

Table continued from the previous page...

Field	Function
VLD	Indicates whether the IPCR IDATZ, and SEQID stored in this target group queue are valid and the queue is locked. XSPI does not set this bit if ERR is 1. 0b - Not valid 1b - Valid and queue is locked
30-29 ERR	Error Indicates whether the initiator storing the IPCR has the required access attributes with respect to the target group MDAD. 00b - Required attributes 01b - IPCR DATZ without required attributes 10b - IPCR SEQID without required attributes 11b - IPCR IDATSZ and SEQID without required attributes
28 CLR	Clear Clears this register. Only a secure initiator (TG*n*MDAD[SA] = 10b or 11b) can write to this field. When you write 1 to this field, if there is a valid transaction present in the MDAD queue, XSPI updates IPCRS based on that transaction. Otherwise, XSPI clears the register (writes 0000_0000h to it). It does not clear the register if the secure attribute is non-secure (TG*n*MDAD[SA] = 00b). **NOTE** This field behaves differently for register reads and writes. When reading 0b - Conveys no useful information When writing 0b - No action 1b - Clears
27-25 —	Reserved
24 —	Reserved
23 —	Reserved
22 ARB_UNLOCK	Arbitration Unlock Indicates if the target queue has requested arbitration unlock. 0b - Not requested

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Requested
21 ARB_LOCK	Arbitration Lock Indicates if the target queue has requested arbitration lock. 0b - Not requested 1b - Requested
20 —	Reserved
19-16 SEQID	SEQID Value Indicates the sequence ID for the target group queue.
15-0 IDATSZ	IP Data Transfer Size Indicates the IP data transfer size in bytes of the target group queue.

41.7.2.70 Initiator Global Configuration (MGC)

Offset

Register	Offset
MGC	920h

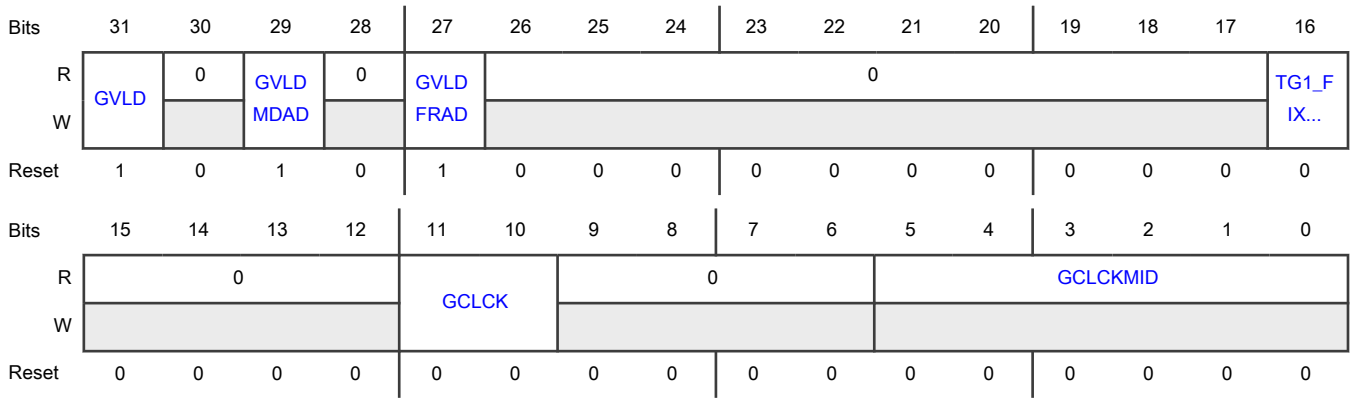
Function

Specifies several aspects of initiator domain behavior, and indicates the global configuration lock owner.

NOTE

Only an initiator with an ID equal to 000000b can access this register. For MGC, MRC, MTO, and SFP_ARB_TIMEOUT, XSPI uses the initiator ID for the access check. For transactions inside MDAD and FRAD, it uses the domain ID for the access check.

Diagram



Fields

Field	Function
31 GVLD	Global Valid Access Control Enables MDADs globally. 0b - Disables. XSPI does not perform a descriptor comparison check, and allows all transactions. 1b - Enables
30 —	Reserved
29 GVLDMDAD	Global Valid MDAD Enables MDADs globally. 0b - Disables 1b - Enables
28 —	Reserved
27 GVLDFRAD	Global Valid FRAD Enables FRADs globally. 0b - Disables 1b - Enables
26-17 —	Reserved
16 TG1_FIX_PRIO	Target Group Queue 1 Fixed Priority Enable Enables fixed priority for the target group 1 queue. All other values - TG1 always has fixed priority regardless of this value.
15-12 —	Reserved
11-10 GCLCK	Global Configuration Lock Locks write access to the following registers: • MGC • MRC • MTO • SFP_ARB_TIMEOUT • SFP_LUT_EN*n*

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• LUT*n* • BFGENCR 00b - Unlocks. You can write the registers based on the individual register access attribute. 01b - Locks. The registers remain read-only until the next hard reset. 10b - Locks. Only the global configuration lock owner can write to the registers. 11b - Locks. The registers remain read-only until the next hard reset.
9-6 —	Reserved
5-0 GCLCKMID	Global Configuration Lock Owner Indicates the 6-bit ID of the initiator that owns the global configuration lock. See GCLCK. Sideband signals provide the input value of the global initiator ID.

41.7.2.71 Initiator Read Command (MRC)

Offset

Register	Offset
MRC	924h

Function

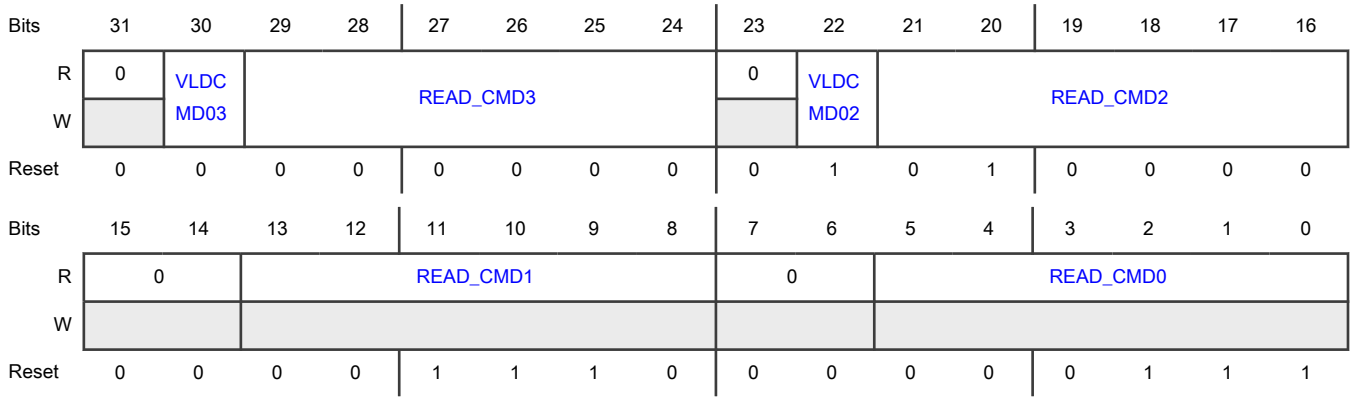
Indicates the encoding for the existing read instruction.

You can write to this register only if the global configuration lock is disabled (GCLCK = 00b).

NOTE

- Only an initiator with an ID equal to 000000b can access this register.
- In the event of a JMP_TO_SEQ instruction in LUT*n*, SFP parses only the first sequence; it does not parse the second sequence for Read commands.

Diagram



Fields

Field	Function
31 —	Reserved
30 VLDCMD03	Valid Command 3 Indicates if READ_CMD3 is valid. 0b - Not valid 1b - Valid
29-24 READ_CMD3	Read Command 3 Programs the additional READ Instruction/Command encoding information, if applicable
23 —	Reserved
22 VLDCMD02	Valid Command 2 Indicates if READ_CMD2 is valid. 0b - Not valid 1b - Valid
21-16 READ_CMD2	Read Command 2 Specifies additional encoding for the READ instruction or command, if applicable.
15-14 —	Reserved
13-8 READ_CMD1	Read Command 1 Indicates the encoding for the existing instruction - READ_DDR command.
7-6	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
5-0 READ_CMD0	Read Command 0 Indicates the encoding for the existing instruction-READ command.

41.7.2.72 Initiator Timeout (MTO)

Offset

Register	Offset
MTO	928h

Function

Specifies the maximum time in clock cycles for XSPI to wait for an ongoing write or read command to complete before terminating the command.

You can write to this register only if the global configuration lock is disabled (GCLCK = 00b).

NOTE

Only an initiator with an ID equal to 000000b can access this register.

Diagram

Fields

Field	Function
31-0 SFP_ACC_TO	SFP Access Timeout Specifies the maximum time in IPS clock cycles for XSPI to wait for an ongoing write or read command to complete before terminating the command. The timeout counter begins when any target group queue

Table continues on the next page...

Field	Function
	wins the access arbitration and XSPI is idle (FSMSTAT[STATE] != 00b). If the timeout counter expires and generates an interrupt (if enabled), XSPI clears the SFP queue. See ERRSTAT[TO_ERR]. **NOTE** MTO should be programmed with a large value such that MTO cannot occur when the data is getting transmitted to flash.

41.7.2.73 Flash Sequence Request (FLSEQREQ)

Offset

Register	Offset
FLSEQREQ	92Ch

Function

Indicates information about the last executed flash memory sequence request.

NOTE

This register retains its value if a timeout error occurs (FLSEQREQ[TIMEOUT]. XSPI updates it with a new value when you clear the timeout error (write 1 to ERRSTAT[TO_ERR]).

Diagram

26-25 —	Reserved
24 —	Reserved
23 —	Reserved
22 CMD	Instruction Type Indicates the instruction type of the last executed flash memory sequence request. 0b - Read 1b - Non-read
21-20 —	Reserved
19-16 SEQID	Sequence ID Indicates the sequence ID of the last executed flash memory sequence request.
15 —	Reserved
14-12 FRAD	Flash Region Descriptor Number Indicates the number of the flash region (FRAD) for the last executed flash memory sequence request. XSPI does not update this value for read instructions.
11 —	Reserved
10	Arbitration Lock

Table continues on the next page...

Table continued from the previous page...

Field	Function
ARB_LOCK	Indicates the arbitration lock status of the last executed flash memory sequence request. 0b - Not locked 1b - Locked
9 PA	Privilege Attribute Indicates the privilege attribute of the last executed flash memory sequence request. 0b - Non-privilege 1b - Privilege
8 SA	Secure Attribute Indicates the secure attribute of the last executed flash memory sequence request. 0b - Non-secure 1b - Secure
7 —	Reserved
6 REQ_TG	FlashSeq Request Target Group Indicates the target group queue that passed the last executed transaction. 0b - TG0 1b - TG1
5-0 REQ_MID	Flash Sequence Request Initiator ID Indicates the initiator ID of the last executed flash memory sequence request.

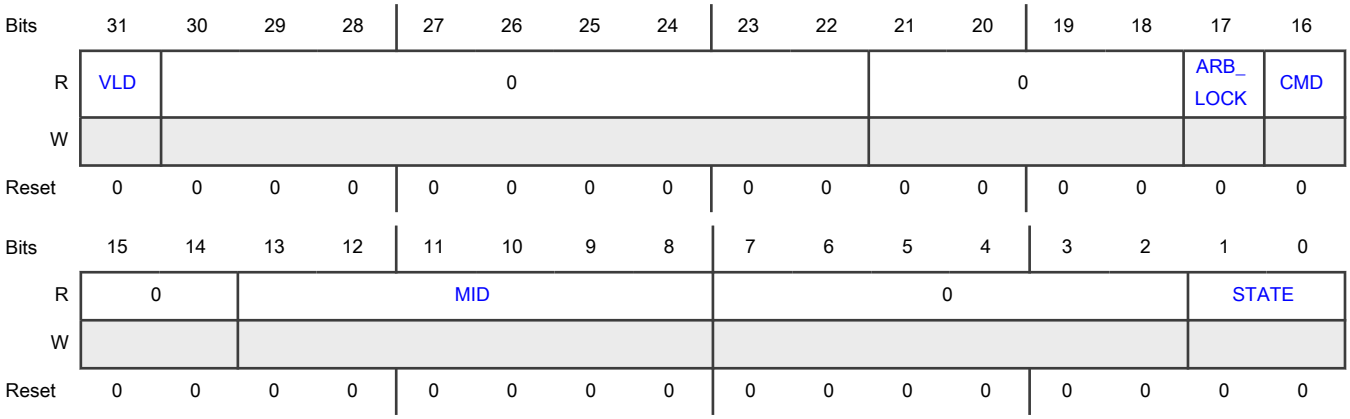
41.7.2.74 FSM Status (FSMSTAT)

Offset

Register	Offset
FSMSTAT	930h

Function
Indicates the finite state machine status.

Diagram



Fields

Field	Function
31 VLD	Valid Indicates whether the FSM status is valid. 0b - Not valid. No IPS transfer is queued. 1b - Valid. The IPS transfer is granted arbitration or execution.
30-22 —	Reserved
21-18 —	Reserved
17 ARB_LOCK	Arbitration Lock Indicates the status of arbitration lock for the current request. 0b - Not locked 1b - Locked
16 CMD	Command Indicates the instruction type of the currently initiated flash memory sequence transaction. 0b - Read instruction sequence 1b - Non-read instruction sequence
15-14 —	Reserved
13-8 MID	Initiator ID Indicates the initiator ID of the currently initiated flash memory sequence transaction.
7-2	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
1-0 STATE	FSM State Indicates the current state of the FSM. 00b - Transaction granted. Transaction is granted but XSPI is busy with one of the following: an ongoing previous DMA transaction; RDBFL contains residue data; or an interrupt is pending. 01b - TBDR lock open. IPS initiator can write to TBDR. 10b - Write transfer triggered. XSPI has received the SEQID. 11b - Read transfer triggered. XSPI has received the SEQID.

41.7.2.75 IPS Error (IPSERROR)

Offset

Register	Offset
IPSERROR	934h

Function

Indicates the error status of an IPS write on the SFAR or IPCR registers if they are not qualified for any of the target group queues .

Only privilege initiators can write to this register.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-30	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
29 CLR	Clear Clears the status of this register and the IPS_ERR flag. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Conveys no useful information When writing 0b - No action 1b - Clears
28-25 —	Reserved
24-22 —	Reserved
21-19 —	Reserved
18-16 —	Reserved
15 FRADPROG	FRAD Program Status Indicates the FRAD programming status. 0b - Some or all FRADs programmed 1b - No FRADs programmed
14 MDADPROG	TG/MDA Descriptor Program Status Indicates the target group or MDA descriptor programming status. 0b - One or both target group descriptors programmed 1b - None of the target group descriptors are programmed or valid
13-12 TGnMID	TGn Initiator-ID Status Indicates the status of the initiator-ID check. 0b - Passed 1b - Failed

Table continues on the next page...

Table continued from the previous page...

Field	Function
11-10 TGnSEC	TG Security Status Indicates the security status of the target group. 0b - Security attribute check passed 1b - Security attribute check failed
9-8 TGnLCK	TGn Lock Indicates the lock status of the TG. 0b - SEQID not written yet 1b - SEQID written and queue locked
7-6 —	Reserved
5-0 MID	IPS Initiator ID Indicates the IPS initiator ID for the transaction that generated this IPS transfer error.

41.7.2.76 Error Status (ERRSTAT)

Offset

Register	Offset
ERRSTAT	938h

Function

Provides error and status information about the current transaction.

Only privilege initiators can write to this register.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 —	Reserved
30 LOCK_ERR	Lock Register Error Indicates an attempt to write a locked register. See Register lock access error. XSPI captures the new error address only after you clear the error by writing 1 to this field. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No action 1b - Clears
29 ARB_LOCK_TO	Arbitration Lock Timeout Error Indicates that arbitration lock has timed out. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No action 1b - Clears flag
28 ARB_WIN	Arbitration Win Event Status Indicates that the target group queue request was granted access (it won arbitration) and XSPI has generated an interrupt. Clear this flag by writing 1 to it. **NOTE** If the corresponding interrupt is not enabled (INT_EN[ARB_WIN_IE] = 0), this field has no meaning. **NOTE** This field behaves differently for register reads and writes. When reading

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Request not granted or the interrupt is already cleared 1b - Request granted and interrupt generated When writing 0b - No action 1b - Clears interrupt
27-24 —	Reserved
23-16 —	Reserved
15 —	Reserved
14 TO_ERR	Timeout Error Indicates that a flash memory transaction has triggered a timeout error and has been terminated by SFP. Clear this error by writing 1 to the field. XSPI keeps the error indication latched in FLSEQREQ[TIMEOUT] until you clear this error. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No action 1b - Clears
13-12 TGnIPCR	TG IPCR Error Indicates that an IPCR write has triggered an error while being written to the corresponding target group queue. Clear this field by writing 1 to TGIPCRS[CLR]. 0b - No error 1b - Error
11-10 TGnSFAR	TG SFAR Error Indicates that an SFAR write triggered an error while being written to the corresponding target group queue. Clear this field by writing 1 to TGSFARS[CLR]. 0b - No error 1b - Error

Table continues on the next page...

Table continued from the previous page...

Field	Function
9 IPS_ERR	IPS Error Indicates that a common error has occurred and XSPI has generated an IPS bus transfer error. Find the error details in IPSERROR. Clear this field by writing 1 to IPSERROR[CLR]. 0b - No error 1b - Error
8-1 FRADnACC	FRAD Access Error Indicates that the transaction address lies within the address range of the corresponding FRAD but it does not pass the access permission checks for the FRAD or the FRAD is under exclusive lock (FRAD*n*_WORD3[EAL] = 10b or 11b) by another initiator. It may also indicate that the transaction address qualifies for multiple FRAD regions. Clear this flag and CMP_ERR by writing 1 to this field. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error. Transaction triggered an error and cleared the target queue. When writing 0b - No action 1b - Clears
0 FRADMTCH	No FRAD Match Error Indicates that the transaction address does not lie within the address range of any FRAD. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No error 1b - Error When writing 0b - No action 1b - Clears

41.7.2.77 Interrupt Enable (INT_EN)

Offset

Register	Offset
INT_EN	93Ch

Function

Enables the various SFP interrupts.

Only privilege initiators can write to this register.

NOTE

If you enable the queue-specific error interrupts (TG0SFAR, TG1SFAR, TG0IPCR, or TG1IPCR), ensure that the core executing the corresponding interrupt handler can clear TGSFARS and TGIPCRS (the core's security attribute matches the queue). If there is a mismatch in the security attribute (TG*n*MDAD[SA]), you must change the security attribute of that queue to match the core security attribute. The core can clear the error and then you can revert the change to TG*n*MDAD[SA].

0 FRADMTCH	No FRAD Match Error Interrupt Enable Enables the interrupt generated when the transaction address does not lie within the address range of any FRAD. See ERRSTAT[FRADMTCH]. 0b - Disables 1b - Enables

41.7.2.78 IP Configuration (SFP_TG_IPCR)

Offset

Register	Offset
SFP_TG_IPCR	958h

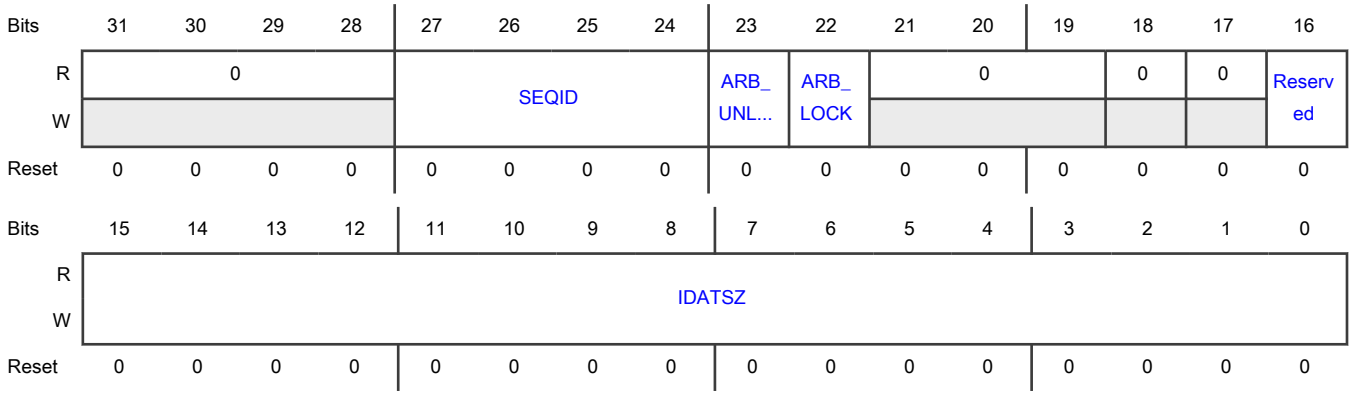
Function

Configures XSPI operation for an IP-initiated command, triggered by writing to SEQID in this register. If the SEQID write is successful, including passing the required SFP checks, XSPI begins the command sequence pointed to by SEQID. This register applies to transactions initiated for TG0.

NOTE

- You should write 1 to only one of ARB_LOCK or ARB_UNLOCK at a time. Writing 1 to both fields simultaneously inverts the lock status. In other words, if the arbitration is already locked, it becomes unlocked and vice-versa.
- If you enable MDAD and FRAD checks (see MGC), but none of the MDADs or FRADs are valid, then any write to this register generates a bus transfer error.
- Only an initiator that passes the security checks (TG*n*MDAD[SA]) can write this register, unless the MDAD is not valid, in which case any initiator can write to it. Otherwise, this register reads 0. It also reads 0 if TG*n*MDAD[SA] is 00b.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-24 SEQID	Sequence ID Specifies the sequence index of the LUT and triggers a transaction on the serial flash memory interface. See Lookup table (LUT).
23 ARB_UNLOCK	Arbitration Unlock Unlocks arbitration. Writing 0 has no effect. XSPI unlocks the arbitration only if the transaction passes both MDAD and FRAD checks. To lock the arbitration, write 1 to ARB_LOCK. See Arbitration lock. 0b - No effect. Always reads 0. 1b - Unlocks
22 ARB_LOCK	Arbitration Lock Locks arbitration for the target queue receiving the transaction. Writing 0 has no effect. XSPI grants the arbitration lock only if the transaction passes both MDAD and FRAD checks. To unlock the arbitration, write 1 to ARB_UNLOCK. See Arbitration lock. 0b - No effect. Always reads 0. 1b - Locks
21-19 —	Reserved
18 —	Reserved
17 —	Reserved

Table continued from the previous page...

Field	Function
16 —	Reserved
15-0 IDATSZ	IP Data Transfer Size Specifies the data transfer size, in bytes, of the IP command.

41.7.2.79 Serial Flash Memory Address (SFP_TG_SFAR)

Offset

Register	Offset
SFP_TG_SFAR	95Ch

Function

Specifies the address for a memory transaction. XSPI automatically translates this address on the memory map to the address on the memory device. When XSPI is in 24-bit mode, it sends only bits 23–0 to memory. In 32-bit mode, it sends bits 27–0 and drives 31–28 to 0 when you specify 0 for the column address space (SFACR[CAS]). For example, in 24-bit mode, if SFACR[CAS] is 3 (0011b), then XSPI sends bits 26-3 to the memory as the page address. The total number of address bits requested by memory, for page and column address, must not exceed 32 bits.

For the mapping between the access mode and the SFAR content, see Serial flash memory address assignment. For information about command triggering and command execution, see Normal mode overview. You must ensure that the address you provide is in the valid memory address range, as described in Serial flash memory address assignment.

Use this register for transactions on TG0.

NOTE

- If you enable MDAD and FRAD checks (MGC) but none of the descriptors are valid, then any write on this register generates a bus transfer error.
- Only an initiator that passes the security checks (TG*n*MDAD[SA]) can write this register, unless the MDAD is not valid, in which case any initiator can write to it. Otherwise, this register reads 0. It also reads 0 if TG*n*MDAD[SA] is 00b.

Fields

Field	Function
31-0 SFADR	Serial Flash Memory Address Indicates the serial memory address for IP commands. The address is the address of the device without the base address.

41.7.2.80 LUT Access Enable (SFP_LUT_EN0 - SFP_LUT_EN1)

Offset

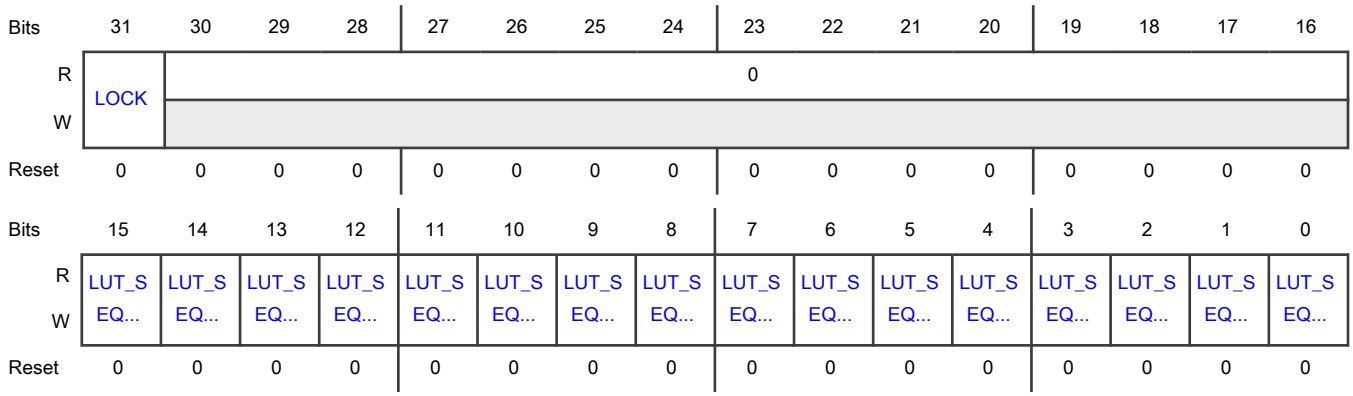
Register	Offset
SFP_LUT_EN0	960h
SFP_LUT_EN1	964h

Function

Controls access to the LUT sequence for the corresponding target queue. Only an initiator with ID equal to 6'd0 can access this register.

You can write to this register only if the global configuration lock is disabled (GCLCK = 00b).

Diagram



Fields

Field	Function
31 LOCK	Locks access to this register. When you write 1 to this field, it remains 1 until hard reset. 0b - No effect 1b - Locks
30-16 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-0 LUT_SEQn_EN	LUT Sequence Enable Enables valid LUT SEQID values to be used by the corresponding TG. See LUT access enable. **NOTE** This LUT sequence access check applies only to write transactions. 0b - Enables 1b - Disables

41.7.2.81 SFP Lock Error Address (SFP_LOCK_ERR_ADDR)

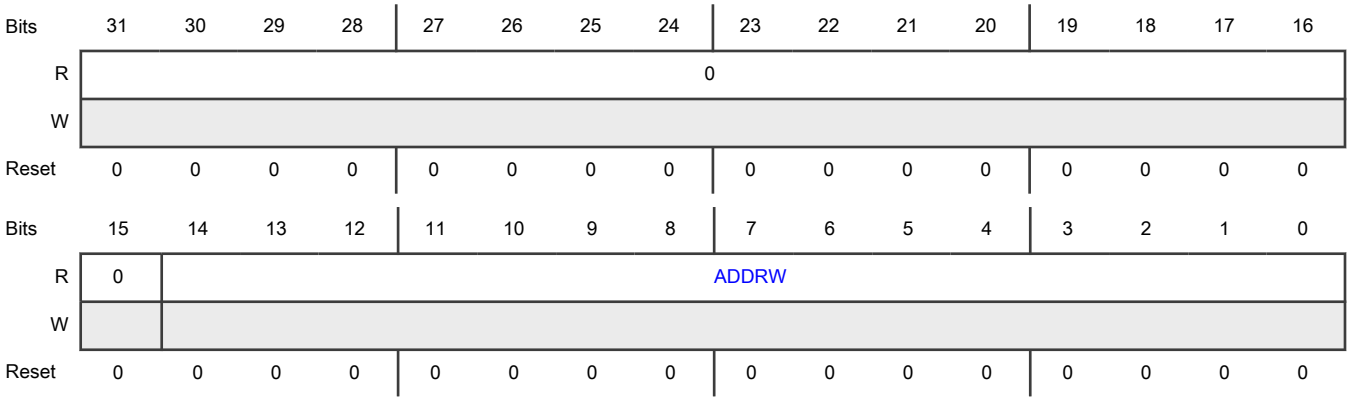
Offset

Register	Offset
SFP_LOCK_ERR_ADDR	A7Ch

Function

Latches the address of the register on which write access is attempted when the register write access is locked by any of the configuration bits.

Diagram



Fields

Field	Function
31-15 —	Reserved
14-0 ADDRW	Address Indicates the address that triggered the lock error. Only valid when there is a lock error (LOCK_ERR = 1).

41.7.2.82 IP Configuration (SFP_TG_SUB_1_IPCR)

Offset

Register	Offset
SFP_TG_SUB_1_IPCR	A80h

Function

Configures an IP-initiated command for the corresponding TG that can be triggered by writing to SEQID. If the write to SEQID is successful and it passes the required SFP checks, it initiates a new command to the external serial flash memory per the sequence pointed to by that field. See Normal mode overview.

NOTE

- You should write 1 to only one of ARB_LOCK and ARB_UNLOCK at a time. Writing 1 to both fields at the same time inverts the lock status. If arbitration was already locked, it unlocks and vice-versa.
- If you enable MDAD and FRAD checks MGC) but none of the descriptors are valid, then any write to this register generates a bus transfer error.
- Only an initiator that passes the security checks in TGnMDAD[SA] can read this register, unless the MDAD is not valid, in which case any initiator can read it. Otherwise, this register reads 0. It also reads 0 if TG*n*MDAD[SA] = 00b.

41.7.2.83 Serial Flash Memory Address (SFP_TG_SUB_1_SFAR)

Offset

Register	Offset
SFP_TG_SUB_1_SFAR	A84h

Function

Specifies the address for a memory transaction. XSPI automatically translates this address on the memory map to the address on the memory device. When XSPI is in 24-bit mode, it sends only bits 23–0 to memory. In 32-bit mode, it sends bits 27–0 and drives 31–28 to 0 when you specify 0 for the column address space (SFACR[CAS]). For example, in 24-bit mode, if SFACR[CAS] is 3 (0011b), then XSPI sends bits 26-3 to the memory as the page address. The total number of address bits requested by memory, for page and column address, must not exceed 32 bits.

For the mapping between the access mode and the SFAR content, see Serial flash memory address assignment. For information about command triggering and command execution, see Normal mode overview. You must ensure that the address you provide is in the valid memory address range, as described in Serial flash memory address assignment.

Use this register for transactions on the corresponding TG.

NOTE

- If you enable MDAD and FRAD checks (MGC) but none of the descriptors are valid, then any write on this register generates a bus transfer error.
- Only an initiator that passes the security checks (TG*n*MDAD[SA]) can write this register, unless the MDAD is not valid, in which case any initiator can write to it. Otherwise, this register reads 0. It also reads 0 if TG*n*MDAD[SA] is 00b.

21 ARB_LOCK	Arbitration Lock Indicates if the target queue has requested arbitration lock. 0b - Not requested 1b - Requested
20 —	Reserved
19-16 SEQID	SEQID Value Indicates the sequence ID for the target group queue.
15-0 IDATSZ	IP Data Transfer Size Indicates the IP data transfer size in bytes of the target group queue.

41.7.3 Serial flash memory address assignment

The serial flash memory address assignment can be modified by writing into Serial Flash Memory Top Address (SFA1AD) and Serial Flash Memory Top Address (SFA2AD) for device A.

Table 405. Serial flash memory address assignment

Parameter	Function	Access mode
XSPI_AMBA_BASE ((31:10) - 22 bits)	XSPI AHB base address First address of the serial flash memory device as presented to the XSPI controller. This might be the base of the serial flash memory in the system address map or it may be a remapping, for instance to 0h, performed by the system. (See the system address map file attached to this document)	
TOP_ADDR_MEMA1(TPADA1)	Top address for the external flash memory A1 (first device of the dual-die flash memory A, or the first of the two independent flash memories sharing the IOFA)	Any access to the address space between TOP_ADDR_MEMA1 and XSPI_AMBA_BASE is routed to serial flash memory A1.

Table continues on the next page...

Table 405. Serial flash memory address assignment (continued)

Parameter	Function	Access mode
TOP_ADDR_MEMA2(TPADA2)	Top address for the external flash memory A2 (second device of the dual-die flash memory A, or the second of the two independent flash memories sharing the IOFA)	Any access to the address space between TOP_ADDR_MEMA2 and TOP_ADDR_MEMA1 is routed to serial flash memory A2.

41.8 Flash memory mapped AMBA bus

XSPI_AMBA_BASE defines the address to be used as the start address of the serial flash memory device, as defined by the system memory map. Note that this may be a remapping of the physical address of the serial flash memory in the system. See the system address map for details.

Table 406. XSPI AMBA bus memory map

Address	Register name
XSPI_AMBA_BASE to (TOP_ADDR_MEMA2 - 1h)	• See Memory-mapped serial flash memory data—individual flash memory mode on flash memory A. • For information about byte ordering, see Table 335 and Table 336.

NOTE

Any read access to non-implemented addresses provides undefined results.

In individual flash memory modes, the 3/4 address bytes (as programmed in the instruction/operand in the sequence) available for the flash memory address are determined by SFADR[23:0] or SFADR[31:0] as provided in the table shown above.

41.8.1 AHB bus access read considerations

Note that all logic in the XSPI module implementing the AHB bus access is designed to read the content of an external serial flash memory device. Therefore, the following restrictions apply to the XSPI module with respect to accesses to the AHB bus:

- AHB bus read access types—NONSEQ and BUSY—are fully supported.
- AHB read access type—SEQ—is treated in the same way as NONSEQ. See Flash memory mapped AMBA bus for details.
- Early burst termination is not supported for AHB transactions.
- An AHB error response is provided on occurrence of either of the following:
  - Data learning failure
  - If FR[AIBSEF] flag is set during the AHB transfer

  Also, interrupts (if enabled) are provided along with the AHB error response. See Flag (FR) for complete list of errors.

41.8.2 Memory-mapped serial flash memory data—individual flash memory mode on flash memory A

Starting with address XSPI_AMBA_BASE, the content of the first external serial flash memory device is mapped into the address space of the device containing the XSPI module. Serial flash memory byte address 0h corresponds to bus address, XSPI_AMBA_BASE, in an increasing order. Assuming that a dual-die flash memory is connected to the first set of external pads, the address space is divided into two parts, one for each device of the dual-die package. See the following table for the address mapping. The byte ordering for 32-bit access is provided in Table 335 and for 64-bit read access, the byte ordering is provided in Table 336.

Table 407. Memory-mapped individual flash memory mode—flash memory A address scheme

Memory-mapped address 32-bit access	Memory-mapped address 64-bit access	Serial flash memory byte address	Flash memory device
XSPI_AMBA_BASE + 0h	XSPI_AMBA_BASE + 0h	0h to 3h	A1
XSPI_AMBA_BASE + 4h		4h to 7h	
...	...	...	
TOP_ADDR_MEMA1 - 8h	TOP_ADDR_MEMA1 - 8h	(TOP_ADDR_MEMA1- 8h) to (TOP_ADDR_MEMA1 - 0h4 -0h1)	
TOP_ADDR_MEMA1 - 4h		(TOP_ADDR_MEMA1 - 4h) to (TOP_ADDR_MEMA1 - 0h1)	
TOP_ADDR_MEMA1 + 4h	TOP_ADDR_MEMA1 + 0h	0h to 3h	A2
TOP_ADDR_MEMA1 + 0h4		4h to 7h	
...	...	...	
TOP_ADDR_MEMA2 - 8h	TOP_ADDR_MEMA2 - 8h	(TOP_ADDR_MEMA2 - 8h) to (TOP_ADDR_MEMA2 - 4h - 1h)	
TOP_ADDR_MEMA2 - 4h		(TOP_ADDR_MEMA2 - 4h) to (TOP_ADDR_MEMA2 - 1h)	

The available address range depends on the size of the external serial flash memory device. Any access beyond the size of the external serial flash memory provides undefined results.

For details concerning the read process, see Flash memory read using IP command.

Chapter 42
Cache Controller (CACHE64_CTRL)

42.1 Chip-specific CACHE64_CTRL information

Table 408. Reference links to related information

Topic	Related module	Reference
Full description	Cache controller	CACHE64_CTRL
Peripheral memory map		Memory map overview
Clocking		Clock overview Clock controller
Power management	PMC	Power overview PMC
Signal multiplexing	IOPCTL	External signals and pin multiplexing IO PAD controller
CACHE64 policy select	CACHE64_POLSEL	CACHE64_POLSEL
External serial peripheral interface	XSPI	XSPI

NOTE

The CACHE64_CTRL module works in conjunction with the CACHE64_POLSEL module. The CACHE64_POLSEL determines the cache policy to be applied for a given AHB address and passes this information to the CACHE64_CTRL.

42.1.1 Module instances

This device has two instances of the CACHE64_CTRL module, CACHE64_CTRL0 and CACHE64_CTRL1.

Table 409. CACHE64_CTRL instances

	CACHE64_CTRL0	CACHE64_CTRL1
Located in	VDD2_COMP	VDD2_COMP
Access	CPU0, HiFi4, EZH-V, eDMA0, eDMA1	CPU0, HiFi4, EZH-V, eDMA0, eDMA1
Cache for XSPI	XSPI0	XSPI1
Related CMX_PERFMON	CMX_PERFMON2	CMX_PERFMON3

NOTE

Only accesses to XSPI0 and XSPI1 from COMP_VDD bus initiators, like CPU0, eDMA0, eDMA1, are routed through the CACHE64_CTRL and CACHE64_POLSEL instances. HiFi4 and EZH-V can access the CACHE64_CTRL registers, but their accesses to XSPI0 and XSPI1 do NOT go through the cache.

42.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

42.1.3 CSAR register

For this chip, the CSAR[28] must be configured as 0b.

42.2 Overview

A cache is a block of high-speed memory locations that contains address information (commonly known as a tag) and its associated data. It decreases the average time of a memory access. CACHE64_CTRL includes cache memory controller (CACHE64), which is a general purpose AMBA AHB bus protocol cache.

42.2.1 Block diagram

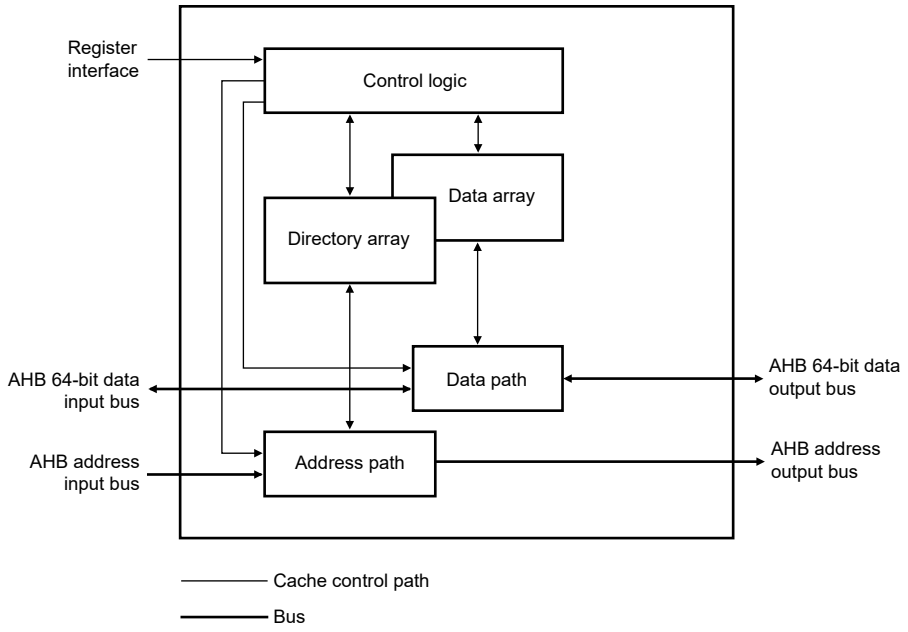

Figure 162. Block diagram

42.2.2 Features

CACHE64_CTRL is designed to work with AMBA AHB bus systems. It includes:

- An input (Controller) AHB bus that you can access using Cache mode attributes for cacheable copyback, cacheable write-through, or noncacheable mode operation and write bufferable mode operation on an access-by-access basis.
- An output (Target) 64-bit data path AHB bus for downstream cache read miss, cache write-through write, and noncacheable accesses.
- A peripheral interface for accessing the cache's program model.

42.3 Functional description

A cache operates on two principles of locality:

- Spatial locality — Access to one location possibly follows an access from adjacent locations (for example, sequential instruction execution or usage of a data structure).
- Temporal locality — Access to an area of memory possibly repeats within a short period of time (for example, execution of a code loop).

To minimize the quantity of control information stored, the spatial locality property groups several locations together, under the same tag. This logical block is known as a cache line.

You achieve temporal locality by retaining recently accessed lines in the cache.

When data loads into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a cache hit, and other accesses are known as cache misses.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the bus controller wants to access a cacheable location, the cache is checked. If the access is a cache hit, the access occurs immediately. Otherwise, a location is allocated, and the cache line is loaded from memory. Different cache topologies and access policies are possible. However, they must comply with the memory coherency model of the underlying architecture.

Caches introduce a number of potential problems, mainly because of:

- Memory accesses occurring at times other than when the programmer would normally expect them.
- The existence of multiple physical locations where a data item can be held.

42.3.1 Operations

42.3.1.1 Cache configuration

CACHE64_CTRL receives manager bus requests on the manager (M) bus.

You can access the cache programming model via the cache controller's AMBA AHB bus.

CACHE64_CTRL then processes the cacheable accesses as needed, when bypassing the noncacheable, cache write-through, cache miss, and cache maintenance accesses to its subordinate bus.

The cache on this chip has a 2-way set associative cache structure with a total size of 32 KB. The cache has a 32-bit address, 64-bit data paths, and a 32-byte line size. The cache tags and data storage use single-port, synchronous RAMs.

For this 32 KB cache, each cache TAG function uses two 512 x 20-bit RAM arrays, and the cache DATA function uses two 2048 x 64-bit RAM arrays. The cache TAG entries store 18 bits of the upper address as well as a modified and valid bit per cache line. The cache DATA entries store eight bytes of code or data.

All normal cache accesses use physical addresses. This leads to the use of the following cache address:

CACHE - 32 KB size = (512 sets) x (32-byte lines) x (2-way set associative)

Table 410. Tag cache address use

Tag cache address use	Cache
Tag hit address range	Address[31:14]
Tag set select address range	Address[13:5] used to select 1 of 512 sets
Not used	Address[4:0]

Table 411. Data cache address use

Data cache address use	System cache
Not used	Address[31:14]
Data set select address range	Address[13:5] used to select one of 512 sets

Table continues on the next page...

Table 411. Data cache address use (continued)

Data cache address use	System cache
64-bit word select	Address[4:3] used to select one of four 64-bit words within a set
Byte select	Address[2:0] used to select the byte within the 64-bit word

42.3.1.2 Cache control

The cache is disabled at reset. Cache tag and data arrays are not cleared at reset. Therefore, to enable and configure the cache, you must clear the cache commands and initialize the required tag array.

42.3.1.2.1 Cache set commands

The cache set commands may operate on one of the following:

- All of way 0
- All of way 1
- All of both ways (complete cache)

Cache set commands are specified using the upper bits in Cache Control (CCR). Cache set commands perform their operation on the cache independent of CCR[ENCACHE].

You initiate a cache set command by writing 1 to CCR[GO]. This field also acts as a busy bit for set commands. The field remains 1 when the command is active, and the module writes 0 to it after the set command completes.

Supported cache set commands are provided in Table 412. Following are the set commands:

- Invalidate — Unconditionally clears valid and modify bits of a cache entry.
- Push — Pushes a cache entry if it is valid and modified, then clears the modify bit. If the entry is not valid or not modified, leave it as is.
- Clear — Pushes a cache entry if it is valid and modified, then clears the valid and modify bits. If the entry is not valid or not modified, clear the valid bit.

Table 412. Cache set commands

Cache Control (CCR)[27:24]				Command
PUSHW1	INVW1	PUSHW0	INVW0	
0	0	0	0	No operation (NOP)
0	0	0	1	Invalidate all of way 0
0	0	1	0	Push all of way 0
0	0	1	1	Clear all of way 0
0	1	0	0	Invalidate all of way 1
0	1	0	1	Invalidate all of way 1 and way 0 (invalidate complete cache)
0	1	1	0	Invalidate all of way 1; push all of way 0
0	1	1	1	Invalidate all of way 1; clear all of way 0
1	0	0	0	Push all of way 1
1	0	0	1	Push all of way 1; invalidate all of way 0

Table continues on the next page...

Table 412. Cache set commands (continued)

Cache Control (CCR)[27:24]				Command
PUSHW1	INVW1	PUSHW0	INVW0	
1	0	1	0	Push all of way 1 and way 0 (push complete cache)
1	0	1	1	Push all of way 1; clear all of way 0
1	1	0	0	Clear all of way 1
1	1	0	1	Clear all of way 1; invalidate all of way 0
1	1	1	0	Clear all of way 1; push all of way 0
1	1	1	1	Clear all of way 1 and way 0 (clear complete cache)

After a reset, complete an invalidate cache command before using the cache. It is possible to combine the cache invalidate command with the cache enable. That is, writing 8500_0001h to Cache Control (CCR) invalidates the cache and enables the cache.

42.3.1.2.2 Cache line commands

Cache line commands operate on a single line in the cache at a time. You can perform these commands using a physical or cache address that consists of a set address and a way select. The line command acts on the specified cache line.

Cache line commands with physical addresses first search both ways of the cache set specified by the following physical address bits. If they hit, the commands perform their action on the hit way: For cache- [13:5].

You specify cache line commands using the upper bits in Cache Line Control (CLCR). Cache line commands perform their operation on the cache independent of CCR[ENCACHE]. Using a cache address, the command can be completely specified using Cache Line Control (CLCR). Using a physical address, the command must also use Cache Search Address (CSAR) to specify the physical address.

You can initiate a line cache command by writing 1 to CLCR[LGO] or CSAR[LGO]. This field also acts as a busy bit for line commands. The field remains 1 when the command is active and CACHE64_CTRL writes 0 to it after the set command completes.

Table 413. Cache line commands

Cache Line Control (CLCR)[27:24]			Command
CLCR[LACC]	CLCR[LADSEL]	CLCR[LCMD]	
0	0	00	Search by cache address and way
0	0	01	Invalidate by cache address and way
0	0	10	Push by cache address and way
0	0	11	Clear by cache address and way
0	1	00	Search by physical address
0	1	01	Invalidate by physical address
0	1	10	Push by physical address
0	1	11	Clear by physical address
1	0	00	Write by cache address and way
1	0	01	NOP

Table continues on the next page...

Table 413. Cache line commands (continued)

Cache Line Control (CLCR)[27:24]			Command
CLCR[LACC]	CLCR[LADSEL]	CLCR[LCMD]	
1	0	10	NOP
1	0	11	NOP
1	1	*xx*	NOP

42.3.1.2.2.1 Executing a series of line commands using cache addresses

You can perform a series of line commands with incremental cache addresses by writing to Cache Line Control (CLCR):

1. Place the command in Cache Line Control (CLCR)[27:24].
2. Write 1 to CLCR[WSEL] and CLCR[TDSEL] as needed.
3. Place the cache address in CLCR[CACHEADDR].
4. Write 1 to CLCR[LGO].
5. Wait for the command to complete (CLCR[LGO] becomes 0).
6. Increment the cache address (at bit 3 to step through data or at bit 5 to step through lines).
7. Write 1 to CLCR[LGO].
8. Wait for the command to complete (CLCR[LGO] becomes 0).
9. Repeat steps 5 - 8 as needed.

42.3.1.2.2.2 Executing a series of line commands using physical addresses

You can perform a series of line commands with incremental physical addresses using the following steps:

1. Write to Cache Line Control (CLCR):
   a. Place the command in Cache Line Control (CLCR) [27:24].
   b. Write 1 to CLCR[TDSEL].
2. Place the physical address in CSAR[PHYADDR] and write 1 to CSAR[LGO].
3. Wait for the command to complete (CLCR[LGO] becomes 0).
4. Increment the physical address (at bit 3 to step through data or at bit 5 to step through lines).
5. Write 1 to CLCR[LGO].
6. Wait for the command to complete (CLCR[LGO] becomes 0).
7. Repeat steps 3 - 6 as needed.

Cache Line Control (CLCR) and Cache Search Address (CSAR) both contain a field called LGO, and this field has the same functionality. Therefore, you can complete the above steps in a single write to Cache Search Address (CSAR).

42.3.1.2.2.3 Line command results

At completion of a line command, Cache Line Control (CLCR) contains information on the initial state of the line targeted by the command. For line commands with cache addresses, read this information before performing a line command action from the targeted cache line. For line commands with physical addresses, read this information on a hit before the line command action is performed from the hit cache line. In the cache, for line commands with a physical address miss, CLCR[LCIVB] becomes 0, and no line command action is performed. In general, if CLCR[LCIVB] becomes 0, the targeted line is invalid at the start of the line command and no line operation is performed.

Table 414. Line command results

Cache Line Control (CLCR)[22:20]			For cache address commands	For physical address commands
CLCR[LCWAY]	CLCR[LCIMB]	CLCR[LCIVB]		
0	0	0	Way 0 line is invalid	No hit
0	0	1	Way 0 valid and not modified	Way 0 valid and not modified
0	1	0	Way 0 line is invalid	No hit
0	1	1	Way 0 valid and modified	Way 0 valid and modified
1	0	0	Way 1 line is invalid	No hit
1	0	1	Way 1 valid and not modified	Way 1 valid and not modified
1	1	0	Way 1 line is invalid	No hit
1	1	1	Way 1 valid and modified	Way 1 valid and modified

On completion of a line command other than a write, Cache Read/Write Value (CCVR) contains information on the initial state of the line tag or data targeted by the command. For line commands, CLCR[TDSEL] selects between tag and data. If the line command used a physical address and missed, the data is don't care. For write commands, Cache Read/Write Value (CCVR) holds the write data.

The cache does not have line lock capability.

42.3.2 Modes of operation

Table 415. Modes of operation

Mode	Description
Write-Through	Access to address spaces with this cache mode are cacheable: • If all cacheable spaces are read-only spaces, then cache contains read-only data and all writes to the cache cause a fault. See the chip-specific cacheable space information. • A read miss on the input bus causes a line read on the output bus of a 32-byte-aligned memory address that contains the desired address. A read miss data loads into the cache and marks as valid and not modified. • A read hit to a valid cache location returns data from the cache with no output bus accesses. • A write miss bypasses the cache and writes to the output bus (no allocation on write-miss policy for Write-Through mode spaces). • A write hit updates the cache hit line with the write data and writes to the output bus. • The caches are bus-controller-local and do not support hardware cache coherency. If the bus controller accesses write-through regions and another bus controller that can access the same target memory, without going through the cache (such as DMA), must update these

Table continues on the next page...

Table 415. Modes of operation (continued)

Mode	Description
	regions, you must first perform explicit cache clears to ensure all modified cache lines update their associated memories, before they are modified by external controllers and subsequent cache bus controller accesses get the updated memory.
Write-Back	Access to address spaces with this cache mode are cacheable: • A read miss on the input bus causes a line read on the output bus of a 32-byte-aligned memory address that contains the desired address. This miss data loads into the cache and marks it as valid and not modified. • A read hit to a valid cache location returns data from the cache with no output bus access. • A write miss performs a read-to-write (executes write-miss policy for Write-Back mode spaces). You perform a line read on the output bus of a 32-byte-aligned memory address containing the desired write address. This miss data is loaded into the cache and marked as valid and modified. Then the write data updates the appropriate cache data locations. • A write hit updates the cache hit line with the write data and marks the line as modified. • Caches do not support hardware cache coherency. If the cache's bus controller has written to write-back regions, and another bus controller that can access the same target memory without going through the cache must see these updates, you must perform explicit cache pushes to any needed cache memory range to ensure that all modified cache lines update their associated memories before being this controller reads them. Likewise, if the cache's bus controller has accessed write-back regions, and another bus controller that can access the same target memory without going through the cache must update these regions, you must first perform explicit cache clears to any needed cache memory range to ensure that all modified cache lines update their associated memories before this controller modifies them, and subsequent cache controller bus accesses get the updated memory.
Noncacheable	Access to address spaces with this cache mode are not cacheable. These accesses bypass the cache and access the output bus.

42.3.3 Clocking

Caches use the AHB manager bus clock.

42.3.4 Reset

Caches are disabled at reset. However, cache tag and data arrays are not cleared at reset. See Initialization and Cache control for more information regarding cache initialization and configuration.

42.3.5 Interrupts

CACHE64_CTRL has no interrupts.

42.4 External signals

There are no external signals for CACHE64_CTRL.

42.5 Initialization

Perform this procedure to initialize cache:

1. Write 1 to CCR[INVW1] and CCR[INVW0].
2. Write 1 to CCR[GO].
3. Write 1 to CCR[ENCACHE].

NOTE

Steps 1, 2 and 3 can be done simultaneously. That is, writing 8500_0003h to Cache Control (CCR) invalidates the cache and enables the cache and write buffer.

42.6 Memory map and registers

The cache programmer's model provides a variety of registers for configuring and controlling the cache, as well as indirect access paths to all cache tag and data storage.

NOTE

The cache registers are accessible in Supervisor mode only.

42.6.1 CACHE64 register descriptions

42.6.1.1 CACHE64 memory map

CACHE64_CTRL0 base address: 4003_5000h

CACHE64_CTRL1 base address: 4003_6000h

Offset	Register	Width (In bits)	Access	Reset value
800h	Cache Control (CCR)	32	RW	0000_0000h
804h	Cache Line Control (CLCR)	32	RW	0000_0000h
808h	Cache Search Address (CSAR)	32	RW	0000_0000h
80Ch	Cache Read/Write Value (CCVR)	32	RW	0000_0000h

42.6.1.2 Cache Control (CCR)

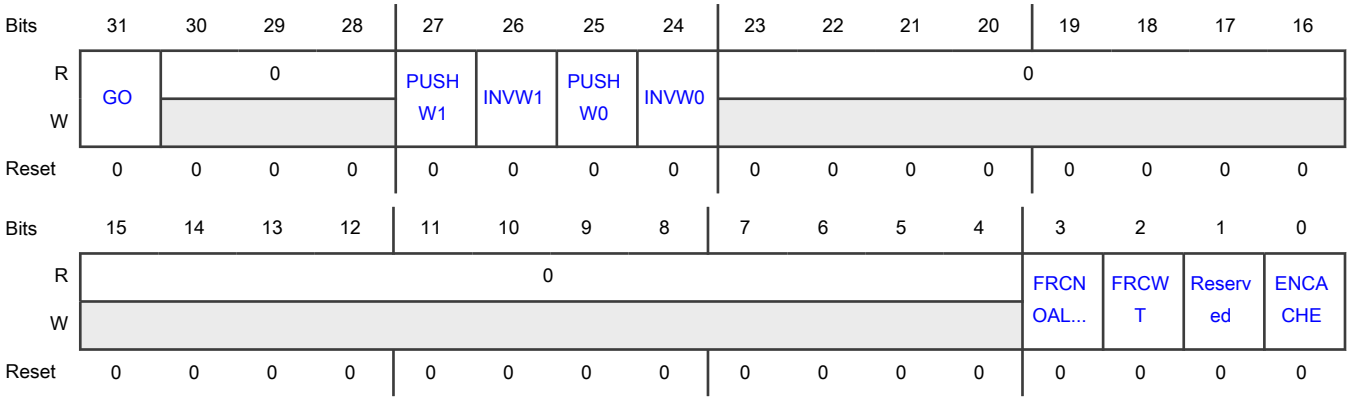
Offset

Register	Offset
CCR	800h

Function

Enables the cache. This register also contains the fields used for commands specified in Cache set commands.

Diagram



Fields

Field	Function
31 GO	Initiate Cache Command Initiates the cache command that CCR[INVW0], CCR[PUSHW0], CCR[INVW1], and CCR[PUSHW1] indicate, if you write 1 to this field. Reading this field indicates whether a cache command is active. **NOTE** This field remains 1 until the cache command completes. Writing 0 has no effect. 0b - Write: no effect; Read: no cache command active 1b - Write: initiates cache command; Read: cache command active
30-28 —	Reserved
27 PUSHW1	Push Way 1 Specifies the cache command to execute the next time CCR[GO] becomes 1. 0b - No operation 1b - Push all modified lines in way 1
26	Invalidate Way 1

Table continues on the next page...

Table continued from the previous page...

Field	Function
INVW1	Specifies the cache command to execute the next time CCR[GO] becomes 1. **NOTE** If CCR[PUSHW1] and CCR[INVW1] are 1, then after you write 1 to CCR[GO], this field pushes all modified lines in way 1 and invalidates all lines in way 1 (clear way 1). 0b - No operation 1b - Invalidates all lines in way 1
25 PUSHW0	Push Way 0 Specifies the cache command to execute the next time CCR[GO] becomes 1. 0b - No operation 1b - Push all modified lines in way 0
24 INVW0	Invalidate Way 0 Specifies the cache command to execute the next time CCR[GO] becomes 1. **NOTE** If CCR[PUSHW0] and CCR[INVW0] are 1, then after you write 1 to CCR[GO], this field pushes all modified lines in way 0 and invalidates all lines in way 0 (clear way 0). 0b - No operation 1b - Invalidates all lines in way 0
23-4 —	Reserved
3 FRCNOALLC	Forces No Allocation On Cache Misses 0b - Allocation on cache misses 1b - Forces no allocation on cache misses (FRCWT must be asserted)
2 FRCWT	Force Write Through Mode Specifies whether all cacheable spaces to write through are forced. 0b - Does not force 1b - Force
1 —	This field is reserved. Software should write 0 to this bit to maintain compatibility.
0 ENCACHE	Cache Enable Enables the cache. 0b - Disables 1b - Enables

Table continues on the next page...

Field	Function

42.6.1.3 Cache Line Control (CLCR)

Offset

Register	Offset
CLCR	804h

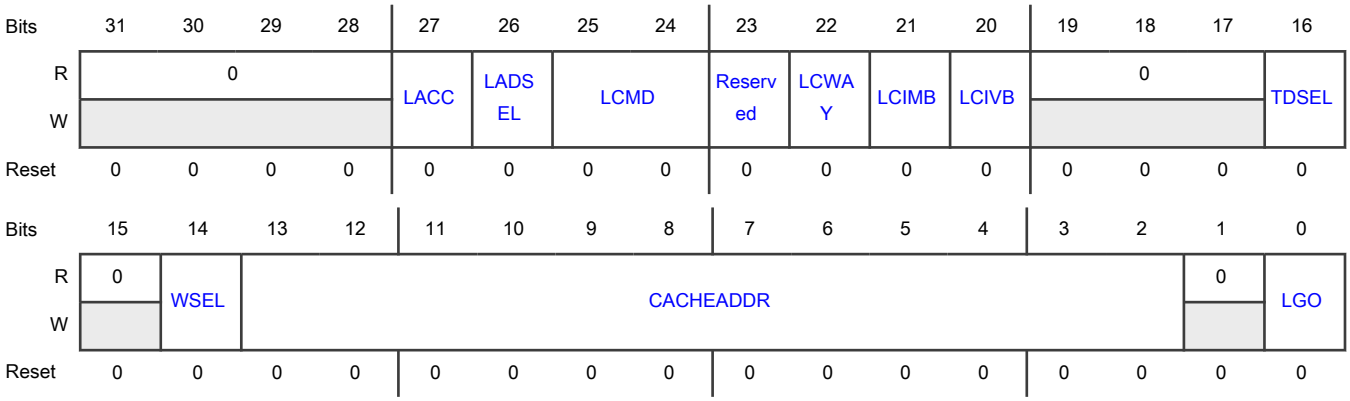
Function

Defines the commands specified in Cache line commands that you must perform using a specific cache line address or physical address.

If you specify the physical address, you can search cache in both the ways, and the command only performs on the way that hits.

You can write to CLCR[LCWAY], CLCR[LCIMB], and CLCR[LCIVB]; however, the values that you write to these fields have no functional purpose.

Diagram



Fields

Field	Function
31-28 —	Reserved
27 LACC	Line Access Type Specifies the operation that you must perform (read or write) after a hit, when performing a search command. **NOTE** Only used for search commands (CLCR[LCMD] = 00). 0b - Read

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Write
26 LADSEL	Line Address Select Specifies the address (cache or physical). When using the cache address (specified in CLCR[WSEL] and CLCR[CACHEADDR]), the way must also be specified in CLCR[WSEL]. When using the physical address (specified in Cache Search Address (CSAR)), both ways are searched and the command is performed only after a hit. 0b - Cache 1b - Physical
25-24 LCMD	Line Command Performs one of the four commands after a cache hit. CLCR[LACC] determines whether the operation is a read or write. 00b - Search and read or write 01b - Invalidate 10b - Push 11b - Clear
23 —	Reserved
22 LCWAY	Line Command Way Indicates the way that the line command uses. Applies only if CLCR[LCIVB] = 1. 0b - Way 0 1b - Way 1
21 LCIMB	Line Command Initial Modified Bit Shows the initial state of the modified bit. If this field = 0, and the command uses cache address and way, this field shows the initial state of the modified bit, which is 0. If the command uses physical address and a hit, this field shows the initial state of the modified bit, which is 0. If the command uses physical address and is a miss, this field reads 0. If this field = 1, and the command uses cache address and way, this field shows the initial state of the modified bit, which is 1. If the command uses physical address and way, this field shows the initial state of the modified bit, which is 1. If a miss, this field reads 0. 0b - Initial state 0 1b - Initial state 1
20 LCIVB	Line Command Initial Valid Bit Shows the initial state of the valid bit.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	If this field = 0, and the command uses cache address and way, this field shows the initial state of the valid bit, which is 0. If the command uses physical address and a hit, this field shows the initial state of the valid bit, which is 0. If the command uses physical address and is a miss, this field reads 0. If this field = 1, and the command uses cache address and way, this field shows the initial state of the valid bit, which is 1. If the command uses physical address and way, this field shows the initial state of the valid bit, which is 1. If a miss, this field reads 0. 0b - Initial state 0 1b - Initial state 1
19-17 —	Reserved
16 TDSEL	Tag Or Data Select Selects tag or data for search and read or write commands. 0b - Data 1b - Tag
15 —	Reserved
14 WSEL	Way Select Selects the way for line commands. 0b - Way 0 1b - Way 1
13-2 CACHEADDR	Cache Address Represents bits [13:2] of the cache address: CLCR[13:5] accesses the tag arrays. CLCR[13:3] accesses the data arrays. CLCR[2] specifies which half of the 64 bits of data to place in Cache Read/Write Value (CCVR).
1 —	Reserved
0 LGO	Initiate Cache Line Command Initiates the cache command that CLCR[LCMD], CLCR[LADSEL], and CLCR[LACC] indicate, if you write 1 to this field. Reading this field indicates whether a cache command is active.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE • This field remains 1 until the command completes. Writing 0 has no effect. • This field is shared with CSAR[LGO]. You can write either register address bit[0] interchangeably. This saves cache writes (helps performance), when performing cache operations. Cache line operations start when you write to Cache Line Control (CLCR) with CLCR[LGO] being 1 or the cache search address can be changed and a search is started by writing to Cache Search Address (CSAR) with CSAR[LGO] being 1. 0b - Write: no effect; Read: no line command active 1b - Write: initiate line command; Read: line command active

42.6.1.4 Cache Search Address (CSAR)

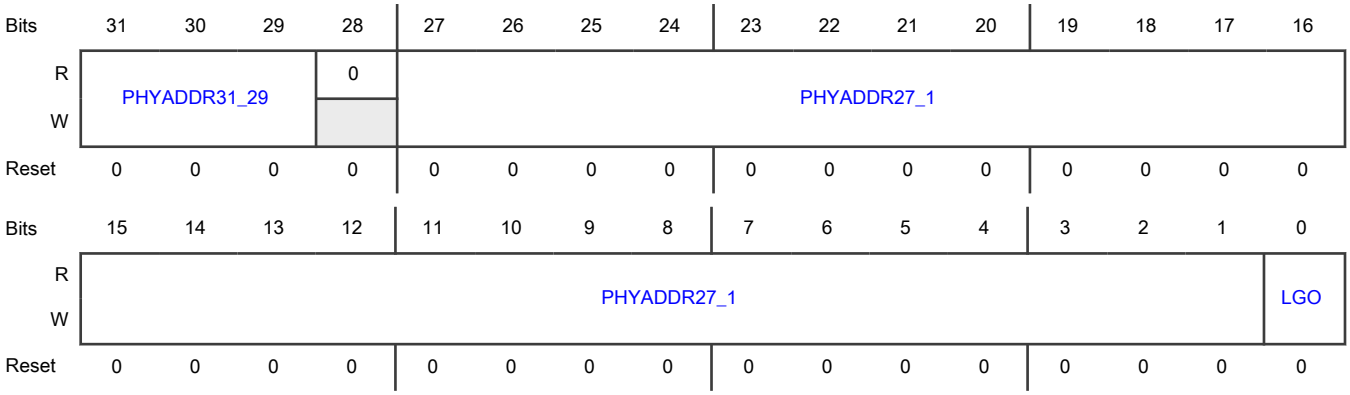
Offset

Register	Offset
CSAR	808h

Function

Defines the physical address for cache line commands, when CLCR[LADSEL] = 1.

Diagram



Fields

Field	Function
31-29	Physical Address PHYADDR31_29 represents bits [31:29] and PHYADDR27_1 represents bits [27:1] of the system address.

Table continues on the next page...

Table continued from the previous page...

Field	Function
PHYADDR31_29	CSAR[31:14] is used for tag compare. CSAR[13:5] accesses the tag arrays. CSAR[13:3] accesses the data arrays. CSAR[2] specifies which half of the 64 bits of data to place in Cache Read/Write Value (CCVR). CSAR[1] is not used. Writes to this bit are allowed, and the read value is the previously written value. This bit is not functionally used.
28 —	Reserved Always read as zero.
27-1 PHYADDR27_1	Physical Address PHYADDR31_29 represents bits [31:29] and PHYADDR27_1 represents bits [27:1] of the system address. CSAR[31:14] is used for tag compare. CSAR[13:5] accesses the tag arrays. CSAR[13:3] accesses the data arrays. CSAR[2] specifies which half of the 64 bits of data to place in Cache Read/Write Value (CCVR). CSAR[1] is not used. Writes to this bit are allowed, and the read value is the previously written value. This bit is not functionally used.
0 LGO	Initiate Cache Line Command Initiates the cache command that CSAR[PHYADDR] indicates, if you write 1 to this field. Reading this field indicates whether a cache command is active. **NOTE** • This field remains 1 until the command completes. Writing 0 has no effect. • This field is shared with CLCR[LGO]. 0b - Write: no effect; Read: no line command active 1b - Write: initiate line command; Read: line command active

42.6.1.5 Cache Read/Write Value (CCVR)

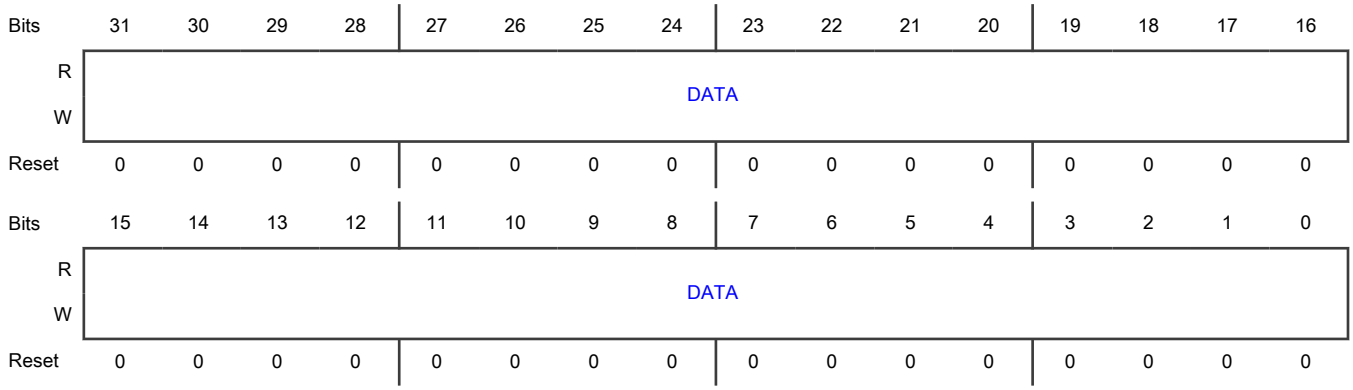
Offset

Register	Offset
CCVR	80Ch

Function

Sources write data or return read data when a search line command is requested (CLCR[LCMD] = 00). CLCR[LACC] determines whether the access is a read or write, and CLCR[TDSEL] determines whether the access is to the data or tag arrays.

Diagram



Fields

Field	Function
31-0 DATA	Cache Read/Write Data Reads or writes data during tag search and data search. For tag search, read or write: • CCVR[31:14] for tag array R/W value. • CCVR[13:5] for tag set address on reads; unused on writes. • CCVR[4:2] are reserved. • CCVR[1] for tag modify bit. • CCVR[0] for tag valid bit. For data search, read or write: • CCVR[31:0] for data array R/W value.

Chapter 43
CACHE64 Policy Select (CACHE64_POLSEL)

43.1 Chip-specific CACHE64_POLSEL information

Table 416. Reference links to related information

Topic	Related module	Reference
Full description	CACHE64_POLSEL	CACHE64_POLSEL
Peripheral memory map		Memory map overview
Clock controller		Clock controller
Power management	PMC	Power overview PMC
CACHE64 controller	CACHE64_CTRL	CACHE64_CTRL
External serial peripheral interface	XSPI	XSPI

NOTE

Each of the CACHE64_CTRL modules interface to a XSPI module for access to off-chip memory. The 128 MB space divided into three policy regions, is allocated for each CACHE64 POLSEL interface. POLICY_SEL register has three 2-bit fields associated with the three defined regions. Each field designates the policy to be applied to addresses falling within that region. The three policies are completely independent so, it is possible to assign the same policy to all three regions.

43.1.1 Module instances

This device has two instances of the CACHE64_POLSEL module, CACHE64_POLSEL0 and CACHE64_POLSEL1.

Table 417. CACHE64_POLSEL instances

	CACHE64_POLSEL0	CACHE64_POLSEL1
Located in	VDD2_COMP	VDD2_COMP
Access	CPU0, HiFi4, EZH-V, eDMA0, eDMA1	CPU0, HiFi4, EZH-V, eDMA0, eDMA1

NOTE

Only accesses to XSPI0 and XSPI1 from COMP_VDD bus initiators, like CPU0, eDMA0, eDMA1, are routed through the CACHE64_CTRL and CACHE64_POLSEL instances. HiFi4 and EZH-V can access the CACHE64_POLSEL registers, but their accesses to XSPI0 and XSPI1 do NOT go through the cache.

43.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

43.2 Overview

CACHE64_POLSEL monitors incoming AHB addresses to define the policy that the cache controller (CACHE64_CTRL) uses. Both CACHE64_POLSEL and the cache controller work in tandem with each other.

43.2.1 Features

- Provides cache policy information to the cache controller.
- Supports up to three regions, each with a programmable cache policy:
  - Each region can be independently designated as noncache, write-through cache, and write-back cache.
  - User-defined boundaries are supported between the three regions with 1 KB granularity.

43.3 Functional description

CACHE64_POLSEL permits dividing the memory space that the cache controller accesses into three contiguous regions and applies one of these three cache policies to each region:

- First region (region 0) starts at the bottom (lowest address) in the target address space and goes up to the top of the 1 KB boundary designated in REG0_TOP.
- Second region (region 1) starts at the next address and extends to the top of the boundary designated in REG1_TOP.
- Third region starts at the address after that and continues to the top of the memory space accessed via the cache controller.

43.3.1 Region mapping

CACHE64_POLSEL controls the cache policy for memory between the base address and end address. Within the CACHE64_POLSEL memory area, you can define up to three contiguous memory regions, with each region having independently programmable cache policy settings.

As shown in the following figure, REG0_TOP and REG1_TOP control the boundaries between the regions. These registers provide bits 26-10 of the address and the lower 10 bits (9-0) are always 1s. For example, if REG0_TOP is 0001_0000h, then region 0 ends at BASE_ADDRESS + 0001_03FFh. Region 1 starts at 0001_0400h.

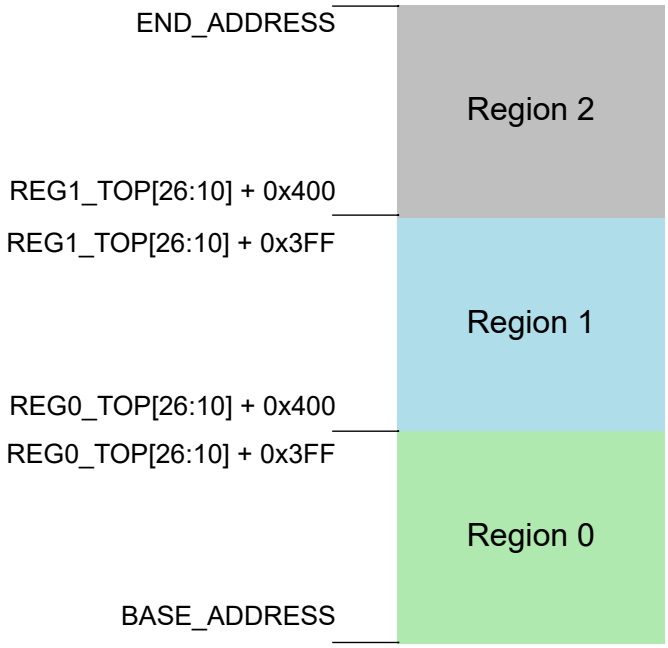


Figure 163. Cache memory regions

For CACHE64_POLSEL implementations that have multiple memory regions (more than one base address and end address), the regions are aliased across all of the memory regions. Therefore, the configured cache policies are also aliased across all of the memory regions.

43.3.2 Region priority

When you access an address, CACHE64_POLSEL attempts to match it to one of the regions in a sequential order that starts with region 0. In pseudocode, the region hit logic does this:

```
if (address < REG0_TOP + 0x3FF)
  address hits in Region 0;
else
  if (address < REG1_TOP + 0x3FF)
    address hits in Region 1;
  else
    address hits in Region 2;
```

NOTE

If you configure REG0_TOP and REG1_TOP to create overlapping regions, then the lowest number region in which the address hits, is used.

43.4 Application information

This section provides an example CACHE64_POLSEL configuration. The example assumes:

- The MCU has two memory regions mapped to CACHE64_POLSEL:

— Nonsecure region: BASE_ADDRESS = 0800_0000h, END_ADDRESS = 0FFF_FFFFh

— Secure region: BASE_ADDRESS = 1800_0000h, END_ADDRESS = 1FFF_FFFFh

- Region 0: 56 MB is configured as write-through.
- Region 1: 8 MB is configured as noncacheable.
- Region 2: The remaining memory region is unused and configured as invalid.

The following register settings are used to achieve this configuration:

- REG0_TOP = 037F_FC00h
- REG1_TOP = 03FF_FC00h
- POLSEL = 0000_0031h

The following figure shows the resulting memory configuration.

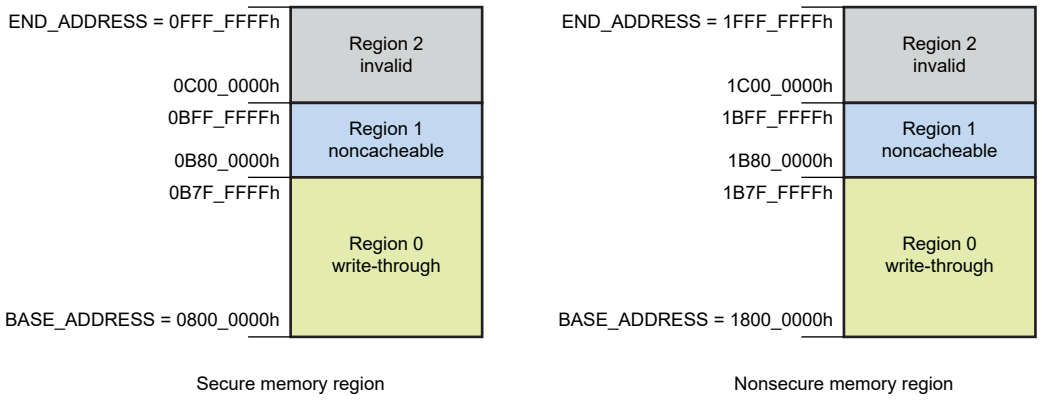

Figure 164. CACHE64_POLSEL configuration example

43.5 Memory map and register definition

The CACHE64_POLSEL registers are included in the register space of the CACHE64 module, utilizing addresses that CACHE64 does not use internally.

43.5.1 CACHE64_POLSEL register descriptions

43.5.1.1 CACHE64_POLSEL memory map

CACHE64_POLSEL0 base address: 4003_5000h

CACHE64_POLSEL1 base address: 4003_6000h

Offset	Register	Width (In bits)	Access	Reset value
14h	Region 0 Top Boundary (REG0_TOP)	32	RW	02AA_A800h
18h	Region 1 Top Boundary (REG1_TOP)	32	RW	0555_5400h
1Ch	Policy Select (POLSEL)	32	RW	0000_0000h

43.5.1.2 Region 0 Top Boundary (REG0_TOP)

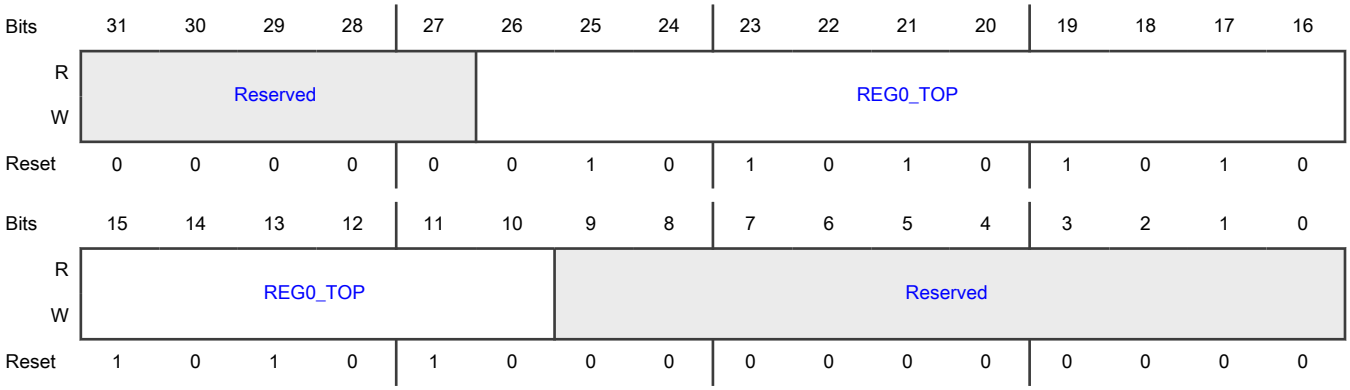
Offset

Register	Offset
REG0_TOP	14h

Function

Provides bits 26-10 of the region 0 compare address. The actual granularity implemented is 1 KB.

Diagram



Fields

Field	Function
31-27 —	Reserved
26-10 REG0_TOP	Upper Limit Of Region 0 Provides bits 26-10 of the region 0 compare address. The value provided here is concatenated with 3FFh to create the full compare address. For Example, if REG0_TOP[26:10] = 0b00000000000_111111, the region 0 end address is BASE_ADDRESS + 0000_FFFFh (64 KB).
9-0 —	Reserved

43.5.1.3 Region 1 Top Boundary (REG1_TOP)

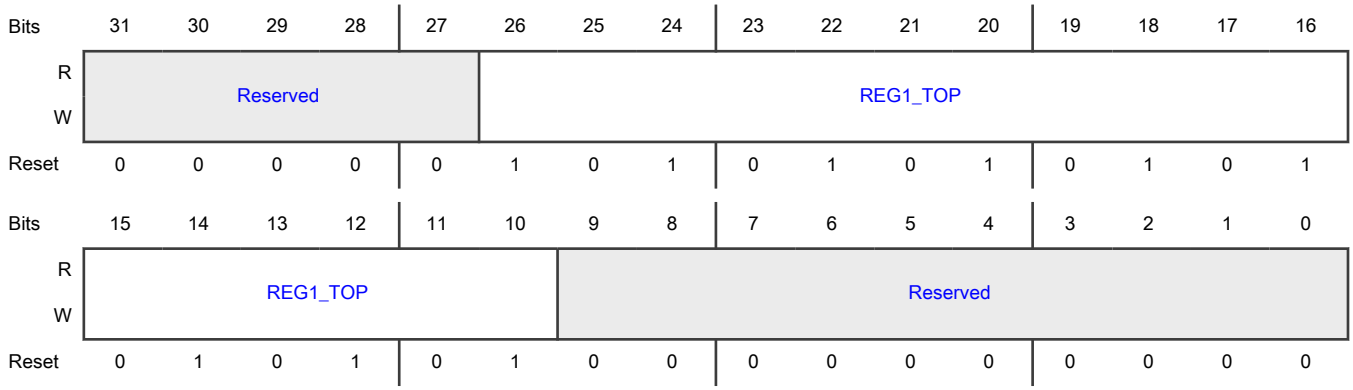
Offset

Register	Offset
REG1_TOP	18h

Function

Provides bits 26-10 of the region 1 compare address. The actual granularity implemented is 1 KB.

Diagram



Fields

Field	Function

44.1.1 Module instances

This device contains three instances of the MMU module, MMU0, MMU1 and MMU2.

Table 419. MMU instances

	MMU0	MMU1	MMU2
Located in	VDD2_COMP	VDD2_COMP	VDD2_MEDIA
Access	CPU0, HiFi4, EZH-V, eDMA0, eDMA1	CPU0, HiFi4, EZH-V, eDMA0, eDMA1	CPU0, CPU1, HiFi4, EZH-V, eDMA0, eDMA1, eDMA2, eDMA3
Related XSPI	XSPI0	XSPI1	XSPI2
4 KB block-size unit support	No	No	Support only on memory region of 6000_0000h-67FF_FFFFh

44.1.2 Security considerations

For secure applications, NXP recommends that this module is configured for secure and privileged access only to prevent unintentional or malicious modification of the system operation by nonsecure software. The secure AHB controller controls the security level for access to peripherals and does default to secure and privileged access for all peripherals.

44.1.3 Registers protection

The CTRL, ADDR_RANGE, LUT_WDATA registers are protected by GLIKEY modules.

Table 420. Registers protected by GLIKEY module

Registers in MMU instance	Protected by GLIKEY instance	WRITE_INDEX
MMU0	GLIKEY0	15
MMU1	GLIKEY0	14
MMU2	GLIKEY2	15

44.2 Overview

MMU remaps the advanced high-performance bus (AHB) access address to another address that the MMU lookup table (LUT) SRAM indicates. You can configure the remapped address in LUT SRAM by using the internal register bus (IPS).

MMU allows software a way to use large memory devices without having prior knowledge of the location of an application at compile time, thus spares the need of complex linker scripts. It can be used for example, to support partial retention of external pseudo-static RAM (PSRAM) by remapping external memory space into a single region for retention purposes. It can also support flash swap or provide support for multiple software images in external flash.

44.2.1 Block diagram

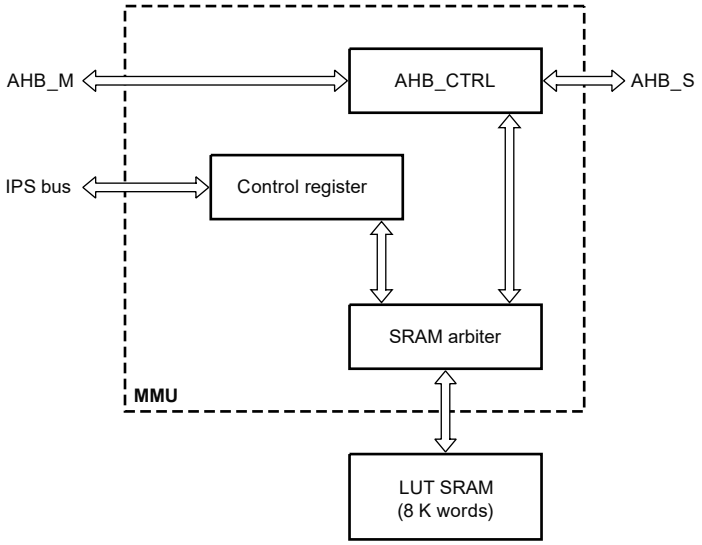

Figure 165. Block diagram

44.2.2 Features

- Automatically initializes LUT SRAM after reset
- Supports single- and burst-write modes for LUT SRAM settings
- Supports block sizes of 4 KB, 8 KB, 16 KB, 32 KB, and 64 KB
- Supports parity check of the address in LUT SRAM

44.3 Functional description

44.3.1 Operations

- LUT SRAM write operation, which includes these methods to initialize LUT SRAM: Single-write operation and Burst-write operation
- LUT SRAM read operation
- LUT SRAM read-verify operation
- LUT SRAM address-map operation

44.3.1.1 Single-write operation

Perform the following procedure for a single-write operation:

1. Configure Write Pointer (WRITE_PTR) with the LUT SRAM address.

2. Write data to LUT Write Data (LUT_WDATA). Ensure LUT_WDATA[COUNT] = 0 to trigger a write operation to LUT SRAM.

   Every write to LUT Write Data (LUT_WDATA) increases the value of Write Pointer (WRITE_PTR) by 1. Therefore, you can write to LUT Write Data (LUT_WDATA) multiple times without configuring Write Pointer (WRITE_PTR) again for subsequent LUT SRAM addresses.

   For example, to initialize LUT SRAM addresses 2 and 3 with values 1234h and 5678h, respectively, perform the following procedure:

   a. Write 2h to Write Pointer (WRITE_PTR).

   b. Write 1234h to LUT Write Data (LUT_WDATA).

   c. Write 5678h to LUT Write Data (LUT_WDATA).

44.3.1.2 Burst-write operation

1. Configure Write Pointer (WRITE_PTR) with the LUT SRAM address.
2. Write data to LUT_WDATA[VALID] and LUT_WDATA[ADDR], with LUT_WDATA[COUNT] > 0. This triggers COUNT + 1 write operations to LUT SRAM, incrementing the write address and data written each time.

   For example, to initialize LUT SRAM addresses 2 and 3 with values 1234h and 1235h, respectively, perform the following procedure:

   a. Write 2h to Write Pointer (WRITE_PTR).

   b. Write 00011234h to LUT Write Data (LUT_WDATA).

3. Wait for the burst-write operation to complete by polling STS[BUSY] before the next IPS action.

44.3.1.3 Read operation

1. Configure Read Pointer (READ_PTR) with the LUT SRAM address.
2. Read data from LUT Read Data (LUT_RDATA). This triggers a read operation from LUT SRAM.

   Every read from LUT Read Data (LUT_RDATA) increases the value of Read Pointer (READ_PTR) by 1. Therefore, you can read from LUT Read Data (LUT_RDATA) multiple times without configuring Read Pointer (READ_PTR) again for subsequent LUT SRAM addresses.

   For example, to read LUT SRAM addresses 2 and 3, perform the following procedure:

   a. Write 2h to Read Pointer (READ_PTR).

   b. Read from LUT Read Data (LUT_RDATA); the register returns data from LUT SRAM address 2.

   c. Read from LUT Read Data (LUT_RDATA); the register returns data from LUT SRAM address 3.

44.3.1.4 Read-verify operation

This operation performs a burst read, and compares the values read from the LUT against expected data.

1. Configure Read Pointer (READ_PTR) with the LUT SRAM address.
2. Write data to Read Verify (READ_VFY). This triggers COUNT + 1 read operations from LUT SRAM, incrementing the read address and expected data[1] each time.

   For example, the expected values for LUT SRAM addresses 2 and 3 are 1234h and 1235h, respectively. Perform the following procedure to verify:

   a. Write 2h to Read Pointer (READ_PTR).

   b. Write 00011234h to Read Verify (READ_VFY).

[1] The expected data is used for checks in read verify operations. MMU compares the read data against the expected data.

c. MMU reads LUT SRAM address 2 and compares read data with 1234h. STS[IPS_READ_ERROR] is set if the compare fails.

d. MMU reads LUT SRAM address 3 and compares read data with 1235h. STS[IPS_READ_ERROR] is set if the compare fails.

3. Wait for the read-verify operation to complete by polling STS[BUSY] before the next IPS action.

44.3.1.5 Address-map operation

MMU has 8 KB words of LUT SRAM. It can be separated in 4 pages as configured by CTRL[PAGE_MODE].

Example 1:

Perform address-map operation where LUT SRAM works as 1 page (CTRL[PAGE_MODE] = 0).

The following table shows the address-map bit settings.

Table 421. MMU address bits map 1

Unit size	Initiator address	Address for LUT SRAM	Data from LUT SRAM (map address)	Target address
4 KB	`mhaddr[31:0]`[1]	`mhaddr[24:12]`	`mapaddr[14:0]`[2]	`{mhaddr[31:28], 1'b0, mapaddr[14:0], mhaddr[11:0]}`
8 KB	`mhaddr[31:0]`	`mhaddr[25:13]`	`mapaddr[14:0]`	`{mhaddr[31:28], mapaddr[14:0], mhaddr[12:0]}`
16 KB	`mhaddr[31:0]`	`mhaddr[26:14]`	`mapaddr[14:0]`	`{mhaddr[31:28], mapaddr[13:0], mhaddr[13:0]}`
32 KB	`mhaddr[31:0]`	`mhaddr[27:15]`	`mapaddr[14:0]`	`{mhaddr[31:28], mapaddr[12:0], mhaddr[14:0]}`
64 KB	`mhaddr[31:0]`	`mhaddr[28:16]`	`mapaddr[14:0]`	`{mhaddr[31:28], mapaddr[11:0], mhaddr[15:0]}`

1. `mhaddr` = initiator AHB address
2. `mapaddr` = map address from LUT SRAM

Example 2:

Perform address-map operation where LUT SRAM works as 4 pages (CTRL[PAGE_MODE] = 1).

The following table shows the address-map bit settings.

Table 422. MMU address bits map 2

Unit size	Initiator address	Address for LUT SRAM	Data from LUT SRAM (map address)	Target address
4 KB	`mhaddr[31:0]`[1]	`{page_sel, mhaddr[22:12]}`[2]	`mapaddr[14:0]`[3]	`{mhaddr[31:28], 1'b0, mapaddr[14:0], mhaddr[11:0]}`

Table continues on the next page...

Table 422. MMU address bits map 2 (continued)

Unit size	Initiator address	Address for LUT SRAM	Data from LUT SRAM (map address)	Target address
8 KB	mhaddr[31:0]	{page_sel, mhaddr[23:13]}	mapaddr[14:0]	{mhaddr[31:28], mapaddr[14:0], mhaddr[12:0]}
16 KB	mhaddr[31:0]	{page_sel, mhaddr[24:14]}	mapaddr[14:0]	{mhaddr[31:28], mapaddr[13:0], mhaddr[13:0]}
32 KB	mhaddr[31:0]	{page_sel, mhaddr[25:15]}	mapaddr[14:0]	{mhaddr[31:28], mapaddr[12:0], mhaddr[14:0]}
64 KB	mhaddr[31:0]	{page_sel, mhaddr[26:16]}	mapaddr[14:0]	{mhaddr[31:28], mapaddr[11:0], mhaddr[15:0]}

1. mhaddr = initiator AHB address
2. page_sel = page selection value that ranges from 0 to 3
3. mapaddr = map address from LUT SRAM

Example 3:

For AHB secure access using address-map page 3, CTRL[UNIT_SIZE] = 64 KB:

- Assume that the AHB initiator address is A456CDEFh; therefore, mhaddr is A456CDEFh.
- The page_sel element is 3h and mhaddr[26:16] is 456h; therefore, read address for LUT SRAM must be 1C56h.
- Assume that the read data from LUT SRAM is 8AFAh. Bit 15 indicates that the read data is valid, and the lower 15 bits indicate the map address (mapaddr).
- The AHB target address must be AAFACDEFh.

44.3.2 Modes of operation

Table 423. Modes of operation

Mode	Description
Initialization	MMU enters Initialization mode when hardware reset is deasserted. Contents of the LUT SRAM become 0 in this mode. STS[BUSY] remains 1 until the initialization sequence completes.
Bypass	MMU enters Bypass mode when CTRL[MMU_EN] is 0. In this mode, the AHB transaction passes through MMU without address remapping.
Normal	MMU enters Normal mode when CTRL[MMU_EN] is 1. In this mode, the addresses of the AHB transaction are remapped by looking up LUT SRAM.

44.3.3 Clocking

CTRL[CLK_DIS] controls clock gating of the AHB clock. Write 1 to CTRL[CLK_DIS] to disable MMU's AHB clock to save power when MMU is not utilized.

44.3.4 Reset

Write 1 to CTRL[SWRST] to reset the MMU logic.

44.3.5 Interrupts

MMU includes an interrupt output signal. It is generated by interrupts in MMU Status (STS) when the related interrupt enable fields are set.

Interrupt sources are included when the following conditions are met:

- The LUT SRAM value is invalid.
- The AHB access address is not in the valid address range.
- Parity of the LUT SRAM value is not correct.
- You write to LUT Write Data (LUT_WDATA) when the LUT SRAM is locked.
- A read error occurs when reading from LUT Read Data (LUT_RDATA).

44.4 External signals

This module has no external signals.

44.5 Initialization

Step	Purpose	Programming
1	Enable the MMU clock.	Write 0 to CTRL[CLK_DIS].
2	Define the basic unit used in the memory map.	Configure CTRL[UNIT_SIZE].
3	Define the valid address range.	Configure Address Range (ADDR_RANGE).
4	Configure the LUT SRAM.	Write appropriate values to Write Pointer (WRITE_PTR) and LUT Write Data (LUT_WDATA).
5	Enable the MMU remap function.	Write 1 to CTRL[MMU_EN].

44.6 Memory map and register definition

44.6.1 MMU register descriptions

44.6.1.1 MMU memory map

MMU0 base address: 4003_0000h

MMU1 base address: 4003_1000h

MMU2 base address: 400A_8000h

<tr><td>4
INV_ADDR_MODE</td><td>Invalid Address Mode
Specifies MMU behavior when an invalid address is detected. If this field is 0, MMU responds with a transfer error when an invalid address is detected. The transfer address is recorded in Fail Address (FAIL_ADDR), and STS[INVALID_ADDR] is 1. If this field is 1, MMU allows transfer when</td></tr>
</table>

Table continues on the next page...

Table continued from the previous page...

Field	Function
	an invalid address is detected. The transfer address is recorded in Fail Address (FAIL_ADDR), and STS[INVALID_ADDR] is 1. 0b - Respond with a transfer error 1b - Allow transfer
3 LOCK_LUT	Lock LUT Locks LUT SRAM to avoid an accidental update. 0b - Unlock 1b - Lock
2 CLK_DIS	Clock Gate Disables the MMU clock for internal logic. 0b - Enable 1b - Disable
1 MMU_EN	MMU Enable Enables MMU memory map. 0b - Disable 1b - Enable
0 SWRST	Software Reset Specifies whether the MMU logic is reset. Writing 1 to this field resets the MMU logic. This field does not clear itself; therefore, when writing 1, you must allow a sufficient delay (4–6 NOP cycles) for reset propagation before writing 0 to disable the software reset. Asserting the software reset does not clear the registers. 0b - No reset 1b - Reset MMU logic

44.6.1.3 MMU Status (STS)

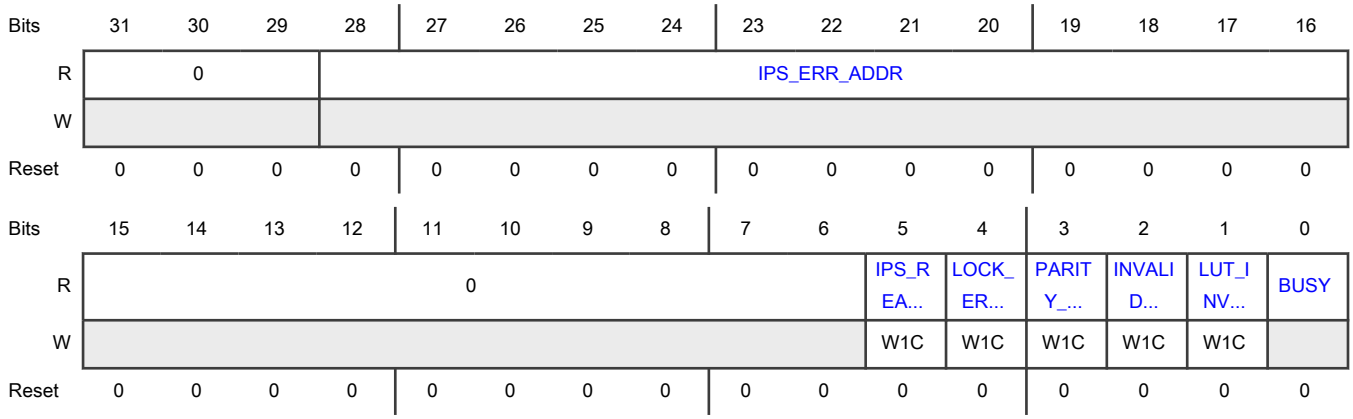
Offset

Register	Offset
STS	4h

Function

Provides interrupt fields that indicate the module status.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-16 IPS_ERR_ADDR	IPS Error Address Indicates the LUT SRAM address when an error is detected for IPS read operation.
15-6 —	Reserved
5 IPS_READ_ERROR	IPS Read Error Indicates whether an IPS read error is detected when writing to LUT Read Data (LUT_RDATA). This includes IPS read parity error and read-verify mismatch error. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag
4 LOCK_ERROR	Lock Error Indicates whether a lock error is detected when writing to LUT Write Data (LUT_WDATA). **NOTE** This field behaves differently for register reads and writes.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	When reading 0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag
3 PARITY_ERROR	Parity Error Indicates whether a parity error is detected in the access address. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Not detected 1b - Detected When writing 0b - No effect 1b - Clear the flag
2 INVALID_ADDR	Invalid Address Indicates whether the AHB access address is out of the valid address range. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Within range 1b - Out of range When writing 0b - No effect 1b - Clear the flag
1 LUT_INVALID	LUT Invalid Indicates whether the valid bit in access address is 0, which means the access operation is invalid in LUT. **NOTE** This field behaves differently for register reads and writes. When reading

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Valid 1b - Invalid When writing 0b - No effect 1b - Clear the flag
0 BUSY	Busy Indicates whether MMU is in a busy state. Wait for it to clear before taking action. Following are the possible reasons for this field to become 1: • Initialization sequence • Burst-write operation • Read-verify operation 0b - Not busy 1b - In initialization sequence, burst-write operation, or read-verify operation

44.6.1.4 Interrupt Enable (INTEN)

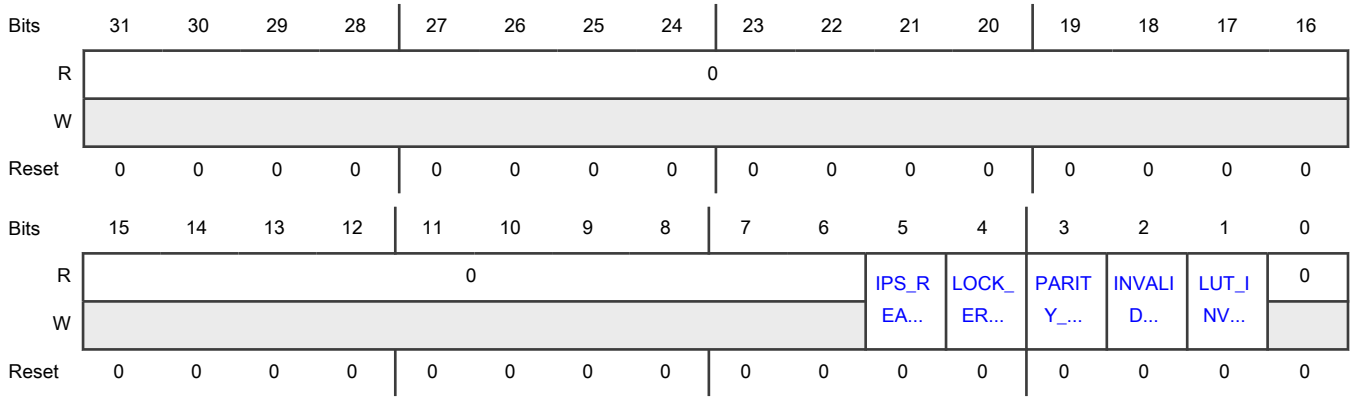
Offset

Register	Offset
INTEN	8h

Function

Enables the MMU interrupt fields.

Diagram



Fields

Field	Function
31-6 —	Reserved
5 IPS_READ_ERROR_EN	IPS Read Error Enable Enables the interrupt for STS[IPS_READ_ERROR]. 0b - Disable 1b - Enable

3 PARITY_ERROR_EN	Parity Error Enable Enables the interrupt for STS[PARITY_ERROR]. 0b - Disable 1b - Enable
2 INVALID_ADDR_EN	Invalid Address Enable Enables the interrupt for STS[INVALID_ADDR]. 0b - Disable 1b - Enable
1 LUT_INVALID_EN	LUT Invalid Enable Enables the interrupt for STS[LUT_INVALID]. 0b - Disable 1b - Enable
0 —	Reserved

44.6.1.5 Address Range (ADDR_RANGE)

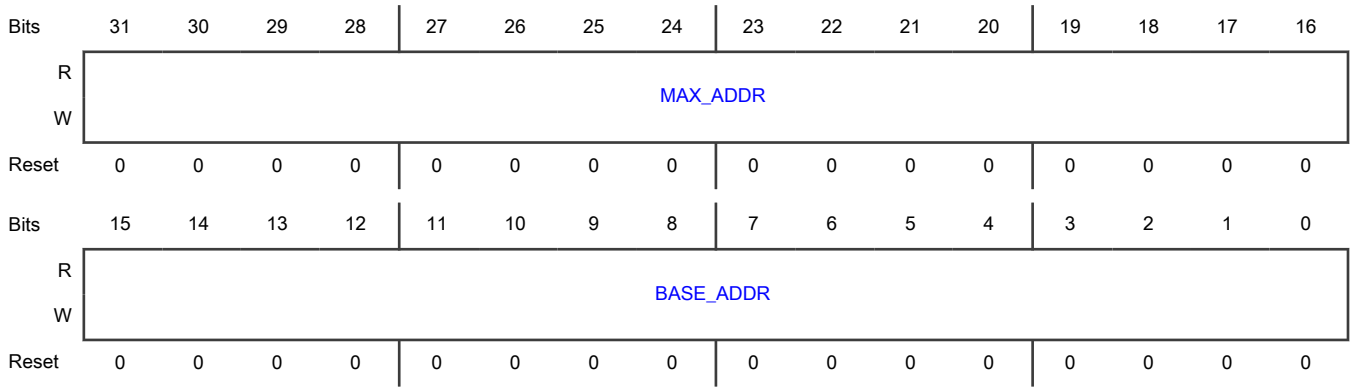
Offset

Register	Offset
ADDR_RANGE	Ch

Function

Specifies the upper 16 bits of valid address range definitions. Only the addresses between ADDR_RANGE[BASE_ADDR] and ADDR_RANGE[MAX_ADDR] are valid. For example, if ADDR_RANGE is 511F_5100h, only the AHB addresses from 5100_0000h to 511F_FFFFh are valid. This register is write-protected by a security component.

Diagram



Fields

Field	Function
31-16 MAX_ADDR	Maximum Address Specifies the upper 16 bits of the maximum address.
15-0 BASE_ADDR	Base Address Specifies the upper 16 bits of the base address.

44.6.1.6 Fail Information (FAIL_INFO)

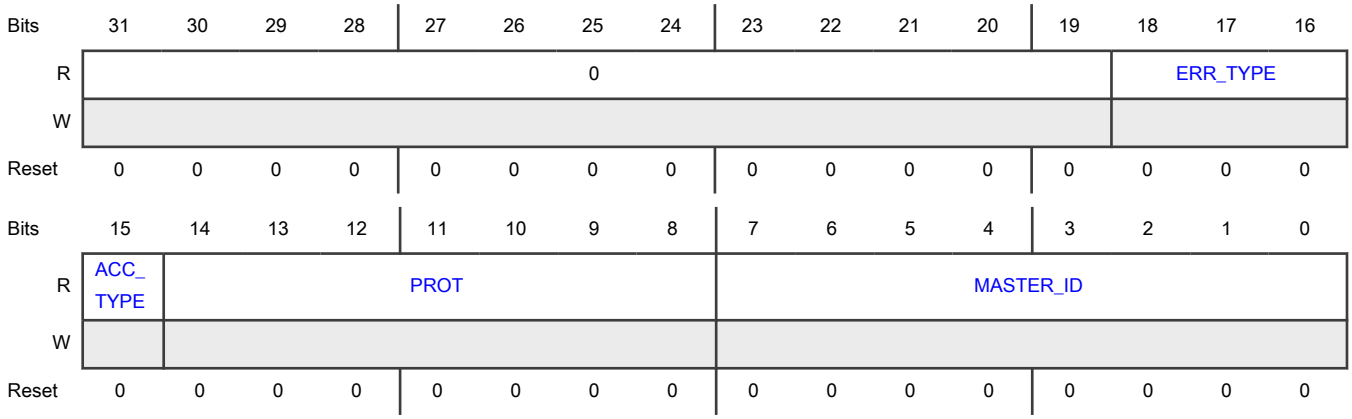
Offset

Register	Offset
FAIL_INFO	10h

Function

Indicates the transaction information when an error occurs. This register records the transfer information from the initiator side.

Diagram



Fields

Field	Function
31-19 —	Reserved
18-16 ERR_TYPE	Error Type Indicates the error type information of the transfer. 1xxb - Parity error x1xb - Invalid address error xx1b - LUT invalid error
15 ACC_TYPE	Access Type Indicates the access type of the transfer. 0b - Read 1b - Write
14-8 PROT	Protection Indicates the AHB HPROT state when an error occurs.
7-0 MASTER_ID	Initiator ID Indicates the initiator ID of the transfer.

44.6.1.7 Fail Address (FAIL_ADDR)

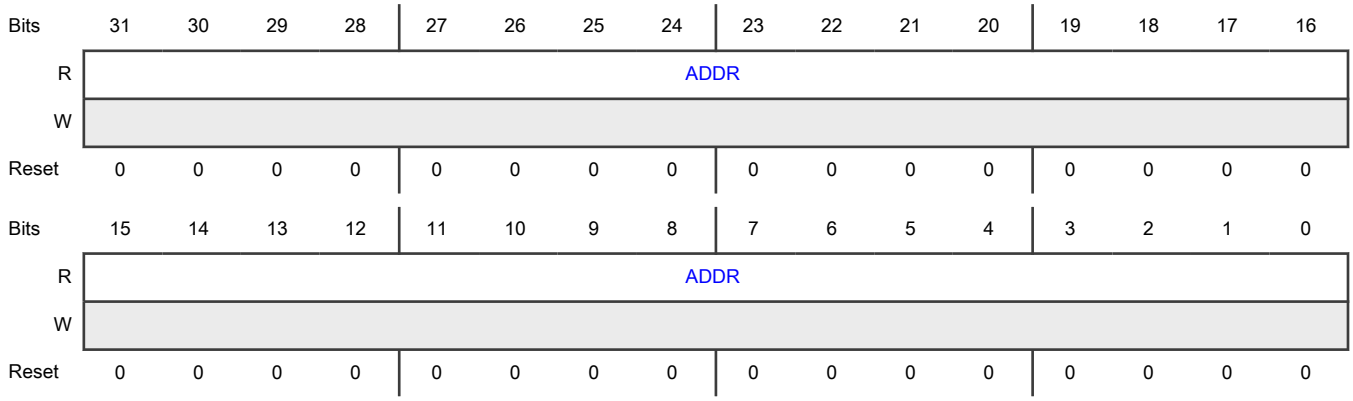
Offset

Register	Offset
FAIL_ADDR	14h

Function

Indicates the LUT address where an error occurs. This register records the AHB address from the initiator side.

Diagram



Fields

Field	Function
31-0 ADDR	Address Indicates the fail address.

44.6.1.8 LUT Write Data (LUT_WDATA)

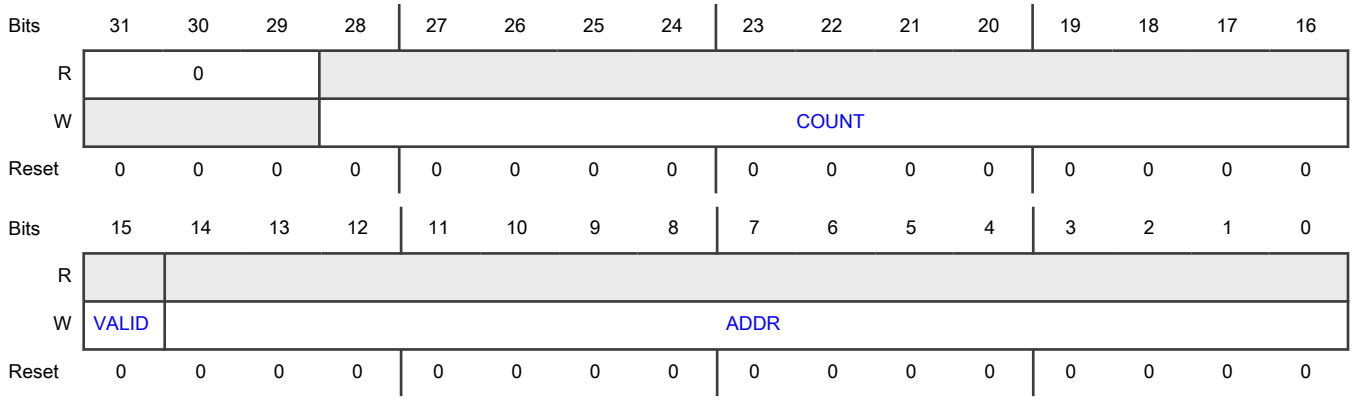
Offset

Register	Offset
LUT_WDATA	18h

Function

Specifies the write data to LUT SRAM that is addressed by Write Pointer (WRITE_PTR). This register is write-protected by a security component.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-16 COUNT	Write Count Specifies the write count to LUT SRAM. Writing to LUT Write Data (LUT_WDATA) triggers COUNT + 1 write operations to LUT SRAM, incrementing Write Pointer (WRITE_PTR) and the data written each time. When COUNT is 0, it triggers a write to LUT SRAM.
15 VALID	LUT Address Valid Specifies whether the address in the LUT is valid. 0b - Not valid 1b - Valid
14-0 ADDR	LUT Address Map Bits Specifies the address mapped to LUT SRAM.

44.6.1.9 LUT Read Data (LUT_RDATA)

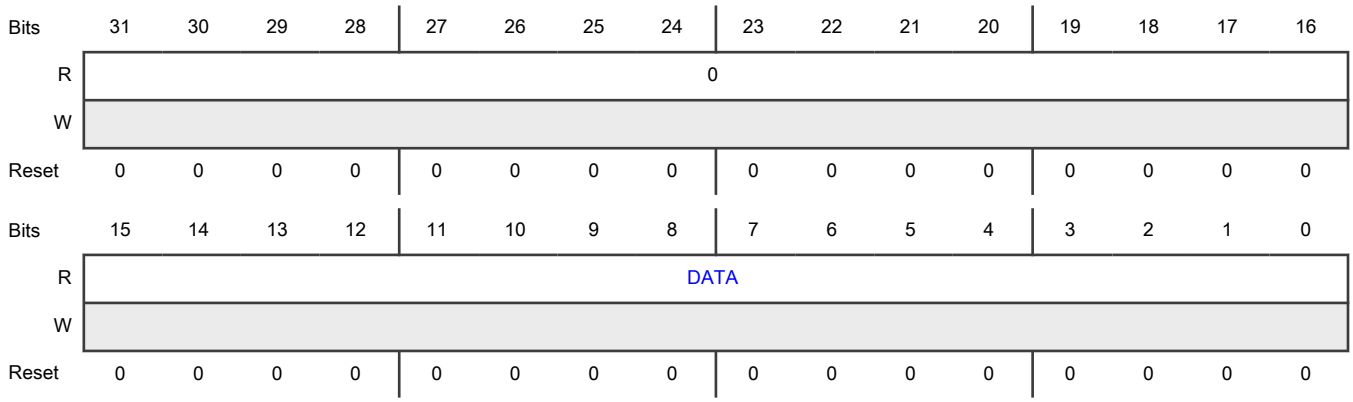
Offset

Register	Offset
LUT_RDATA	1Ch

Function

Indicates the read data from LUT SRAM addressed by Read Pointer (READ_PTR).

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 DATA	Read Data Indicates the read data from LUT SRAM.

44.6.1.10 Write Pointer (WRITE_PTR)

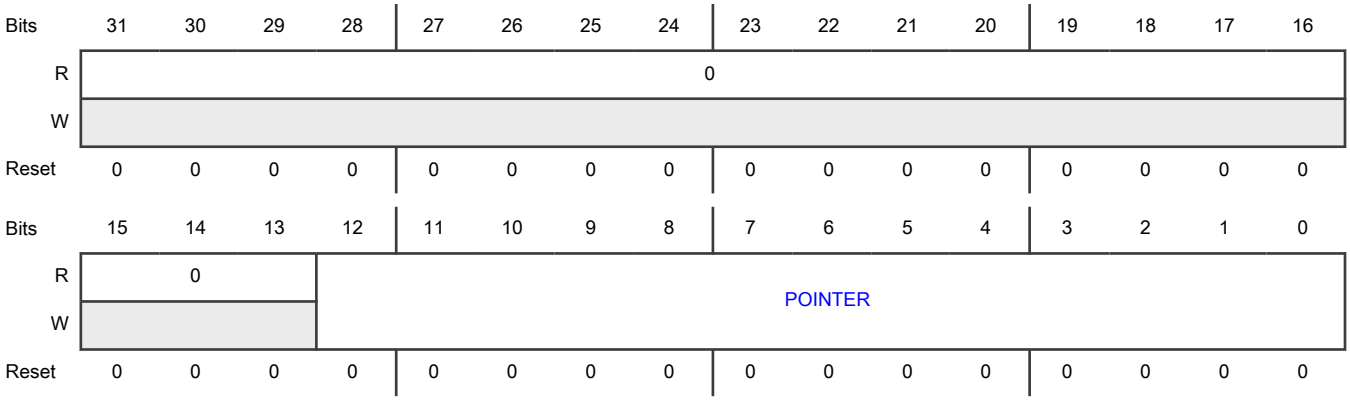
Offset

Register	Offset
WRITE_PTR	20h

Function

Specifies the write pointer for a write operation initiated by writing to LUT Write Data (LUT_WDATA).

Diagram



Fields

Field	Function
31-13 —	Reserved
12-0 POINTER	Write Pointer Specifies the write pointer of LUT SRAM. It is automatically increased by 1 when writing to LUT Write Data (LUT_WDATA).

44.6.1.11 Read Pointer (READ_PTR)

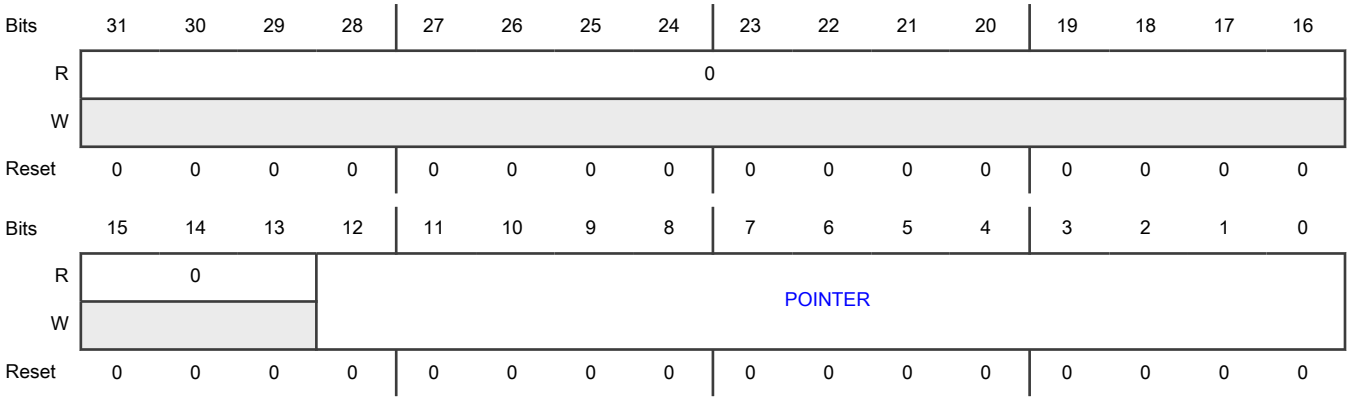
Offset

Register	Offset
READ_PTR	24h

Function

Specifies the read pointer for a read operation initiated by reading from LUT Read Data (LUT_RDATA).

Diagram



Fields

Field	Function
31-13 —	Reserved
12-0 POINTER	Read Pointer Specifies the read pointer of LUT SRAM. It is automatically increased by 1 when reading from LUT Read Data (LUT_RDATA).

44.6.1.12 Read Verify (READ_VFY)

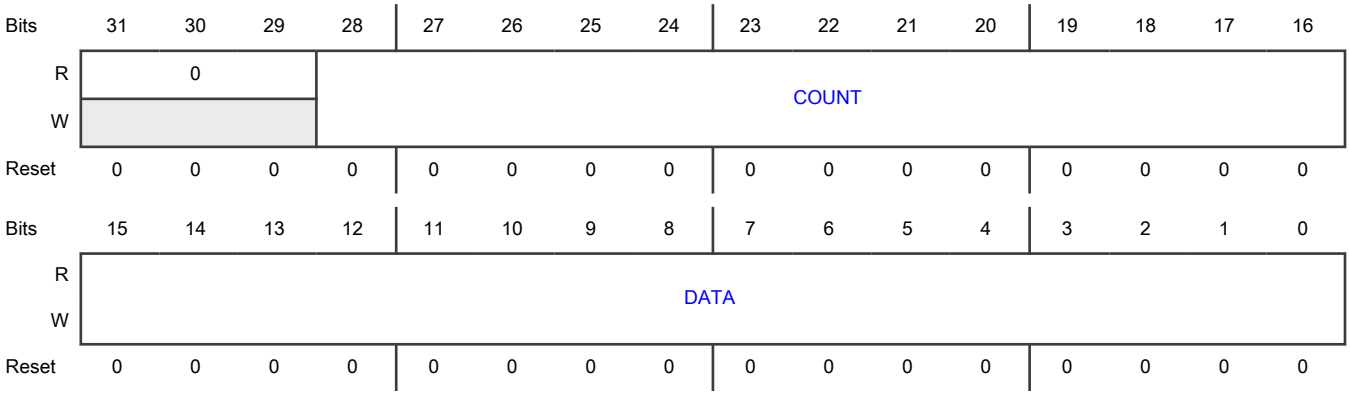
Offset

Register	Offset
READ_VFY	28h

Function

Specifies the golden data and count for read-verify check from LUT SRAM that is addressed by Read Pointer (READ_PTR).

Diagram



Fields

Field	Function
31-29 —	Reserved
28-16 COUNT	Read Count Specifies the read count to LUT SRAM. Writing to Read Verify (READ_VFY) triggers COUNT + 1 read-verify operations to LUT SRAM. This operation reads LUT SRAM and compares it against DATA. This increments Read Pointer (READ_PTR) and DATA each time. When COUNT is 0, it triggers one read-verify operation.
15-0 DATA	Read Data Specifies the golden data for the read-verify operation.

45.2 Overview

This chapter provides information on the features supported by the eIQ® Neutron N3-64 NPU. For enablement details and constraints, see the documentation that is part of eIQ Toolkit at http://nxp.com/eiq.

The NPU is an on-chip hardware accelerator that provides efficient processing of machine-learning workloads. It works in conjunction with the chip's CPU to deliver higher performance and lower power consumption for neural network (NN) inference.

In addition to managing Multiply-Accumulate (MAC) compute blocks throughput, NPU also:

- Optimizes arrangement of weights
- Manages memory accesses
- Provides rescaling, activation, and pooling functions

Enablement support for the eIQ Neutron N3-64 NPU is provided with the eIQ Toolkit and eIQ Machine Learning (ML) Software Development Environment. Some of the features and operators listed in this chapter may not be enabled in eIQ software. See References for links to eIQ documentation that lists the features and operators enabled in the latest eIQ software.

You can import your trained and quantized NN into eIQ Toolkit. The eIQ tooling generates an NPU-optimized model that can be integrated into an ML application running on the target device.

45.2.1 Block diagram

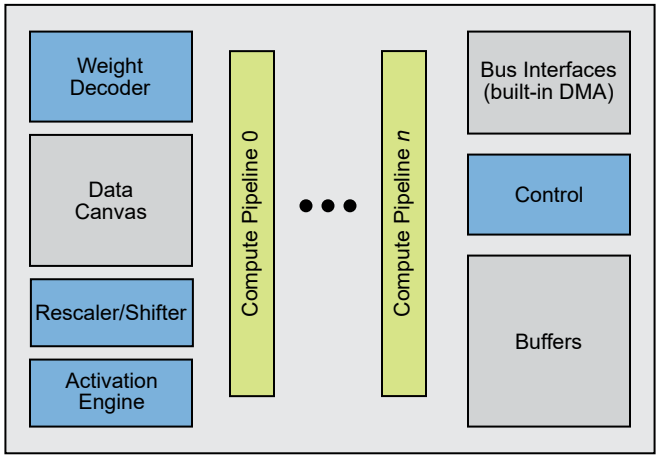

Figure 166. eIQ Neutron NPU architecture

Table 426.

Component	Description
Activation Engine	Provides activation functions. See the list of supported activation functions.
Buffers	Data buffers for pipeline input data and MAC results.
Bus Interfaces	Provide Interconnect fabric designed for efficient data transfer between memories and compute blocks.
Control	Provides control and status functions.
Data Canvas	Provides 2D circular data buffer that enables data reuse among compute pipelines.
Rescaler/Shifter	Provides post-scaling of MAC compute block results. See Rescale support.
Weight Decoder	Manages decompression, if necessary, for weight fetches. See Weight decode support.

45.2.2 Features

- Performance:
  - Up to 64 MACs/cycle for 8-bit × 8-bit operations
  - Up to 32 MACs/cycle for 8-bit × 16-bit operations
  - Up to 4 MACs/cycle for 16-bit × 16-bit operations
- Supported data types:
  - Input data:
    - 8-bit unsigned asymmetric
    - 8-bit signed asymmetric
    - 8-bit signed symmetric
    - 16-bit signed symmetric
    - 16-bit unsigned symmetric
  - Weights:

    - 8-bit signed symmetric
    - 8-bit unsigned symmetric
    - 16-bit signed/unsigned (only for fully connected operator element-wise multiplication)
  - Arithmetic operations:
    - 8-bit data × 8-bit weight
    - 16-bit data × 8-bit weight (at 1/2 peak performance of pure 8-bit)
    - 16-bit data × 16-bit weight (at 1/16 peak performance of pure 16-bit)
  - Activation × Activation (transformers, for example):
    - 8-bit symmetric × 8-bit symmetric (signed or unsigned)
    - symmetric or asymmetric weights and data for 8bit dynamic tensors
  - Bias:
    - Custom FP16 format (1-bit sign, 5-bit up-shift, 10 bits significant value)
  - Results:
    - 32-bit symmetric signed
    - 16-bit symmetric signed/unsigned
    - 8-bit symmetric/asymmetric signed/unsigned
- Supported operators: see Operator summary.
- Custom activation function f(x). Implement through Activate Function Interpolator (piece-wise polynomial interpolator):
  - Implement TFLite operators: RSQRT, EXP (for x>0), SWISH, ABS, and so on.
  - Cannot be fused with convolutions, except for fully connected and 16 × 16
  - Trade-off in accuracy versus speed and memory size (more information below)
- Constraints for Spatial Compute (Convolution, for example):
  - Padding. Individually selectable for Top/Bottom/Left/Right; maximum padding is 31 pixels.
  - Stride. Up to 31 pixels (horizontal and vertical).
  - Dilation. Up to 31 pixels (horizontal and vertical).
  - Kernel size. Maximum weight matrix row length = 64 k.
  - Kernel height. Maximum = 64 pixels (Includes pixels skipped due to dilation).
  - Kernel width. Maximum = 63 pixels (Includes pixels skipped due to dilation).

NOTE

Larger kernel-shapes, strides, and so on, can be achieved through cascading multiple layers.

- Accumulation support:

  eIQ Neutron N3-64 NPU uses a 32-bit accumulation scheme, which prevents saturation—even in large neural networks—for 8-bit × 8-bit computations.

  For 8-bit × 16-bit computations, eIQ Neutron NPU offers an accumulator downshift, configurable to 0, 4, 8, or 12 bits. This enables the data to keep sufficient precision with the tradeoff of losing some of the lower bits, to avoid saturation of the accumulator.
- Weight decode support:
  - 8-bit weights direct (no decode)
  - 16-bit weights direct (no decode)

- Mini-weights (<8 bits) through sign extension
- Mini-weights (≤6 bits). Weights are translated using a codebook. You can use weight clustering to have fewer used 8-bit values and then encode the chosen values by using an index table. NPU uses the weights as indices to select appropriate 8-bit values as the weights are loaded into compute.

- Rescale support:

  Rescales 32-bit accumulator results.

  - In a typical case in which the quantizer can rely on the integer precision dynamic range to perform the ReLU clipping and max value clipping, this function scales values to the desired 8-bit or 16-bit output directly.
  - Rescaling is also used to scale the accumulator result so it can be presented as 16-bit data to NPU's Activation Engine.

  The general form of the rescaling stage is:

```
Output = Round((accumulator × scaleFactor)>>downshiftFactor)
```

  eIQ Neutron N3-64 NPU supports the following rescaling schemes:

  - 32-bit rescale factor: 16-bit scaler, 6-bit downshift factor
  - 16-bit rescale factor: 10-bit scaler, 6-bit downshift factor
  - FP32 rescale factors

- Activation Engine:

  eIQ Neutron N3-64 NPU provides built-in activation functions and a hardware engine to perform activation. The Activation Engine works on 16-bit signed data produced by rescaling.

  The activation functions are executed “in-pipeline” together with the computation preceding it. No extra cycles are consumed and there is no need for spilling higher precision data into memory than the activated data size.

  Activation engine accuracy is 8-bit precision, except for ReLU, which essentially has no modification to values, and exp(x), which is output as 16-bit data.

  The supported built-in activation functions are:

  - 8-bit:
    - ReLU
    - ReLUx
    - Sigmoid
    - Tanh
    - LeakyReLU (limited to Alpha = 0.25, 0.125, and 0.0625)
  - 16-bit:
    - ReLU
    - ReLUx
    - LeakyReLU (8-bit precision for scaling LeakyReLU data)
    - exp(x) (For negative input values—this function is only valid for Softmax calculations)

  The second activation method is the use of the Activation Function Interpolator, which enables you to program your own custom activation functions.

  eIQ Neutron NPU supports first, second, third, and fourth order polynomial-based interpolation, enabling you to configure your own custom activation function, or to create an application-specific version of any activation function.

  This feature is controlled by a table that contains the desired number of segments (minimum is 16, maximum is 32k). For each segment, you assign 16-bit signed coefficients for computing the interpolated value. The data input to the interpolator

is 16 bits. The segment coefficients determine how many of the most significant bits of the data are used to decode the polynomial segment.

The interpolator enables you to trade-off accuracy for speed and memory footprint. It can theoretically represent any function at any accuracy (up to full/bit-exact 16 bit), by increasing the number of table entries and/or the interpolation order.

Note that an interpolator-based implementation of a function has a maximum throughput of at most 1 result every *n+1* cycles, where *n* is the maximum order of the used polynomial fit. In contrast, the built-in activations functions provide up to 8 results per cycle and are therefore much faster.

SoftMax	SOFTMAX	8	8	• Constraint: Only on 8-bit accuracy • Reciprocal of sum of e^x offloaded to CPU
Split Tensor	SPLIT, SPLIT_V	8, 16	8, 16	
Squeeze Tensor	SQUEEZE	N/A	N/A	Operation is not performed by NPU hardware
Strided Slice	STRIDED_SLICE	8, 16	8, 16	
Subtract Tensor-Tensor	SUB	8, 16	8, 16	• Includes scaling to match quantization scales • 8-bit data × 8-bit weight • 16-bit data × 8-bit weight
Subtract Tensor-Constant	SUB	8, 16	8, 16	• Includes scaling to match quantization scales • 8-bit data × 8-bit weight • 16-bit data × 8-bit weight
Tanh / hyperbolic tangent function	TANH	8, 16	8	As fused activation or TFLite operator TANH
Transpose Convolution 2D	TRANSPOSE_CONV	8, 16	8, 16	Includes possibility of upsampling input (zero-filled) before operation
Unidirectional LSTM	UNIDIRECTIONAL_SEQUENCE_LSTM	8, 16	8, 16	
Unpack Tensor	UNPACK	N/A	N/A	No operation is performed by NPU hardware

1. Some of the operators in listed in this table may not be enabled in eIQ software. See References for links to eIQ documentation that lists the operators enabled in the latest eIQ software.
2. Inputs are always 8- or 16-bit.
3. Output can be 8-,16-, or 32-bit. Note that this is a format—it does not imply 32-bit precision, but output can be generated in int32 format with whatever data is generated. This can be useful if you want to run, for example, a convolution with the intent of running activation outside of Neutron. It is also sometimes useful to export results as 16-bit data to have symmetric data instead of 8-bit asymmetric data.

45.3.2 Clocking

This module has no clocking considerations.

45.3.3 Interrupts

This module has no interrupts.

46.1.2 EZH-V related registers in SYSCON

You can use SYSCON registers to configure the following EZH-V features.

Table 430. EZH-V related registers in SYSCON

Registers	Descriptions
SYSCON4.EZHV_MEM_CTRL	Configures input and power gating for EZH-V memory.
SYSCON4.EZHV2ARM_INT_EN	Controls EZH-V to Arm interrupts.
SYSCON4.EZHV2ARM_INT_CHAN	indicates EZH-V interrupt channel.
SYSCON4.ARM2EZHV_INT_CTRL	Controls Arm To EZH-V interrupts.
SYSCON4.EZHV_RSTBASE	Allows system integrators to be able to specify and relocate the base address of the reset exception handler. These inputs are used to form the upper 30 bits of the instruction access following negation of reset which is used to fetch the initial instruction of the reset exception handler.
SYSCON4.EZHV_RSTMTVEC	Allows system integrators to be able to specify and relocate the base address of the exception vector table at reset. These inputs are used to initialize MTVEC on reset to a value appropriate for the system in order to support certain exceptions which could occur prior to software being able to configure the MTVEC register.
SYSCON4.EZHV_RSTSTVEC	Allows system integrators to be able to specify and relocate the base address of the exception vector table at reset. These inputs are used to initialize STVEC on reset to a value appropriate for the system in order to support certain exceptions which could occur prior to software being able to configure the STVEC register.

Table continues on the next page...

Table 430. EZH-V related registers in SYSCON (continued)

Registers	Descriptions
SYSCON4.EZHV_VOFFSET_T	Provides a vector offset to be used when exception processing begins for an incoming interrupt request.

46.2 Introduction

The EZH-V is primarily implemented to provide a “smart DMA” engine for post-processing graphics data assembled by either or both the GPU and CPU, and then passing it to the FLEXIO or MIPI DSI for output. Processing operations may include data packing and endianness adjustment. The EZH-V is available for any other general-purpose handling that may be required and supports an extensive selection of trigger inputs from GPIOs and most on-chip peripherals.

The EZH-V is a 4-stage little-endian single-issue 32-bit RISC-V Zen-V core. The ISA of EZH-V was extended to support multiple additional instructions that provide hardware multiply and divide capability, improved code density, a separate address space of Control and Status registers, and additional instructions for floating point embedded numerics and bit manipulation that are not part of the standard RISC-V ISA.

46.3 Features

The EZH-V supports the following instructions:

- Full support for RV32I Base Integer Instruction Set
- Full support for RV32C Standard Extension for Compressed Instructions
- Full support for RV32M Integer Multiplication and Division Instruction Set Extension
- Specific extensions
  - Zicsr, which supports 4096 control and status registers (CSR), as well as instructions to atomically read-modify-write a single CSR
  - Zfinx, which provides for support real-time single-precision floating-point embedded numerics operations using the general-purpose registers.
  - Zbb, which enables bit manipulation to enable code size reduction, performance improvement, and energy reduction.

With the assistance of the EZH-V, the Cortex-M33 cores can be freed to perform other tasks. While the EZH-V is executing the assigned task, the CM33 cores can execute other tasks in parallel.

46.4 Block diagram

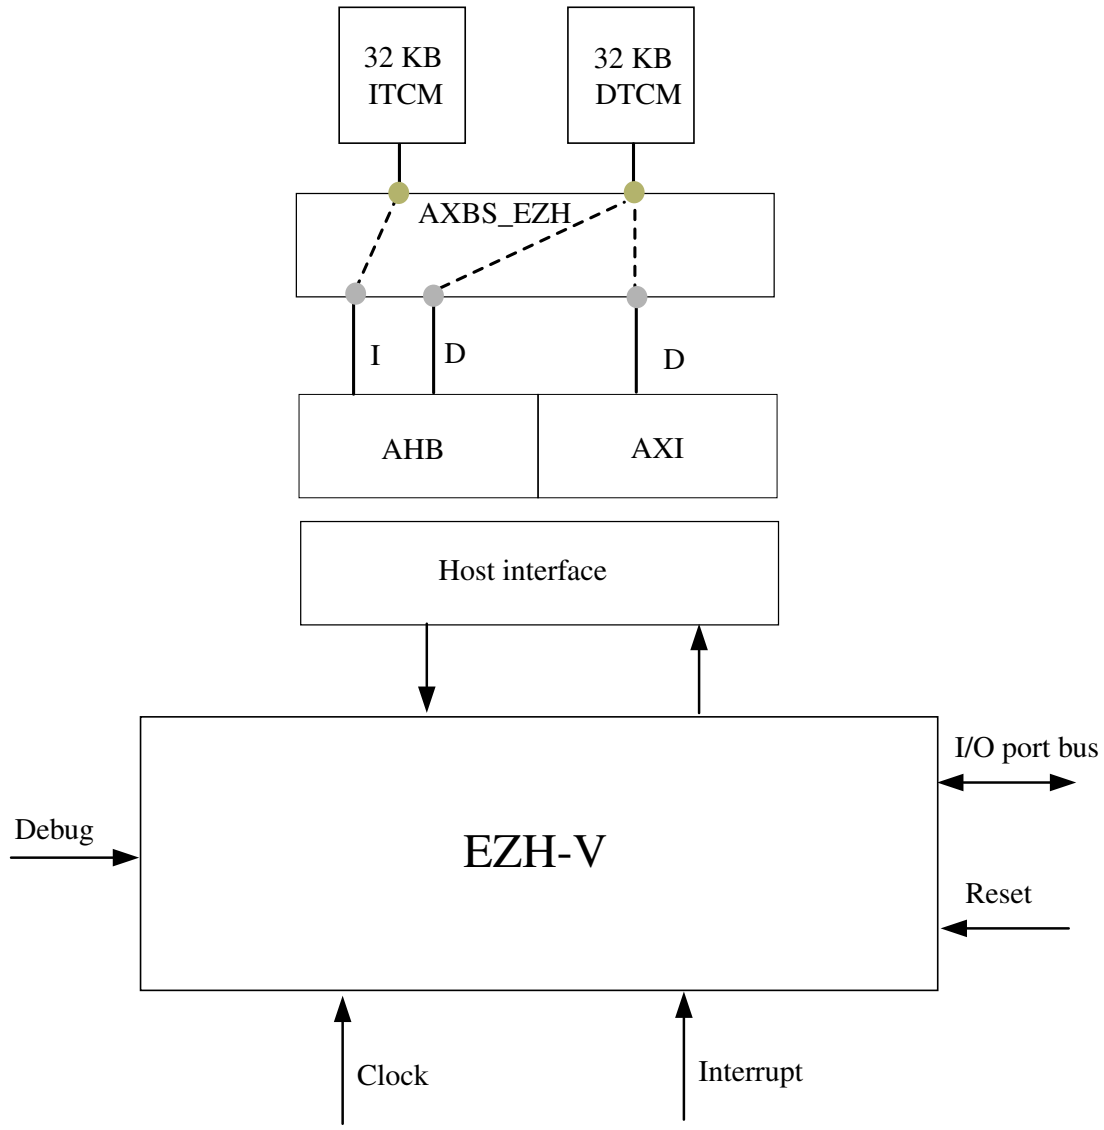

Figure 167. EZH-V block diagram

46.5 Functional description

46.5.1 Host and memory interface

The EZH-V has two dedicated Tightly Coupled Memories (TCM):

- 32 KB Instruction TCM
- 32 KB Data TCM

It also has three bus interfaces:

- Single 32-bit AHB system interface that provides connections to peripherals, DTCM, ITCM, system memory
- Single 64-bit AXI system interface that provides connections to peripherals, DTCM, and system memory
- I/O port bus interfacing to the GPIO

46.5.2 Clocking

The EZH-V employs a simple clocking scheme. It is derived from the system bus clock, media_main_clk.

46.5.3 Interrupts

EZH-V interrupts are available for CPU0 and CPU1 along with the HiFi4 DSP via the INPUTMUX. Additionally, this IP can also wake CPU0 and CPU1 from Deep Sleep mode.

46.5.4 Reset

This module can be reset via a domain reset (warm/cold) or software reset.

46.5.5 External signals

The GPIO port bus consists of up to 28 external signals associated with the EZH-V: 28 input/output signals, EZH_PIOn.

46.5.6 Debug

This EZH-V supports standard SWD/JTAG debug port.

47.2 Overview

JPEGDEC is one of the submodule in JPGDECWRAP. In addition to decoding standard-compliant baseline and extended JPEG streams, JPEGDEC can decompress the video payload of many standard motion JPEG container formats.

NOTE

This Chapter is only feature specification. See Chapter JPGDECWRAP for more usage reference.

47.2.1 Block diagram

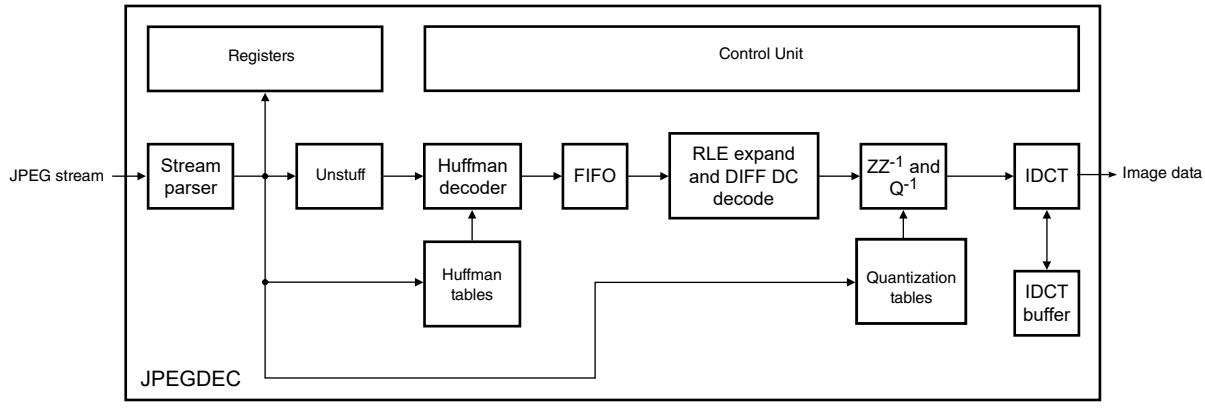

Figure 168. Block diagram

47.3 Functional description

47.3.1 Architectural overview

JPEGDEC is fully self-configured by parsing the marker segments present in the input JPEG stream.

JPEGDEC receives the JPEG stream via its JPEG_In interface. It checks input JPEG marker segments against a subset of possible errors and signals when an error is detected. You can configure the decoded image parameters to control other system peripherals, such as a block-to-raster scan converter.

JPEGDEC decodes one or more entropy-coded data segments after parsing the marker segments. Then, it outputs the decoded image samples in their native Minimum coded unit (MCU) block scan order via its Pixel-Out interface.

A single control register can control JPEGDEC, which you can access via the control interface.

47.3.2 Clocking

All JPEGDEC input and output ports operate synchronously to the input clock, except for the RST input port, which is an asynchronous reset line.

The RST asynchronous reset line drives all registers using the clock. All inputs are sampled only on the rising edge of the clock. All outputs are updated only on the rising edge of the clock.

47.3.3 Reset

JPEGDEC uses a common RST, which can be asserted at any time, but must be deasserted in synchronization with the clock.

47.3.4 Interrupts

This module has no interrupts.

47.4 External signals

This module has no external signals.

47.5 Initialization

CLK, CLR, RST, and ENABLE signals will be initialized by the JPEG decoder wrapper module.

47.6 Memory map and register definition

For JPEGDEC register information, see "JPEGDEC register descriptions" in JPEG Decoder Wrapper (JPGDECWRP) chapter.

48.1.1 Module instances

This device contains one instance of the JPGDECWRP module.

Table 434. JPGDECWRP instance

Features	JPGDECWRP
Located in	VDD2_MEDIA
Access	CPU0, CPU1, HiFi4, HiFi1, eDMA0, eDMA1, eDMA2, eDMA3

48.2 Overview

JPGDECWRP is a high-performance JPEG decoder for still image and video decompression applications. It supports 230 MSamples/S for decode with 230 MHz clock. JPGDECWRP has DMA channels for bit stream fetching and decoded pixel data storing, as well as a register interface and chained descriptors for frame or bit stream buffer switching.

48.2.1 Block diagram

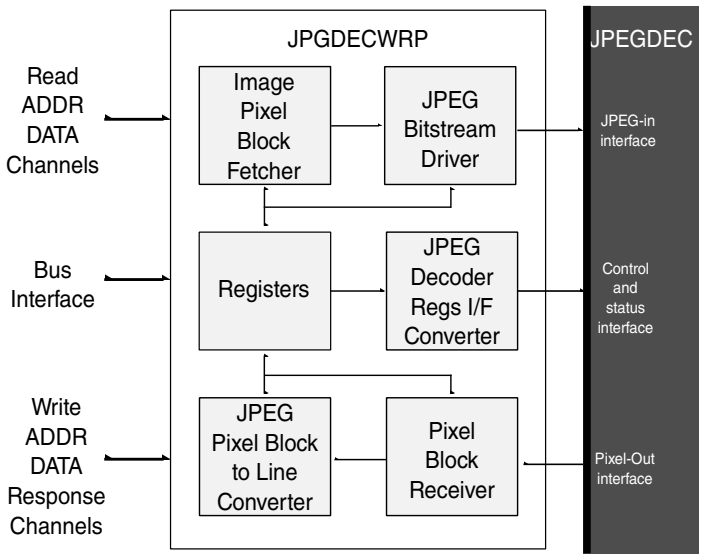

Figure 169. Block diagram

48.2.2 Features

- Baseline and extended ISO/IEC 10918-1 JPEG compliance[2]:
  - Four Huffman tables (2 DC and 2 AC coefficients tables at maximum)
  - Four 8-bit or 16-bit quantization tables (at maximum)
  - Single scan configuration and all possible JPEG formats for input data
  - Restart markers[3]
- DMA engines for fetching the JPEG bit stream from system memory and feeding it to the decoder
- DMA engines for storing the decoded pixel data into the system memory
- Conversion of the pixel MBT format to linear format
- Multi-bit-stream context switch based on frame
- Chained DMA or bit stream descriptors for frame or bit stream buffer updates with minimum software interference
- Bit stream buffer, half or full, and return features for bit stream buffer management
- YUV444, YUV420, YUV422, RGB, ARGB, and Gray formats are supported at the maximum resolution of 8k * 8k. As for minimum resolution,
  - YUV422: larger or equal to 64 * 32 (width is a multiple of 16, height is a multiple of 8).
  - YUV420: larger or equal to 64 * 64 (both width and height are a multiple of 16).
  - YUV444, RGB, ARGB, and GRAY: larger or equal to 32 * 32 (both width and height are a multiple of 8).
- 8-bit and 12-bit pixels precision

[2] See Limitations related to the ISO/IEC 10918-1 JPEG standard for limitations associated with the ISO/IEC 10918-1 JPEG standard.

[3] JPEGDEC supports decoding of noncorrupted JPEG bit streams with or without restart segments and does not support decoding of corrupted bit streams with or without restart segments.

48.3 Functional description

48.3.1 Modes and operations

Table 435 lists modes of operation.

Table 435. Modes of operation

Mode	Description	Section
Single Bit Stream and Single Frame	Decoding stops at each frame.	Single Bit Stream and Single Frame mode
Single Bit Stream Repeat	Decoding gets a new frame buffer address from the descriptor and continues.	Single Bit Stream Repeat mode
Context Switch	Switches to new bit stream or frame buffer after the current frame or bit stream decoding is completed on a frame basis. The descriptor defines a new bit stream or frame and supports up to four bit streams.	Context Switch mode

For each mode, perform the following procedures at first:

1. write 0 to CTRL[LP] and CTRL[SWR], and write 1 to CTRL[GO].

Then, follow the operation procedures of each mode.

48.3.1.1 Single Bit Stream and Single Frame mode

If SLOT*n*_NXT_DESCPT_PTR[NXT_DESCPT_EN] is 0, the wrapper is in Single Bit Stream and Single Frame mode. To start decoding, write 1 to GLB_CTRL[DEC_GO]. After the decoding of each frame is completed, the decoding pauses until you write 1 to GLB_CTRL[DEC_GO].

48.3.1.2 Single Bit Stream Repeat mode

If SLOT*n*_NXT_DESCPT_PTR[NXT_DESCPT_EN] is 1, and if GLB_CTRL[SLOT_EN] enables only one slot, JPGDECWRP works in Single Bit Stream Repeat mode. It completes the current frame decoding, then fetches the next frame buffer address from the location that the descriptor pointer defines. In this mode, the bit stream remains the same.

48.3.1.3 Context Switch mode

If SLOT*n*_NXT_DESCPT_PTR[NXT_DESCPT_EN] is 1, and if GLB_CTRL[SLOT_EN] enables more than one slot, JPGDECWRP is in Content Switch mode. It completes the current frame decoding, then fetches the next frame buffer address from the location that the descriptor pointer defines, as well as the bit stream buffer for the next bit stream. When switching, the current bit stream buffer pointer is saved and restored when the current bit stream is switched back.

In this mode, each bit stream is assigned with one bit stream ID and up to four bit streams are supported. Each bit stream context has its own interrupt and status register, and occupies one 64 KB slot.

48.3.2 Limitations related to the ISO/IEC 10918-1 JPEG standard

- Up to four image components are supported: component identifiers 0 to 3 or 1 to 4.
- Sampling factors three or above four are not supported.
- Up to four (two DC and two AC) Huffman tables are supported.
- RST markers decoding support is available:

— No corrupted, valid streams without restart markers: Yes

— No corrupted, valid streams with restart markers: Yes

— Corrupted, invalid streams without restart markers: No

— Corrupted, invalid streams with restart markers: No

48.3.3 Clocking

JPGDECWRP uses two clocks: main (global) clock and APB bus clock.

Table 436. Clock signal

Clock signal	Description
Global clock (clk)	It aligns with the "jpeg_clk" of System clocks in this chip.
APB bus clock (pclk)	Controls the access to the registers of the JPGDECWRP module.

48.3.4 Interrupts

Each slot has its interrupt status or enable registers. See JPGDECWRP register descriptions for a detailed description of these registers.

48.3.5 Reset

JPGDECWRP uses a common reset, which can be asserted at any time, but must be deasserted in synchronization with the clock. It also has software resets. You can do software reset by setting GLB_CTRL[SFTRST] and CTRL[SWR] independently.

48.4 External signals

JPGDECWRP does not have any chip external interfaces. All its interface are chip internal AXI bus, APB interface, and interrupts.

48.5 Initialization

To initialize JPGDECWRP:

1. Resets JPGDECWRP.
2. Enables clock.
3. Configures registers (see Mode and operation for more details).
4. Writes 1 to GLB_CTRL[JPG_DEC_EN].

48.6 Memory map and register descriptions

48.6.1 JPGDECWRP register descriptions

Decoding descriptors define the bit stream buffer location, output frame buffer locations, image format, and so on. JPGDECWRP supports context switching on a frame basis, which means you can load those registers from the memory that the Next Decoding Descriptor Pointer (Next Descriptors (SLOT0_NXT_DESCPT_PTR - SLOT3_NXT_DESCPT_PTR)) points to. NXT_DEC_DESCPT can support up to 4 bitstream context switching or single-bit-stream decoding with different output buffer switching on a frame-based interval.

48.6.1.1 JPGDECWRP memory map

JPGDECWRP base address: 400A_6000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Global Control (GLB_CTRL)	32	RW	0000_0000h
4h	Common Status (COM_STATUS)	32	R	0000_0000h
14h	Output Image Frame Buffer0 Base Address (OUT_BUF_BASE0)	32	RW	0000_0000h
18h	Output Image Frame Buffer1 Base Address (OUT_BUF_BASE1)	32	RW	0000_0000h

48.6.1.2 Global Control (GLB_CTRL)

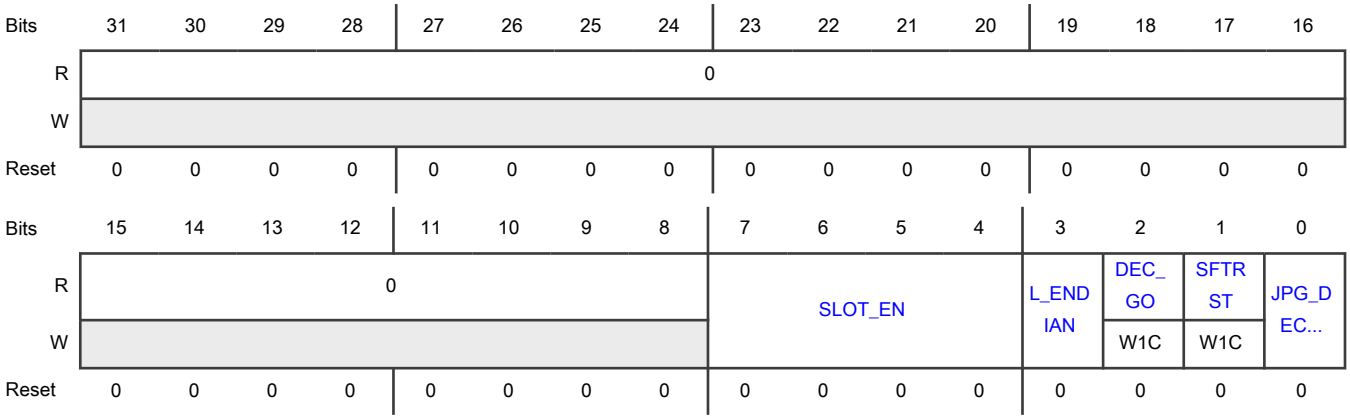
Offset

Register	Offset
GLB_CTRL	0h

Function

Provides control fields for JPGDECWRP.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-4 SLOT_EN	Slots Enable Enables specific bit stream slots for switching on a frame basis. Each bit of this field corresponds to one slot. When this slot is enabled, JPGDECWRP includes the descriptor of this slot for context switching rotation. You must first enable one slot and then update SLOT*n*_NXT_DESCPT_PTR[NXT_DESCPT_PTR] for this slot. If no valid NXT_DESCPT_PTR is available for an enabled slot, JPGDECWRP does not add this slot to the switching rotation. 0000b - Disables all slots. 0001b - Enables SLOT0. 0010b - Enables SLOT1. 0100b - Enables SLOT2. 1000b - Enables SLOT3. All other values are reserved.
3	Little-Endian Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
L_ENDIAN	Enables the little-endian bit stream format. The default bit stream format is big endian. 0b - Big-Endian 1b - Little-Endian
2 DEC_GO	Start Decoding Starts decoding on a frame basis. The decoding process stops after the frame decoding is complete, if there are no other valid descriptors available. This field becomes 0 automatically. There are two ways to start decoding: • Configure all the common registers and write 1 to this field to manually start the decoding. • Enable one slot and then write to Next Descriptors (SLOT0_NXT_DESCPT_PTR - SLOT3_NXT_DESCPT_PTR) with SLOT*n*_NXT_DESCPT_PTR[NXT_DESCPT_EN] = 1. You can use only manually-started decoding — and no other method — for debug purposes. 0b - Do not start decoding manually. 1b - Starts decoding manually.
1 SFTRST	Engine Soft Reset Resets internal engines and state machines in the submodule JPEG Decoder Wrapper. This soft reset does not reset register bits. This field becomes 0 automatically. 0b - No effect 1b - Performs a soft reset.
0 JPG_DEC_EN	JPEGDEC and JPGDECWRP Enable Enables JPEGDEC and JPGDECWRP simultaneously. 0b - Disable 1b - Enable

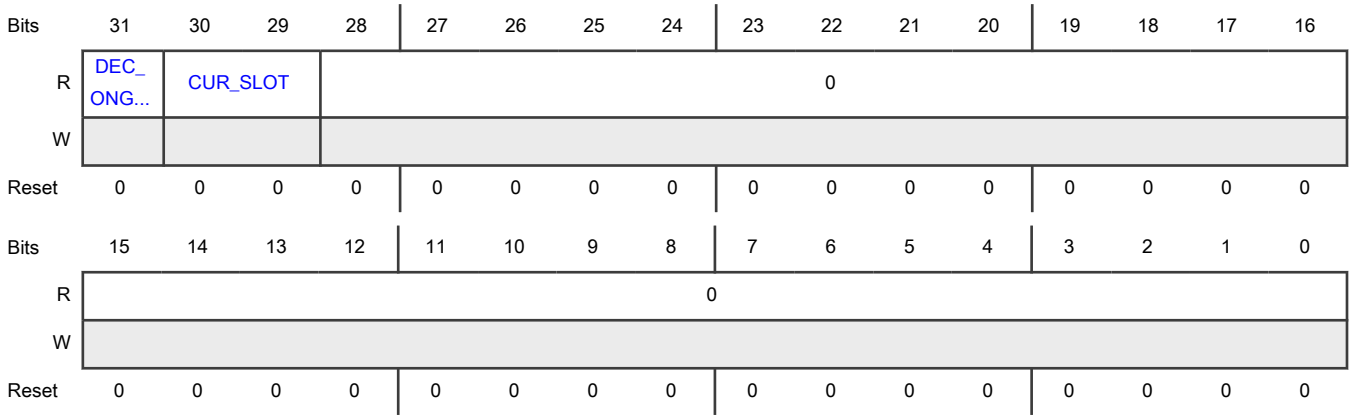
48.6.1.3 Common Status (COM_STATUS)

Offset

Register	Offset
COM_STATUS	4h

Function
Indicates the status of JPGDECWRP.

Diagram



Fields

Field	Function
31 DEC_ONGOING	Decoding Ongoing Indicates whether the decoding is ongoing. Decoding is paused or stopped usually after the decoding of one frame is completed. This field becomes 0 in the following cases: • During the slot switching or descriptor loading, when there is no bit stream for decoding • If there are no other valid descriptors on all enabled slots
30-29 CUR_SLOT	Current Slot Indicates the 2-bit ID of the current executing bit stream slot. This field becomes 0 if no slot is enabled.
28-0 —	Reserved

48.6.1.4 Output Image Frame Buffer0 Base Address (OUT_BUF_BASE0)

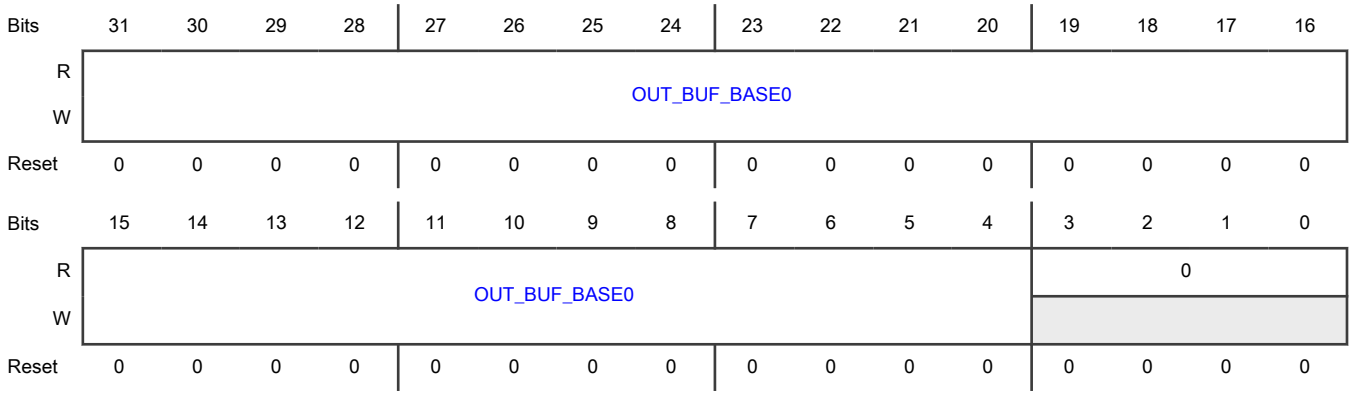
Offset

Register	Offset
OUT_BUF_BASE0	14h

Function

Specifies the base address for output frame buffer0. This register points to the beginning of the output image frame buffer. After the decoding of a frame is complete and the image is output to the memory, you can update this base address to switch to a new frame buffer, which needs to be 16-byte aligned so that the four LSBs are always zero. In context switching during frame interval, the descriptor (NXT_DESCPT_PTR[4h]) loads this register.

Diagram



Fields

Field	Function
31-4 OUT_BUF_BASE0	Pixel Frame Buffer0 Base Specifies the output buffer0 base address. For images in the YUV444, RGB/ARGB, YUV422, and Gray formats, the decoded image pixel is in Interleave mode and stored on the frame buffer starting from this field. For the images in the YUV420 format, the first planner is the Y component and is stored in the frame buffer that this field defines.
3-0 —	Reserved

48.6.1.5 Output Image Frame Buffer1 Base Address (OUT_BUF_BASE1)

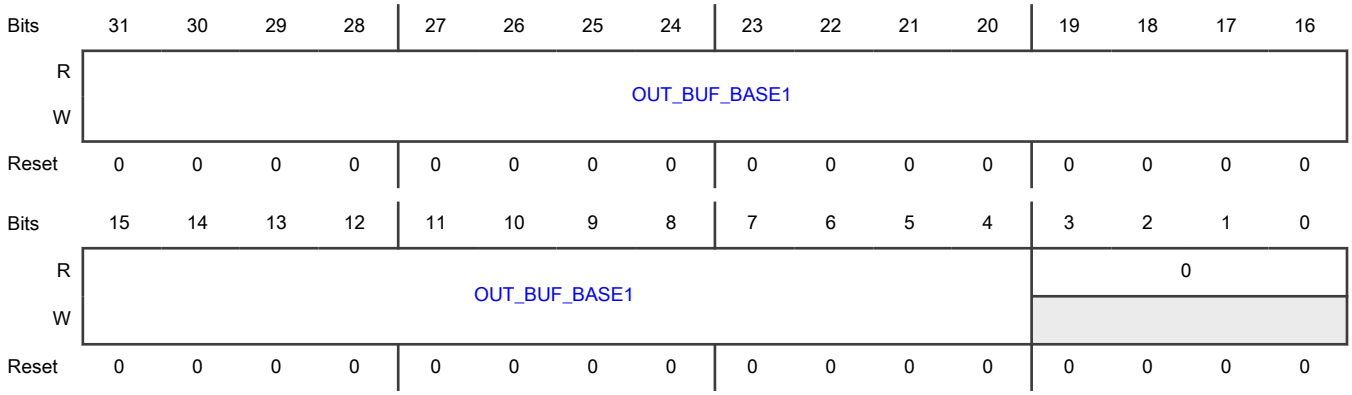
Offset

Register	Offset
OUT_BUF_BASE1	18h

Function

Specifies the base address for output frame buffer1. This register points to the beginning of the second planner output frame buffer. It is only enabled for images in the YUV420 format, and the second planner is UV interleaved. UV components are stored in the frame buffer that this register defines. The first planar for YUV420 is YY and is stored in frame buffer0. After one frame of image decoding is complete, and the image is output to the memory, you can update the base address when the wrapper is fetching the descriptor from memory. In context switching during frame interval, the descriptor (NXT_DESCPT_PTR[8h]) loads this register.

Diagram



Fields

Field	Function
31-4 OUT_BUF_BASE1	Pixel Frame Buffer1 Base Specifies the output buffer1 base address. It is only enabled for images in the YUV420 format, and is used to store the second planner (UV) component.
3-0 —	Reserved

48.6.1.6 Image Output Buffer Pitch (OUT_PITCH)

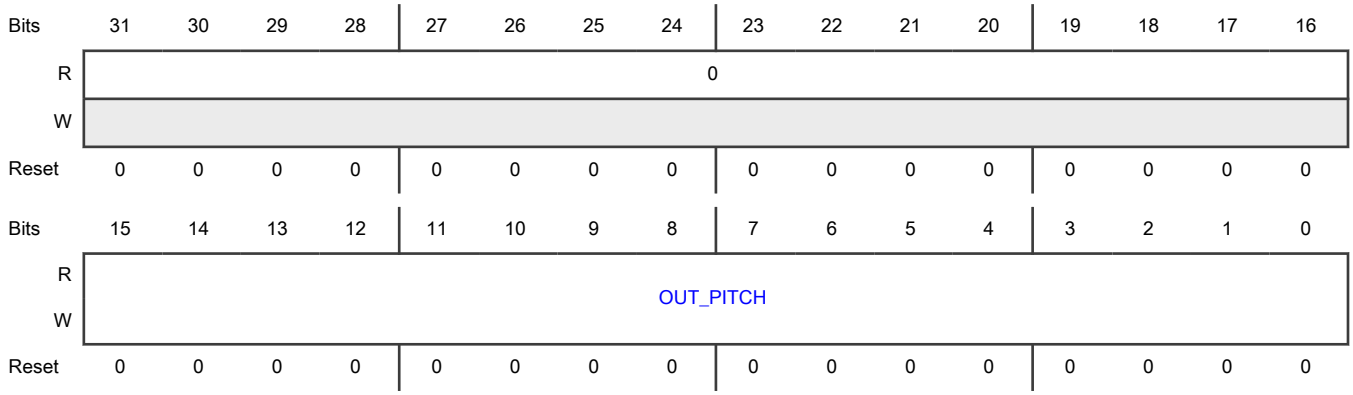
Offset

Register	Offset
OUT_PITCH	1Ch

Function

Specifies the vertical pixel distance, in bytes, of the image in memory (in the frame buffer). Any byte value indicates the vertical pitch, which is used for output pixel address calculation. For YUV420, the image is in a 2-planar format. The line pitch is applied to both planar. In context switching during the frame interval, the descriptor (NXT_DESCPT_PTR[Ch]) loads this register.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 OUT_PITCH	Output Image Pitch Specifies the vertical pixel distance, in bytes, of the image in memory.

48.6.1.7 Input JPEG Stream Buffer Base Address (STM_BUFBASE)

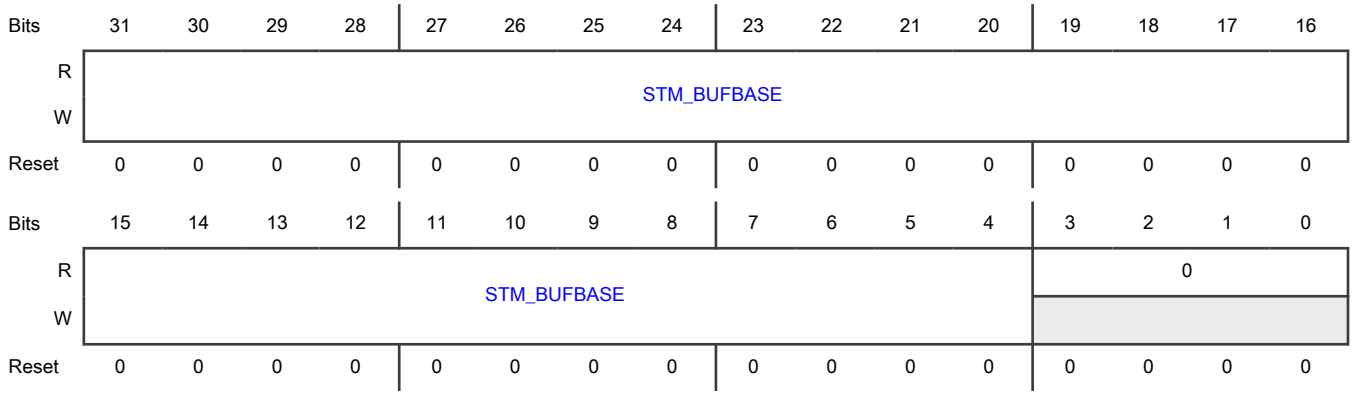
Offset

Register	Offset
STM_BUFBASE	20h

Function

Defines the base address of the stream buffer for decoding. The memory must have a 64K boundary so that the lower 4 bits of this register are always zero. Each slot has one bit stream buffer and one bit stream buffer pointer. The bit stream buffer pointer keeps tracking from where the slot is switched out and when this slot is switched in again. The decoding also continues from this bit stream buffer pointer for this slot. In context switching during frame interval, the register (NXT_DESCPT_PTR[10h]) loads this register.

Diagram



Fields

Field	Function
31-4 STM_BUFBASE	Bit Stream Buffer Base Specifies the base address of the stream buffer.
3-0 —	Reserved

48.6.1.8 Input JPEG Stream Buffer Size (STM_BUFSIZE)

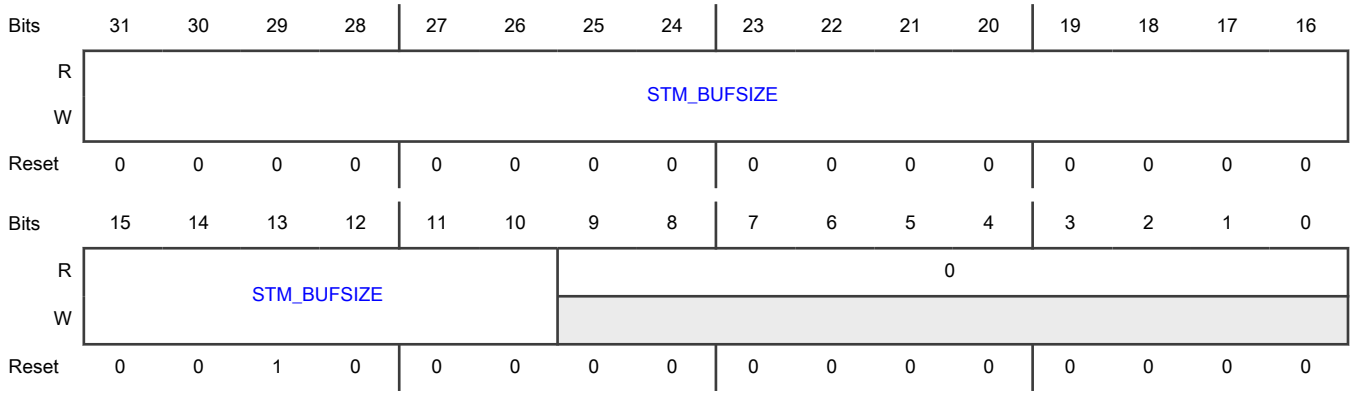
Offset

Register	Offset
STM_BUFSIZE	24h

Function

Defines the size of the stream buffer. JPGDECWRP can generate an interrupt when the stream buffer pointer reaches half the size of the buffer, or wraps around the buffer. So, the buffer works like double-bit-stream buffer mode. In context switching during frame interval, the descriptor (NXT_DESCPT_PTR[14h]) loads this register.

Diagram



Fields

Field	Function
31-10 STM_BUFSIZE	Bit Stream Buffer Size Specifies the stream buffer size. It has to be integer times of 1 KB.
9-0 —	Reserved

48.6.1.9 Image Resolution (IMGSIZE)

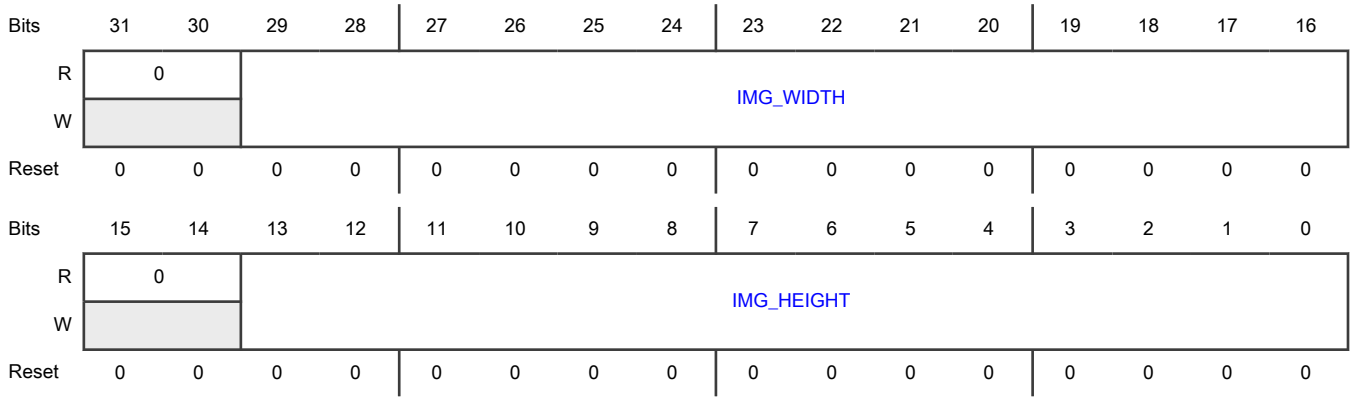
Offset

Register	Offset
IMGSIZE	28h

Function

Defines the resolution of the image to be decoded. In context switching during frame interval, the descriptor (NXT_DESCPT_PTR[18h]) loads this register.

Diagram



Fields

Field	Function
31-30 —	Reserved
29-16 IMG_WIDTH	Image Width Specifies image width resolution in pixel unit. The maximum horizontal resolution supported is 8K (2000h). The horizontal resolution must be integer times of 8.
15-14 —	Reserved
13-0 IMG_HEIGHT	Image Height Specifies image height resolution in pixel unit. The maximum vertical resolution supported is 8K (2000h). The vertical resolution must be integer times of 8.

48.6.1.10 Bit Stream and Switching Control (STM_CTRL)

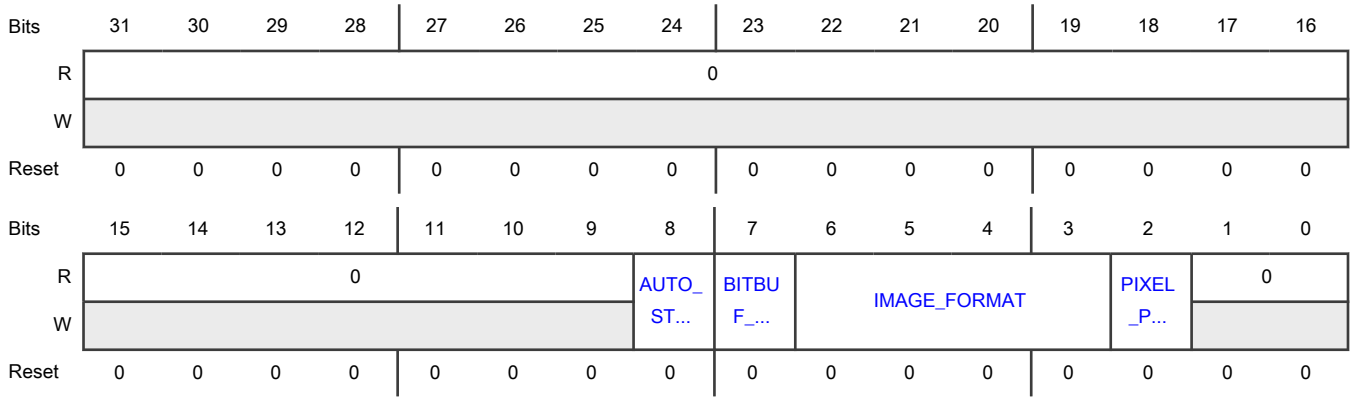
Offset

Register	Offset
STM_CTRL	2Ch

Function

Enables you to configure the current bit stream slot for decoding. In context switching during frame interval, the descriptor (NXT_DESCPT_PTR[1Ch]) loads this register.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 AUTO_START	Auto Start In some cases, JPEGDEC needs to write 1 to CTRL[GO] to start operation (configuration or decoding). Automatically writes 1 to CTRL[GO] in JPEGDEC when this field is 1 after the context is switched. 0b - Do not write 1 to CTRL[GO] in JPEGDEC. 1b - Writes 1 to CTRL[GO] in JPEGDEC.
7 BITBUF_PTR_CLR	Bit Buffer Pointer Clear Clears or restores the bit stream buffer pointer from the save pointer. If this field is 0, after context switching completion, the bit stream buffer pointer is restored to the last time when the bit stream was switched out. If this field is 1, the bit stream buffer pointer is cleared after context switching completion. 0b - Restores the bit stream buffer pointer from the save pointer. 1b - Clears the bit stream buffer pointer from the save pointer.
6-3 IMAGE_FORMAT	Image Format Specifies the color component number in the current bit stream. 0h–3h indicate the current decoding image format and its output format in memory. 0000b - YUV420 (2-planar, Y at the first planar, and UV at the second planar) 0001b - YUV422 (1-planar in the YUYV sequence) 0010b - RGB (BGRBGR packed format) 0011b - YUV444 (first planar in the YUVYUV sequence) 0100b - Gray (Y8 or Y12) or single component 0101b - Reserved 0110b - ARGB
2 PIXEL_PRECISION	Pixel Precision Specifies current decoding precision of the pixel to be decoded. 0b - 8-bit 1b - 12-bit
1-0 —	Reserved

48.6.1.11 Bit Stream Status (SLOT0_STATUS - SLOT3_STATUS)

Offset

Register	Offset
SLOT0_STATUS	200h
SLOT1_STATUS	400h
SLOT2_STATUS	600h
SLOT3_STATUS	800h

Function

Indicates bit stream slot status. Each bit stream ID has one set of status registers that only takes effect for its own bit stream or decoding operation. Each bit stream ID has its interrupt lines associated with the status register.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31 DEC_ONGOING	Decoding Ongoing Indicates whether the decoding is ongoing. The field becomes 0 if there are no more descriptors to be fetched for each slot, or when the slot is switched in frame interval. 0b - Paused or stopped 1b - Ongoing
30-29 CUR_SLOT	Current Slot Indicates the current executing bit stream slot.
28-12 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
11 PIXEL_WT_ERR	Pixel Write Error Flag Indicates whether a pixel write error happened when writing the decoded image pixel to memory. You must clear any slot errors for JPGDECWRP to continue working. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No pixel write error occurred. 1b - A pixel write error occurred. When writing 0b - No effect 1b - Clears the flag.
10 BIT_RD_ERR	Bit Read Error Flag Indicates whether a bit read error happened during bit stream fetching. You must clear any slot errors for JPGDECWRP to continue working. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No bit read error occurred. 1b - A bit read error occurred. When writing 0b - No effect 1b - Clear the flag
9 DES_RD_ERR	Descriptor Read Error Flag Indicates whether a descriptor read error happened during bit stream fetching. You must clear any slot errors for the JPGDECWRP to continue working. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No descriptor read error occurred. 1b - A descriptor read error occurred. When writing 0b - No effect 1b - Clears the flag.

Table continues on the next page...

Table continued from the previous page...

Field	Function
8 DECERR	Decoding Error Flag Indicates whether there is an error in the JPEG bit stream. You must clear any slot errors for JPGDECWRP to continue working. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No decoding error occurred. 1b - A decoding error occurred. When writing 0b - No effect 1b - Clears the flag.
7-4 —	Reserved
3 FRMDONE	Frame Done Flag Indicates whether one full frame of image is decoded and the image pixels are stored in the memory frame buffer. The wrapper switches to the next slot. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Decoding is not completed. 1b - Decoding is completed. When writing 0b - No effect 1b - Clears the flag.
2 SWITCHED_IN	Switched In Flag Indicates whether the current slot is switched in during context switching. JPGDECWRP completes fetching the descriptor and switches in to the current slot. New decoding operation immediately starts. **NOTE** This field behaves differently for register reads and writes. When reading 0b - The current slot is not switched in during context switching. 1b - The current slot is switched in during context switching. When writing

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No effect 1b - Clears the flag.
1 STMBUF_RTND	Stream Buffer Returned Flag Indicates whether the bit stream buffer for the current slot has passed the top mark of the buffer and is wrapped around to the bottom of the buffer. You can now safely refresh the higher half of the bit stream buffer. **NOTE** This field behaves differently for register reads and writes. When reading 0b - The bit stream buffer pointer for the current slot has not passed the top mark of the buffer. 1b - The bit stream buffer pointer for the current slot passed the top mark of the buffer. When writing 0b - No effect 1b - Clears the flag.
0 STMBUF_HALF	Stream Buffer Half Flag Indicates whether the bit stream buffer pointer for the current slot passed half of the buffer size. You can safely refresh the lower half of the bit stream buffer after that for decoding. **NOTE** This field behaves differently for register reads and writes. When reading 0b - The bit stream buffer pointer for the current slot has not passed half of the buffer size. 1b - The bit stream buffer pointer for the current slot passed half of the buffer size. When writing 0b - No effect 1b - Clears the flag.

48.6.1.12 Bit Stream Interrupt Enable (SLOT0_IRQ_EN - SLOT3_IRQ_EN)

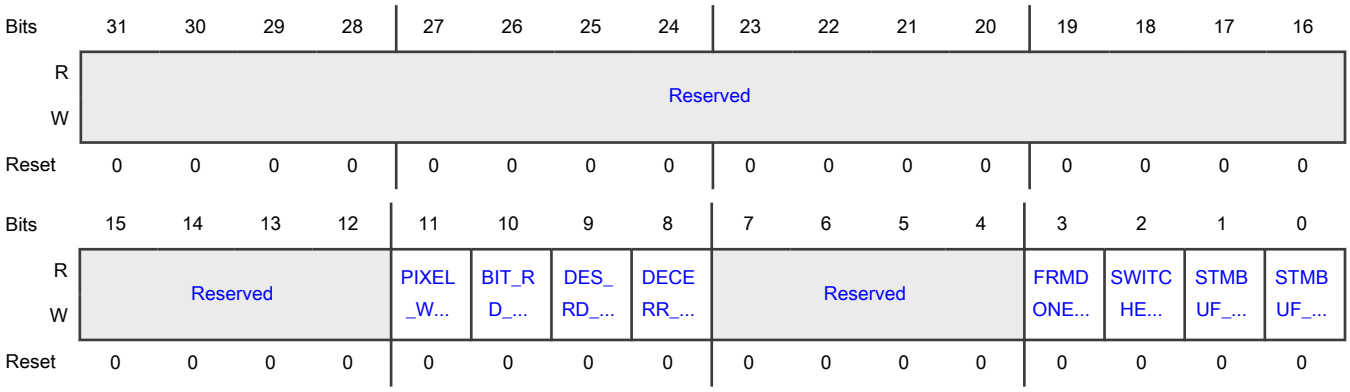
Offset

Register	Offset
SLOT0_IRQ_EN	204h
SLOT1_IRQ_EN	404h
SLOT2_IRQ_EN	604h
SLOT3_IRQ_EN	804h

Function

Enables IRQ for the bit stream context operation. Each bit stream ID has its own interrupt enable register and interrupt request.

Diagram



Fields

Field	Function
31-12 —	Reserved
11 PIXEL_WT_ERR_IRQ_EN	Pixel Write Error Interrupt Enable Enables an AXI write error interrupt for pixel storing of the current slot when SLOT0_STATUS[PIXEL_WT_ERR] = 1. 0b - Disable 1b - Enable
10 BIT_RD_ERR_IRQ_EN	Bit Read Error Interrupt Enable Enables an AXI read error interrupt for bit stream fetching of the current slot when SLOT0_STATUS[BIT_RD_ERR] = 1. 0b - Disable 1b - Enable
9 DES_RD_ERR_IRQ_EN	Descriptor Read Error Interrupt Enable Enables an AXI read error interrupt for descriptor fetching of the current slot when SLOT0_STATUS[DES_RD_ERR] = 1. 0b - Disable 1b - Enable
8 DECERR_IRQ_EN	Decoding Error Status Interrupt Enable Enables an interrupt for the current slot when a decoder error happens. 0b - Disable

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enable
7-4 —	Reserved
3 FRMDONE_IRQ_EN	Frame Done Interrupt Enable Enables an interrupt for the current bit stream after decoding is complete. 0b - Disable 1b - Enable
2 SWITCHED_IN_IRQ_EN	Switched In Interrupt Enable Enables an interrupt for the current bit stream when the current slot is switched into during context switching. 0b - Disable 1b - Enable
1 STMBUF_RTND_IRQ_EN	Stream Buffer Returned Interrupt Enable Enables an interrupt for the current slot when its bit stream buffer pointer has wrapped around from the buffer top to bottom. 0b - Disable 1b - Enable
0 STMBUF_HALF_IRQ_EN	Stream Buffer Half Interrupt Enable Enables an interrupt for the current slot when its bit stream buffer pointer has passed half the size of the buffer. 0b - Disable 1b - Enable

48.6.1.13 Bit Stream Buffer Pointer (SLOT0_BUF_PTR - SLOT3_BUF_PTR)

Offset

Register	Offset
SLOT0_BUF_PTR	208h
SLOT1_BUF_PTR	408h
SLOT2_BUF_PTR	608h
SLOT3_BUF_PTR	808h

Function

Points to the location of stream buffer for the current bit stream ID. The next frame decoding must begin with this bit stream ID. This register keeps the bit stream buffer pointer on track in context switching for each slot. When the context is switched back to one of the bit streams (identified by the bit stream ID), the decoding can continue to move forward from where it was switched. The pointer starts from the bit stream buffer base, and goes up to the upper buffer size limit, and then wraps back to the bit stream base again. You can configure JPGDECWRP to generate an interrupt when the pointer hits half the size of the buffer or top of the buffer, and wraps around to the base again. This can make the buffer work in a double buffer mode while each buffer is half of the buffer size limit. You can clear the bit stream buffer during context switching when switched to one slot, with STM_CTRL[BITBUF_PTR_CLR] in the descriptor.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	STMBUF_PTR															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	STMBUF_PTR															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 STMBUF_PTR	Stream Buffer Pointer Points to the location of the bit stream buffer that you can clear during context switching by writing 1 to STM_CTRL[BITBUF_PTR_CLR] in the descriptor. Each bit stream ID has one stream buffer pointer.

48.6.1.14 Current Descriptors (SLOT0_CUR_DESCPT_PTR - SLOT3_CUR_DESCPT_PTR)

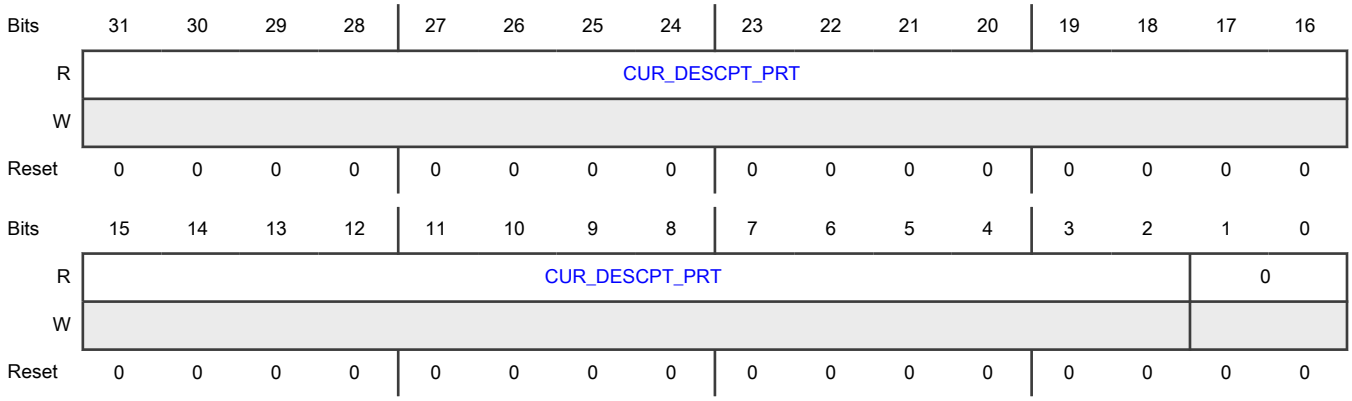
Offset

Register	Offset
SLOT0_CUR_DESCPT_PTR	20Ch
SLOT1_CUR_DESCPT_PTR	40Ch
SLOT2_CUR_DESCPT_PTR	60Ch
SLOT3_CUR_DESCPT_PTR	80Ch

Function

Indicates the address of the descriptor that has already been executed or is currently executing for the current slot.

Diagram



Fields

Field	Function
31-2 CUR_DESCPT_PRT	Current Decoding Descriptor Pointer Indicates a pointer to the current descriptor that is currently executing or has already been executed.
1-0 —	Reserved

48.6.1.15 Next Descriptors (SLOT0_NXT_DESCPT_PTR - SLOT3_NXT_DESCPT_PTR)

Offset

Register	Offset
SLOT0_NXT_DESCPT_PTR	210h
SLOT1_NXT_DESCPT_PTR	410h
SLOT2_NXT_DESCPT_PTR	610h
SLOT3_NXT_DESCPT_PTR	810h

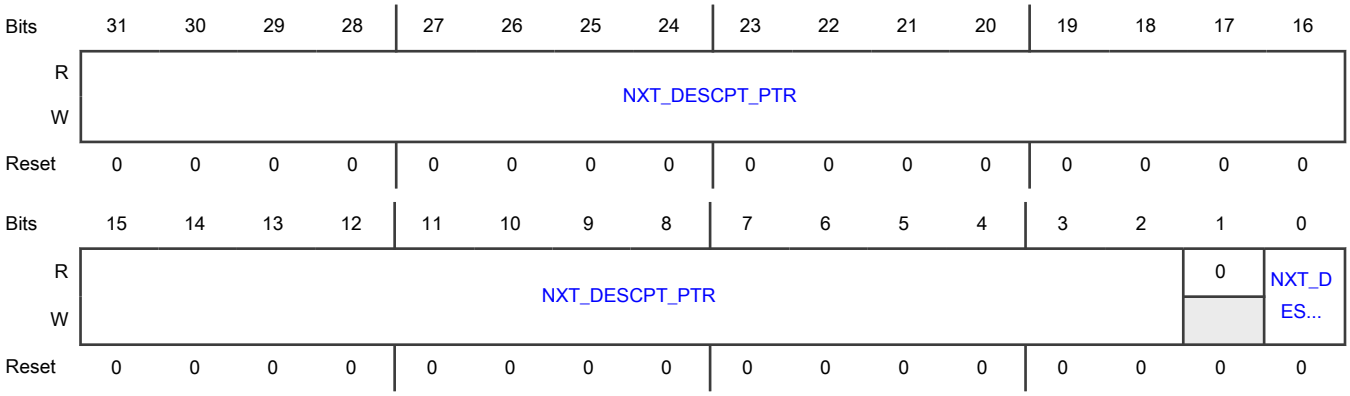
Function

Points to the base of the next decoding descriptors in the current slot. NXT_DESCPT_EN indicates whether the next descriptor is valid. If it is not, JPGDECWRP does not execute it. The current slot is excluded from rotation in decoding. When the controller of the slot gets the descriptor pointed by this register ready, it writes 1 to NXT_DESCPT_EN. If GLB_CTRL[SLOT_EN] = 1, this slot is scheduled into the execution rotation in a round-robin sequence. At the end of a frame decoding, the wrapper fetches the descriptor that this register points to. Also, the descriptor (NXT_DESCPT_PTR[0h]) loads this register. The descriptor contains eight 32-bit words:

- NXT_DESCPT_PTR[0h]: NXT_DESCPT_PTR

- NXT_DESCPT_PTR[4h]: OUT_BUF_BASE0
- NXT_DESCPT_PTR[8h]: OUT_BUF_BASE1
- NXT_DESCPT_PTR[Ch]: OUT_LINE_PITCH
- NXT_DESCPT_PTR[10h]: STM_BUFBASE
- NXT_DESCPT_PTR[14h]: STM_BUFSIZE
- NXT_DESCPT_PTR[18h]: IMGSIZE
- NXT_DESCPT_PTR[1Ch]: STM_CTRL

Diagram



Fields

Field	Function
31-2 NXT_DESCPT_PTR	Next Descriptor Pointer Contains a pointer to the next descriptor in memory. When the next descriptor is enabled for the current slot, this slot is included in context switching in a round-robin sequence. Also, when the current slot is executing, JPGDECWRP fetches the descriptor that this register points to.
1 —	Reserved
0 NXT_DESCPT_EN	Next Stream Descriptor Pointer Enable Enables the next stream descriptor pointer. If the next descriptor pointer is invalid, JPGDECWRP does not include the current slot in context switching rotation, even the current slot is set in GLB_CTRL[SLOT_EN]. After a slot if enabled in Global Control (GLB_CTRL), the slot owner can write to this register to enable the descriptor pointer, and thus the current slot is included in the context-switching rotation. If you want to pause the current slot and exclude it from the decoding rotation, then write 0 to this field. 0b - Disable 1b - Enable

48.6.2 JPEGDEC register descriptions

This section includes the JPEGDEC module memory map and detailed descriptions of all registers.

The submodule JPEG Decoder Wrapper has four slots. Only the active slot can access JPEGDEC's control register. This means, for example, you can access the jpeg_decode0 registers only when slot0 is active, and so on.

48.6.2.1 JPEGDEC memory map

JPEGDEC base address: 400A_6100h

Offset	Register	Width (In bits)	Access	Reset value
34h	Control (CTRL)	32	RW	0000_0001h

48.6.2.2 Control (CTRL)

Offset

Register	Offset
CTRL	34h

Function

Enables control for the core.

Although the Control register can be written at all times, it affects the core operation after the completion of the current decoding process. An exception to this rule is the SWR and LP bits, which affect the core operation four cycles after they have been altered. The Control Register is also mapped at address 0x0D of the status interface.

Bit 0 (LP) provides the means to force the core to enter into a low-power state, where all internal registers apart from those participating in the control register programming are frozen. Software resetting the core is feasible by setting bit 1 (SWR) to 1.

Power management	PMC	Power overview PMC

49.1.1 Module instances

This device contains one instance of the PNGDEC module.

Table 438. PNGDEC instance

Features	PNGDEC
Located in	VDD2_MEDIA
Access	CPU0, CPU1, HiFi4, HiFi1, eDMA0, eDMA1, eDMA2, eDMA3

49.2 Overview

PNGDEC decodes pictures in the PNG source format. PNGDEC includes a DMA engine.

49.2.1 Block diagram

Figure 170 shows the submodules of PNGDEC.

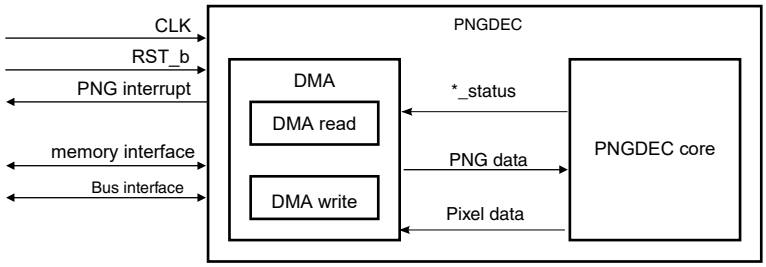

Figure 170. Block diagram

49.2.2 Features

PNGDEC has the following features:

- 64-bit AXI DMA engines used to fetch PNG bitstreams from the system memory and feed them into PNGDEC, and store decoded RGB-A raw pixel data and ancillary data

- If the image is grayscale, R, G and B will have the same value. If the image uses 16 bits per channel, R, G, and B are down converted to 8 bits by eliminating the 8 least significant bits. Finally, if the image has no transparency layer, then A is 255.
- The ancillary data consists of the PNG header followed by the ancillary chunks (except CRC) in the standard PNG format.
- Byte-order configuration
- Huffman encoded data (both static and dynamic)
- Gray scale, RGB (8- or 16-bit depth) and indexed color (8-bit depth) with and without alpha channel
- Full control through PNG header while decoding
- LZ77 sliding window with a maximum length of 32 KB
- Image with a maximum width of 1024 pixels
- Ancillary data drop

NOTE

PNGDEC does not support interlacing, uncompressed data chunks, or bit depths lower than 8 bits.

49.3 Functional description

The following sections describe the functionalities of PNGDEC.

49.3.1 Operating modes

PNGDEC operates in two modes: DMA and Drop.

Table 439. Operating modes

Mode	Description
DMA	Reads the PNG file, sends it to the decoder for decoding, and writes RGB-A raw pixel and ancillary data.
Drop	Enables ancillary data drop. DMA only writes RGB-A raw pixel data.

49.3.1.1 DMA mode

When the enable bit fields in the Global Control (GLB_CTRL) register are set to 1, DMA read copies the PNG file from the system memory and performs decoding. During decoding, DMA write starts copying the decoded RGB-A raw pixel and ancillary data to the system memory until the DMA interrupt showing a status of done occurs, and the PNG file decoding is completed.

49.3.1.2 Drop mode

In drop mode, PNGDEC operates in the similar way as DMA mode. However, you must write 1 to GLB_CTRL[ANC_DROP_EN] to enable the ancillary data drop function. You do not need to check DEC_INT_STS[DEC_ANC_DMA_DONE].

49.3.2 Operations

49.3.2.1 DMA mode operation

To operate in DMA mode, perform the following procedures:

1. Write 1 and then write 0 to CNT_CTRL_CLR to clear the dirty counter.
2. Write 1 to every bit of DEC_INT_STS to clear the dirty status.
3. Set ENC_DATA_DMA_SRC_LEN[SRC_LEN] to configure the PNG file DMA source length.
4. Set ENC_DATA_DMA_SRC_ADDR[SRC_ADDR] to configure the PNG file DMA source address.

5. Set DEC_PIXEL_DMA_DES_ADDR[PIXEL_DES_ADDR] to configure the PNG decode pixel destination address.
6. Set DEC_ANC_DMA_DES_ADDR[ANC_DES_ADDR] to configure the PNG decode ancillary destination address.
7. Write 1 to GLB_CTRL[DEC_EN] to enable the decode function.
8. Write to DEC_INT_STS_EN to enable the interrupt status.
9. Write 1 and then write 0 to DMA_TRIG[DMA_TRIG] to trigger the DMA copy engine. After some time, the interrupt appears.
10. Read DEC_INT_STS, making sure that the "*_done" status appears and "err_*" does not appear.
11. Read DEC_PIXEL_DMA_LEN and Decode Ancillary Destination Length (DEC_ANC_DMA_DES_LEN) to get the information of read total decoded pixel length and total decoded ancillary length, respectively. This data is your decoded result.

After one PNG decoding is done, wait for the next picture and repeat the aforementioned steps.

49.3.2.2 Drop mode operation

In drop mode, perform the following procedures (most of the steps are the same as in DMA mode operation):

1. Write 1 and then write 0 to CNT_CTRL_CLR to clear the dirty counter.
2. Write 1 to every bit of DEC_INT_STS to clear the dirty status.
3. Set ENC_DATA_DMA_SRC_LEN[SRC_LEN] to configure the PNG file DMA source length.
4. Set ENC_DATA_DMA_SRC_ADDR[SRC_ADDR] to configure the PNG file DMA source address.
5. Set DEC_PIXEL_DMA_DES_ADDR[PIXEL_DES_ADDR] to configure the PNG decode pixel destination address.
6. Write 1 to GLB_CTRL[DEC_EN] to enable the decode function.
7. Write 1 to GLB_CTRL[ANC_DROP_EN] to enable the ancillary drop function.
8. Write to DEC_INT_STS_EN to enable the interrupt status.
9. Write 1 and then write 0 to DMA_TRIG[DMA_TRIG] to trigger the DMA copy engine. After some time, the interrupt appears.
10. Read DEC_INT_STS, making sure that:
    - Both the "enc_data_dma_done" and "dec_pixel_dma_done" statuses appear.
    - The "err_*" status does not appear.
11. Read DEC_PIXEL_DMA_DES_LEN to get the information of read total decoded pixel length.

After one PNG decoding is done, wait for the next picture and repeat the aforementioned steps.

49.3.3 Clocking

PNGDEC uses the following clock.

Table 440. Clock

Clock	Description
CLK	All submodules of PNGDEC share the same clock.

49.3.4 Reset

PNGDEC has hardware and software resets. You can do software reset for PNGDEC by setting GLB_CTRL[DMA_SW_LOGIC_RST_EN] and GLB_CTRL[IPCORE_SW_LOGIC_RST_EN] independently, for example, write 1 and then write 0 to reset logic.

49.3.5 Interrupts

You can check the interrupt status of PNGDEC in the DEC_INT_STS register, and enable interrupts by setting bitfields in DEC_INT_STS_EN.

49.4 External signals

This module has no external signals.

49.5 Initialization

PNGDEC does not require initialization.

49.6 PNGDEC register descriptions

This section includes the PNGDEC module memory map and detailed descriptions of all registers for accessing DMA registers and PNG decode core status through PNGDEC's bus.

49.6.1 PNGDEC memory map

PNGDEC base address: 400A_7000h

Offset	Register	Width (In bits)	Access	Reset value
0h	Global Control (GLB_CTRL)	32	RW	0000_0000h
4h	DMA Trigger (DMA_TRIG)	32	RW	0000_0000h
8h	Count Control Clear (CNT_CTRL_CLR)	32	RW	0000_0000h
20h	Encode Data Source Address (ENC_DATA_DMA_SRC_ADDR)	32	RW	0000_0000h
24h	Encode Data Source Length (ENC_DATA_DMA_SRC_LEN)	32	RW	0000_0000h
28h	Decode Pixel Destination Address (DEC_PIXEL_DMA_DES_ADDR)	32	RW	0000_0000h
2Ch	Decode Pixel Destination Length (DEC_PIXEL_DMA_DES_LEN)	32	R	0000_0000h
30h	Decode Ancillary Destination Address (DEC_ANC_DMA_DES_ADDR)	32	RW	0000_0000h
34h	Decode Ancillary Destination Length (DEC_ANC_DMA_DES_LEN)	32	R	0000_0000h
80h	Decode Interrupt Status (DEC_INT_STS)	32	RW	0000_0000h
84h	Interrupt Enable (DEC_INT_STS_EN)	32	RW	0000_0000h
A0h	AXI3 Encoded Data Read Bytes Counter (AXI3_ENC_DATA_RD_BYTE_CNT)	32	R	0000_0000h
A4h	AXI3 Decoded Pixel Write Bytes Counter (AXI3_DEC_PIXEL_WR_BYTE_CNT)	32	R	0000_0000h
A8h	AXI3 Decode Ancillary Write Bytes Counter (AXI3_DEC_ANC_WR_BYTE_CNT)	32	R	0000_0000h

49.6.2 Global Control (GLB_CTRL)

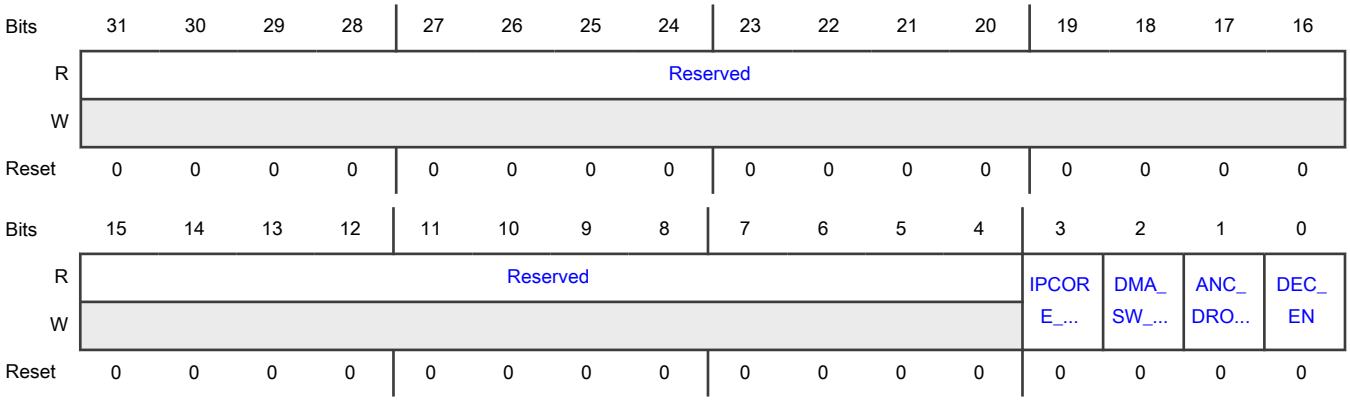
Offset

Register	Offset
GLB_CTRL	0h

Function

Controls PNGDEC operation.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 IPCORE_SW_LOGIC_RST_EN	Core Software Logic Reset Enable Enables software reset for all PNGDEC core logic except for registers. You can write 1 and then write 0 to reset logic. 0b - Disable 1b - Enable
2 DMA_SW_LOGIC_RST_EN	DMA Software Logic Reset Enable Enables software reset for all DMA logic except for registers. You can write 1 and then write 0 to reset logic. 0b - Disable 1b - Enable
1	Ancillary Data Drop Enable Enables the ancillary data drop function.

Table continues on the next page...

Table continued from the previous page...

Field	Function
ANC_DROP_EN	0b - Disable 1b - Enable
0 DEC_EN	Decode Enable Enables PNG decoding. 0b - Disable 1b - Enable

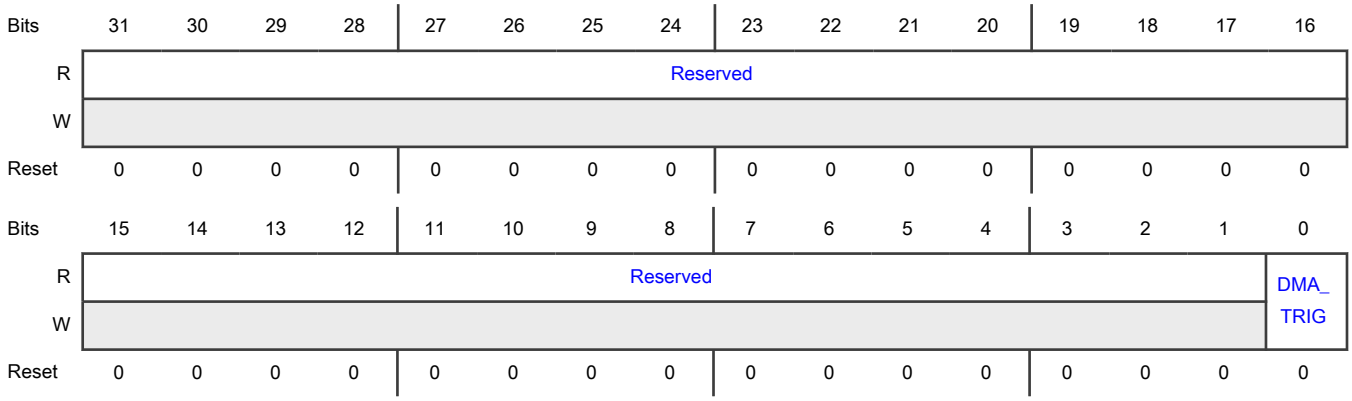
49.6.3 DMA Trigger (DMA_TRIG)

Offset

Register	Offset
DMA_TRIG	4h

Function
Triggers DMA.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 DMA_TRIG	DMA Trigger Triggers PNGDEC to start the DMA-copy and PNG-decoding operations.

Table continues on the next page...

Table continued from the previous page...

Fields

Field	Function
31-11 —	Reserved
10 DEC_ANC_DMA_DONE	Ancillary Decode and DMA Copy Done Flag Indicates whether the ancillary-decode and DMA-copy-done interrupt occurred. If this field is 0, ancillary decoding and DMA copying are not done. If this field is 1, ancillary decoding and DMA copying are done. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No interrupt occurred. 1b - Interrupt occurred. When writing 0b - No effect 1b - Clears status flag.
9 DEC_PIXEL_DMA_DONE	Decode Pixel and DMA Copy Done Indicates whether the decode-pixel and DMA-copy-done interrupt occurred. If this field is 0, pixel decoding and DMA copying are not done. If this field is 1, pixel decoding and DMA copying are done. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No interrupt occurred. 1b - Interrupt occurred. When writing 0b - No effect 1b - Clears status flag.
8 ENC_DATA_DMA_DONE	Encoded Data and DMA Copy Done Indicates whether the encoded-data and DMA-copy-done interrupt occurred. If this field is 0, DMA is not initiated or DMA loading is in progress. If this field is 1, DMA completes loading encoded PNG data to the decoder module. **NOTE** This field behaves differently for register reads and writes.

Table continues on the next page...

Located in	VDD2_MEDIA
Access	CPU0, CPU1, HiFi4, EZH-V, eDMA0, eDMA1, eDMA2, eDMA3

50.2 Overview

NOTE

This chapter describes the Vivante® IP GC555 GPU and contains copyright material disclosed with permission of VeriSilicon.

VGPU provides a high-performance UI-based graphic core to enable hardware acceleration of the OpenVG API and display vector graphics. The DECNano (Decoder/Encoder Core) series pixel compression and decompression fabric provides a unified lossy pixel compression and decompression infrastructure and support for pixel processing pipelines.

In addition to support for the OpenVG API, VGPU also supports the Vivante® VGLite API to enable the GPU acceleration through customized applications. The Vivante® VGLite API also provides an ultralow memory footprint.

50.2.1 Block diagram

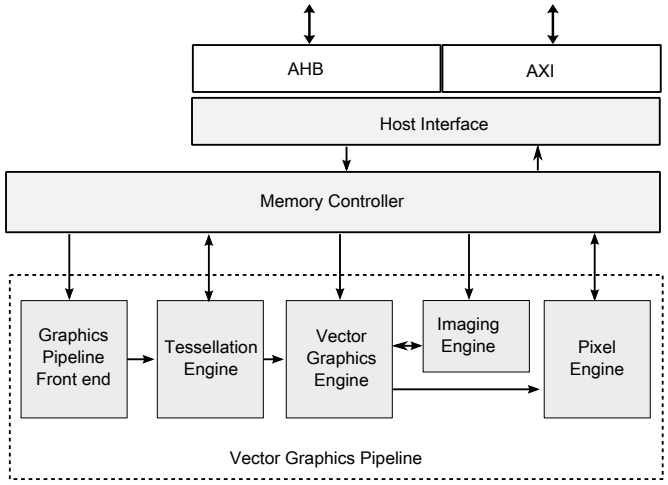

Figure 171. Block diagram with vector graphics pipeline

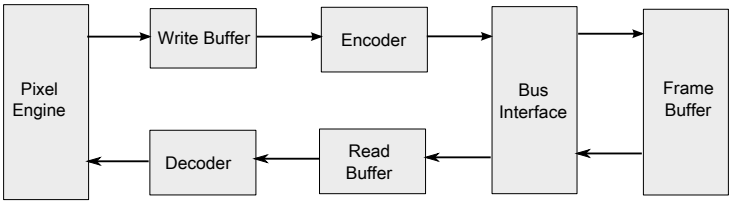

Figure 172. DECNano series architecture

The block diagram outlines the functional blocks of VGPU with a vector graphic pipeline as below:

Table 443. VGPU functional blocks

Module name	Description
Host interface	Allows the VGPU to communicate with external memory and the CPU through the bus in this block data crosses clock domain boundaries.
Memory controller	Internal memory management unit that controls the block-to-host memory request interface.
Graphics pipeline front end	Inserts high level primitives and commands into the graphics pipeline.
Tessellation engine	Transforms vertices and control points, and tessellates lines, quadratic and cubic Bezier curves.
Vector graphics engine	Rasterizer that converts primitives to pixels.
Imaging engine	Paint and image generator that colors each pixel.
Pixel engine	Renderer that combines different sources into the final pixel value. It provides pixel manipulation and filtering on rendered images.

Table continues on the next page...

Table 443. VGPU functional blocks (continued)

Module name	Description
DEC encoder	Encoder unit processes uncompressed RGB data (scanline or tiled data)
DEC decoder	Decoder unit uncompressed RGB data (scanline or tiled data)
Write buffers	Buffer for data being input from a pixel engine to the DEC encoder
Read buffers	Buffer for output data being sent from the DEC decoder to a pixel engine
Frame buffer	Output result buffer
Tessellation buffer	Tessellation result buffer

50.2.2 Features

VGPU has the following features:

- External data access: 1 x 64-bit AXI
- Configuration interface: 1 x3 2-bit AHB
- AXI version compatibility: 4 (partial)
- Clock source: clk1x
- Image source read
- Open VG 1.1
- Vivante VGLite API support
- Linear paint
- Pixel input format support
- YUY2 input support
- INDEX 1/2/4/8 support
- DECNano compression/decompression
- ETC2 decompression
- Transformation support: 3 x 3 perspective and affine

50.3 Functional description

The following sections describe VGPU functionalities.

50.3.1 Host and memory interface features

Table 444 shows the host and memory interface features of VGPU.

Table 444. Host and memory interface features

Feature	VGPU support
AHB interface	32-bit (alternately APB) for configuration
AXI interface	1 64-bit AXI interface for external memory access

Table continues on the next page...

Table 444. Host and memory interface features (continued)

Feature	VGPU support
DEC interface	Encoder and decoder have the same signals.
Code and data memory location restrictions	Unrestricted; arbitrary memory reads and writes
Physical address	32 bits
Read write request size support	Memory controller supports 8, 16, 32, 48, 64 byte read and write requests
Resource locks with CPU	Semaphore lock
Memory optimization	• fixed (reduced size) path and stroke caches • fixed (reduced size) tessellation window and buffer size • RGBA color transformations

50.3.2 Hardware features

Table 445 describes vector graphics hardware features.

Table 445. Graphics hardware features

Feature	Description
Coordinate systems and transformations	Image drawing uses a 3 x 3 perspective transformation matrix
Scissoring and viewport clipping	Yes
Porter-Duff blending	Yes
Blending	Porter Duff blending plus additional blend modes
Rotation	To any angle
Fill rules	Odd/even and non-zero
Paint paths	Linear and radial gradient paint paths
Paints	Solid, linear, and radial gradient
Compression/Decompression	DECNano/ETC2 (only supports decompression)
Coordinate systems and transformations	Tessellation uses 3 x 3 affine transformation
YUY2 and YUV420 video image conversion	YUY2 and YUV420 video image conversion
Anti-aliasing	4x and 16x Coverage Sample Anti-aliasing(CSAA)
Image filters and interpolations	Point, linear, and bi-linear blends
Pixel formats for image interpolation	Pixel formats for image interpolation
Transformations	sRGBA color transformation

50.3.3 Format support

Table 446. Graphics formats

Feature	VGPU Support			
Image formats	The graphics engine supports the following formats for source image and destination render targets.			
	Bit depth	Format	Supported for source image	Supported for destination
	1	INDEX1	Yes	-
	2	INDEX2	Yes	-
	4	INDEX4	Yes	-
	4	A4	Yes	-
	8	A8	Yes	Yes
	8	INDEX8	Yes	-

	16	YUY2	Yes	-
	16	NV16	Yes	-
	16	YV16	Yes	-
	16	A4R4G4B4	Yes	Yes
	20	ANV12	No	-
	24	A8R5G6B5	Yes	Yes
	24	R8G8B8	Yes	Yes
	24	AYUY2	No	-
	24	YV24	Yes	-
	32	A8R8G8B8	Yes	Yes
	32	X8R8G8B8	Yes	Yes
DECNano format compression support	**Bit Depth**	**Format**	**Supported for Source**	**Supported for Destination**
	32	A8R8G8B8	No	Yes
	32	X8R8G8B8	No	Yes

Table continues on the next page...

Table 446. Graphics formats (continued)

	NOTE DECNano can be bypassed by software configuration.
ETC2 format decompression support	**Bit Depth** / **Format** / **Supported for Source** / **Supported for Destination** 32 / A8R8G8B8 / Yes / -
Color component swizzle support	SWIZZLE_ABGR, SWIZZLE_ARGB, SWIZZLE_BGRA and SWIZZLE_RGBA

50.3.4 Encode and decode hardware features

Below lists the key features of the DEC compression unit.

Table 447. Encode and decode hardware features

Feature	DEC Support
Input and output pixel formats	See Data formats.
Compression scheme	Lossy compression and decompression
Compression modes	Three modes: • No sample • Horizontal only • Horizontal and vertical
Compression de-compression ratio	1.8 to 4.0 dependent on color format and compression mode
Pixel data organization support (in pixels)	Tile (4 x 4) and raster scan (16 x 1)
User controls*	GPU controls compression.
Compression units	64 bytes
Burst size	4 bytes
By-pass scheme	Uncompressed data travels through the GPU pipeline directly bypassing the DEC compression or decompression logic, and then travels across the AXI interface through standard memory-to-the memory display path. You can configure DECNano bypass via software.
Codec pixel data rate	1 pixel per cycle encode/decode for 32 bpp
Bandwidth reduction	2-3X with lossy compression

50.3.4.1 DECNano lossy data compression overview

Supported formats, tile modes and compression modes

The DECNano series supports the following formats, tile modes and compression modes.

- Formats are 32 bit-per-pixel ARGB8 and XRGB8, specified in signal format. A or X is in the upper bits and B is in the lower bits.

- Tile mode is either linear 16 x 1 pixels or tiled 4 x 4 pixels. Each tile occupies 64 bytes.
- Three compression modes are supported:
  - None
  - Horizontal sample
  - Horizontal and vertical sample. Note that this mode is not supported for linear scanlines.

One of three compression modes is specified in the signal comp_mode, where 0 = no sample, 1 = Horizontal sample of 4:1, or 2 = Horizontal and vertical sample of 1. A Nano_core_error_o=1 signal will be generated if a configuration attempts to configure a tile with a tilemode=0: 16x1 and comp_mode =2: Horizontal and Vertical Sampling.

Table 448. Compression ratios per compression mode

Compression mode	Color Subsample	
	ARGB	XRGB
No sample	1.8:1	2.4:1
Horizontal only (raster or tile)	2.4:1	3.0:1
Horizontal and vertical (tile only)	3.0:1	4.0:1

Table 449. Format, tile mode and compression mode summary for DECNano

Format	Tile Mode tilemode 0 = 16 x 1; 1 = 4 x 4	Compression Mode comp_mode 0= ; 1=no sample; 2=Horizontal 4:1; 3=Horizontal&Vertical 1
ARGB8 (format=0) or XRGB8 (format=1)	16 x 1	No sample
		H
	4 x 4	No sample
		H
		HV

Considerations

The DECNano series provide basic lossy compression capabilities. As such, it provides a limited subset of formats, tile modes, compression modes and advanced features. Note that:

- Compression and decompression are supported.
- Lossless compression is not supported. Only lossy compression/decompression is available.
- The tile to be compressed must be 64 bytes. If not, an error will result.
- The decompressed tile must be 64 bytes. If not, an error will result.
- No YUV format support is provided. Only A/XRGB8 formats are supported.
- A2RGB10 is not supported.
- Bypass is supported.
- Burst size is 4 bytes.
- Throughput is 1 RGBA or RGB pixel per cycle.

50.3.4.2 Codec data throughput and formats

50.3.4.2.1 Pixel throughput

- Compression throughput maximum with 32-bit data
  - 1 pixel/cycle for 32 bpp formats (A8R8G8B8, X8R8G8B8)
- Decompression throughput maximum with 32-bit data
  - 1 pixel/cycle for 32 bpp formats (A8R8G8B8, X8R8G8B8)

50.3.4.2.2 Alignment

The companion IP controls the alignment:

- Compression unit is 64 bytes.
- Burst size is 4 bytes.

50.3.4.2.3 Formats for encode and decode with DECNano

Supported color formats and tile mode combinations are summarized in the table below.

Table 450. Color format bit depths supported for encode and decode

Color formats	Format	Bits per component	DECNano series Support
RGB formats	A/X4R4G4B4	4 (16 bpp)	NA
	R5G6B5	16 bpp	NA
	A/X8R8G8B8	8 (32 bpp)	Yes
	A/XR10G10B10	32 bpp	NA
YUV formats	NA	NA	NA

50.3.5 Clocking

VGPU employs a simple clocking scheme. There are four independent clock domains:

- Core clock domain, which is derived from the clk1x pin,
- AHB interface clock domain for register access, which is derived from the HCLK pin, and
- AHB interface clock domain for memory access, which is derived from the ACLK pin.
- AXI interface clock domain, which is derived from the clk pin.

HCLK is the clock for register access. clk1x is the functional clock for the core logic. ACLK is the interface clock domain for memory access.

Communication between the different domains in the GPU occurs mostly by way of asynchronous FIFOs. All the clocks are asynchronous to each other. There is no communication between clock domains.

Table 451. Clock definitions

GPU clock pins	Description
HCLK	AHB interface clock for register access. It is provided external to the IP.

Table continues on the next page...

Table 451. Clock definitions (continued)

GPU clock pins	Description
ACLK	AXI or AHB interface clock for memory access. It is provided external to the IP.
clk1x	clk1x is the main core clock. It is provided external to the IP.
clk	clk is the DEC core clock. It is provided internal to the IP.

50.3.6 Interrupts

This module has no interrupts.

50.4 Software API

The following hardware platform and operating system independent APIs are available. These APIs provide user controls for optimizing the acceleration capabilities available with VGPU.

50.4.1 OpenVG 1.1 API standard for vector graphics acceleration

OpenVG is a royalty-free, cross-platform API managed by the member-funded consortium known as Khronos Group. It provides a low-level hardware acceleration interface for vector graphics libraries such as Flash and SVG. OpenVG is used for acceleration of high-quality vector graphics for user interfaces and text on small screen devices.

50.4.1.1 Core API features of OpenVG

VGPU fully supports the following key features of the Khronos API:

- Coordinate systems and transformations (image drawing uses a 3x3 perspective transformation matrix)
- Viewport clipping, scissoring and alpha masking
- Paths
- Images
- Image filters
- Paint (gradient and pattern)
- Blending
- Dithering

50.4.1.2 OpenVG rendering pipeline

The OpenVG rendering pipeline is that:

- Stage 1: Path, transformation, stroke, and paint
- Stage 2: Stroked path generation
- Stage 3: Transformation
- Stage 4: Rasterization
- Stage 5: Clipping and masking
- Stage 6: Paint generation
- Stage 7: Image interpolation
- Stage 8: Blending and anti-aliasing

50.4.2 VGLite graphics API

VGLite Graphics API is an ultralow memory footprint API, provides an easier mechanism to use the VGPU. It provides mechanisms for hardware accelerated two-dimensional vector and raster graphics, thereby allowing to develop high quality graphics application optimized for a overall resource requirements. The VGLite Graphics API allows for fine granularity in the features supported by the GPU and their memory usage.

50.4.2.1 Organization of VGLite graphics API

The VGLite API is partitioned to provide controls for three main areas of functionality:

- Initialization - for hardware and software initialization
- Blit - for raster rendering
- Draw - for draw operations

Hardware supported blit and/or draw capabilities available for software control through the API include:

Table 452. Blit and draw controls in VGLite API

Capability	GC555 GPU with VGLite API support
Fill	Non-zero or even-odd
Path coordinate formats	S8, S16, S32, and FP32
HW anti-alias levels	Low, medium, and high
Blending	SrcOver, DstOver, SrcIn, DstIn, Screen, Multiply, Additive, and Subtractive
Data formats	INDEX1/2/4/8, ARGB2/4/8, XRGB8, RGB8, A8RGB565, A4/8, L8, YUY2, and BRGA/X variants.
Path definitions	Bounding box, path quality, coordinate format, buffer pointer, path length, and path data

51.2 Overview

USB provides a high-performance functionality that conforms to *Universal Serial Bus Specification Revision 2.0*.

USB supports *USB 2.0 Link Power Management (LPM) Addendum* and *Errata for LPM*.

USB includes a port that you can use either as a downstream (host) or an upstream (device) port.

USB supports a PHY that conforms to *Embedded USB 2.0 Physical Layer (eUSBPHY) supplement to the USB revision 2.0 specification (revision 1.1)*.

51.2.1 Block diagram

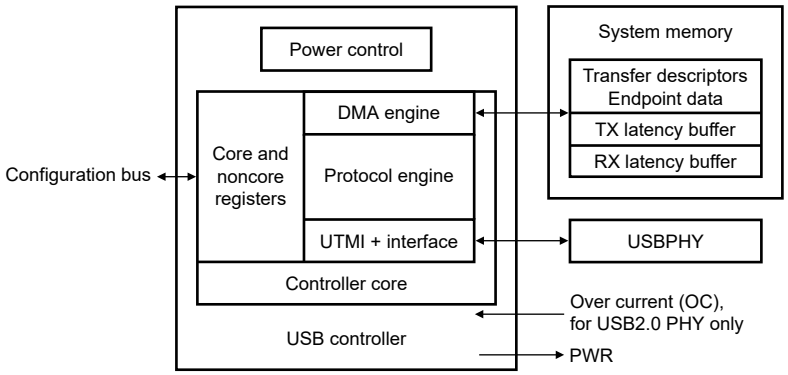

Figure 173. Block diagram

51.2.2 Features

- Compatibility with the enhanced host controller interface (EHCI) specification in Host mode
- High-speed (HS), full-speed (FS), and low-speed (LS) operations in Host mode
- HS and FS operations in Device mode
- Eight bidirectional endpoints in Device mode
- Low-Power Suspend mode (L2) with local and remote wake-up capability
- Low-Power Sleep mode (L1) with local and remote wake-up capability
- Embedded DMA controller
- UTMI+ interface to PHY

51.3 Functional description

51.3.1 Register interface

USB configuration, control, and status registers are divided into the categories shown in the following table.

EHCI registers are listed along with device registers to show the complementary nature of host and device control.

Table 455. Core register sets

Offset	Register sets	Functional description
000h–07Ch	Identification registers	• Used to declare the subordinate interface presence • Include the complete set of hardware configuration parameters
100h–124h	Static, read-only capability registers	• Define the software limits, restrictions, and capabilities of host and device controller implementation • Used as parameters to the host and device controller driver
080h–0FCh 140h–1FCh	Operational registers	• Dynamic control or status registers that can have read-only, read/write, or read/write-to-clear accesses • Used to control and monitor the operational state of the host and device controller

51.3.1.1 Configuration, control, and status register sets

Table 456. Device and host capability registers

Offset (hex)	Size (bytes)	Register name and mnemonic	Device mode	Host mode
000	4	Identification (ID)	O[1]	O
004	4	Hardware General (HWGENERAL)	O	O
008	4	Host Hardware Parameters (HWHOST)	X[2]	O

1B8	4	Endpoint Status (ENDPTSTAT)	O	X
1BC	4	Endpoint Complete (ENDPTCOMPLETE)	O	X
1C0 1C4 1C8 1CC 1D0 1D4 1D8 1DC	64	Endpoint Control 0 (ENDPTCTRL0) Endpoint Control 1 (ENDPTCTRL1) Endpoint Control 2 (ENDPTCTRL2) Endpoint Control 3 (ENDPTCTRL3) Endpoint Control 4 (ENDPTCTRL4) Endpoint Control 5 (ENDPTCTRL5) Endpoint Control 6 (ENDPTCTRL6) Endpoint Control 7 (ENDPTCTRL7)	O	X

1. O means that the register is available in Host and Device operation modes.
2. X means that the register is reserved in Host and Device operation modes.

51.3.1.2 Identification registers

USB uses identification registers to declare the subordinate interface presence. They include hardware configuration parameters.

51.3.2 Host data structures

For detailed information, see the "Data Structures" chapter in *Enhanced Host Controller Interface (EHCI) Specification for Universal Serial Bus, revision 1.0*.

51.3.3 Host operational model

For detailed information, see the "Operational Model" chapter in *Enhanced Host Controller Interface (EHCI) Specification for Universal Serial Bus, revision 1.0*.

51.3.4 EHCI deviation

For the purposes of a dual-role host or device controller with support for On-The-Go (OTG) applications, you must deviate from EHCI specification. Device and OTG operations are not specified in EHCI; therefore, the implementation supported in this core is proprietary.

The Host mode operation of the core is EHCI compatible, with a few minor differences documented in this section. The following is a summary of these deviations.

Table 457. EHCI deviation

Deviations	Description
Embedded transaction translator	Allows direct attachment of the FS and LS devices in Host mode without the need for a companion controller (see Embedded transaction translator function for more information).
Device operation	Generally disabled; therefore, Device mode is mostly transparent when in Host mode (exceptions are provided in the following sections). See Device operation for more information.
Embedded design interface	Does not have a PCI; therefore, the PCI configuration registers described in the EHCI specification are not applicable (see Embedded design interface for more information).
OTG operation	Includes an OTG for port #1.

51.3.4.1 Embedded transaction translator function

USB supports directly connected FS and LS devices, without requiring a companion controller, by including the capabilities of a USB 2.0 HS hub transaction translator.

Although there is no separate transaction translator block in the system, the transaction translator function that is normally associated with an HS hub is implemented within the DMA and protocol engine blocks. The embedded transaction translator function is an extension of the EHCI interface, but makes use of the standard data structures and operational models that already exist in the EHCI specification to support FS and LS devices.

51.3.4.1.1 Discovery-EHCI deviation

In a standard EHCI controller design, the EHCI host controller driver detects an FS or LS device by analyzing whether PORTSC1[PE] becomes 1 after the port reset operation.

PORTSC1[PE] becomes 1 in a standard EHCI controller implementation after the port reset operation and when the host and device negotiate an HS connection (that is, after chirp completes successfully). Because this controller has an embedded transaction translator, PORTSC1[PE] always becomes 1 after the port reset operation, regardless of the host device chirp result. PORTSC1[PSPD] indicates the resulting port speed. Therefore, the standard EHCI host controller driver requires an alteration to handle directly connected FS and LS devices or hubs.

Table 458. Summary of EHCI

Standard EHCI	EHCI with embedded transaction translator
After PORTSC1[PE] becomes 1 following a connection and reset sequence, the device or hub is assumed to be in HS.	After PORTSC1[PE] becomes 1 following a connection and reset sequence, PORTSC*n* indicates the device or hub speed.
FS and LS devices are assumed to be downstream from an HS hub; therefore, all port-level controls are performed using the hub class through the nearest hub.	FS and LS devices can either be downstream from an HS hub or directly attached. When an FS or LS device is downstream from an HS hub, the port-level control is performed using the hub class through the nearest hub. When an FS or LS device is directly attached, the port-level control is accomplished using PORTSC*n*.
FS and LS devices are assumed to be downstream from an HS hub with HubAddr = X, where HubAddr > 0 and HubAddr is the address of the hub where the bus transitions from HS to either FS or LS (that is, a split target hub).	FS and LS devices can be either downstream from an HS hub with HubAddr = X [HubAddr > 0] or directly attached, where HubAddr = 0 and HubAddr is the address of the root hub where the bus transitions from HS to either FS or LS (that is, a split target hub is the root hub).

51.3.4.1.2 Operational model

The operational models support the behavior of the transaction translator (see the USB 2.0 specification) and support the EHCI controller moving packets between the system memory and a USB-HS hub. Because the embedded transaction translator exists within the host controller, there is no physical bus between the EHCI host controller driver and the USB FS and LS bus.

The following sections briefly discuss the operational model for how the EHCI and transaction translator operational models are combined without a physical bus existing between them. These sections assume that you are familiar with both the EHCI and USB 2.0 transaction translator operational models.

51.3.4.1.2.1 Microframe pipeline

The EHCI operational model uses the concept of H-frames and B-frames to describe the pipeline between the host (H) and the bus (B). The embedded transaction translator must use the same pipeline algorithms specified in the USB 2.0 specification for a hub-based transaction translator.

All periodic transfers begin at B-frame 0 (after SOF) and continue until the stored periodic transfers are complete. As an example of the microframe pipeline implemented in the embedded transaction translator, all periodic transfers that are tagged in EHCI to execute in H-frame 0 are ready to execute on the bus in B-frame 0.

When programming the S-mask and C-mask fields in the EHCI data structures to schedule periodic transfers for the embedded transaction translator, the EHCI host controller driver must follow the same rules specified in EHCI for programming those fields for downstream hub-based transaction translators.

After periodic transfers are exhausted, any stored asynchronous transfer is moved. Asynchronous transfers are opportunistic; they must execute whenever possible, and their operation is not tied to H-frame and B-frame boundaries. However, an asynchronous transfer cannot babble through the start of B-frame 0 (SOF).

51.3.4.1.2.2 Split-state machines

The start- and complete-split operational model differs from EHCI slightly because there is no bus medium between the EHCI controller and the embedded transaction translator.

A start- or complete-split operation occurs by requesting the split to the HS hub. The start-complete split operation is an internal operation to the embedded transaction translator. The following table summarizes the conditions where handshakes are emulated from an internal state instead of actual handshakes to the HS split bus traffic.

Table 459. Summary of handshake conditions

Condition	Emulate TT response
Start-split: All asynchronous buffers full	NAK
Start-split: All periodic buffers full	ERR
Start-split: Success for start of an asynchronous transaction	ACK
Start-split: Start periodic transaction	No handshake (OK)
Complete-split: Failed to find transaction in queue	Bus time out
Complete-split: Transaction in queue is busy	NYET
Complete-split: Transaction in queue is complete	Actual handshake from an LS or FS device

51.3.4.1.2.3 Asynchronous transaction scheduling and buffer management

Table 460. Asynchronous transaction scheduling and buffer management

USB 2.0 specification items	Implementation in the embedded transaction translator
11.17.3	Sequencing is provided and a packet length estimator ensures that no FS or LS packet babbles exist in the SOF time.
11.17.4	Transaction tracking happens for two data pipes.

51.3.4.1.2.4 Periodic transaction scheduling and buffer management

Table 461. Periodic transaction scheduling and buffer management

USB 2.0 specification items	Implementation in the embedded transaction translator
11.18.6.[1-2]	• Abort of pending start-split conditions: — End of frame (EOF), and not started in six microframes — Idle for more than four microframes • Abort of pending complete-split conditions: — EOF — Idle for more than four microframes
11.18.[7-8]	• Transaction tracking for up to 16 data pipes • Complete-split transaction searching **NOTE** There is no data schedule mechanism for these transactions other than the microframe pipeline. The embedded TT assumes that the number of packets scheduled in a frame does not exceed the frame duration (1 ms); otherwise, it results in an undefined behavior.

51.3.4.1.2.5 Multiple transaction translators

HCSPARAMS[N_TT] indicates the maximum number of embedded transaction translators that USB currently supports.

51.3.4.2 Device operation

The coexistence of a device operational controller within the host controller has little effect on the EHCI compatibility for host operation, except as discussed in the following sections.

51.3.4.2.1 USBMODE

You cannot initialize the dual-role controller in Host or Device modes. Considering this, you must program USB Device Mode (USBMODE) for a host operation before the EHCI host controller driver can begin EHCI host operations.

51.3.4.2.2 Fields with nonzero values in USB core registers

Some of the reserved fields and reserved addresses in the capability and operational registers are used in Device mode. For Device mode, you must adhere to the following requirements:

- Always write 0 to all EHCI reserved fields (some of which are device fields) in the operational registers. This is an EHCI requirement of the device controller driver.
- Read operations by the host controller must properly mask EHCI reserved fields (some of which are device fields) because fields that are used exclusively for the device are undefined in Host mode.

51.3.4.2.3 SOF interrupt

The start of frame (SOF) interrupt for Device mode is shared as a free-running 125 µs interrupt for Host mode.

EHCI does not specify this interrupt, but it has been added for convenience and as a potential software time base. See USB Status (USBSTS) and Interrupt Enable (USBINTR) for more information.

51.3.4.3 Embedded design interface

This is an embedded USB host controller, defined by the EHCI specification, and thus does not implement the PCI configuration registers.

51.3.4.3.1 Frame adjust register

Considering that the optional PCI configuration registers are not included in this implementation, there is no corresponding bit-level timing adjustment. The start of microframes is timed precisely to 125 µs using the transceiver clock as a reference clock. That is, a 30 MHz transceiver clock for 16-bit physical interfaces.

51.3.4.4 Miscellaneous variations from EHCI

51.3.4.4.1 Programmable physical interface behavior

This design supports multiple physical interfaces that can operate in different modes if you program the core with software-programmable physical interface modes. Software programmability allows you to select the physical interface part during the board design phase, instead of selection during the chip design phase. Port Status and Control (PORTSC1) provides the control fields for selecting the physical interface operating mode, a capability that EHCI does not define.

51.3.4.4.2 Device discovery

51.3.4.4.2.1 Port reset

The port connect methods that EHCI specifies require you to set PORTSC1[PR] for a duration of 10 ms. Because of the complexity involved in supporting the attachment of devices that are not high speed, there are counters already present in the design that can count the 10 ms reset pulse to alleviate the software requirement to measure this duration. Perform the following procedure to establish the basic connection.

Table 462. Port reset

Step	Purpose	Programming	Notes
1	Change the port.	Wait for the port change interrupt.	A port connect change occurs to notify the host controller driver that a device is attached.
2	Reset the device.	Write 1 to PORTSC1[PR].	—
3	Reset the device after 10 ms.	Write 0 to PORTSC1[PR].	This step, which is necessary in a standard EHCI design, can be omitted with this implementation. If the EHCI host controller driver attempts to write 0 to PORTSC1[PR]

Table continues on the next page...

Table 462. Port reset (continued)

Step	Purpose	Programming	Notes
			when a reset is in progress, the write is ignored and the reset continues until completion.

A port enable change occurs to notify the host controller that the device in now operational, and at this point, the port speed is determined.

51.3.4.4.2.2 Port speed detection

After the port change interrupt indicates that a port is enabled, the EHCI stack must determine the port speed. Unlike the EHCI implementation, which reassigns the port owner for any device that does not connect at HS, this host controller supports direct attachment of non-HS devices.

Consider the following differences for port-speed detection:

- PORTSC1[PO] is read-only and always reads 0.
- PORTSC1[PSPD] provides the current operating speed of the port to the host controller driver.

51.3.4.4.3 Port Test Control mode

This mode behaves exactly as described in EHCI. An alternate host controller driver procedure is neither necessary nor supported.

51.3.5 Device data structures

This section defines the interface data structures used to communicate control, status, and data between the device controller driver (DCD) software and device controller.

The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of device queue heads and transfer descriptors.

NOTE

You must ensure that no interface data structure reachable from the device controller spans a 4 KB page boundary.

The data structures defined in this chapter are, from the device controller's perspective, a mix of read-only (RO) and read/write (R/W) fields. The device controller must preserve the RO fields on all data structure writes.

Figure 174 shows the organization of the device endpoint queue head (dQH).

Endpoint queue heads are arranged in an array, in a continuous area of memory indicated by Endpoint List Address (ENDPTLISTADDR). The even-numbered device queue heads in the list support receive endpoints (Out/Setup) and the odd-numbered queue heads in the list are used for transmit endpoints (In/Interrupt). That is, the device queue heads in the list with an even offset support receiver endpoints (Out) and the queue heads in the list with an odd offset are used for the transmit endpoint (In). The device controller indexes into this array based on the endpoint number received from the USB bus. All information necessary to respond to transactions for all primed transfers is contained in this list so that the device controller can readily respond to incoming requests without having to traverse a linked list.

NOTE

The endpoint queue head list must be aligned to a 2 KB boundary.

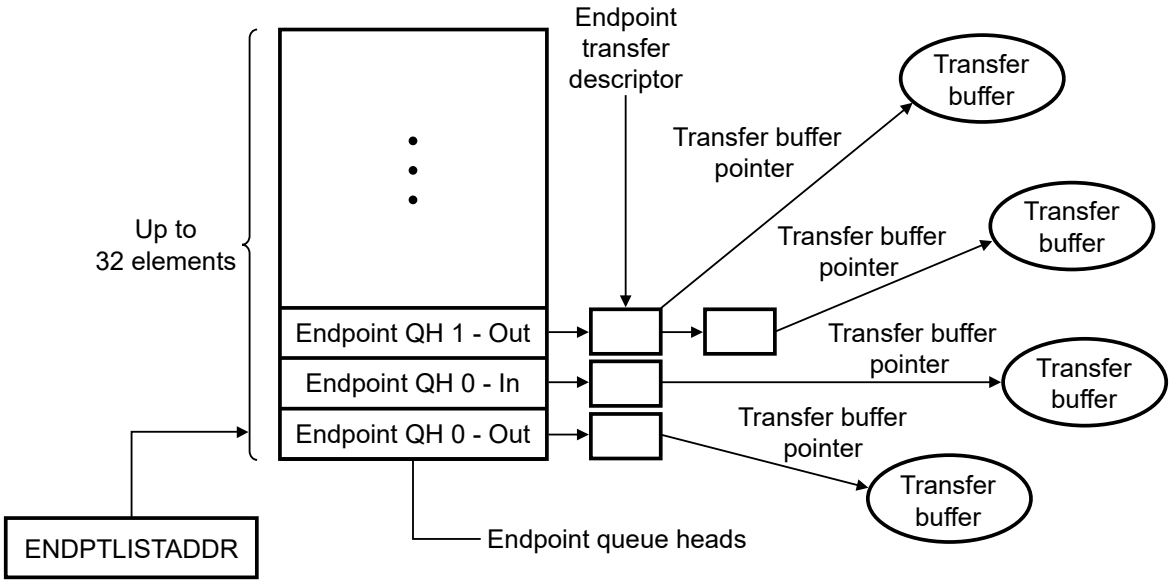

Figure 174. Endpoint queue head organization

51.3.5.1 Device endpoint queue head (dQH)

The dQH is where all transfers for a given endpoint are managed. It is a 48-byte data structure, but must be aligned on 64-byte boundaries.

During priming of an endpoint, the device transfer descriptor (dTD) is copied into the overlay area of the dQH, which starts at the next dTD pointer DWORD and continues through the end of the buffer pointer. After a transfer is complete, the dTD status DWORD is updated in the dTD indicated by the current dTD pointer. When a packet is in progress, the overlay area of the dQH is used as a staging area for the dTD so that the device controller can access the required information with minimal latency.

Table 463. dQH structure [1]

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

2. Transfer overlay starts at T and continues through the buffer pointer (page 4).

51.3.5.1.1 Endpoint capabilities and characteristics

This DWORD specifies static information about the endpoint; in other words, this information does not change over the lifetime of the endpoint. The device controller software must not attempt to modify this information when the corresponding endpoint is enabled.

Table 464. Endpoint capabilities and characteristics

Field	Function
31-30 MULT	Multiplier Indicates the number of packets executed per transaction description. • 00 – Execute *n* transactions as demonstrated by the USB variable length packet protocol, where *n* is computed using dQH and dTD. • 01 – Execute one transaction • 10 – Execute two transactions • 11 – Execute three transactions **NOTE** You must write 00b to this field for non-ISO endpoints, and 01b, 10b, or 11b, as needed, for ISO endpoints.
29 ZLT	Zero-Length Termination Select Enables a zero-length packet for use to terminate transfers, where the total transfer length is a multiple of the maximum packet length. This field is not relevant for isochronous transfer types. • 0 – Enable a zero-length packet to terminate transfers equal to a multiple of the maximum packet length (default) • 1 – Disable the zero-length packet on transfers that are equal in length to a multiple maximum packet length

Table continues on the next page...

Table 464. Endpoint capabilities and characteristics (continued)

Field	Function
28-27 Reserved	Reserved for future use; must be 0.
26-16 Maximum Packet Length	Maximum Packet Length Corresponds to the maximum packet size of the associated endpoint (wMaxPacketSize). The maximum value this field can contain is 400h (1024).
15 IOS	Interrupt On Setup Used for control type endpoints to indicate whether USBINTR is configured in response to a setup being received.
14-0 Reserved	Reserved for future use; must be 0.

51.3.5.1.2 Transfer overlay-endpoint queue head

The seven DWORDS in the overlay area represent a transaction working space for the device controller.

The general operational model is that the device controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, it does not read the associated endpoint.

After an endpoint is ready, the device controller copies the dTD into the queue head overlay area. Until a transfer is expired, you must not write to the queue head overlay area or the associated transfer descriptor. After the transfer is complete, the device controller writes the results back to the original transfer descriptor and advances the queue.

See Device endpoint transfer descriptor (dTD) for a description of the overlay fields.

51.3.5.1.3 Current dTD pointer

The device controller uses the current dTD pointer to locate the transfer in progress. This word is for device controller (hardware) use only, and the DCD software must not modify it.

The following table describes the dTD pointer.

Table 465. Current dTD pointer

Bit	Description
31-5 Current dTD	Current dTD Points to the dTD that is represented in the transfer overlay area. The device controller modifies this field to the next dTD pointer during endpoint priming or queue advance.
4-0 Reserved	Reserved for future use; must be set to 0.

51.3.5.1.4 Setup buffer

The setup buffer is a dedicated storage for the 8-byte data that follows a setup PID.

NOTE

Each endpoint has a TX and an RX dQH associated with it, and only the RX queue head is used for receiving setup data packets.

Table 466. Setup buffer bytes

DWORD	Bits	Description
1	31-0	Setup Buffer 0 Contains bytes 3–0 of an incoming setup buffer packet. The device controller writes to it so you can read it.
2	31-0	Setup Buffer 1 Contains bytes 7–4 of an incoming setup buffer packet. The device controller writes to it so you can read it.

51.3.5.2 Device endpoint transfer descriptor (dTD)

The dTD informs the device controller of the location and quantity of data to be sent and received for a given transfer.

The DCD must not attempt to modify any field in an active dTD except the next like pointer, which you must modify only as described in Managing transfers with transfer descriptors.

Table 467 describes the dTD structure.

Table 467. dTD structure[1]

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Next link pointer																											0				T
0	Total bytes															IOC	0			MULTO		0		Status							
Buffer pointer (page 0)																				Current offset											
Buffer pointer (page 1)																				0	Frame number										
Buffer pointer (page 2)																				Reserved											
Buffer pointer (page 3)																				Reserved											
Buffer pointer (page 4)																				Reserved											

1. The shaded cells indicate host controller read/write fields and unshaded cells indicate host controller read-only fields.

Table 468 describes the dTD pointer.

Table 468. Next dTD pointer

Field	Function
31-5 Next Transfer Element Pointer	Next Transfer Element Pointer Contains the physical memory address of the next dTD to be processed. This field corresponds to memory address signals [31:5], respectively.
4-1 Reserved	Reserved for future use; must be 0.
0 T	Terminate Indicates to the device controller whether there are valid entries in the queue. • 0 – Pointer is valid (points to a valid transfer element descriptor) • 1 – Pointer is invalid

Table 469 describes the dTD token.

Table 469. dTD token

Field	Function
31 Reserved	Reserved for future use; must be 0.
30-16 Total Bytes	Total Bytes Specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes moved during the transaction, after the successful completion of the transaction. The maximum value you can store in the field is 5 × 4KB (5000h). This is the maximum number of bytes that 5-page pointers can access. Although it is possible to create a transfer up to 20 KB, this assumes that the first offset into the first page is 0. When the offset cannot be predetermined, crossing past the fifth page can be guaranteed by limiting the total bytes to 16 KB. Therefore, the maximum recommended transfer is 16 KB (4000h). If the value of this field is 0 when the host controller fetches this transfer descriptor (and the active bit is 1), the device controller executes a zero-length transaction and retires the transfer descriptor. "In" transfers do not require that dTD be an even multiple of the Maximum Packet Length field in dQH. If you build such a transfer descriptor for an "In" transfer, the last transaction is always less than the value of the Maximum Packet Length field.
15 IOC	Interrupt On Complete Indicates whether USBINTR will be configured in response to the device controller being finished with this dTD.
14-12 Reserved	Reserved for future use; must be 0.
11-10 MULTO	Multiplier Override

Table continues on the next page...

Table 469. dTD token (continued)

Field	Function
	Can be used for transmit-ISO (that is, ISO-IN) to override the multiplier in the queue head. This field must be zero for all packet types that are not transmit-ISO. For example, if QH.multiplier = 3, the Maximum Packet Size field = 8, the Total Bytes field = 15, and the MULTO field = 0 (default), then three packets are sent: {Data2(8); Data1(7); Data0(0)}. If QH.multiplier = 3, the Maximum Packet Size field = 8, the Total Bytes field = 15, and the MULTO field = 2, then two packets are sent: {Data1(8); Data0(7)}. For maximal efficiency, you must calculate MULTO = greatest integer of (the Total Bytes field ÷ the Maximum Packet Size field). In cases where the Total Bytes field = 0, the MULTO field must be 1. For non-ISO and non-TX endpoints, you must write 0 to the MULTO field.
9-8 Reserved	Reserved for future use; must be 0.
7-0 Status	Status Used by the device controller to communicate individual command execution states back to the device controller software. This field contains the status of the last transaction performed on this dTD. The following are the bit encodings: • 0, 2, and 4 - Reserved • 3 - Transaction error • 5 - Data buffer error • 6 - Halted • 7 - Active

Table 470 describes the dTD buffer page pointer list.

Table 470. dTD buffer page pointer list

Field	Function
31-12 Buffer Pointer	Selects the page offset in memory for the packet buffer. Nonvirtual memory systems typically set the buffer pointers to a series of incrementing integers.
0, 11-0 Current Offset	Indicates the current offset that offsets into the 4 KB buffer where the packet will begin.
1, 10-0 Frame Number	Indicates the frame number in which a packet finishes. You typically use it to correlate relative completion times of packets on an ISO endpoint. The device controller writes to this field.

51.3.6 Device operational model

The function of the device operation is to transfer a request in the memory image to and from USB.

The device controller performs the data transfers (pointed to by the queue head) using a set of linked list transfer descriptors. The following sections explain the use of the device controller from the point-of-view of the DCD, and further describe how specific USB bus events relate to status changes in the device controller programmer's interface.

51.3.6.1 Port state and control

From a chip or system reset, the device controller enters the powered state. A transition from the powered state to the attach state occurs when USBCMD[RS] = 1.

After receiving a reset on the bus, the port enters the defaultFS or defaultHS state in accordance with the reset protocol described in Appendix C.2 of *USB 2.0 Specification Rev. 2.0*.

The following state diagram depicts the state of a USB 2.0 device.

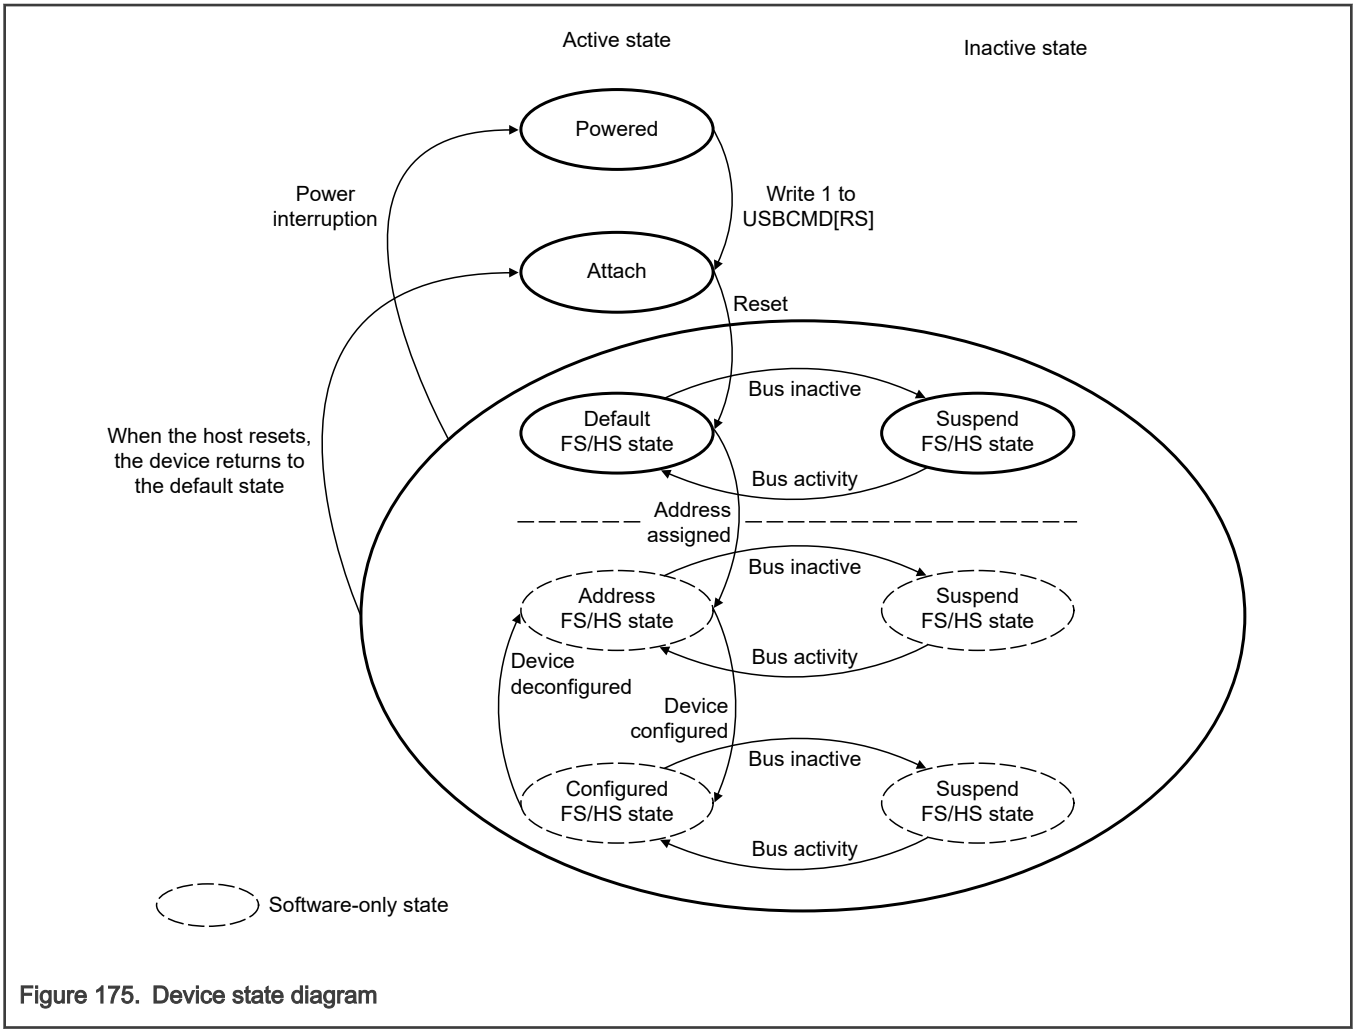

Figure 175. Device state diagram

The powered, attach, defaultFS, defaultHS, suspendFS, and suspendHS states are implemented in the device controller and communicated to the DCD using the following device controller state information fields:

- USBSTS[SLI]
- USBSTS[URI]
- USBSTS[PCI]
- PORTSC1[HSP]

It is the responsibility of the DCD to maintain a state variable to differentiate between the defaultFS and defaultHS states, and the Address and Configured states. A change of state from Default to Address or Configured is part of the enumeration process described in the device framework section of the USB 2.0 specification.

As a result of entering the Address state, the DCD must program DEVICEADDR.

Entry into the Configured state indicates that you have properly initialized all endpoints to be used in the operation of the device by programming the ENDPTCTRL*x* registers and initializing the associated queue heads.

51.3.6.1.1 Bus reset

The host uses a bus reset to initialize downstream devices.

When a bus reset is detected, the device controller renegotiates its attachment speed, resets the device address to 0, and notifies the DCD by interrupt (assuming USBINTR[URE] = 1). After a reset is received, all endpoints (except endpoint 0) are disabled, and the device controller cancels any primed transactions. The following table explains the concept of priming, and the tasks that DCD must perform when a reset is received.

Table 471. Bus reset

Step	Purpose	Programming
1	Clear all setup token semaphores.	Read Endpoint Status (ENDPTSTAT) and write the same value back to ENDPTSTAT.
2	Clear all the endpoint-complete status fields.	Read Endpoint Complete (ENDPTCOMPLETE) and write the same value back to ENDPTCOMPLETE.
3	Cancel primed status.	Wait until all fields in Endpoint Prime (ENDPTPRIME) become 0 and then write FFFFFFFFh to Endpoint Flush (ENDPTFLUSH).

Read PORTSC1[PR] and make sure that it is still active. A USB reset occurs for a minimum of 3 ms and the DCD must reach this point in the reset cleanup before the end of the reset occurs; otherwise, a hardware reset of the device controller is recommended. This is a rare scenario.

You can perform a hardware reset by writing 1 to USBCMD[RST]. By writing 0 to USBCMD[RS], a hardware reset causes the device to detach from the bus. Thus, the DCD must completely reinitialize the device controller after a hardware reset.

Additionally, you must free up all allocated dTDs because the device controller will no longer execute them. If this is the first time the DCD is processing a USB reset event, then it is likely that no dTDs are allocated.

At this time, the DCD can release the control back to the OS because no further changes to the device controller are permitted until a port change detect is indicated.

After a port change detect, the device reaches the default state and the DCD can read Port Status and Control (PORTSC1) to determine whether the device is operating in FS or HS mode. At this time, the device controller reaches its normal operating mode and DCD can begin enumeration according to *USB 2.0 specification chapter 9: Device Framework*.

NOTE

The device DCD may use the FS or HS mode information to determine the bandwidth mode of the device.

In some applications, it may not be possible to enable one or more pipes when in FS mode. There is no difference in DCD operations in FS and HS modes, except for the data rate issue.

51.3.6.1.2 Suspended state and Resume signal

Table 472. Operational models for Suspended state and Resume signal

Suspended	Resume
To conserve power, USB devices automatically enter Suspended state when the device observes no bus traffic for a specified period. When suspended, the USB device maintains any internal status, including its address and configuration. The attached devices must be prepared to suspend at any time when they are powered, regardless of whether they are assigned a nondefault address, are configured, or neither of the two conditions exist. Bus activity may cease because of the host entering a suspend mode of its own. In addition, a USB device must enter the Suspended state when the attached hub port is disabled. A USB device exits Suspend mode when there is bus activity. It may also request the host to exit Suspend mode or selectively suspend by using electrical signaling to indicate remote wake-up. The ability of a device to signal remote wake-up is optional. If the USB device is capable of remote wake-up signaling, the device must support the ability of the host to enable and disable this capability. When the device is reset, remote wake-up signaling must be disabled. The device controller moves into the Suspended state when suspend signaling is detected or activity is missing on the upstream port for more than a specific period. After the device controller enters the Suspended state, an interrupt notifies the DCD (assuming that PORTSC1[SUSP] is 1, which means, the device controller is suspended). The DCD response, when the device controller is suspended, is application-specific and may involve switching to a low-power operation. See the USB 2.0 specification for information about bus power limits in Suspended state.	If the device controller is suspended, its operation is resumed when an active signal is received on its upstream facing port. In addition, the device can signal the system to resume operation by forcing resume signaling to the upstream port by writing 1 to PORTSC1[FPR] when the device is in the Suspended state. Sending resume signal to an upstream port must cause the host to issue resume signaling and bring the suspended bus segment (one more device) back to the active condition. **NOTE** Before using resume signaling, the host must enable it via the set feature command defined in the device framework (chapter 9 of the USB 2.0 specification).

51.3.6.2 Managing endpoints

The USB 2.0 specification defines an endpoint (also called a device endpoint or an address endpoint) as a uniquely addressable portion of a USB device that can source or sink data in a communications channel between the host and the device.

The combination of the endpoint number and endpoint direction specifies the endpoint address.

The channel between the host and an endpoint at a specific device represents a data pipe. Endpoint 0 for a device is always a control type data channel used for device discovery and enumeration. Other types of endpoints that USB supports include bulk, interrupt, and isochronous. Each endpoint type has a specific behavior related to packet response and error handling.

The USB device controller hardware supports up to eight endpoint numbers.

Each endpoint direction is essentially independent, and you can configure it with differing behaviors in each direction. For example, the DCD can configure endpoint "1-In" as a bulk endpoint and endpoint "1-Out" as an isochronous endpoint. This helps to conserve the total number of endpoints required for device operation. The only exception is that control endpoints must use both directions on a single endpoint number to function as a control endpoint. Endpoint 0 is, for example, always a control endpoint and uses both directions.

Each endpoint direction requires a queue head allocated in memory. To support the eight endpoint numbers, 16 queue heads are required. The operation of an endpoint and use of queue heads are described later in this document.

See the USB 2.0 specification for more information about endpoint operations.

51.3.6.2.1 Endpoint initialization

After hardware reset, all endpoints except endpoint 0 are uninitialized and disabled. The DCD must configure and enable each endpoint by configuring ENDPTCTRL*x*.

Each 32-bit ENDPTCTRL*x* is split into an upper and a lower half. The lower half of ENDPTCTRL*x* is used to configure the receive or "Out" endpoint, and the upper half is used to configure the corresponding transmit or "In" endpoint. You must configure the control endpoints in the same way for both the upper and lower halves of ENDPTCTRL*x*; otherwise, the behavior is undefined. The following table shows the fields and corresponding values for device controller endpoint initialization.

Table 473. Device controller endpoint initialization: configuration settings

Step	Purpose	Programming
1	Reset the PID sequence.	Write 1 to ENDPTCTRL*x*[TXR] and ENDPTCTRL*x*[RXR].
2	Configure receive data toggle sequencing.	Write 0 to ENDPTCTRL*x*[TXI] and ENDPTCTRL*x*[RXI].
3	Select the endpoint type.	Configure ENDPTCTRL*x*[TXT] and ENDPTCTRL*x*[RXT].
4	Configure the endpoint stall condition.	Write 0 to ENDPTCTRL*x*[TXS] and ENDPTCTRL*x*[RXS].

51.3.6.2.2 Stalling

The following are the occasions in which the device controller may need to return a STALL response to the host:

- In case of a functional stall: It is a condition that DCD sets, as described in the USB 2.0 device framework. This kind of a stall is only used on noncontrol endpoints, and can be enabled in the device controller by writing 1 to ENDPTCTRL*x*[TXS] and ENDPTCTRL*x*[RXS], associated with the given endpoint and the given direction. In a functional stall condition, the device controller continues to return STALL responses to all transactions occurring on the respective endpoint and direction until DCD writes 0 to ENDPTCTRL*x*[TXS] and ENDPTCTRL*x*[RXS].
- In case of a protocol stall: Unlike a function stall, it is used on control endpoints. The device controller automatically clears it at the start of a new control transaction (setup phase). When enabling a protocol stall, the DCD must enable ENDPTCTRL*x*[TXS] and ENDPTCTRL*x*[RXS] (both directions) as a pair. A single write to ENDPTCTRL*x* can ensure that both ENDPTCTRL*x*[TXS] and ENDPTCTRL*x*[RXS] become 1 at the same instant.

NOTE

Any write to ENDPTCTRL*x* in Operational mode must preserve ENDPTCTRL*x*[TXT] and ENDPTCTRL*x*[RXT], which means you must perform a read-modify-write operation.

Table 474. Device controller stall response matrix

USB packet	Value of ENDPTCTRL*x*[TXS] and ENDPTCTRL*x*[RXS]	Effect on ENDPTCTRL*x*[TXS] and ENDPTCTRL*x*[RXS]	USB response
Setup packet that a noncontrol endpoint receives	N/A	None	STALL
In, Out, or Ping packet that a noncontrol endpoint receives	1	None	STALL
In, Out, or Ping packet that a noncontrol endpoint receives	0	None	ACK, NAK, or NYET
Setup packet that a control endpoint receives	N/A	Cleared	ACK
In, Out, or Ping packet that a control endpoint receives	1	None	STALL
In, Out, or Ping packet that a control endpoint receives	0	None	ACK, NAK, or NYET

51.3.6.2.3 Data toggle

Data toggle is a mechanism to maintain data coherency between the host and device for a given data pipe.

For more information about data toggle, see the USB 2.0 specification.

51.3.6.2.3.1 Data toggle reset

The DCD can reset ENDPTCTRL*x*[TXR] and ENDPTCTRL*x*[RXR] and cause the data toggle sequence to reset in the device controller by writing 1 to ENDPTCTRL*x*[TXR] and ENDPTCTRL*x*[RXR].

This is necessary only when configuring or initializing an endpoint, or returning from a STALL condition.

51.3.6.2.3.2 Data toggle inhibit

Writing 1 to ENDPTCTRL*x*[TXI] and ENDPTCTRL*x*[RXI] causes the device controller to ignore the data toggle pattern that is normally sent, and accepts all incoming data packets regardless of the data toggle state.

During normal operation, the device controller checks the DATA0 and DATA1 fields against the data toggle to determine whether the packet is valid. If the data PID does not match either ENDPTCTRL*x*[TXR] or ENDPTCTRL*x*[RXR] (that the device controller maintains for that endpoint), the data toggle is considered invalid. In this case, the device controller assumes that the packet is already received and discards the packet without reporting it to the DCD. To prevent the host controller from resending the same packet, the device controller responds to the error packet by acknowledging it with either an ACK or NYET response.

NOTE

This feature is for test purposes only; you must never use it during a normal device controller operation.

51.3.6.2.3.3 Priming transmit (TX) endpoints

Priming a transmit endpoint causes the device controller to fetch the device transfer descriptor (dTD) for the transaction that the dQH points to.

After the dTD is fetched, it is stored in the dQH until the device controller completes the transfer described by the dTD. Storing the dTD in the dQH allows the device controller to fetch the operating context needed to handle a request from the host, without the need to follow the linked list, starting at the dQH when the host request is received.

After the device has loaded the dTD, the leading data in the packet is stored in a FIFO in the device controller. This FIFO is split into virtual channels so that the leading data can be stored for any endpoint, with the maximum number of endpoints configured at the device synthesis time.

After a priming request is complete, Endpoint Status (ENDPTSTAT) indicates an endpoint state of primed transmit. For this, the device controller can respond to an "In" request from the host and meet the stringent bus turnaround time of HS USB.

Because only the leading data is stored in the device controller FIFO, the device controller must begin filling in leading data after the transaction starts. The FIFO must be sized to account for the maximum latency that the system memory bus can incur.

51.3.6.2.3.4 Priming receive (RX) endpoints

From the point of view of the DCD, priming receive endpoints is identical to priming transmit endpoints. Considering the device controller, the major difference in the operational model is that there is no data movement of the leading packet data because the data will be received from the host.

As part of the architecture, the FIFO for the receive endpoints is not partitioned into multiple channels like the transmit FIFO. Thus, the size of the receive FIFO does not scale with the number of endpoints.

51.3.6.3 Operational model for packet transfers

The host initiates all transactions on the USB bus, and in turn, the device must respond to any request from the host within the turnaround time stated in the USB 2.0 specification.

With USB 1.1 FS and LS rates, this turnaround time was significant and the USB 1.1 device controllers were architected in a way that enabled the device controller to access the main memory or interrupt a host protocol processor in order to respond to the USB 1.1 transaction. The architecture of the USB 2.0 device controller is different because the same methods do not meet the USB 2.0 HS turnaround time requirements from the increased clock rate.

A USB host sends requests to the device controller in an order that cannot be precisely predicted as a single pipeline, so it is not possible to prepare a single packet for the device controller to execute. However, the order of packet requests is predictable if the endpoint number and direction are considered. For example, if endpoint 3 (transmit direction) is configured as a bulk pipe, then the host is expected to send "In" requests to that endpoint. This device controller is architected in a way that enables it to prepare packets for each endpoint or direction in anticipation of the host request. The process of preparing the device controller to send or receive data in response to host-initiated transactions on the bus is referred to as priming the endpoint. This term is used throughout the chapter to describe the device controller operation so you can use priming to appropriately architect the DCD. Furthermore, the term flushing is used to describe the action of clearing a packet that is queued for execution.

51.3.6.3.1 Interrupt and bulk endpoint operational model

The behaviors of the device controller for interrupt and bulk endpoints are identical.

All valid "In" and "Out" transactions to bulk pipes handshake with a NAK unless the endpoint is primed. After the endpoint is primed, data delivery commences.

The device controller retires a dTD after the packets described in the transfer descriptor are completed. Each dTD describes "N" packets to be transferred according to the USB variable length transfer protocol. Equation 5, Table 475, and Table 476 describe how the device controller computes the number and length of packets that USB must send and receive. These vary according to the total number of bytes and maximum packet length. Also, Table 477 describes when TX-dTD and RX-dTD are considered complete.

With ZLT = 0, N = INT (number of bytes ÷ maximum packet length) + 1

With ZLT = 1, N = MAXINT (number of bytes ÷ maximum packet length)

N = MAXINT (number of bytes ÷ maximum packet length)

Equation 5. Formula for N

Table 475. Variable length transfer protocol example (ZLT = 0)

Bytes (dTD)	Maximum packet length (dQH)	N	P1	P2	P3
511	256	2	256	255	—
512	256	3	256	256	0
512	512	2	512	0	—

Table 476. Variable length transfer protocol example (ZLT = 1)

Bytes (dTD)	Maximum packet length (dQH)	N	P1	P2	P3
511	256	2	256	255	—
512	256	2	256	256	—
512	512	1	512	—	—

NOTE

You must write 00 to the MULT field in the dQH (see Device endpoint queue head (dQH)) for bulk, interrupt, and control endpoints.

Table 477. TX-dTD and RX-dTD completion status

TX-dTD is considered complete when:	RX-dTD is considered complete when:
All packets described in dTD are successfully transmitted. When this occurs, the total bytes in dTD become zero.	• All packets described in dTD are successfully received. When this occurs, the total bytes in dTD become zero. • A short packet (number of bytes < maximum packet length) is received. This is a successful transfer completion. DCD must check the total bytes in dTD to determine the number of bytes that are remaining. From the total bytes remaining in the dTD, the DCD can compute the actual bytes received. • A long packet is received: (number of bytes > maximum packet size) OR (total bytes received > total bytes specified). This is an error condition. The device controller discards the remaining packet and sets the Data Buffer Error bit in the Status field of the dTD (see Device endpoint transfer descriptor (dTD)). In addition, the endpoint is flushed and the USBERR interrupt becomes active.

After the successful completion of the packet(s) that dTD describes, the Active bit in the Status field of the dTD is cleared and the next pointer is followed when the Terminate field in dTD is clear. When the Terminate field is set, the device controller flushes the endpoint or direction and ceases operations for that endpoint or direction.

After an unsuccessful completion of a packet (in the case of a long packet), the dQH points to the dTD in error. To recover from this error condition, the DCD must properly reinitialize the dQH by clearing the Active bit and updating the next dTD pointer before attempting to reprime the endpoint.

NOTE

The device controller automatically retires all packet level errors, such as a missing handshake or CRC error. An interaction with the DCD is not required for handling such errors.

51.3.6.3.1.1 Interrupt and bulk endpoint bus response matrix

The following table shows the device controller's response to packets on interrupt and bulk endpoint, according to the device controller's state. In the table:

- Bus error refers to force bit stuff error.
- NYET or ACK: If the transfer descriptor has packets remaining (according to the USB variable length protocol), the response is ACK. Otherwise, the response is NYET.

A system error (SYSERR) should not occur when the latency FIFOs are correctly sized and the DCD is responsive.

Table 478. Interrupt and bulk endpoint bus response matrix

Token type	Stall	Not primed	Primed	Underflow	Overflow
Setup	Ignore	Ignore	Ignore	N/A	N/A
In	STALL	NAK	Transmit	Bus error	N/A
Out	STALL	NAK	Receive + NYET or ACK	N/A	NAK
Ping	STALL	NAK	ACK	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

51.3.6.3.2 Control endpoint operation model

51.3.6.3.2.1 Setup phase

All requests to a control endpoint begin with a setup phase, followed by an optional data phase and a required status phase. The device controller always accepts the setup phase unless the setup lockout is engaged.

The setup lockout engages so that future setup packets are ignored. Lockout of setup packets ensures that when software is reading the setup packet stored in the queue head, that data is not written at the same time because this can potentially cause an invalid setup packet.

You can disable the setup lockout mechanism only one time at initialization (by writing 1 to USBMODE[SLOM]), and a new tripwire type semaphore ensures that the setup packet payload is extracted from the queue head without being corrupted by an incoming setup packet. Setup lockout is not necessary when using the tripwire. This is the preferred behavior because ignoring repeated setup packets because of long software interrupt latency leads to a compliance issue.

After receiving an interrupt and inspecting Endpoint Setup Status (ENDPTSETUPSTAT) to determine that a setup packet is received on a particular pipe, perform the following procedure.

Table 479. Setup phase: associated procedure

Step	Purpose	Programming	Notes
1	Clear the corresponding bit.	Write 1 to ENDPTSETUPSTAT[ENDPTSETUPSTAT].	—
2	—	Write 1 to USBCMD[SUTW].	—
3	Duplicate contents of the Setup Buffer field (in dTD) into a local software byte array.	—	—
4	—	Read USBCMD[SUTW].	If the field is 1, continue to the next step; if the field is 0, go back to step 2.
5	—	Write 0 to USBCMD[SUTW].	—
6	Process the setup packet using a local software byte array copy, and execute the status and handshake phases.	—	After receiving a new setup packet, the status and handshake phases may still be pending from a previous control sequence. These must be flushed and deallocated before linking a new status or handshake dTD for the most recent setup packet.

51.3.6.3.2.2 Data phase

Following the setup phase, the DCD must create a device transfer descriptor for the data phase and prime the transfer.

After priming the packet, the DCD must immediately verify (by reading Endpoint Setup Status (ENDPTSETUPSTAT)) that a new setup packet has not been received. A prime completes when the associated field in Endpoint Prime (ENDPTPRIME) is 0 and the associated field in Endpoint Status (ENDPTSTAT) is 1. If the associated field in Endpoint Prime (ENDPTPRIME) becomes 0 and the associated field in Endpoint Status (ENDPTSTAT) has not become 1, prime fails. This is only due to improper setup of the dQH, the dTD, or a setup arriving during the prime operation. If a new setup packet is indicated after the associated field in Endpoint Prime (ENDPTPRIME) becomes 0, then the transfer descriptor is freed and the DCD must reinterpret the setup packet.

If a setup arrives after the data stage is primed, the device controller automatically clears the prime status (Endpoint Status (ENDPTSTAT)) to enforce data coherency with the setup packet.

NOTE

- You must write 00 to the MULT field in the dQH (see Device endpoint queue head (dQH)) for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is performed in the same way as bulk packets.

51.3.6.3.2.3 Status phase

Similar to the data phase, the DCD must create a transfer descriptor (with byte length equal to 0) and prime the endpoint for the status phase.

The DCD must also perform the same checks associated with ENDPTSETUPSTAT[ENDPTSETUPSTAT], as described in the data phase.

NOTE

- You must write 00 to the MULT field in the dQH (see Device endpoint queue head (dQH)) for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is performed in the same way as bulk packets.

51.3.6.3.2.4 Control endpoint bus response matrix

The following table shows the device controller's response to packets on a control endpoint, according to the device controller's state. In the table:

- Bus error refers to force bit stuff error.
- NYET or ACK: If the transfer descriptor has packets remaining (according to the USB variable length protocol), the response is ACK. Otherwise, the response is NYET.
- System error (SYSERR) must never occur when the latency FIFOs are correctly sized and the DCD is responsive.

Table 480. Control endpoint bus response matrix

Token type	Endpoint state					Setup lockout
	Stall	Not primed	Primed	Underflow	Overflow	
Setup	ACK	ACK	ACK	N/A	SYSERR	—
In	STALL	NAK	Transmit	Bus error	N/A	N/A
Out	STALL	NAK	Receive + NYET or ACK	N/A	NAK	N/A
Ping	STALL	NAK	ACK	N/A	N/A	N/A
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore	Ignore

51.3.6.3.3 Isochronous endpoint operational model

Isochronous endpoints are used for real-time scheduled delivery of data, and their operational model is significantly different from the host throttled bulk, interrupt, and control data pipes.

The device controller accomplishes real-time delivery by using the following techniques:

- Exact MULT packets per microframe are transmitted and received. MULT is a two-bit field in the dQH (see Device endpoint queue head (dQH)). The variable length packet protocol is not used for isochronous endpoints.
- NAK responses are not used. Instead, zero-length packets are sent in response to an "In" request for unprimed endpoints. For unprimed RX endpoints, the response to an "Out" transaction is to ignore the packet within the device controller.
- Prime requests always schedule the transfer described in the dTD for the next microframe. If the ISO-dTD is still active after that frame, then the ISO-dTD is considered ready until the DCD executes or cancels it.

An EHCI-compatible host controller uses the periodic frame list to schedule data exchanges to isochronous endpoints. The operational model for Device mode does not use such a data structure. Instead, the same dTD used for control, bulk, and interrupt endpoints is also used for isochronous endpoints. The difference between bulk and ISO endpoints is in the handling of the dTD:

- Priming an ISO endpoint is a delayed operation so that an endpoint is primed only after an SOF is received. After the DCD writes to the prime bit, the bit is cleared as usual to indicate to software that the device controller completed priming the dTD for transfer. Internal to the design, the device controller hardware masks that prime start until the next frame boundary. This behavior is hidden from the DCD but occurs so that the device controller can match the dTD to a specific microframe.
- With isochronous endpoints, the transaction must fully complete within one microframe. After an ISO transaction is started in a microframe, it retires the corresponding dTD when MULT transactions occur or the device controller finds a fulfillment condition.

  The Transaction Error bit in the Status field of the dTD indicates a fulfillment error condition. When a fulfillment error occurs on the frame after the transfer fails to complete, the device controller force retires the ISO-dTD and moves to the next ISO-dTD.

NOTE

Partially completed packets cause fulfillment errors. If no activity occurs on a primed ISO-dTD, the transaction stays primed indefinitely. This means it is up to you to discard transmit ISO-dTDs that pile up from a failure of the host or to move the data.

- The data level error handling for ISO packets is different. When a CRC error occurs on a received packet, the packet is not retried in the same way as bulk and control endpoints. Instead, the CRC error is noted by setting the Transaction Error bit in the Status field of the dTD, and the data is stored as usual for the application software to manage. The following table shows how a retired ISO packet is managed.

Table 481. Conditions that cause transmit and receive packets to retire

Conditions for transmit packet retirement (all conditions must be fulfilled)	Conditions for receive packet retirement (all conditions must be fulfilled)
• The MULT counter reaches zero. • A fulfillment error occurs. The Transaction Error bit is set in the Status field of the dTD: number of packets occurred > 0 AND number of packets occurred < MULT. **NOTE** For TX-ISO, the MULT counter can be loaded with a lesser value in the dTD MULTO field in hardware versions 2.3 and later. If MULTO is 0, the MULT counter is initialized to the multiplier in the queue head.	• The MULT counter reaches zero. • A non-MDATA PID is received. The exit criteria is only valid in hardware version 2.3 or later. Before this version, any PID sequence that did not exactly match the MULTO field was flagged as a transaction error because of a PID mismatch or fulfillment error. • An overflow error occurs. This happens when: — The packet received is greater than the maximum packet length (the Data Buffer Error bit is set in the Status field of the dTD). — The packet received exceeds the total bytes allocated in the dTD (the Data Buffer Error bit is set in the Status field of the dTD). • A fulfillment error occurs (the Transaction Error bit is set in the Status field of the dTD): number of packets occurred > 0 AND number of packets occurred < MULT. • A CRC error occurs (the Transaction Error bit is set in the Status field of the dTD).

NOTE

For ISO, when a dTD is retired, the next dTD is primed for the next frame. For a continuous microframe-to-microframe operation, the DCD must ensure that the dTD linked-list is ahead of the device controller by at least two microframes.

51.3.6.3.3.1 Isochronous pipe synchronization

When it is necessary to synchronize an isochronous data pipe to the host, the microframe number (specified by FRINDEX) can be used as a marker.

To cause a packet transfer to occur at a specific microframe number ("N"), the DCD must interrupt on SOF during frame N-1. If FRINDEX = N-1, the DCD must write to the prime bit. The device controller primes the isochronous endpoint in microframe N-1 so that the device controller is able to execute delivery during microframe N.

NOTE

Priming an endpoint towards the end of microframe N-1 does not guarantee delivery in microframe N. The delivery may actually occur in microframe N+1 if the device controller does not have enough time to complete the prime before the SOF for packet N is received.

51.3.6.3.3.2 Isochronous endpoint bus response matrix

The following table shows the device controller's response to packets on isochronous endpoints, according to the device controller's state. In the table:

- Bus error refers to force bit stuff error.
- Null packet refers to zero-length packet.

Table 482. Isochronous endpoint bus response matrix

Token type	Stall	Not primed	Primed	Underflow	Overflow
Setup	Stall	Stall	Stall	N/A	N/A
In	Null packet	Null packet	Transmit	Bus error	N/A
Out	Ignore	Ignore	Receive	N/A	Drop packet
Ping	Ignore	Ignore	Ignore	Ignore	Ignore
Invalid	Ignore	Ignore	Ignore	Ignore	Ignore

51.3.6.4 Managing queue heads

The dQH points to the linked list of transfer tasks; the dTD depicts each of these tasks. An area of memory that ENDPTLISTADDR points to contains a group of all dQHs in a sequential list, as shown in Figure 176. The even elements in the list of dQHs are used for receive endpoints (Out and Setup) and the odd elements are used for transmit endpoints (In and Interrupt). Device transfer descriptors are linked, head to tail, starting at the queue head and ending at the Terminate bit of the dTD. After the dTD retires, it is no longer a part of the linked list from the queue head. Therefore, software is required to track all transfer descriptors because pointers do not exist within the queue head after the dTD is retired (see Software link pointers).

In addition to the current and next pointers, and the dTD overlay examined in Operational model for packet transfers, the dQH also contains the following parameters for the associated endpoint: Multiplier (MULT), Maximum Packet Length, and Interrupt On Setup (IOS). The next section discusses the complete initialization of the dQH, along with these fields.

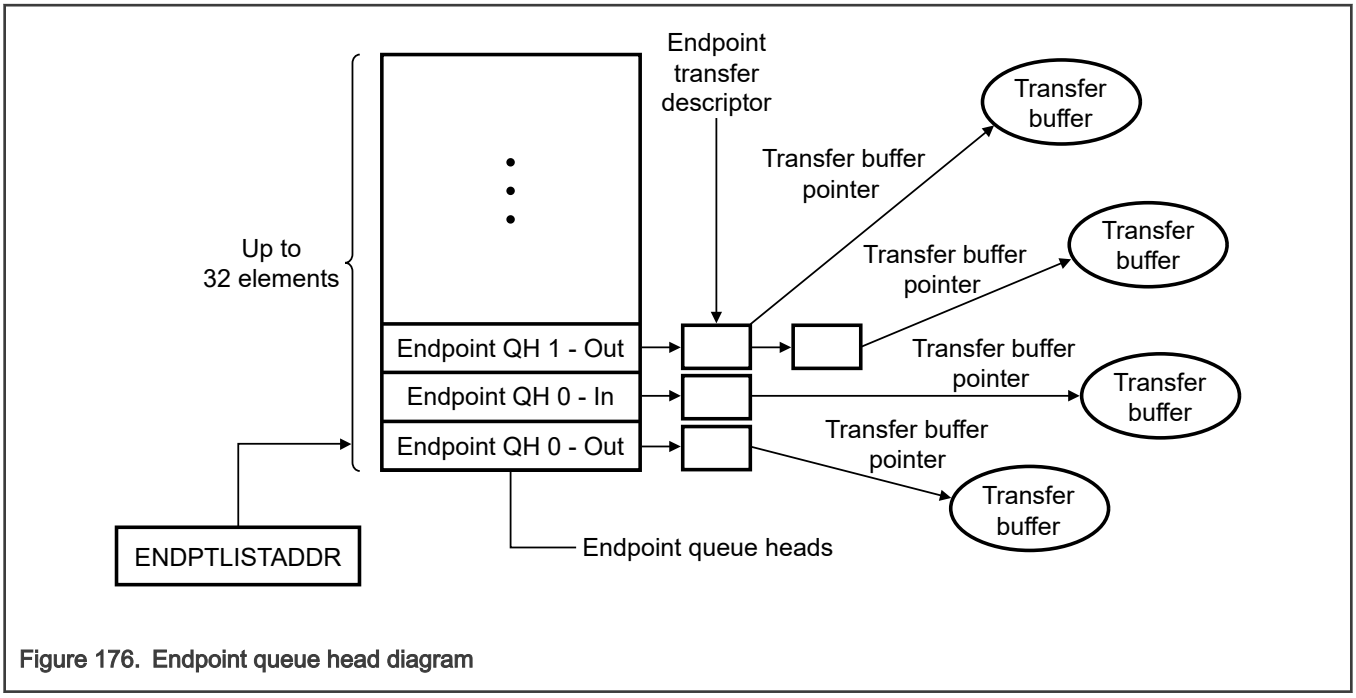

Figure 176. Endpoint queue head diagram

51.3.6.4.1 Queue head initialization

You must initialize a device queue head for each active endpoint. Perform the following procedure to initialize it.

Table 483. Queue head initialization

Step	Programming	Notes
1	Write to the wMaxPacketSize field as either the USB chapter 9 or application-specific protocol requires.	—
2	Write 0 to the MULT field in dQH for control, bulk, and interrupt endpoints.	Set the multiplier to 1, 2, or 3, for ISO endpoints, as the required bandwidth and in conjunction with the USB chapter 9 protocol. In FS mode, the MULT field in dQH can only be 1 for ISO endpoints.
3	Write 1 to the next Terminate field in dTD.	—
4	Write 0 to the Active bit in the Status field of dTD.	—
5	Write 0 to the Halt bit in the Status field of dTD.	—

NOTE

The DCD must only modify dQH if the associated endpoint is not primed and there are no outstanding dTDs.

51.3.6.4.2 Operational model for setup transfers

As discussed in Control endpoint operation model, the DCD gives special treatment to setup transfer. It does not use a dTD, but instead stores the incoming data from a setup packet in an 8-byte buffer within the dQH.

After receiving a notification of the setup packet, the DCD must manage the setup transfer as provided in the following procedure.

Table 484. Setup transfers: associated procedure

Step	Purpose	Programming	Notes
1	Copy setup buffer contents from dQH–RX to software buffer.	—	—
2	Acknowledge setup backup.	Write 1 to the corresponding bit in ENDPTSETUPSTAT[ENDPTSETUPSTAT].	• The acknowledgement must occur before continuing to process the setup packet. • After the acknowledgement has occurred, the DCD must not attempt to access the setup buffer in the dQH–RX. Only the local software copy must be examined.
3	Check for pending data or status dTDs from previous control transfers and flush, if any exist.	See Flushing and de-priming an endpoint.	—
4	—	Decode the setup packet, and prepare data phase (optional) and status phase transfers as required by either the USB chapter 9 or application-specific protocol.	—

NOTE

The device controller can receive setup packets before the completion of previous control transfers. Existing control packets in progress must be flushed and the new control packet must be completed.

51.3.6.5 Managing transfers with transfer descriptors

51.3.6.5.1 Software link pointers

The DCD software must maintain head and tail pointers to the linked list of dTDs for each respective queue head.

This is necessary because the dQH only maintains pointers to the currently working dTD and the next dTD to be executed. The operations described in the next section for managing the dTD assume that the DCD can use the head and tail of the dTD linked list. The following figure shows the software link pointers.

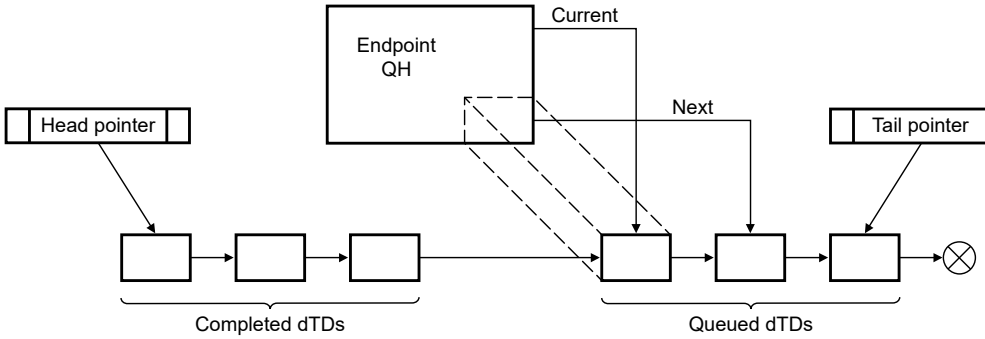

Figure 177. Software link pointers

NOTE

To conserve memory, the reserved fields at the end of the dQH can be used to store the head and tail pointers, but it still remains the responsibility of the DCD to maintain the pointers.

51.3.6.5.2 Building a transfer descriptor

Before executing a transfer from the linked list, you must build a dTD to describe the transfer.

As a prerequisite, allocate 8-DWORD dTD block of memory aligned to 8-DWORD boundaries. For example, bit address 4:0 is equal to 00000. Then perform the following procedure to build a dTD.

Table 485. Building a transfer descriptor: associated procedure

Step	Purpose	Programming
1	—	Write 0 to the first seven DWords.
2	—	Write 1 to the Terminate field in dTD.
3	—	Write the transfer size to the Total Bytes field in dQH.
4	—	Write 1 to the Interrupt On Complete (IOC) field in dTD, if desired.
5	Initialize the Status field.	Write 1 to the Active bit of the Status field and write 0 to all remaining Status bits.
6	Point to the start of the data buffer.	Fill in buffer pointer page 0 and the current offset.
7	—	Initialize buffer pointer page 1 through page 4 to be one greater than each of the previous buffer pointers.

51.3.6.5.3 Executing a transfer descriptor

To safely add a dTD, the DCD must perform the procedures listed in Table 486, based on the case. These procedures manage the event in which the device controller reaches the end of the dTD list at the same time a new dTD is added to the end of the list.

Determine whether the link list is empty by checking the DCD driver. This evaluates whether the pipe is empty (the internal representation of the linked list must indicate whether any packets are outstanding).

Table 486. Executing a transfer descriptor

Step	Case 1: If the link list is empty	Step	Case 2: If the link list is not empty
1	Write to the dQH next pointer and write 0 to the dQH Terminate bit as a single DWORD operation.	1	Add dTD to the end of linked list.
2	Clear the active and halt bits in dQH (in case they are set from a previous error).	2	Read the appropriate field in ENDPTPRIME. If it is 1, it is done; otherwise, continue to read the field.
3	Prime the endpoint by writing 1 to the appropriate field in ENDPTPRIME. You must check that the dTD and dQH content in external memory is updated before writing 1 to the field in ENDPTPRIME.	3	Write 1 to USBCMD[ATDTW].
—	—	4	Read the appropriate status field in ENDPTSTAT (store in a temporary variable for later use).
—	—	5	Read USBCMD[ATDTW]: • If the field is 0, go back to step 3. • If the field is 1, move forward to step 6.
—	—	6	Write 0 to USBCMD[ATDTW]: • If the status field read at step 4 is 1, the procedure is complete. • If the status field read at step 4 is 0, then go to step 1 of case 1.

51.3.6.5.4 Transfer completion

After you initialize a dTD and prime the associated endpoint, the device controller executes the transfer on the host-initiated request. The DCD is notified with a USB interrupt if the Interrupt On Complete (IOC) bit in the dTD is set. Alternately, the DCD can poll ENDPTCOMPLETE to find when the dTD was executed. After a dTD is executed, the DCD can also check the associated status bits to determine execution success or failure.

NOTE

Multiple dTDs can be completed in a single endpoint-complete notification. After clearing the notification, DCD must search the dTD linked list and retire all dTDs that are complete (the Active bit in the dTD Status field is cleared).

By reading the status fields of the completed dTDs, the DCD can determine whether the transfers completed successfully. The following combination of status bits determine the transfer completion success:

- Active = 0
- Halted = 0
- Transaction Error = 0
- Data Buffer Error = 0

If any combination other than the aforementioned one exists, the DCD must take proper action. Device error matrix indicates the transfer failure mechanisms.

In addition to checking the status bit, the DCD must read the Transfer Bytes field to determine the actual bytes transferred. When a transfer is complete, the total bytes transferred is decremented by the actual bytes transferred. For transmit packets, a packet is considered complete only after the actual byte count is zero. For receive packets, the host can send fewer bytes in the transfer according to the USB variable length packet protocol.

51.3.6.5.5 Flushing and de-priming an endpoint

The DCD must flush to de-prime another endpoint on a USB device reset or during a broken control transfer.

Some application-specific requirements may exist to stop transfers in progress. The DCD can perform the following procedure to stop a transfer in progress:

1. Write 1 to the corresponding field(s) in ENDPTFLUSH.
2. Wait until all fields in ENDPTFLUSH become 0.

   NOTE

   This operation may take quite a long time, depending on the USB bus activity. You must not have this wait loop within an interrupt service routine.

3. Read ENDPTSTAT to ensure that the corresponding fields are now 0 for all endpoints commanded to be flushed. The following is the reason for a flush failure, if the corresponding bits are still 1 after completion of step 2:

   In very rare cases, a packet is already in progress to a particular endpoint when the previous endpoint commands the flush operation by writing to ENDPTFLUSH. A safeguard is in place to refuse the flush, to ensure that the packet in progress completes successfully. The DCD may need to repeatedly flush any endpoints that fail to flush by repeating steps 1–3 until each endpoint is successfully flushed.

51.3.6.5.6 Device error matrix

Table 487 summarizes packet errors that the device controller does not manage automatically.

Table 487. Device error matrix

Error	Direction	Packet type	Data buffer error bit	Transaction error bit
Overflow	RX	Any	1	0
ISO packet error	RX	ISO	0	1
ISO fulfillment error	Both	ISO	0	1

The device controller manages all errors on bulk, control, and interrupt endpoints, except for a data buffer overflow. However, for ISO endpoints, error packets are not retried and errors are tagged as indicated in Table 488.

Table 488. Error descriptions

Error	Description
Overflow	Indicates that the number of bytes received exceeded the maximum packet size or total buffer length. This error also sets the Halt bit in the dQH, and if there are dTDs remaining in the linked list for the endpoint, then those are not executed.
ISO packet error	Indicates a CRC error on the received ISO packet. Contents are not guaranteed to be correct.

Table continues on the next page...

Table 488. Error descriptions (continued)

Error	Description
ISO fulfillment error	Indicates that the host failed to complete the number of packets, defined in the dQH MULT field, within the given microframe. For scheduled data delivery, the DCD may need to readjust the data queue because a fulfillment error causes the device controller to cease data transfers on the pipe for one microframe. During the dead microframe, the device controller reports an error on the pipe and primes for the following frame.

51.3.7 Modes of operation

USB has two main modes of operation.

Table 489. Modes of operation

Mode	Description
Normal	USB can operate in Host mode and Device (Peripheral) mode.
Low-Power	USB supports Suspend mode and Sleep mode to reduce power consumption. It has an associated power control subblock that is clocked on a low-power, low-frequency clock. When the USB bus is idle, the transceiver can be placed in Low-Power mode, after which you can stop the USB clocks. This low-power clock must remain active because it is needed for wake-up detection. **NOTE** See the chip-specific USB information for the low-power clock in Suspend mode and Sleep mode. As the USB 2.0 specification describes, the device can go into the Suspend state after it sees a constant Idle state on the upstream-facing port (UFP). USB enters Suspend mode after 3 ms of inactivity on the port when it is in Device Operation mode. The host controller does not suspend automatically; you can place it in Suspend mode. Either the local Arm platform, the remote USB host, or a peripheral can initiate a wake-up sequence to resume USB communication. For more information on Suspend and Resume states, see Power control.

51.3.7.1 Power control

USB supports suspend and wake-up functionalities.

The power control block allows you to place the transceiver in USB Low-Power mode when the USB bus is in the Idle state, and supports local and remote wake-up to bring the transceiver out of the USB Low-Power mode, when needed. Additionally, the power control block can wake up the Arm platform by generating an interrupt.

51.3.7.1.1 Entering a low-power suspend (L2) mode

In Device Operation mode, after the host drive is in the Idle state for 3 ms, an SLI interrupt is issued (USBSTS[SLI]). After SLI is received, perform the steps listed in the last column of the following table.

Low-Power Suspend mode is always entered under the control of the driver software by writing 1 to the appropriate field in PORTSC1. After the controller is suspended, the clocks to the USB controller can be stopped.

For entering a low-power suspend (L2) mode, the device can be in Low-Power mode.

Table 490. Entering a low-power suspend (L2) mode

Step	When in Host Operation mode:	Step	When in Device Operation mode (after SLI is received):
1	Write 0 to USBCMD[ASE] and USBCMD[PSE], and wait until USBSTS[AS] and USBSTS[PS] become 0.	1	Write 1 to PORTSC1[PHCD].
2	Write 1 to PORTSC1[SUSP].	2	Select the wake-up sources.
3	For an HS operation, wait for 4 ms.	3	Wait for 3 µs.
4	Write 1 to PORTSC1[PHCD].	—	—
5	Select the wake-up sources.	—	—
6	Wait for 3 µs.	—	—

51.3.7.1.2 Entering a low-power sleep (L1) mode

For entering a low-power sleep (L1) mode, the device can be in Low-Power mode but the low-power clock must be available for wake-up from L1.

Table 491. Entering a low-power sleep (L1) mode

Step	When in Host Operation mode:	Step	When in Device Operation mode:
1	Write 0 to USBCMD[ASE] and USBCMD[PSE], and wait until USBSTS[AS] and USBSTS[PS] become 0.	1	Write 1 to LPM_CSR0[LPM_EN].
2	Write 1 to LPM_CSR0[LPM_EN].	2	Write 1 to the interrupt enable fields, such as USBINTR[PCE], USBINTR[SLE], USBINTR[LPM_L1_ENTRYIE], and USBINTR[LPM_L1_EXITIE].
3	Write 1 to LPM_CSR0[LPM_ERRATA_EN] to support *Errata for USB 2.0 ECN: Link Power Management (LPM) 7/2007*.	3	Write 1 to LPM_CSR0[LPM_ERRATA_EN] to support *Errata for USB 2.0 ECN: Link Power Management (LPM) 7/2007*.
4	Configure LPM_CSR2[LPM_HST_DEVADD], LPM_CSR2[LPM_HST_BESL], and LPM_CSR2[LPM_HST_RWKEN]. These fields are sent via the LPM token to the device.	4	Configure LPM_CSR1[LPM_DEV_BESLTHRES] and LPM_CSR1[LPM_DEV_RES].
5	Write 1 to the interrupt enable fields, such as USBINTR[PCE], USBINTR[LPM_L1_ENTRYIE], and USBINTR[LPM_L1_EXITIE].	5	After the host sends the LPM token, the device automatically replies with field values ACK, NYET, or STALL, according to the current situation. The received LPM token content is recorded in LPM_CSR1[LPM_DEV_BESLRCVD], LPM_CSR1[LPM_DEV_LNKSTRCVD], or LPM_CSR1[LPM_DEV_RWKENRCVD]. The device's response is recorded in LPM_CSR1[LPM_DEV_RSPSTS] too.
6	Write 1 to LPM_CSR2[LPM_HST_SEND] to send the LPM token to the device. This field automatically becomes 0 after the LPM transaction is completed.	6	USBSTS[LPM_DEV_RCVDI] interrupt can be issued.

Table continues on the next page...

Table 491. Entering a low-power sleep (L1) mode (continued)

Step	When in Host Operation mode:	Step	When in Device Operation mode:
	USBSTS[LPM_HST_COMPI] becomes 1 after receiving the device's response to the LPM token. The response is recorded in LPM_CSR2[LPM_HST_STSRCVD].		
7	PORTSC1[SUSP] automatically becomes 1 after the ACK response is received and LPM_CSR0[LPM_L1_ACTIVE] is 1. The host is in the L1 state.	7	After the TL1TokenRetry time, the device starts transitioning to L1. After the TL1Residency time, the device is in L1.
8	PORTSC1[PHCD] automatically becomes 1 after (TL1TokenRetry + TL1Residency) . The host is in Low-Power L1 mode.	8	PORTSC1[PHCD] automatically becomes 1 and the device is in Low-Power Sleep mode.
9	USBSTS[LPM_L1_ENTRYI] interrupt can be issued.	9	USBSTS[SLI] or USBSTS[LPM_L1_ENTRYI] interrupts can be issued.
10	Select the wake up sources.	10	Select the wake-up sources.
11	Wait for 3 µs.	11	Wait for 3 µs.

51.3.7.1.3 Wake-up events

The power control block monitors the USB bus when the USB core is in USB Suspend or Sleep state.

Depending on whether the controller is in Host or Device mode, a number of wake-up conditions are monitored. If the related wake-up interrupt enable field is 1, an asynchronous interrupt is generated to the Arm platform upon detection of a wake-up condition.

51.3.7.1.3.1 Host mode events

The host controller wakes up after any of the following events:

- Remote wake-up request: A peripheral can request the host to reactivate the bus by driving wake-up signaling on the DM or DP lines. The power control block sends a wake-up request to the USB core when a J-K transition on the DM or DP line is detected.
- Wake-up on overcurrent: If a wake-up on overcurrent is enabled (PORTSC1[WKOC] = 1), the power control block sends a wake-up request to the USB core when an overcurrent event is detected.

NOTE

See the chip-specific USB information to know whether the controller supports wake-up on overcurrent.

- Wake-up on disconnect: If wake-up on disconnect is enabled (PORTSC1[WKDC] = 1), the power control block sends a wake-up request to the USB core when a disconnection event is detected (a J-SE0 or K-SE0 transition on the DM or DP line).
- Wake-up on connect: If a wake-up on connect is enabled (PORTSC1[WKCN] = 1), the power control block sends a wake-up request to the USB core when a connection event is detected (an SE0-J or SE0-K transition on the DM or DP line).

51.3.8 Clocking

Table 492. USB clock sources

Clock	Description
AHB clock	AHB bus clock
UTMI clock	UTMI clock from USBPHY
Low-power, low-speed clock	Used for wake up from Low-Power mode. See the chip-specific USB information for low-power clock information.

See the "Clock Controller (CLKCTL)" chapter for clock setting, configuration, and gating information.

51.3.9 Interrupts

51.3.9.1 USB core interrupts

The USB core uses a dedicated vector in the interrupt table.

With the exception of wake-up interrupts, the USB core controls all interrupt sources. See Interrupt Enable (USBINTR) for more information.

51.3.9.2 USB wake-up interrupts

The USB core has an associated wake-up interrupt. These interrupts are generated outside the USB core, but use the same vector as the corresponding USB core interrupt.

The power control blocks generate these interrupts, which run on a low-power, low-speed clock. The wake-up interrupt is designed to work even when the USB and Arm platform clocks are disabled so that a wake-up condition on the USB bus can reactivate the Arm platform clocks.

Because the wake-up interrupt is generated and cleared on a low-power, low-speed clock, this interrupt request responds very slowly to clear actions. For this reason, you must disable the wake-up interrupt to clear the request flag. Disabling the interrupt masks the request instantaneously because it is clocked by the Arm platform clock. You must wait for at least three low-power clock cycles before re-enabling this interrupt to allow sufficient time for the request flag to clear. Because this interrupt is used only during USB low-power modes, it is sufficient to enable the wake-up interrupt just prior to entering the USB Suspend mode.

51.3.9.3 Interrupts: host operational model

For detailed information about interrupt capability that the EHCI host controller hardware provides, see the "Interrupts" section in *Enhanced Host Controller Interface (EHCI) Specification for Universal Serial Bus, revision 1.0*.

51.3.9.4 Servicing interrupts

The interrupt service routine must consider that there are high-frequency, low-frequency, and error operations, and consider the order of interrupts accordingly.

51.3.9.4.1 High-frequency interrupts

You must manage high-frequency interrupts in the order shown in the following table. The most important of these is listed first because the DCD must acknowledge a setup buffer as promptly as possible.

Table 493. High-frequency interrupt events

Execution order	Interrupt	Action
1a	USB interrupt (see ENDPTSETUPSTAT)	Copy the contents of the setup buffer and acknowledge the setup packet (as indicated in Figure 176). Process the setup packet according to USB 2.0 chapter 9 or the application-specific protocol.
1b	USB interrupt[1] (see ENDPTCOMPLETE)	Handle the completion of dTD as indicated in Figure 176.
2	SOF interrupt	Perform the action that the application considers necessary. This interrupt may not be used in all applications.

1. It is common for multiple interrupts to stack up on any call to and during the interrupt service routine.

51.3.9.4.2 Low-frequency interrupts

Low-frequency interrupts do not occur often compared to high-frequency interrupts. You can handle low-frequency interrupts in any order.

Table 494. Low-frequency interrupt events

Interrupt	Action
Port change	Change software state information.
Sleep enable (suspend)	Change software state information. Perform low-power handling as necessary.
Reset received	Change software state information. Abort pending transfers.

51.3.9.4.3 Error interrupts

Error interrupts are infrequent. You must place them last in the interrupt service routine.

Table 495. Error interrupt events

Interrupt	Action
USB error interrupt	This error is redundant because it combines a USB interrupt and an error status in the dTD. The DCD handles packet-level errors more appropriately by checking the dTD status field upon receipt of the USB interrupt (by using ENDPTCOMPLETE).
System error	Unrecoverable error that requires immediate reset of core; you must free up transfer buffers in progress and restart the DCD.

51.4 External signals

Table 496. USB external signals

Signal	Description	Direction
OC	External input for VBUS overcurrent detection from GPIO	I
PWR	Used to control PMIC to supply VBUS voltage	O

See the chip-specific USB information for the external signals that this chip supports.

51.5 Initialization

This section provides the information required to properly initialize USB.

51.5.1 Host controller initialization

For detailed information, see the "Host Controller Initialization" section in *Enhanced Host Controller Interface (EHCI) Specification for Universal Serial Bus, revision 1.0*.

51.5.2 Device controller initialization

After hardware reset, the device is disabled until you write 1 to USBCMD[RS]. In the Disabled state, the pull-up on USB D+ is not active, and that prevents an attach event from occurring. The minimum requirement is to have the queue heads setup for endpoint 0 before the device attach occurs.

Soon after you enable the device, a USB reset occurs followed by a setup packet arriving at endpoint 0. A queue head must be prepared so that the device controller can store the incoming setup packet.

51.5.2.1 Prerequisite for initializing a device

You must reset the device controller for transitioning from Host mode to Device mode, before modifying USBMODE.

You must also prime endpoint 0 initially because the first packet received is always a setup packet. The contents of the first setup packet require a response in accordance with the USB device framework (chapter 9) command set.

51.5.2.2 Procedure to initialize a device

Table 497. Device controller initialization: associated procedure

Step	Purpose	Programming	Notes
1	Specify the controller mode.	Write 10b to USBMODE[CM].	—
2	Allocate and initialize device queue heads in the system memory. At a minimum, you must initialize device queue heads 0 TX and 0 RX.	—	You must initialize all device queue heads for control endpoints before the endpoint is enabled, and noncontrol device queue heads before you can use the endpoint. For information about device queue heads, see Device data structures.
3	Specify the endpoint list pointer.	Configure ENDPTLISTADDR.	—
4	Enable the microprocessor interrupt associated with the USB core.	NXP recommends that you enable all device interrupts including USBSTS[UI], USBSTS[UEI], USBSTS[PCI], USBSTS[URI], and USBSTS[SLI].	For a list of available interrupts, see Interrupt Enable (USBINTR) and USB Status (USBSTS).
5	Specify whether the controller is executing the operation.	Write 1 to USBCMD[RS].	After this is done and the device is connected to a host, the host downstream port issues a bus reset. The DCD must monitor the reset event and adjust the software state as described in Bus reset.

NOTE

Endpoint 0 is designed as a control endpoint only; you do not need to configure it using Endpoint Control 0 (ENDPTCTRL0).

51.6 Application information

51.6.1 eUSBPHY configuration

Perform the following procedure to configure eUSBPHY. You must complete this sequence first to enable the controller.

Table 498. eUSBPHY configuration: associated procedure

Step	Purpose	Programming	Notes
0	Configure PHY analog.	• Write 3'b011 to EUSB_CTRL1[EUSB_SQ]. • Write 2'b01 to EUSB_CTRL1[EUSB_FSTX_OPT].	—
1	Select work modes.	Use EUSB_CTRL0[NATIVE_MODE].	—
2	Select the HS receiver termination mode.	Use EUSB_CTRL0[UN_TERMINATED_MODE].	This field is only used for the host HS native mode.
3	Enable the eUSBPHY PLL reference clock and wait until it is stable.	—	—
4	Enable the CM.RAP feature, if needed.	Write 1 to EUSB_RAP[CM_RAP_INIT_EN].	—
5	Enable eUSBPHY.	Write 1 to EUSB_CTRL0[PONRST].	—
6	Confirm that the UTMI clock from the USB PHY is valid.	Poll CTRL2[UTMI_CLK_VLD] until it becomes 1.	—

51.6.2 eUSB CM.RAP operation

The following is the control sequence for the register access protocol (CM.RAP). Perform the following procedure to control CM.RAP.

Table 499. Controlling the CM.RAP feature

Step	Purpose	Programming	Notes
1	Enable the CM.RAP feature.	Write 1 to EUSB_RAP[CM_RAP_INIT_EN].	—
2	Confirm that the internal state is ready for CM.RAP transmission.	Poll EUSB_RAP[CM_RAP_INIT_READY] until it returns 1.	—
3	Specify the CM.RAP command type.	Write to EUSB_RAP[CM_RAP_OP], EUSB_RAP[CM_RAP_ADDR], and EUSB_RAP[CM_RAP_WRDATA].	Table 500 shows the details of the CM.RAP command and Table 501 shows the CM.RAP address and data format.

Table continues on the next page...

Table 499. Controlling the CM.RAP feature (continued)

Step	Purpose	Programming	Notes
4	Send the command and communicate with CM.	Write 1 to EUSB_RAP[CM_RAP_START].	—
5	Confirm that the CM.RAP command completed successfully.	Poll EUSB_RAP[CM_RAP_DONE] or EUSB_RAP[CM_RAP_FAIL] until they return 1 and 0, respectively.	—
6	Retrieve the data.	Read EUSB_RAP[CM_RAP_RDDATA] (read command only).	—
7	Complete the command execution.	Write 0 to EUSB_RAP[CM_RAP_START] after EUSB_RAP[CM_RAP_DONE] or EUSB_RAP[CM_RAP_FAIL] becomes 1.	—
8	Perform the next CM.RAP command operation, until all required commands are executed.	Repeat steps 3 to 7.	—
9	Disable the CM.RAP feature.	Write 0 to EUSB_RAP[CM_RAP_INIT_EN].	—

Table 500. CM.RAP command description

CMD	Operation	Description
00b	Write	Data is written to the register address.
01b	Read	Data is read from the register address.
10b	Clear	Active-high, bitwise clear with the data on the register address.
11b	Set	Bit-wise OR with the data on the register address.

Table 501. CM.RAP format of address and data

Address						Data							
a0	a1	a2	a3	a4	a5	d0	d1	d2	d3	d4	d5	d6	d7

The following is an example of the CM.RAP write command. EUSB_RAP[CM_RAP_ADDR] and EUSB_RAP[CM_RAP_WRDATA] are randomly used in this example. For a read command, you can access EUSB_RAP[CM_RAP_RDDATA] after EUSB_RAP[CM_RAP_DONE] becomes 1. Perform the following procedure to use the CM.RAP command.

Table 502. Using the CM.RAP command

Step	Purpose	Programming
1	Enable the CM.RAP feature.	Write 1 to EUSB_RAP[CM_RAP_INIT_EN].
2	Confirm that the internal state is ready for CM.RAP transmission.	Poll EUSB_RAP[CM_RAP_INIT_READY] until it returns 1.

Table continues on the next page...

Table 502. Using the CM.RAP command (continued)

Step	Purpose	Programming
3	Configure the write command content.	1. Write 00b to EUSB_RAP[CM_RAP_OP]. 2. Write 6'd30 to EUSB_RAP[CM_RAP_ADDR]. 3. Write 8'd113 to EUSB_RAP[CM_RAP_WRDATA].
4	Enable CM.RAP start.	Write 1 to EUSB_RAP[CM_RAP_START].
5	Confirm that the CM.RAP command completed successfully.	Poll EUSB_RAP[CM_RAP_DONE] and EUSB_RAP[CM_RAP_FAIL] until they return 1 and 0, respectively.
6	Complete the command execution.	Write 0 to EUSB_RAP[CM_RAP_START].
7	Disable CM.RAP.	Write 0 to EUSB_RAP[CM_RAP_INIT_EN].

51.7 USB noncore memory map and register definitions

51.7.1 USBNC register descriptions

USB supports two types of registers: core and noncore. The USB core registers are used to control USB core functions and are more independent of USB features. The USB controller core has its own core registers. The USB noncore registers are additional to USB core registers and are more dependent on USB features. The USB noncore registers support the 32-bit, 16-bit, and 8-bit register accesses.

This section describes only the USB noncore registers. For detailed descriptions of the USB core registers, see Register interface.

NOTE

For reserved bits, preserve the value when writing (read its reset value, then write this value back).

51.7.1.1 USBNC memory map

USBNC0 base address: 4041_8200h

USBNC1 base address: 4041_9200h

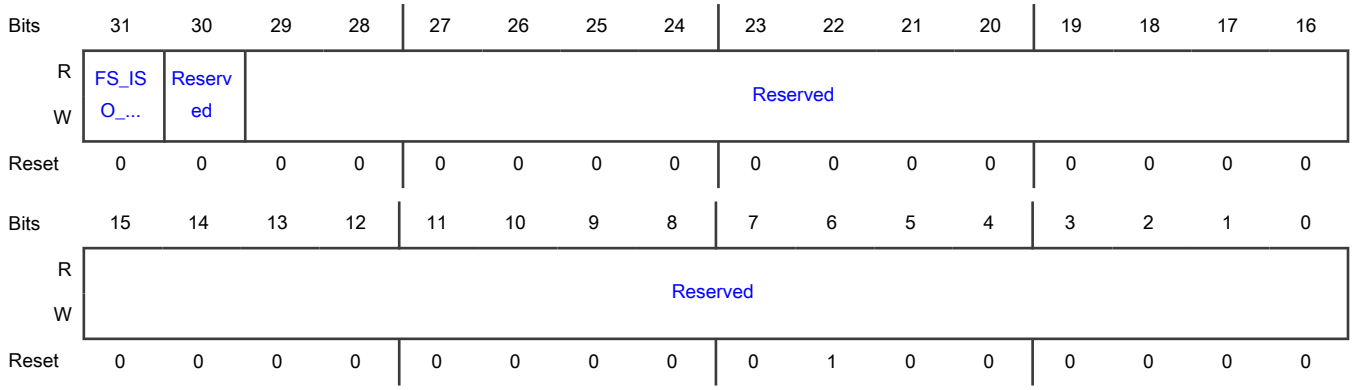
51.7.1.4 HSIC DLL Configuration 4 (HSIC_DLL_CFG4)

Offset

Register	Offset
HSIC_DLL_CFG4	2Ch

Function
Holds the internal control register bits of the PHY.

Diagram



Fields

Field	Function
31 FS_ISO_B2B_FIXEN	FS Isochronous Back-to-Back Transfer Enable Enables two connected FS isochronous transfers when the first length is longer than about 280 bytes in case the USB controller directly connects to an FS device. Such transfers are not supported by default. **NOTE** This bit must not be set in other cases, for example, when the FS device is connected to the USB controller through a hub. 0b - Disables 1b - Enables
30 —	This field must retain its reset value.
29-0 —	This field must retain its reset value.

51.7.1.5 USB LPM Control and Status 0 (LPM_CSR0)

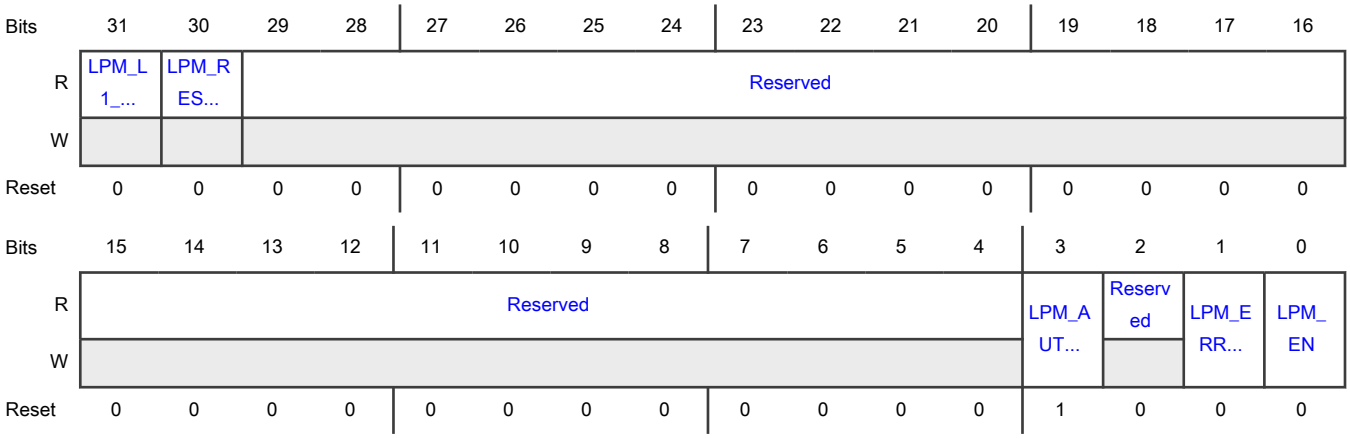
Offset

Register	Offset
LPM_CSR0	A0h

Function

Includes the common control and status fields for the host or device controller's LPM mode.

Diagram



Fields

Field	Function
31 LPM_L1_ACTIVE	LPM Active Indicates whether L1 is active. This flag means the device or host is in the L1 state: • For Device mode, this flag is set after the device sends an ACK response to the host. • For Host mode, this flag is set when the host receives an ACK response for the LPM extension transaction. 0b - Inactive 1b - Active
30 LPM_RESUME_OK	LPM Resume OK Indicates whether LPM can initiate a resume or accept a resume from host: • For Device mode, this flag means LPM can initiate a resume or accept a resume from the host. • For Host mode, this flag means LPM can initiate a resume or accept a resume from the device. • For HS Device mode, the controller waits for TL1TokenRetry to start the transition to FS mode after sending the LPM ACK response. Then, after TL1Residency, this flag is set.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	• For FS Device mode, the controller waits for TL1TokenRetry after sending the LPM ACK response. Then, this flag is set. • For HS Host mode, the controller starts the transition to FS mode after receiving the LPM ACK response. Then, after (TL1TokenRetry + TL1Residency), this flag is set. • For FS or LS Host mode, this flag is set after receiving the LPM ACK response. 0b - Cannot resume 1b - Can resume
29-4 —	Reserved
3 LPM_AUTO_PHCD	Auto Low-Power Mode Enables automatic Low-Power mode. The PHY is put in Low-Power mode when in L1. PORTSC1[PHCD] becomes 1 automatically in L1. 0b - Disables 1b - Enables
2 —	Reserved
1 LPM_ERRATA_EN	Link Power Management ECN Errata Feature Enable Enables the link power management ECN errata feature. The host or device supports *Errata for USB 2.0 ECN: Link Power Management (LPM) - 7/2007*. If this field is 0, the host-initiated resume duration is defined by this errata: the HIRD or BESL value (0000b) equals 50 µs and each additional increment adds 75 µs. If this field is 1, the host-initiated resume duration is defined by table X-X1 in the errata. 0b - Disables 1b - Enables
0 LPM_EN	Link Power Management Feature Enable Enables the link power management feature. The host or device supports the USB 2.0 link power management addendum. 0b - Disables 1b - Enables

51.7.1.6 USB LPM Control and Status 1 (LPM_CSR1)

Offset

Register	Offset
LPM_CSR1	A4h

Function

Includes the control and status fields for the device controller's LPM mode.

Fields

Field	Function
31-28 LPM_DEV_BESLRCVD	LPM Device Received BESL Indicates the device received BESL field from the LPM transaction. See LPM_CSR1[LPM_DEV_BESLTHRES] for the timing definition.
27-24 LPM_DEV_LNKSTRCVD	LPM Device Received bLinkState Indicates the value of the device received bLinkState field from the LPM transaction. 0000b - Reserved for future use 0001b - L1 (Sleep mode) 0010b-1111b - Reserved for future use
23 LPM_DEV_RWKENRCVD	LPM Device Received bRemoteWake Indicates the value of the bRemoteWake field in the received LPM transaction. You can issue a remote wake-up only when this field is 1. 0b - 0 1b - 1
22	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
21-20 LPM_DEV_RSPSTS	LPM Device Response Status Indicates the device's response to the host in LPM transactions. 00b - Invalid 01b - ACK 10b - NYET 11b - STALL
19-6 —	Reserved
5 LPM_DEV_DP	LPM Device Data Pending Specifies whether LPM device data is pending. If this field is 0, the device returns a handshake on every LPM token that it receives, based on LPM_CSR1[LPM_DEV_RES]. If this field is 1, the device returns an NYET handshake after every LPM token it receives. 0b - Not pending 1b - Pending
4 LPM_DEV_RES	LPM Device Response Determines whether the additional fourth condition, mentioned below, is needed. This field is effective only when LPM_CSR1[LPM_DEV_DP] is 0. The controller responds with an ACK response when at least the first three of the following conditions are satisfied: 1. There are no PID checks or CRC5 errors in both the EXT and LPM tokens (otherwise, a response timeout error occurs). 2. Received bLinkState is 0001b (L1) (otherwise, a response STALL error occurs). 3. Received BESL or HIRD value is larger than or equal to that of LPM_CSR1[LPM_DEV_BESLTHRES] (otherwise, a response STALL error occurs). 4. No data is pending in the transmit FIFO (otherwise, a response NYET error occurs). 0b - Fourth condition not needed 1b - Fourth condition needed
3-0 LPM_DEV_BESLTHRES	Device Required Host Initiated Resume Duration Specifies the time duration that the device requires to come out of LPM-initiated suspend state after receiving the host-initiated LPM resume signal. If the received value of LPM_CSR1[LPM_DEV_BESLRCVD] is less than the value of this field, the device sends a STALL response. 0000b - 75 µs, if LPM_ERRATA_EN = 1; 50 µs, if LPM_ERRATA_EN = 0

23-16 REVISION	Revision Number Indicates the revision number of the controller core.
15-14 —	Reserved
13-8 NID	Complement Version Indicates the complement version of the ID.
7-6 —	Reserved
5-0 ID	Configuration Number Indicates the configuration number (05h) and signifies that the peripheral is USB 2.0 HS core.

51.8.1.3 Hardware General (HWGENERAL)

Offset

Register	Offset
HWGENERAL	4h

Function

Indicates general hardware parameters as defined in system-level issues and core configuration.

NOTE

The reset value can vary from instance to instance. Therefore, for more accurate information, see field descriptions and ignore their reset values.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

3-0 —	Reserved

51.8.1.4 Host Hardware Parameters (HWHOST)

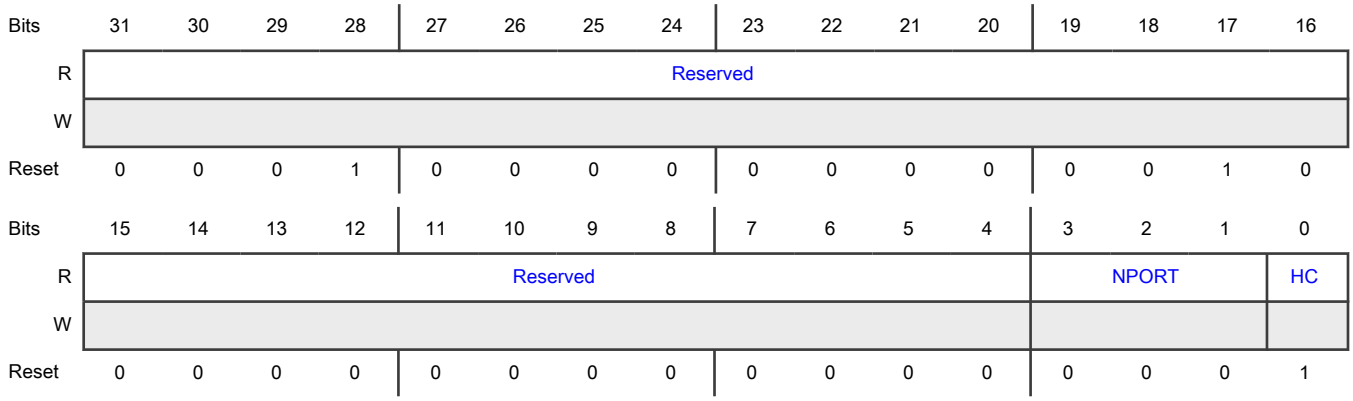
Offset

Register	Offset
HWHOST	8h

Function

Indicates the host hardware parameters, the number of ports, and the mode supported.

Diagram



Fields

Field	Function
31-4 —	Reserved
3-1 NPORT	Number of Ports Indicates the number of downstream ports supported by the host controller. It is defined as NPORT + 1. **NOTE** A value of 000 indicates a single-port host controller.
0 HC	Host Capable Indicates whether Host Operation mode is supported. 0b - Not supported 1b - Supported

51.8.1.5 Device Hardware Parameters (HWDEVICE)

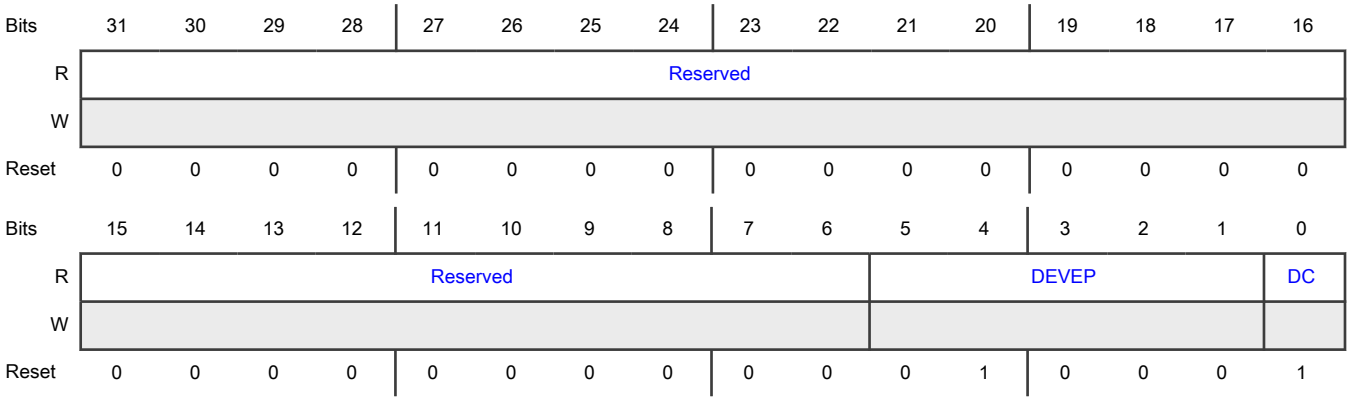
Offset

Register	Offset
HWDEVICE	Ch

Function

Indicates the device hardware parameters such as the device endpoint number and the mode supported.

Diagram



Fields

Field	Function
31-6 —	Reserved
5-1 DEVEP	Device Endpoint Number Indicates the device endpoint number.
0 DC	Device Capable Indicates whether Device Operation mode is supported. 0b - Not supported 1b - Supported

51.8.1.6 TX Buffer Hardware Parameters (HWTXBUF)

Offset

Register	Offset
HWTXBUF	10h

Function

Indicates TX buffer hardware parameters, such as the default burst size and total buffer size.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved								TXCHANADD							
W																
Reset	1	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved								TXBURST							
W																
Reset	0	0	0	0	1	0	1	1	0	0	0	0	1	0	0	0

Fields

Field	Function
31-24 —	Reserved
23-16 TXCHANADD	TX Channel Add Indicates the TX FIFO buffer size. The TX FIFO buffer size is (2^TXCHANADD) × 4 bytes. This field becomes 08h, meaning the buffer size is 256 × 4 bytes. If USB is in Device mode, this is the FIFO buffer size per endpoint. Because the controller has eight TX endpoints, there are eight of these buffers. For the USB controller operating in Host mode, or for host-only controller, the entire buffer memory operates as a single TX buffer. Therefore, there is only one.
15-8 —	Reserved
7-0 TXBURST	TX Burst Indicates the default burst size for memory to TX buffer transfer. This is the reset value of BURSTSIZE[TXPBURST].

51.8.1.7 RX Buffer Hardware Parameters (HWRXBUF)

Offset

Register	Offset
HWRXBUF	14h

Function

Indicates RX buffer hardware parameters, such as the default burst size and total buffer size.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	RXADD								RXBURST							
W																
Reset	0	0	0	0	1	0	0	0	0	0	0	0	1	0	0	0

Fields

Field	Function
31-16 —	Reserved
15-8 RXADD	RX Add Indicates the RX FIFO buffer size. The total buffer size for all receive endpoints is: (2^RXADD). RX buffer size is: (2^RXADD) × 4 bytes. This field becomes 08h, meaning the buffer size is 256 × 4 bytes. There is a single receive FIFO buffer in the USB controller. The buffer is shared for all endpoints when USB is in Device mode.
7-0 RXBURST	RX Burst Indicates the default burst size for memory to RX buffer transfer. This is the reset value of BURSTSIZE[RXPBURST].

51.8.1.8 General Purpose Timer 0 Load (GPTIMER0LD)

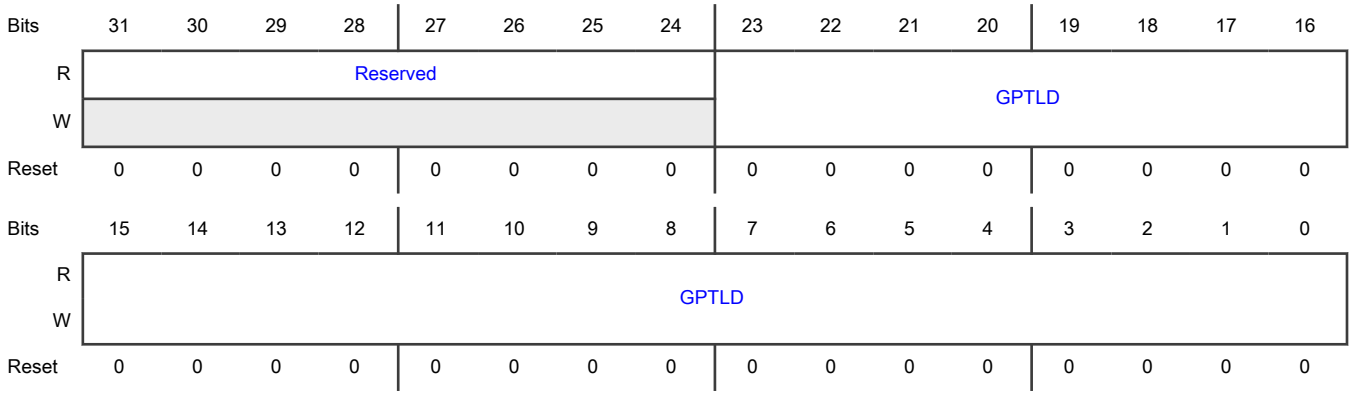
Offset

Register	Offset
GPTIMER0LD	80h

Function

Controls the load value of the count timer in General Purpose Timer 0 Controller (GPTIMER0CTRL).

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 GPTLD	General Purpose Timer Load Value Indicates the general purpose timer load value. This value represents the time, in microseconds minus 1, of the timer duration. The value of this field is loaded to GPTIMER0CTRL[GPTCNT], if GPTIMER0CTRL[GPTRST] is 1. For example, for a one millisecond timer, load 1000 - 1 = 999 (or 0003E7h). **NOTE** The maximum value is FFFFFFh or 16.777215 seconds.

51.8.1.9 General Purpose Timer 0 Controller (GPTIMER0CTRL)

Offset

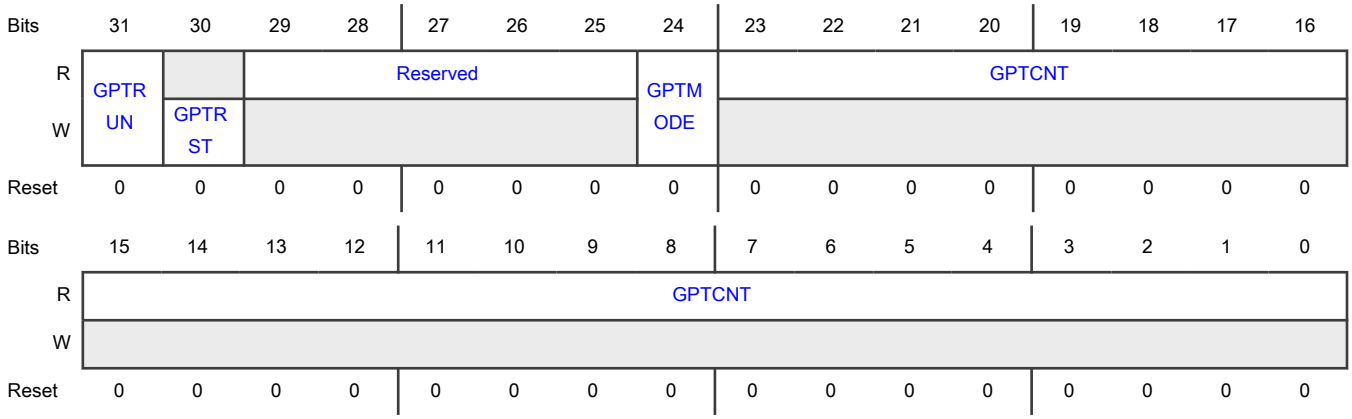
Register	Offset
GPTIMER0CTRL	84h

Function

Contains the control for the general purpose countdown timer 0. A data field can be queried to determine the running count value. This timer has granularity on 1 µs and you can program it to a little over 16 seconds. There are two counter modes that are described in this register. When the timer counter value transitions to zero, an interrupt may be generated if it is enabled.

USBSTS[TI0] is the interrupt status field, and USBINTR[TIE0] is the interrupt enable field.

Diagram



Fields

Field	Function
31 GPTRUN	General Purpose Timer Run Specifies whether the general purpose timer is running or has stopped counting. GPTIMER0CTRL[GPTCNT] is not impacted when writing 1 or 0 to this field. 0b - Stopped counting 1b - Running
30 GPTRST	General Purpose Timer Reset Loads counter value from GPTIMER0LD[GPTLD]. 0b - No action 1b - Load counter value
29-25 —	Reserved
24 GPTMODE	General Purpose Timer Mode Specifies the general purpose timer mode. In One Shot mode, the timer counts down to zero, generates an interrupt, and halts until you reset the counter. In Repeat mode, the timer counts down to zero, generates an interrupt, and automatically reloads the counter value from General Purpose Timer 1 Load (GPTIMER1LD) to start again. 0b - One Shot mode 1b - Repeat mode
23-0 GPTCNT	General Purpose Timer Counter Indicates the count value of the countdown timer.

51.8.1.10 General Purpose Timer 1 Load (GPTIMER1LD)

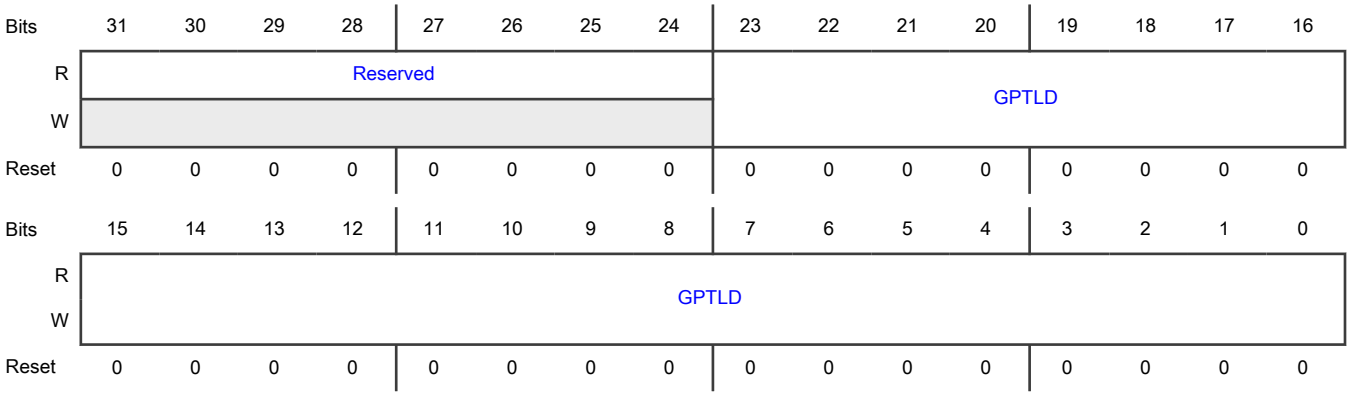
Offset

Register	Offset
GPTIMER1LD	88h

Function

Controls the load value of the count timer in General Purpose Timer 1 Controller (GPTIMER1CTRL).

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 GPTLD	General Purpose Timer Load Value Indicates the general purpose timer load value. The value of this field is loaded to GPTIMER0CTRL[GPTCNT], if GPTIMER0CTRL[GPTRST] is 1. This value represents the time, in microseconds minus 1, of the timer duration. For example, for a 1 ms timer, load 1000 - 1 = 999 (or 0003E7h). **NOTE** The maximum value is FFFFFFh or 16.777215 seconds.

51.8.1.11 General Purpose Timer 1 Controller (GPTIMER1CTRL)

Offset

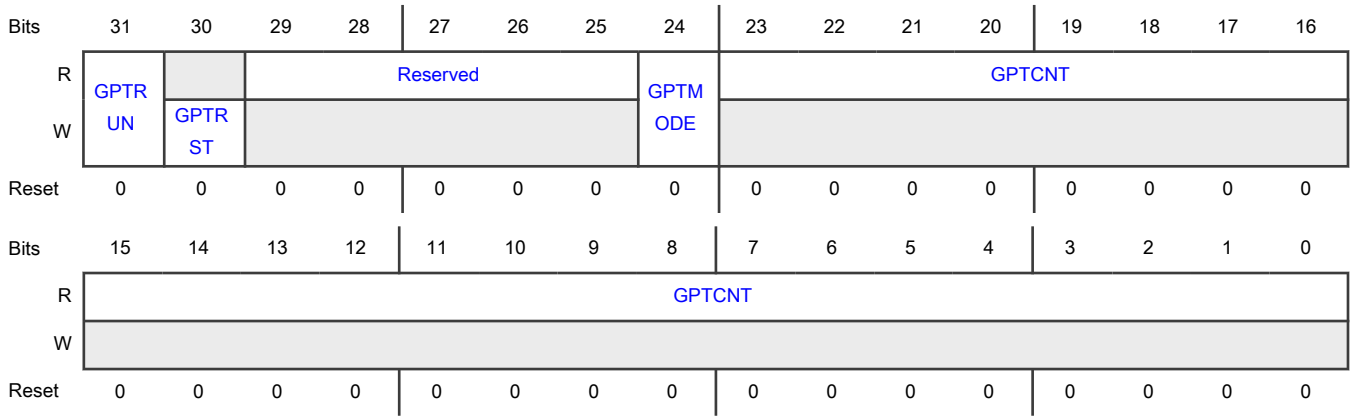
Register	Offset
GPTIMER1CTRL	8Ch

Function

Contains the control for the general purpose countdown timer 1. A data field can be queried to determine the running count value. This timer has granularity on 1 µs and you can program it to a little over 16 seconds. There are two counter modes that are described in this register. When the timer counter value transitions to zero, an interrupt may be generated if it is enabled.

USBSTS[TI1] is the interrupt status field, and USBINTR[TIE1] is the interrupt enable field.

Diagram



Fields

Field	Function
31 GPTRUN	General Purpose Timer Run Specifies whether the general purpose timer is running or has stopped counting. GPTIMER0CTRL[GPTCNT] is not impacted when writing 1 or 0 to this field. 0b - Stopped counting 1b - Running
30 GPTRST	General Purpose Timer Reset Loads counter value from GPTIMER0LD[GPTLD]. 0b - No action 1b - Load counter value
29-25 —	Reserved
24 GPTMODE	General Purpose Timer Mode Indicates the general purpose timer mode. In One Shot mode, the timer counts down to zero, generates an interrupt, and stops until you reset the counter. In Repeat mode, the timer counts down to zero, generates an interrupt, and automatically reloads the counter value from GPTIMER0LD[GPTLD] to start again.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - One Shot mode 1b - Repeat mode
23-0 GPTCNT	General Purpose Timer Counter Indicates the count value of the countdown timer.

51.8.1.12 System Bus Configuration (SBUSCFG)

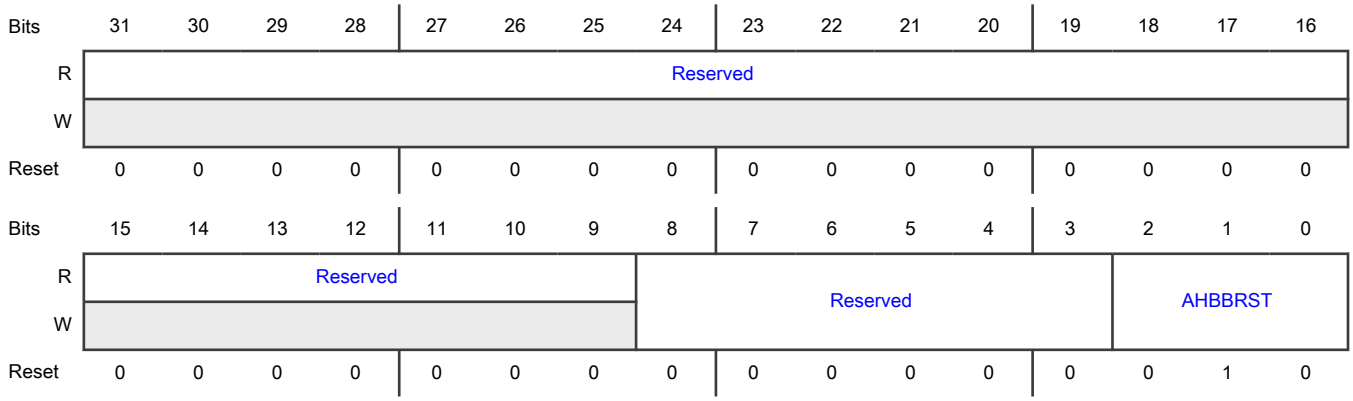
Offset

Register	Offset
SBUSCFG	90h

Function

Defines the system bus configuration.

Diagram



Fields

Field	Function
31-9 —	Reserved
8-3 —	Reserved
2-0 AHBBRST	AHB Manager Interface Burst Configuration Controls the AHB manager transfer type sequence (or priority).

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This register overrides Programmable Burst Size (BURSTSIZE) when the value of AHBBRST is not zero. 000b - Incremental burst of unspecified length only 001b - INCR4 burst, then single transfer 010b - INCR8 burst, INCR4 burst, then single transfer 011b - INCR16 burst, INCR8 burst, INCR4 burst, then single transfer 100b - Reserved, do not use 101b - INCR4 burst, then incremental burst of unspecified length 110b - INCR8 burst, INCR4 burst, then incremental burst of unspecified length 111b - INCR16 burst, INCR8 burst, INCR4 burst, then incremental burst of unspecified length

51.8.1.13 Capability Registers Length (CAPLENGTH)

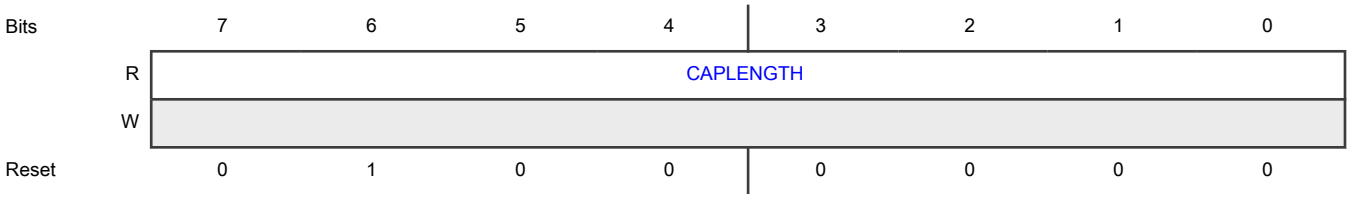
Offset

Register	Offset
CAPLENGTH	100h

Function

Contains the address offset of the operational registers relative to this register.

Diagram



Fields

Field	Function
7-0 CAPLENGTH	Capability Length Indicates the capability length. This field is used as an offset to add to the register base to find the beginning of the operational register. The default value is 40h.

51.8.1.14 Host Controller Interface Version (HCIVERSION)

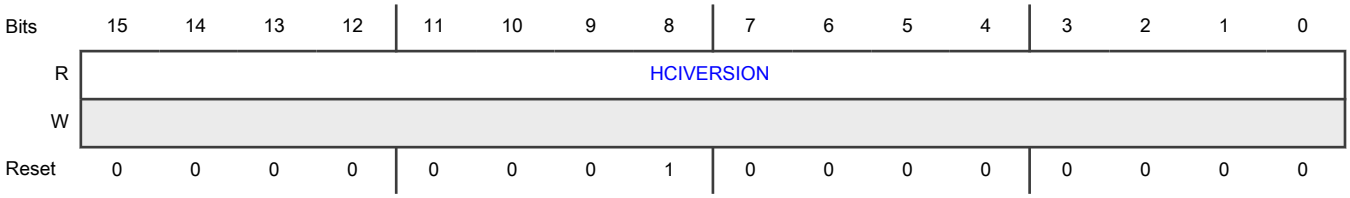
Offset

Register	Offset
HCIVERSION	102h

Function

Contains a BCD encoding of the EHCI revision number that this host controller supports. The most significant byte of this register represents a major revision and the least significant byte indicates the minor revision.

Diagram



Fields

Field	Function
15-0 HCIVERSION	Host Controller Interface Version Number Indicates the host controller interface version number. The default value is 10h, which specifies EHCI rev1.0.

51.8.1.15 Host Controller Structural Parameters (HCSPARAMS)

Offset

Register	Offset
HCSPARAMS	104h

Function

Indicates the port steering logic capabilities of the host control structural parameters (HCSPARAMS).

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-28 —	Reserved
27-24 N_TT	Number of Transaction Translators (N_TT) Indicates the number of embedded transaction translators associated with the USB 2.0 host controller. The value of this field is 0001b for multi-port host, and 0000b for single-port host. The default value of this field is 0000b.
23-20 N_PTT	Number of Ports per Transaction Translator (N_PTT) Indicates the number of ports assigned to each transaction translator within the USB 2.0 host controller. The value of this field is equal to that of HCSPARAMS[N_PORTS] for a multi-port host, and 0000b for a single-port host. The default value of this field is 0000b.
19-17 —	Reserved
16 PI	Port Indicators (P_INDICATOR) Indicates whether the ports support port indicator control. If this field is 1, the port status and control registers include an R/W field for controlling the state of the port indicator. The value of this field is 1b in all controller cores.
15-12 N_CC	Number of Companion Controller (N_CC) Indicates the number of companion controllers associated with the USB 2.0 host controller. The value of this field is 0000b in all controller cores. If this field is 0, there is no internal companion controller and port-ownership hand-off is not supported. If this field is 1, internal companion controllers exist and port-ownership hand-offs are supported.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0000b - No internal companion controller exists 0001b - Internal companion controllers exist
11-8 N_PCC	Number of Ports per Companion Controller Indicates the number of ports supported per internal companion controller. This field is used to indicate the port routing configuration to the system software. For example, if HCSPARAMS[N_PORTS] has a value of 6 and HCSPARAMS[N_CC] has a value of 2, then N_PCC could have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, and so on. In the previous example, N_PCC could have been 4, where the first four are routed to companion controller 1 and the last two are routed to companion controller 2. The value of this field must be consistent with that of HCSPARAMS[N_PORTS] and HCSPARAMS[N_CC]. The value of this field is 0000b in all controller cores.
7-5 —	Reserved
4 PPC	Port Power Control Indicates whether the host controller implementation includes port power control. The value of this field affects the functionality of PORTSC1[PP] in each port status and control register. If this field is 1, it indicates that the ports have port power switches. If this field is 0, it indicates that the ports do not have port power switches. 0b - No port power switches 1b - Port power switches exist
3-0 N_PORTS	Number of Ports Indicates the number of downstream ports. This field indicates the number of physical downstream ports implemented on this host controller. The value of this field determines the number of port registers that are addressable in the operational register. The range of valid values is 1h–Fh. A zero in this field is undefined. The value of this field is always 0001b because all controller cores are single-port hosts.

51.8.1.16 Host Controller Capability Parameters (HCCPARAMS)

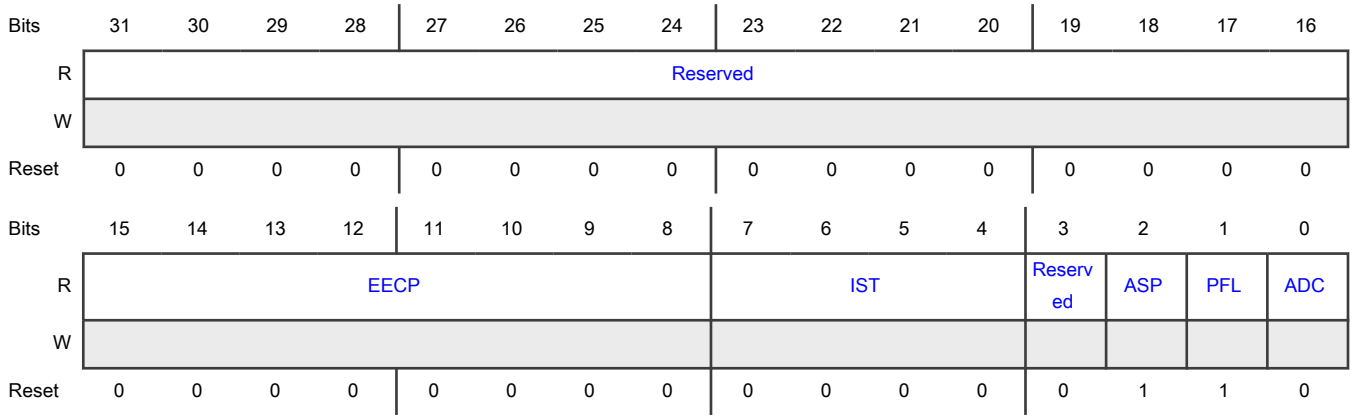
Offset

Register	Offset
HCCPARAMS	108h

Function

Identifies multiple mode control (time-based bit functionality) and addressing capability.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 EECP	EHCI Extended Capabilities Pointer Indicates the existence of a capabilities list. A value of 00h indicates that no extended capabilities are implemented. A nonzero value in this field indicates the offset of the first EHCI extended capability in the PCI configuration space. The pointer value must be 40h or greater (if implemented) to maintain the consistency of the PCI header defined for this class of device. The value of this field is 00h in all controller cores.
7-4 IST	Isochronous Scheduling Threshold Indicates, relative to the current position of the executing host controller, where you can reliably update the isochronous schedule. When bit 7 of this field is 0, the value of the least significant three bits indicates the number of microframes during which a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When the value of bit 7 is 1, then the host software assumes that the host controller can cache an isochronous data structure for an entire frame. The value of this field is 00h in all controller cores.
3 —	Reserved
2 ASP	Asynchronous Schedule Park Capability Indicates whether the park feature for HS queue heads is supported. If this field is 1, the host controller supports the park feature for HS queue heads in the asynchronous schedule. You can enable or disable this feature and set it to a specific level by using USBCMD[ASPE] and USBCMD[ASP].

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 PFL	Programmable Frame List Flag Indicates the frame list length. If this flag is 0, you must use a frame list length of 1024 elements with this host controller. You must write 0 to USBCMD[FS_2] and USBCMD[FS_1]. If this flag is 1, you can specify and use a smaller frame list and configure the host controller via USBCMD[FS_2] and USBCMD[FS_1]. The frame list must always be aligned on a 4 KB page boundary. This requirement ensures that the frame list is always physically contiguous. The value of this flag is 1 in all controller cores.
0 ADC	Addressing Capability Indicates 64-bit addressing capability. This field is 0b in all controller cores, and 64-bit addressing capability is not supported.

51.8.1.17 Device Controller Interface Version (DCIVERSION)

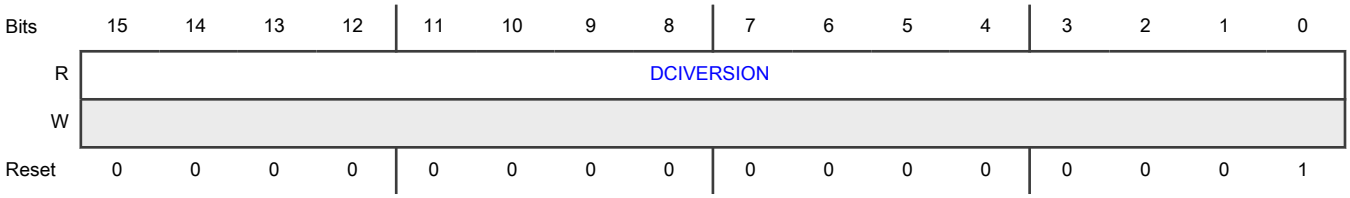
Offset

Register	Offset
DCIVERSION	120h

Function

Indicates the 2-byte BCD encoding of the device controller interface version number.

Diagram



Fields

Field	Function
15-0 DCIVERSION	Device Controller Interface Version Number Indicates the device controller interface version number. The default value of this field is 01h, which specifies rev 0.1.

51.8.1.18 Device Controller Capability Parameters (DCCPARAMS)

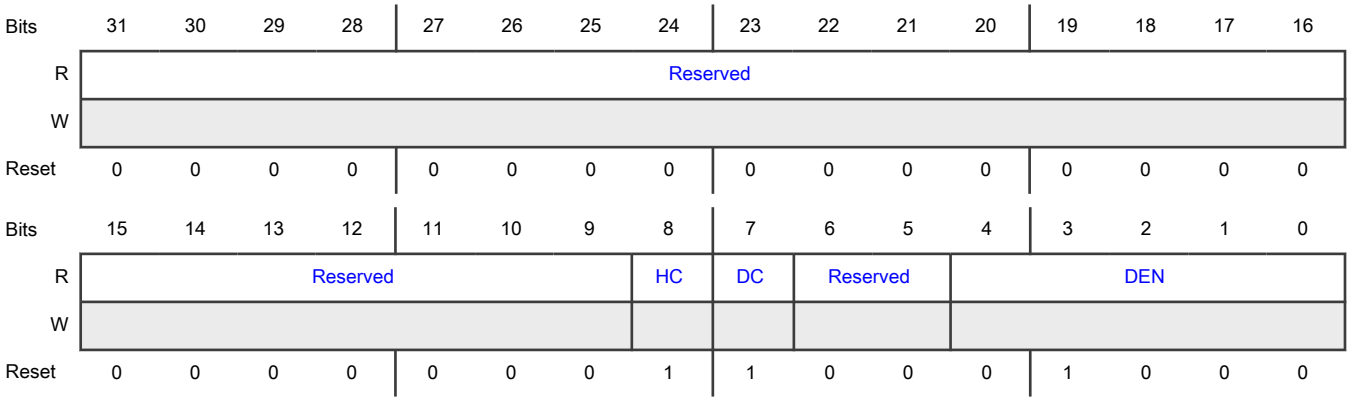
Offset

Register	Offset
DCCPARAMS	124h

Function

Indicates the overall device capability of the controller.

Diagram



Fields

Field	Function
31-9 —	Reserved
8 HC	Host Capable Indicates whether the controller is capable of operation as a host controller. If this field is 1, this controller is capable of operating as an EHCI-compatible USB 2.0 host controller. 0b - Not host capable 1b - Host capable
7 DC	Device Capable Indicates whether the controller is capable of operation. If this field is 1, the controller is capable of operating as a USB 2.0 device. 0b - Not device capable 1b - Device capable
6-5 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
4-0 DEN	Device Endpoint Number Indicates the number of endpoints built into the device controller. If this controller is not device capable, then this field is 0. Valid values are 0–15. 0_0000b - Not device capable 0_0001b - Device capable

51.8.1.19 USB Command (USBCMD)

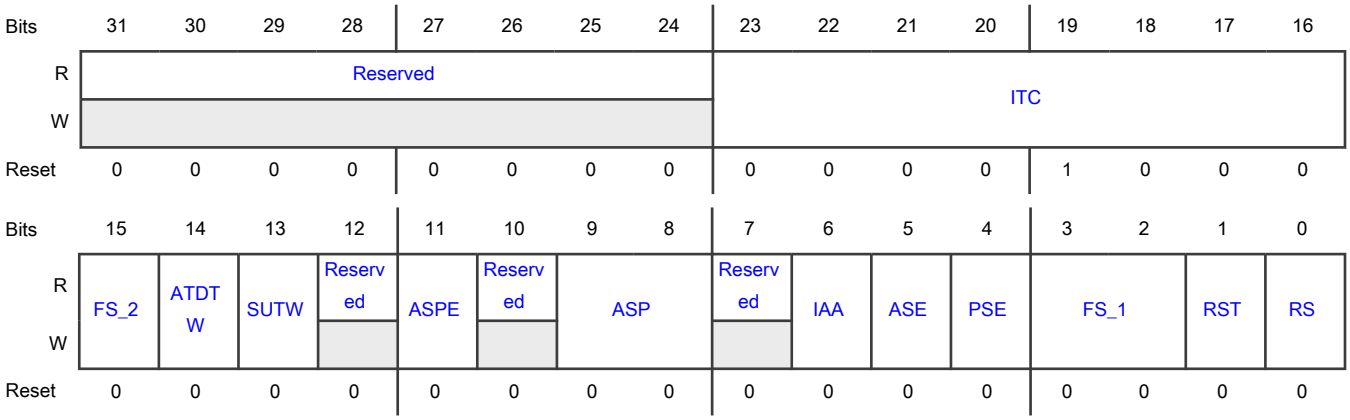
Offset

Register	Offset
USBCMD	140h

Function

Indicates the command that the serial bus host or device controllers must execute. Writing to this register causes a command to be executed.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 ITC	Interrupt Threshold Control Sets the maximum rate at which the host or device controller issues interrupts. This field contains the maximum interrupt interval measured in microframes. Valid values are shown below.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The following values are the valid maximum interrupt intervals: 0000_0000b - Immediate (no threshold) 0000_0001b - 1 microframe 0000_0010b - 2 microframes 0000_0100b - 4 microframes 0000_1000b - 8 microframes 0001_0000b - 16 microframes 0010_0000b - 32 microframes 0100_0000b - 64 microframes
15 FS_2	Frame List Size 2 (Host mode only) Specifies the size of the frame list that controls which fields in FRINDEX you must use for the current frame list index. This field is both readable and writable only if HCCPARAMS[PFL] is 1, otherwise it is only readable. **NOTE** Frame List Size[2:0] = {FS_2, FS_1[1:0]} 000b - 1024 elements (4096 bytes) 001b - 512 elements (2048 bytes) 010b - 256 elements (1024 bytes) 011b - 128 elements (512 bytes) 100b - 64 elements (256 bytes) 101b - 32 elements (128 bytes) 110b - 16 elements (64 bytes) 111b - 8 elements (32 bytes)
14 ATDTW	Add dTD Trip Wire (Device mode only) Works as a semaphore to ensure proper addition of a new dTD to an active (primed) endpoint's linked list. The hardware can also write 0 to this field when state machine is in hazard region for which adding a dTD to a primed endpoint may go unrecognized.
13 SUTW	Setup Trip Wire (Device mode only) Works as a semaphore to ensure that the setup data payload of 8 bytes is extracted from a queue head by the DCD without being corrupted. If the setup lockout mode is off (USBMODE[SLOM] is 1), then there is a hazard when new setup data arrives while the DCD is copying the setup data payload from the queue head of a previous setup packet. The hardware can also write 0 to this field when a hazard is detected.

Table continues on the next page...

Table continued from the previous page...

Field	Function
12 —	Reserved
11 ASPE	Asynchronous Schedule Park Mode Enable Enables Park mode. If HCCPARAMS[ASP] is 1, then this field defaults to 1h with RW as its access type. Otherwise, the field is 0 with access type RO. If this field is 1, Park mode is enabled, and if this field is 0, Park mode is disabled. 0b - Disables 1b - Enables
10 —	Reserved
9-8 ASP	Asynchronous Schedule Park Mode Count Contains a count of the number of successive transactions that the host controller is allowed to execute from an HS queue head on the asynchronous schedule, before continuing traversal of the asynchronous schedule. If HCCPARAMS[ASP] is 1, then this field defaults to 3h, with R/W as the access type. Otherwise, the field defaults to 0, with access type RO. Valid values are 1h–3h. You must not write 0 to this field when USBCMD[ASPE] is 1. Doing so leads to undefined behavior. This field is 3h for all controller cores.
7 —	Reserved
6 IAA	Interrupt on Async Advance Doorbell Acts as a doorbell for the host controller to issue an interrupt the next time it advances an asynchronous schedule. You must write 1 to this field to ring the doorbell. After the host controller evicts all appropriate cached schedule states, it writes 1 to USBSTS[AAI]. If USBINTR[AAE] is 1, then the host controller asserts an interrupt at the next interrupt threshold. The host controller writes 0 to this field after it writes 1 to USBSTS[AAI]. You must not write 1 to this field when the asynchronous schedule is inactive. Doing so yields undefined results. This field is only used in Host mode. Writing 1 to this field in Device mode leads to undefined results.
5 ASE	Asynchronous Schedule Enable Determines whether the host controller skips processing the asynchronous schedule. If this field is 1, Next Asynchronous Address (ASYNCLISTADDR) is used to access the periodic schedule. Only the host controller uses this field. 0b - Do not process the asynchronous schedule

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Access the asynchronous schedule
4 PSE	Periodic Schedule Enable Determines whether the host controller skips processing the periodic schedule. If this field is 1, Frame List Base Address (PERIODICLISTBASE) is used to access the periodic schedule. Only the host controller uses this field. 0b - Do not process the periodic schedule 1b - Process the periodic schedule
3-2 FS_1	Frame List Size 1 See the description of USBCMD[FS_2].
1 RST	Controller Reset Resets the controller. The host or device controller writes 0 to this field after the reset process is complete. You cannot terminate the reset process early by writing 0 to this field. In Host operation mode, the controller resets its internal pipelines, timers, counters, state machines, and so on, to their initial values when you write 1 to this field. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. You must not write 1 to this field when USBSTS[HCH] is 0. Attempting to reset an actively running host controller results in undefined behavior. In Device operation mode, the controller resets its internal pipelines, timers, counters, state machines, and so on, to their initial values when you write 1 to this field. Writing 1 to this field when the chip is in the attached state is not recommended because the effect on an attached host is undefined. To ensure that the chip is not in an attached state before initiating a device controller reset, all primed endpoints must be flushed and USBCMD[RS] must be 0.
0 RS	Run/Stop Specifies whether the controller is executing the operation. In Host operation mode, the controller proceeds with the execution of the schedule if the value of this field is 1b. The controller continues the execution as long as this field is 1. When this field becomes 0, the host controller completes the current transaction on the USB and then halts. The Halted bit in the Status field of the dTD token indicates when the controller has finished the transaction and has entered the stopped state. You must not write 1 to this field unless the controller is in the halted state (that is, USBSTS[HCH] is 1). In Device operation mode, writing 1 to this field causes the controller to enable a pull-up on D+ and initiate an attach event. This control field is not directly connected to the pull-up enable because the pull-up becomes disabled after transitioning into HS mode. You must use this field to prevent an attach event before the controller is properly initialized. Writing 0 to this field leads to a detach event. 0b - Stopped executing 1b - Running

51.8.1.20 USB Status (USBSTS)

Offset

Register	Offset
USBSTS	144h

Function

Indicates various states of the host and device controller and any pending interrupts. This register does not indicate status resulting from a transaction on the serial bus.

Diagram

Fields

Field	Function
31 LPM_HST_COMPI	Host Completes the LPM Transaction Interrupt Flag Indicates when the host receives a handshake or timeout for the LPM transaction. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt did not occur 1b - Interrupt occurred When writing 0b - No effect 1b - Clear the flag
30 LPM_DEV_RCVDI	Device Received Extension Token Interrupt Flag Indicates when the device received the extension token.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - Interrupt did not occur 1b - Interrupt occurred When writing 0b - No effect 1b - Clear the flag
29 LPM_L1_ENTRYI	L1 Entry Interrupt Flag Indicates when the device or host transitions to the L1 state and the PHY is put in Low-Power mode. The field is set when this happens. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt did not occur 1b - Interrupt occurred When writing 0b - No effect 1b - Clear the flag
28 LPM_L1_EXITI	L1 Exit Interrupt Flag Indicates when the device or host exits the L1 state. The field is set when this happens. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt did not occur 1b - Interrupt occurred When writing 0b - No effect 1b - Clear the flag
27-26 —	Reserved
25	General Purpose Timer Interrupt 1 (GPTINT1) Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
TI1	Indicates when the counter in General Purpose Timer 1 Controller (GPTIMER1CTRL) transitions to 0. This field is set when this happens. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt did not occur 1b - Interrupt occurred When writing 0b - No effect 1b - Clear the flag
24 TI0	General Purpose Timer Interrupt 0 (GPTINT0) Flag Indicates when the counter in General Purpose Timer 0 Controller (GPTIMER0CTRL) transitions to 0. This field is set when this happens. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt did not occur 1b - Interrupt occurred When writing 0b - No effect 1b - Clear the flag
23-20 —	Reserved
19 UPI	USB Host Periodic Interrupt Flag Indicates the cause of a periodic interrupt and whether a short packet is detected. The host controller sets this field when the cause of an interrupt is the completion of a USB transaction, where the transfer descriptor (TD) has the IOC field set and the TD is from a periodic schedule. The host controller also sets this field when a short packet is detected (the actual number of bytes received is less than expected) and the packet is on a periodic schedule. The device controller does not use this field; this field is always 0. **NOTE** This field behaves differently for register reads and writes. When reading

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Interrupt did not occur 1b - Interrupt occurred When writing 0b - No effect 1b - Clear the flag
18 UAI	USB Host Asynchronous Interrupt Flag Indicates the cause of an asynchronous interrupt and whether a short packet is detected. The host controller sets this field when the cause of an interrupt is the completion of a USB transaction, where the transfer descriptor (TD) has the IOC field set and the TD is from an asynchronous schedule. The host controller also sets this field when a short packet is detected (the actual number of bytes received is less than expected) and the packet is on an asynchronous schedule. The device controller does not use this field; this field is always 0. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt did not occur 1b - Interrupt occurred When writing 0b - No effect 1b - Clear the flag
17 —	Reserved
16 NAKI	NAK Interrupt Indicates whether a NAK interrupt is detected. Hardware sets this field, when ENDPTNAK[EPTN] and ENDPTNAK[EPRN] are both set for a particular endpoint, and their corresponding fields (ENDPTNAKEN[EPTNE] and ENDPTNAKEN[EPRNE]) are 1. When all enabled TX and RX endpoint NAK fields are cleared, this field is cleared automatically.
15 AS	Asynchronous Schedule Status Reports the current real status of the asynchronous schedule. When this field is 0, the asynchronous schedule status is disabled, and when this field is 1, the status is enabled. The host controller is not required to immediately disable or enable the asynchronous schedule when you transition USBCMD[ASE]. When this field and USBCMD[ASE] are the same value, the asynchronous schedule is either enabled (1) or disabled (0). This field is only used in Host Operation mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disabled 1b - Enabled
14 PS	Periodic Schedule Status Reports the current real status of the periodic schedule. If this field is 0, the periodic schedule is disabled, and if this field is 1, the status is enabled. The host controller is not required to immediately disable or enable the periodic schedule when you transition USBCMD[PSE]. When this field and USBCMD[PSE] are the same value, the periodic schedule is either enabled (1) or disabled (0). This field is only used in Host Operation mode. 0b - Disabled 1b - Enabled
13 RCL	Reclamation Detects an empty asynchronous schedule. This field is only used in Host Operation mode. 0b - Does not detect 1b - Detects
12 HCH	HC Halted Indicates whether the host controller is halted. This field is 0 whenever USBCMD[RS] is 1. The controller writes 1 to this field when you or the controller hardware write 0 to USBCMD[RS] after it has stopped executing (for example, in case of an internal error). This field is only used in Host Operation mode.
11 —	Reserved
10 ULPII	ULPI Interrupt Flag Indicates an event completion in the ULPI viewport. Hardware sets this field to 1b when there is an event completion in the ULPI viewport. You can only use this field if the controller supports UPLI interface mode. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Event completion did not occur 1b - Event completion occurred When writing

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - No effect 1b - Clear the flag
9 —	Reserved
8 SLI	Device Controller Suspend Flag Indicates whether the device controller entered a suspended state. When a device controller enters a suspended state from an active state, this field is set to 1. This field is only used in Device Operation mode. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Did not enter Suspended state 1b - Entered Suspended state When writing 0b - No effect 1b - Clear the flag
7 SRI	SOF Received Flag Indicates whether a start of (micro) frame (SOF) is received. When the device controller detects an SOF, this field is set to 1. When the SOF is extremely late, the device controller automatically sets this field to indicate that an SOF was expected. Therefore, this field is set roughly every 1 ms in device FS mode, and every 125 µs in HS mode. It is synchronized to the actual SOF that is received. Because the device controller is initialized to FS before connect, this field sets at an interval of 1 ms during the prelude to connect and chirp. In Host mode, this bit sets every 125 µs; the host controller driver can use it as a time base. **NOTE** This field behaves differently for register reads and writes. When reading 0b - SOF not received 1b - SOF received When writing 0b - No effect 1b - Clear the flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
6 URI	USB Reset Received Indicates whether a USB reset is received. When the device controller detects a USB reset and enters the default state, this field is set to 1. This field is used only in Device Operation mode. **NOTE** This field behaves differently for register reads and writes. When reading 0b - USB reset not received 1b - USB reset received When writing 0b - No effect 1b - Clear the flag
5 AAI	Interrupt on Asynchronous Advance Flag Indicates the assertion of the interrupt source. You can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing 1 to USBCMD[IAA]. This field is used only in Device Operation mode. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt did not occur 1b - Interrupt occurred When writing 0b - No effect 1b - Clear the flag
4 SEI	System Error Flag Indicates an error response to a read on the system interface. This field is set to 1b when there is an error response to a read on the system interface. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Error response did not occur

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Error response occurred When writing 0b - No effect 1b - Clear the flag
3 FRI	Frame List Rollover Flag Indicates the frame list index has rolled over. The host controller sets this field to 1 when the frame list index rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size. For example, if USBCMD[FS_2] and USBCMD[FS_1] are 000b, USB Frame Index (FRINDEX) rolls over every time FRINDEX[13] toggles. Similarly, if the size is 512, the host controller sets this field to 1 every time FRINDEX[12] toggles. This field is used only in Host Operation mode. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Frame list index did not roll over 1b - Frame list index rolled over When writing 0b - No effect 1b - Clear the flag
2 PCI	Port Change Detect Flag Indicates port change detection. The host controller sets this field to 1 when a connect status occurs on any port, a port enable or disable change occurs, or PORTSC1[FPR] becomes 1 as the result of a J-K transition on the suspended port. The device controller sets this field to 1 when the port controller enters the FS or HS operational state. When the port controller exits the FS or HS operation state because of reset or suspend events, the notification mechanisms are controlled by USBSTS[URI] and PORTSC1[SUSP], respectively. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Port change not detected 1b - Port change detected When writing 0b - No effect 1b - Clear the flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
1 UEI	USB Error Interrupt (USBERRINT) Flag Indicates an error condition after the completion of a USB transaction. The host or device controller sets this field after the completion of a USB transaction results in an error condition. This field is set along with USBSTS[UI], if the TD on which the error interrupt occurred also has its IOC field set in the dTD token. **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt did not occur 1b - Interrupt occurred When writing 0b - No effect 1b - Clear the flag
0 UI	USB Interrupt (USBINT) Flag Indicates the cause of an interrupt. The host or device controller sets this field when the cause of an interrupt is the completion of a USB transaction where the transfer descriptor (TD) also has its IOC field set in the dTD token. The host or device controller also sets this field when a short packet is detected (the actual number of bytes received is less than the expected number of bytes). **NOTE** This field behaves differently for register reads and writes. When reading 0b - Interrupt did not occur 1b - Interrupt occurred When writing 0b - No effect 1b - Clear the flag

51.8.1.21 Interrupt Enable (USBINTR)

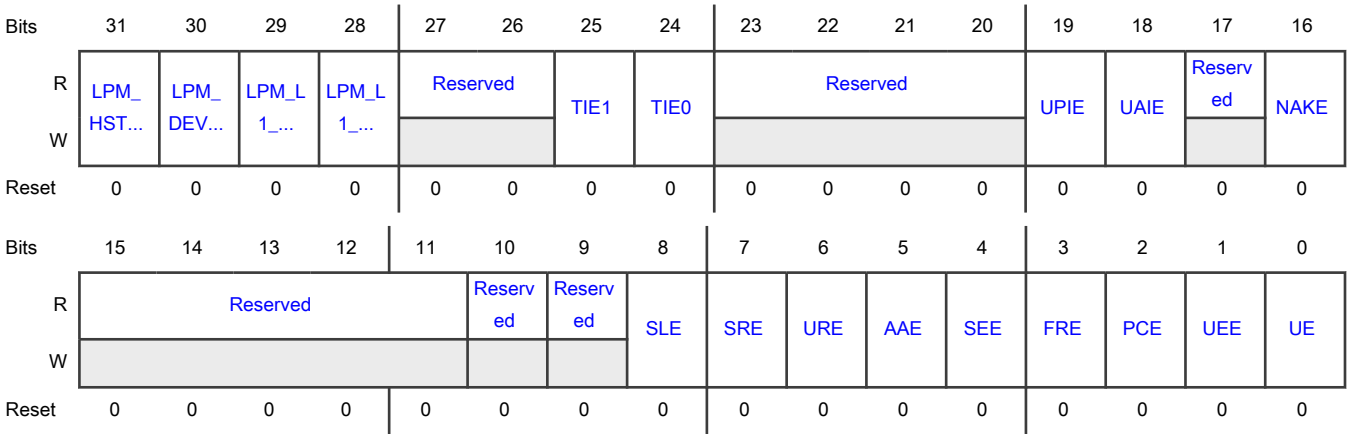
Offset

Register	Offset
USBINTR	148h

Function

Enables interrupts to software. An interrupt is generated when a field in this register is 1 and the corresponding interrupt source is active. USB Status (USBSTS) still shows interrupt sources even if they are disabled by USBINTR, allowing you to poll the interrupt events.

Diagram



Fields

Field	Function
31 LPM_HST_COMPIE	Host Completed LPM Transaction Interrupt Enable Enables LPM transaction interrupt. When this field is 1 and USBSTS[LPM_HST_COMPI] is 1 too, the controller issues an interrupt. This field is used only in Host Operation mode. 0b - Disables 1b - Enables
30 LPM_DEV_RCVDIE	Device Received Extension Token Interrupt Enable Enables device received extension token interrupt. When this field is 1 and USBSTS[LPM_DEV_RCVDI] is 1 too, the controller issues an interrupt. This field is used only in Device Operation mode. 0b - Disables 1b - Enables
29 LPM_L1_ENTRYIE	L1 Entry Interrupt Enable Enables L1 entry interrupt. When this field is 1 and USBSTS[LPM_L1_ENTRYI] is 1 too, the controller issues an interrupt. 0b - Disables 1b - Enables
28	L1 Exit Interrupt Enable

	When this field is 1 and USBSTS[AAI] is 1 too, the controller issues an interrupt. This field is used only in Host Operation mode. 0b - Disables 1b - Enables
4 SEE	System Error Interrupt Enable Enables system error interrupt. When this field is 1 and USBSTS[SEI] is 1 too, the controller issues an interrupt. This field is used only in Host Operation mode. 0b - Disables 1b - Enables
3 FRE	Frame List Rollover Interrupt Enable Enables the frame list rollover interrupt. When this field is 1 and USBSTS[FRI] is 1 too, the controller issues an interrupt. This field is used only in Host Operation mode. 0b - Disables 1b - Enables
2 PCE	Port Change Detect Interrupt Enable Enables port change detect interrupt. When this field is 1 and USBSTS[PCI] is 1 too, the controller issues an interrupt. 0b - Disables 1b - Enables
1 UEE	USB Error Interrupt Enable Enables USB error interrupt. When this field is 1 and USBSTS[UEI] is 1 too, the controller issues an interrupt. 0b - Disables 1b - Enables
0 UE	USB Interrupt Enable Enables USB interrupt. When this field is 1 and USBSTS[UI] is 1 too, the controller issues an interrupt. 0b - Disables 1b - Enables

51.8.1.22 USB Frame Index (FRINDEX)

Offset

Register	Offset
FRINDEX	14Ch

Function

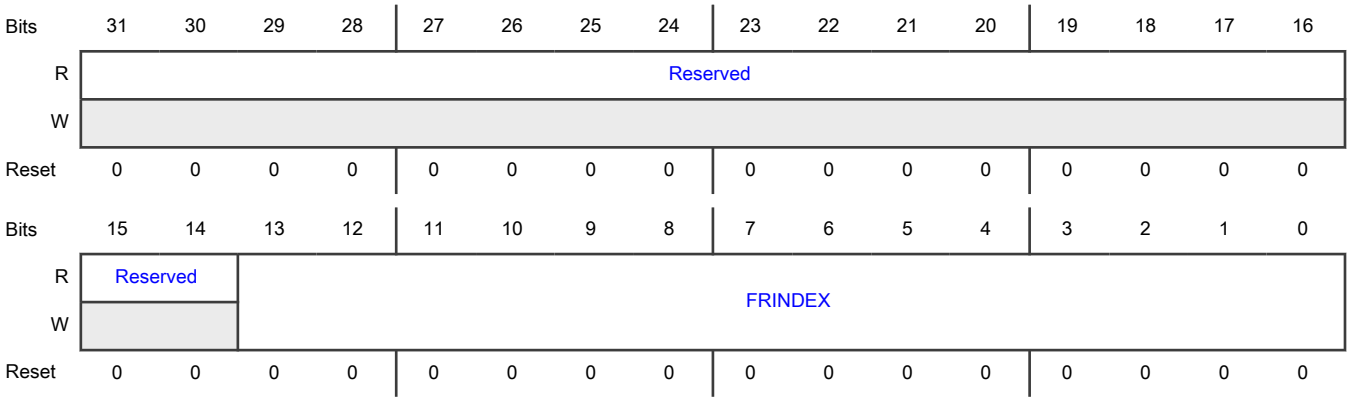
Indexes the periodic frame list.

The host controller uses this field to index the periodic frame list. The register updates every 125 microseconds (once each microframe). Bits[*n*:3] are used to select a particular entry in the periodic frame list during periodic schedule execution. The number of bits used for the index depends on the size of the frame list that you define by using USBCMD[FS_2] and USBCMD[FS_1].

You must write to this register as a DWord. Byte writes produce undefined results. You cannot write to this register unless the host controller is in the Halted state, as indicated by USBSTS[HCH]. A write to this register, when USBCMD[RS] is 1, produces undefined results. Writes to this register also affect the SOF value.

In Device mode, this register is read-only and the device controller updates FRINDEX [13:3] from the frame number indicated by the SOF marker. Whenever the USB bus receives an SOF, FRINDEX [13:3] is checked against the SOF marker. If FRINDEX [13:3] is different from the SOF marker, FRINDEX [13:3] is set to the SOF value and FRINDEX [2:0] is 0 (that is, SOF for 1 ms frame). If FRINDEX [13:3] is equal to the SOF value, FRINDEX [2:0] increments (that is, SOF for 125 µs microframe).

Diagram



Fields

Field	Function
31-14 —	Reserved
13-0 FRINDEX	Frame Index Increments at the end of each time frame (microframe). Bits[*n*:3] are used for the frame list current index. This means that each location of the frame list is accessed eight times (frames or microframes) before moving to the next index. In Host mode, the following values of *n* are based on the values of USBCMD[FS_2] and USBCMD[FS_1].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	In Device mode, the value is the current frame number of the last frame transmitted. It is not used as an index. In either mode, bits 2:0 indicate the current microframe. The following values are represented as USBCMD (frame list size) number elements *n*. 00_0000_0000_0000b - (1024) 12 00_0000_0000_0001b - (512) 11 00_0000_0000_0010b - (256) 10 00_0000_0000_0011b - (128) 9 00_0000_0000_0100b - (64) 8 00_0000_0000_0101b - (32) 7 00_0000_0000_0110b - (16) 6 00_0000_0000_0111b - (8) 5

51.8.1.23 Device Address (DEVICEADDR)

Offset

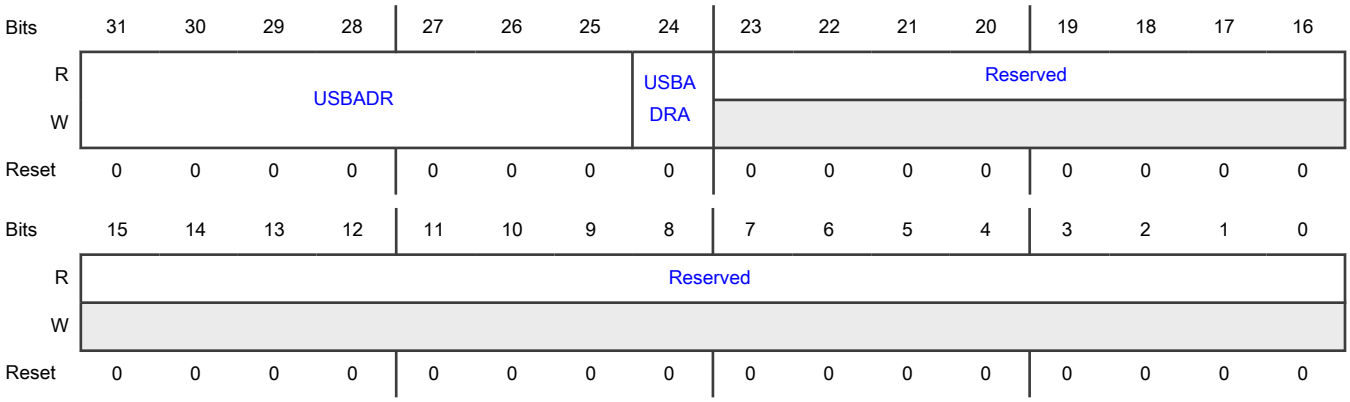
Register	Offset
DEVICEADDR	154h

Function

Contains the device address. After a controller or USB reset, the device address is set to the default address (0) that matches all incoming addresses. You must reprogram the address after receiving a SET_ADDRESS descriptor.

Only the device controller uses this register.

Diagram



Fields

Field	Function
31-25 USBADR	Device Address Represents the USB device address.
24 USBADRA	Device Address Advance Accelerates the SET_ADDRESS sequence by allowing the DCD to preset DEVICEADDR[USBADR] before the status phase of the SET_ADDRESS descriptor. When this field is 0, any writes to USBADR are instantaneous. If you write 1 to this field at the same time or before writing to USBADR, a write to USBADR is staged and held in a hidden register. After an "In" transaction occurs on endpoint 0 and is acknowledged, USBADR loads from the holding register. Hardware writes 0 to this field when all these conditions occur: • The "In" transaction is acknowledged to endpoint 0 (USBADR is updated from the staging register) • "Out" or "Setup" occur to endpoint 0 (USBADR is not updated) • Device reset occurs (USBADR is reset to 0) **NOTE** After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism ensures that this specification is met when the DCD is busy and cannot write to this field within 2 ms from the SET_ADDRESS status phase. If the DCD writes to the USBADR field when USBADRA = 1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR field is programmed instantly at the correct time and meets the 2 ms USB requirement.
23-0 —	Reserved

51.8.1.24 Frame List Base Address (PERIODICLISTBASE)

Offset

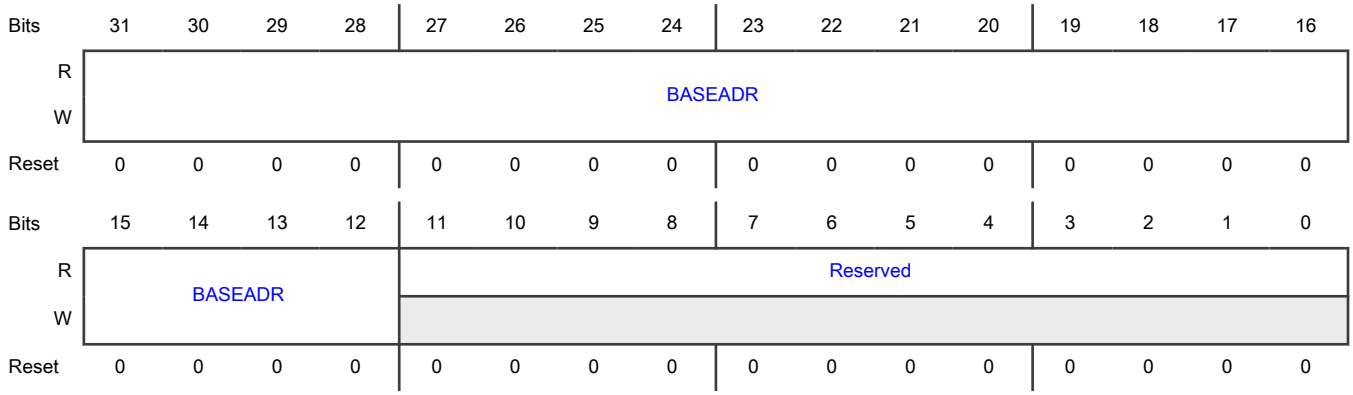
Register	Offset
PERIODICLISTBASE	154h

Function

Contains the beginning address of the periodic frame list in the system memory.

The host controller driver (HCD) loads this register before the host controller starts the schedule execution. The memory structure referenced by this physical memory pointer is assumed to be 4-KB aligned. The contents of this register are combined with USB Frame Index (FRINDEX) to enable the host controller to step through the periodic frame list in sequence.

Diagram



Fields

Field	Function
31-12 BASEADR	Base Address (Low) Specifies the base address. The bits of this field correspond to memory address signals [31:12], respectively. Only the host controller uses this field.
11-0 —	Reserved

51.8.1.25 Next Asynchronous Address (ASYNCLISTADDR)

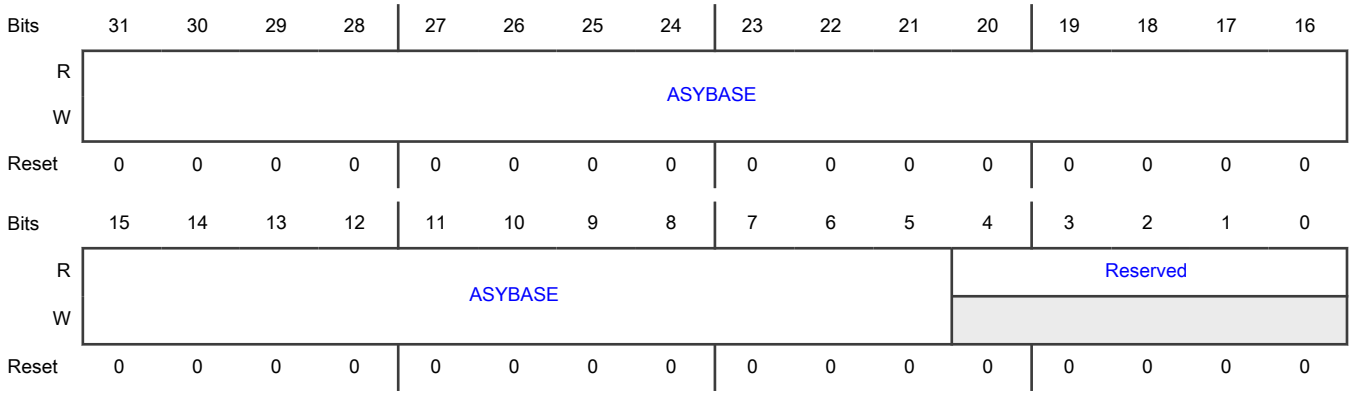
Offset

Register	Offset
ASYNCLISTADDR	158h

Function

Contains the address of the next asynchronous queue head to be executed by the host. You cannot modify bits [4:0] of this register; they always return a 0 when read.

Diagram



Fields

Field	Function
31-5 ASYBASE	Link Pointer Low (LPL) Specifies the link pointer. The bits of this field correspond to memory address signals [31:5], respectively. This field can only reference a queue head. Only the host controller uses this field.
4-0 —	Reserved

51.8.1.26 Endpoint List Address (ENDPTLISTADDR)

Offset

Register	Offset
ENDPTLISTADDR	158h

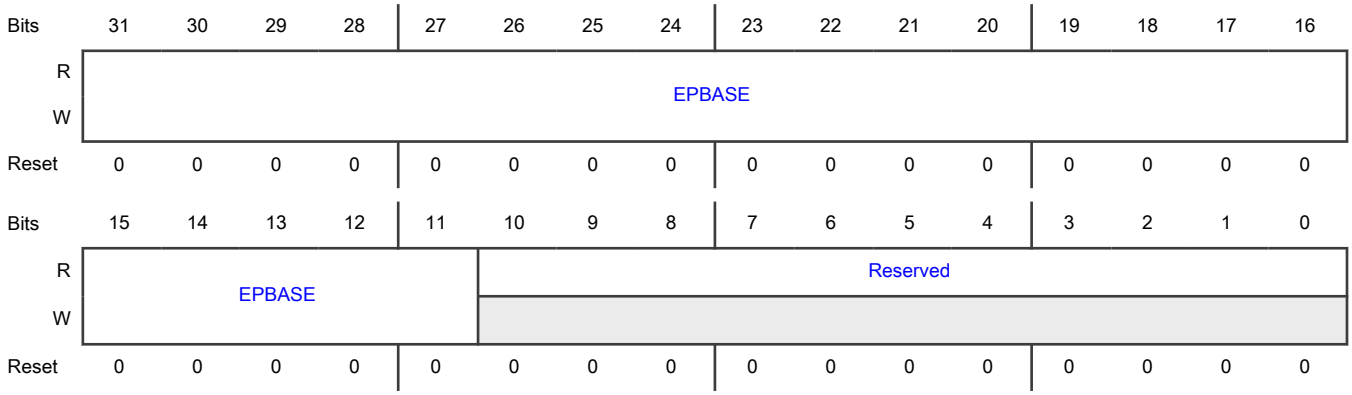
Function

Contains the address of the top of the endpoint list in system memory when in Device mode.

You cannot modify bits[10:0] of this register; they always return a 0 when read.

The memory structure referenced by this physical memory pointer is assumed to be 64 bytes.

Diagram



Fields

Field	Function
31-11 EPBASE	Endpoint List Pointer (Low) Specifies the endpoint list pointer. The bits of this field correspond to memory address signals [31:11], respectively. The field references a list of up to 32 queue heads (that is, one queue head per endpoint and direction). Only the device controller uses this field.
10-0 —	Reserved

51.8.1.27 Programmable Burst Size (BURSTSIZE)

Offset

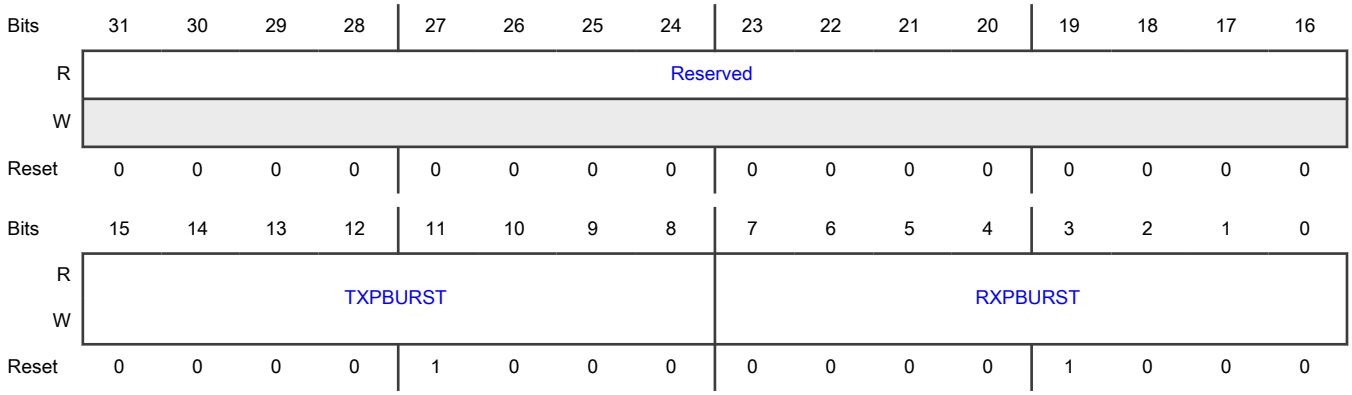
Register	Offset
BURSTSIZE	160h

Function

Controls the burst size used during data movement on the AHB manager interface.

This register is ignored if SBUSCFG[AHBBRST] has a nonzero value.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 TXPBURST	Programmable TX Burst Size Represents the maximum length of a burst, in 32-bit words, when moving data from system memory to the USB bus. HWTXBUF[TXBURST] determines the default value of this field.
7-0 RXPBURST	Programmable RX Burst Size Represents the maximum length of a burst, in 32-bit words, when moving data from the USB bus to system memory. HWRXBUF[RXBURST] determines the default value of this field.

51.8.1.28 TX FIFO Fill Tuning (TXFILLTUNING)

Offset

Register	Offset
TXFILLTUNING	164h

Function

Controls performance tuning associated with how the host controller posts data to the TX latency FIFO before moving the data onto the USB bus.

The specific areas of performance include how much data to post into the FIFO and an estimate for how long that operation must take in the target system.

Following are some related definitions:

- T_0 = Standard packet overhead
- T_1 = Time to send data payload

- T_{ff} = Time to fetch packet into TX FIFO up to the specified level
- T_s = Total packet flight time (send-only) packet
- $T_s = T_0 + T_1$
- T_p = Total packet time (fetch and send) packet
- $T_p = T_{ff} + T_0 + T_1$

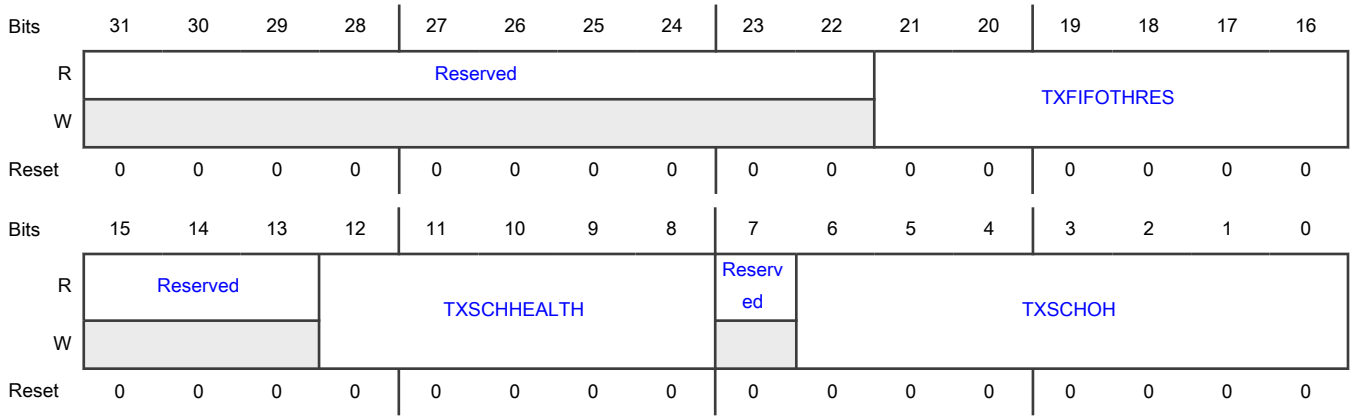
After the discovery of a transmit (Out or Setup) packet in the data structures, the host controller checks to ensure that T_p remains before the end of the microframe. If so, it proceeds to prefill the TX FIFO. If the remaining time in the frame of microframe is < T_s at any time during this operation, then the packet attempt ceases and the packet is tried at a later time.

Although this is not an error condition and the host controller eventually recovers, a mark is created in the scheduler health counter to note the occurrence of a back-off event. When a back-off event is detected, the partial packet fetched may need to be discarded from the latency buffer to make room for periodic traffic that begins after the next SOF. Too many back-off events can waste bandwidth and power on the system bus and should therefore be minimized (although not necessarily eliminated). Back-off events can be minimized by using TXFILLTUNING[TXSCHHEALTH] (T_{ff}).

NOTE

The reset value can vary from instance to instance. In that case, refer to the field descriptions of this register.

Diagram



Fields

Field	Function
31-22 —	Reserved
21-16 TXFIFOTHRES	FIFO Burst Threshold Controls the number of data bursts that are posted to the TX latency FIFO in Host mode before the packet begins on to the bus. This value must be as low as possible to maximize USB performance. The minimum value is two. A higher value can be used in systems with unpredictable latency and insufficient bandwidth, where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from the system memory. This value is ignored if USBMODE[SDIS] is 1.
15-13	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
12-8 TXSCHHEALTH	Scheduler Health Counter Increments when the host controller fails to fill the TX latency FIFO to the level that you program in TXFILLTUNING[TXFIFOTHRES] before running out of time to send the packet before the next SOF. This health counter measures the number of times this occurs to provide feedback for selecting a proper scheduler overhead (TXFILLTUNING[TXSCHOH]). Writing to this register clears this field. The maximum value of the field is 31.
7 —	Reserved
6-0 TXSCHOH	Scheduler Overhead Adds an additional fixed offset to the schedule time estimator described above as T_{ff}. As an approximation, the value selected for this register must limit the number of back-off events captured in TXFILLTUNING[TXSCHHEALTH] to less than 10 per second in a highly utilized bus. Selecting a value that is too high for this register is not recommended because it can needlessly reduce USB utilization. The time unit represented in this register is 1.267 µs when a device is connected in HS mode and is 6.333 µs when a device is connected in LS or FS mode.

51.8.1.29 Endpoint NAK (ENDPTNAK)

Offset

Register	Offset
ENDPTNAK	178h

Function
Configures RX and TX endpoint NAKs.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-24 —	Reserved
23-16 EPTN	TX Endpoint NAK Flag Indicates a transmit endpoint NAK. Each TX endpoint has one bit in this field, and that bit sets when the device sends a NAK handshake on a received "In" token for the corresponding endpoint. Bit [*n*] - Endpoint [*n*], *n* is 0-7. This field is used only in Device mode. **NOTE** This field behaves differently for register reads and writes. When reading 0000_0000b - No NACK 0000_0001b - NACK When writing 0000_0000b - No effect 0000_0001b - Clear the flag
15-8 —	Reserved
7-0 EPRN	RX Endpoint NAK Flag Indicates a receive endpoint NAK. Each RX endpoint has one bit in this field, and that bit sets when the device sends a NAK handshake on a received "Out" or "Ping" token for the corresponding endpoint. Bit [*n*] - Endpoint [*n*], *n* is 0-7 This field is used only in Device mode. **NOTE** This field behaves differently for register reads and writes. When reading 0000_0000b - No NACK 0000_0001b - NACK When writing 0000_0000b - No effect 0000_0001b - Clear the flag

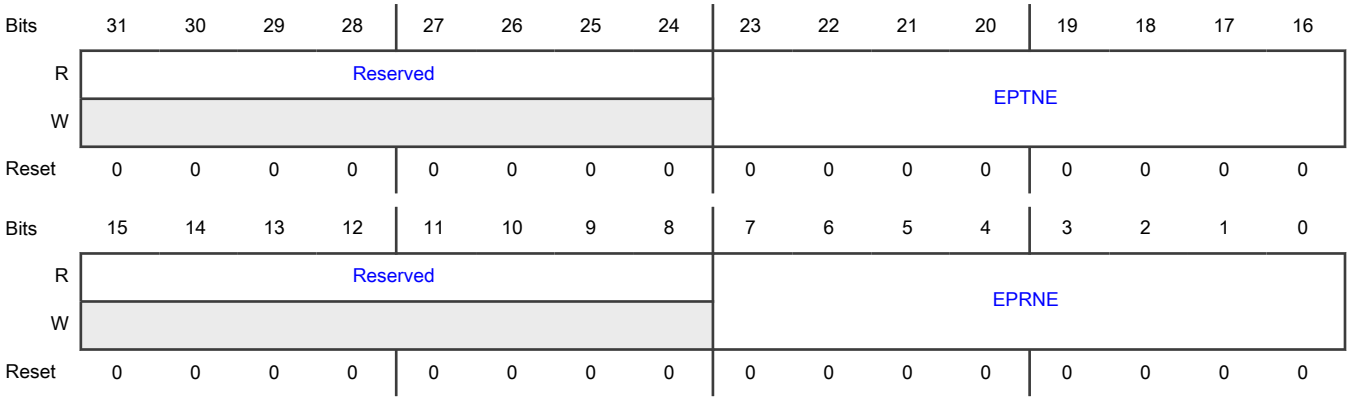
51.8.1.30 Endpoint NAK Enable (ENDPTNAKEN)

Offset

Register	Offset
ENDPTNAKEN	17Ch

Function
Enables RX and TX endpoint NAKs.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 EPTNE	TX Endpoint NAK Enable Enables transmit endpoint NAK. Each bit in this field enables the corresponding TX endpoint NAK bit. If a bit is set and the corresponding TX endpoint NAK bit is set, the NAK interrupt bit is set. Bit [*n*] - Endpoint [*n*], *n* is 0-7
15-8 —	Reserved
7-0 EPRNE	RX Endpoint NAK Enable Enables receive endpoint NAK. Each bit in this field enables the corresponding RX endpoint NAK bit. If a bit is set and the corresponding RX endpoint NAK bit is set, the NAK interrupt bit is set. Bit [*n*] - Endpoint [*n*], *n* is 0-7

51.8.1.31 Configure Flag (CONFIGFLAG)

Offset

Register	Offset
CONFIGFLAG	180h

Function
Controls port-routing control logic.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-1 —	Reserved
0 CF	Configure Flag Controls the default port-routing control logic. You must set this flag as the last action in the process of configuring the host controller. If this flag is 0, the port routing control logic routes each port to an implementation dependent on classic host controller by default. If this flag is 1, the port routing control logic routes all ports to this host controller by default. 0b - Port routing to classic host controller 1b - Port routing to this host controller

51.8.1.32 Port Status and Control (PORTSC1)

Offset

Register	Offset
PORTSC1	184h

Function

Determines and implements ports that need service.

A host controller can implement one to eight port status and control registers. The number is determined by HCSPARAMS[N_PORTS]. You can read this parameter register to determine how many ports need service.

All controller cores on this product are single-port, so there is only one port status and control register for each controller core.

This register is only reset by POR or controller core reset. The following are the initial conditions of a port:

- No device connected
- Port disabled

If the port supports power control, this state remains until software supplies port power.

A device controller operating in Device mode has only PORTSC1 and does not support power control in that mode. Port control in Device mode is only used for status port reset, suspend, and current connect status. It is also used to initiate Test mode or force signaling, and allows you to place the PHY into Low-Power Suspend mode and disable the PHY clock.

Fields

Field	Function
31-30 PTS_1	Parallel Transceiver Select 1 **NOTE** All USB port interface modes are listed in this field description, but not all are supported. For details related to each controller core, see Features. The behavior is unknown when an unsupported interface mode is selected. {bit25, bit31, bit30}:

Table continues on the next page...

Table continued from the previous page...

Field	Function
	000b - UTMI/UTMI+ 001b - Reserved 010b - ULPI 011b - Serial/USB 1.1 PHY/IC-USB (FS only) 100b - HSIC
29 STS	Serial Transceiver Select Selects the serial transceiver. The serial interface engine can be used in combination with the UTMI+/ULPI physical interface to provide FS and LS signaling instead of the parallel interface signals. When this field is 1, the serial interface engine is used instead of parallel interface signals. This field has no effect unless PORTSC1[PTS_1] is 1 (to select the UTMI+/ULPI interface). The serial/USB1.1 PHY/IC-USB uses the serial interface engine for FS and LS signaling regardless of the value of this field. 0b - Parallel interface signals 1b - Serial interface engine
28 PTW	Parallel Transceiver Width Selects the parallel transceiver width. This field has no effect if the serial interface engine is used. 0b - 8-bit UTMI interface (60 MHz) 1b - 16-bit UTMI interface (30 MHz)
27-26 PSPD	Port Speed Indicates the speed at which the port is operating. 00b - FS 01b - LS 10b - HS 11b - Undefined
25 PTS_2	Parallel Transceiver Select 2 See description of PORTSC1[PTS_1].
24 PFSC	Port Force Full Speed Connect Specifies the speed at which the port is connected. If this field is 1, the port is forced to connect at FS only. It disables the chirp sequence that allows the port to identify itself as HS.

Table continues on the next page...

Enables wake-up on disconnect.
Writing 1 to this field enables the port to be sensitive to device disconnects as wake-up events.
This field is 0 if PORTSC1[PP] is 0 or is in Device mode.
0b - Disables
1b - Enables</td></tr>
</table>

Table continues on the next page...

Table continued from the previous page...

Field	Function
20 WKCN	Wake on Connect Enable (WKCNNT_E) Enables port sensitivity. Writing 1 to this field enables the port to be sensitive to device connects as wake-up events. This field is 0 if PORTSC1[PP] is 0 or is in Device mode. 0b - Disables 1b - Enables
19-16 PTC	Port Test Control Defines port test control. See Port Test Control mode for the operational model used for these test modes, and chapter 7 of the USB Specification Revision 2.0 for details on each test mode. FORCE_ENABLE_FS and FORCE ENABLE_LS are extensions to the test mode support specified in the EHCI specification. Writing the FORCE_ENABLE_{HS/FS/LS} values to this field forces the port into the connected and enabled states at the selected speed. Writing the TEST_MODE_DISABLE value to this field allows the port state machines to progress normally from that point. **NOTE** LS operations are not supported as a peripheral device. Any value other than 0 indicates that the port is operating in Test mode. 0000b - TEST_MODE_DISABLE 0001b - J_STATE 0010b - K_STATE 0011b - SE0 (host) or NAK (device) 0100b - Packet 0101b - FORCE_ENABLE_HS 0110b - FORCE_ENABLE_FS 0111b - FORCE_ENABLE_LS 1000b-1111b - Reserved
15-14 PIC	Port Indicator Control Specifies the port indicator. Writing to this field has no effect if HCSPARAMS[PI] is 0. See the USB Specification Revision 2.0 for a description on how these fields must be used. This field is 0 if PORTSC1[PO] is 0. 00b - Port indicators are off 01b - Amber

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - Green 11b - Undefined
13 PO	Port Owner Indicates port ownership. This field is used to release ownership of the port to a selected host controller (in the event that the attached device is not an HS device). This field unconditionally becomes 0 when the configured field in Configure Flag (CONFIGFLAG) makes a transition from 0 to 1. The field unconditionally becomes 1 whenever the configured field is 0. Write 1 to this field when the attached device is not an HS device. If this field is 1, it means that an internal companion controller owns and controls the port. Port owner handoff is not supported in all controller cores; therefore, this field is always 0.
12 PP	Port Power (PP) Works in accordance with HCSPARAMS[PPC]. In other words, the functioning of this field depends on the value of HCSPARAMS[PPC]. • PPC = 0b, PP = 0b (read-only): A controller in Device mode does not have port power control switches. • PPC = 1b, PP = 1b or 0b (read/write): A controller in Host mode requires port power control switches. This field represents the current setting of the switch (0 means off; 1 means on). When power is not available on a port (that is, PP = 0), the port is nonfunctional and does not report attachments, detachments, and so on. When an overcurrent condition is detected on a powered port and PPC is 1, this field, in each affected port, may be transitioned by the controller driver from 1 to 0 (removing power from the port). In Device mode, port power control is not necessary. Therefore, PPC and PP are 0. 0b - Off 1b - On
11-10 LS	Line Status Indicates the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. In Host mode (unlike EHCI), the host controller driver may not necessarily use LineState because the port controller state machine and port routing manage the connection of LS and FS. In Device mode, the device controller driver may not necessarily use LineState. 00b - SE0 01b - K-state 10b - J-state 11b - Undefined

Table continues on the next page...

Table continued from the previous page...

Field	Function
9 HSP	High-Speed Port Indicates whether the host or device connected to the port is in HS mode. This field is redundant for PORTSC1[PSPD] but is included for compatibility. 0b - Not in HS mode 1b - In HS mode
8 PR	Port Reset Specifies whether the port is in reset. In Host mode (read/write), the bus-reset sequence (as defined in the USB Specification Revision 2.0) starts when you write 1 to this field. This field automatically changes to 0 after the reset sequence is complete. This behavior is different from that of EHCI where the host controller driver is required to write 0 to this field after the reset duration is timed in the driver. In Device mode, this is a read-only status field. Device reset from the USB bus is also indicated in USB Status (USBSTS). This field is 0 if PORTSC1[PP] is 0. 0b - Port not in reset 1b - Port in reset
7 SUSP	Suspend Specifies whether the port is in the Suspended state. In Host mode (read/write), this field works with PORTSC1[PEC] to define the port states as follows: If {PE, SUSP} = 0x, the port state is disabled. When in the Suspended state, downstream propagation of data is blocked on this port (except for port reset). Blocking occurs at the end of the current transaction if a transaction was in progress when this field was 1. The port is sensitive to resume detection in the Suspended state. The status of the field does not change until the port is suspended; there may be a delay in suspending a port if a transaction is in progress on USB. The host controller unconditionally writes 0 to this field when you write 0 to PORTSC1[FPR]. The host controller ignores a write of 0 to this field. If host software writes 1 to this field when the port is not enabled (that is, PORTSC1[PE] is 0), the results are undefined. This field is 0 if PORTSC1[PP] is 0 in Host mode. In Device mode, this is a read-only status field. 0b - Port not in Suspended state 1b - Port in Suspended state
6 FPR	Force Port Resume Specifies whether force resume is detected or driven on the port.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	In Host mode, software writes 1 to this field to drive resume signaling. The host controller writes 1 to this field if a J-to-K transition is detected when the port is in the Suspended state. When this field transitions to 1 because a J-to-K transition is detected, USBSTS[PCI] also becomes 1. This field automatically changes to 0 after the resume sequence is complete. This behavior is different from that of EHCI where the host controller driver is required to write 0 to this field after the resume duration is timed in the driver. When the host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (FS "K") is driven on the port until this field remains 1 (that is, until the port has switched to the HS idle state). Writing 0 to this field has no effect because the port controller times the resume operation, clears the field, and the port control state switches to HS or FS idle. This field is non-EHCI compatible and remains 0 if PORTSC1[PP] is 0 in Host mode. In Device mode, you must write 1 to this field to drive resume signaling after the device is in the Suspended state for 5 ms or more. The device controller writes 1 to this field if a J-to-K transition is detected when the port is in the Suspended state. The field becomes 0 when the device returns to normal operation. Additionally, when this field becomes 0 because of a K-to-J transition detection, USBSTS[PCI] also becomes 1. 0b - No resume (K-state) detected or driven on port 1b - Resume detected or driven on port
5 OCC	Overcurrent Change Flag Indicates whether an overcurrent change occurred. Hardware sets this field to 1 when there is a change in an overcurrent active condition. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No change occurred 1b - Change occurred When writing 0b - No effect 1b - Clear the flag
4 OCA	Overcurrent Active Indicates whether the port currently has an overcurrent condition. This field automatically transitions from 1 to 0 when the overcurrent condition is removed. 0b - No overcurrent condition exists 1b - Overcurrent condition exists
3	Port Enable and Disable Change Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
PEC	Indicates whether port enabled and disabled status has changed. In Host mode (for the root hub), this field is set to 1 only when a port is disabled because of disconnect on the port or because of appropriate conditions existing at the EOF2 point. See chapter 11 of the USB specification. This field is zero if PORTSC1[PP] is 0. In Device mode, the device port is always enabled; therefore, this field is always 0. **NOTE** This field behaves differently for register reads and writes. When reading 0b - No change occurred 1b - Change occurred When writing 0b - No effect 1b - Clear the flag
2 PE	Port Enable and Disable Enables a port. In Host mode, this field is reset to 0b. Only the host controller can enable ports as part of reset and enable. You cannot enable a port by writing 1 to this field, and either a fault condition (such as a disconnect event) or host software can disable a port. The status of this field does not change until the port state actually changes. There may be a delay in disabling or enabling a port because of other host controller and bus events. If this field is 0 (the port is disabled), downstream propagation of data is blocked except for reset. In Host mode, this field is 0 if PORTSC1[PP] is 0. In Device mode, this field is always 1 (the device port is always enabled). 0b - Disables 1b - Enables
1 CSC	Connect Status Change Flag Indicates whether a change has occurred in the port's current connect status. In Host mode, the host or device controller sets this field for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the connect status (PORTSC1[CCS]) changes twice before you clear PORTSC1[CSC]. The hub hardware sets an already-set field (that is, CSC remains set). You can clear this field by writing 1 to it. In Host mode, this field is 0 if PORTSC1[PP] is 0. In Device Controller mode, this field is undefined.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field behaves differently for register reads and writes. When reading 0b - No change occurred 1b - Change occurred When writing 0b - No effect 1b - Clear the flag
0 CCS	Current Connect Status Indicates the current port connection status. In Host mode, if this field is 1, the device is present on port, and if this field is 0 (default), no device is present. This value reflects the current state of the port, and may not correspond directly to the event that causes this field to be set. In Host mode, this field is 0 if PORTSC1[PP] is 0. In Device mode, if this field is 1, it indicates that the device is successfully attached and is operating in either HS or FS, as indicated by PORTSC1[HSP]. If this field is 0, it indicates that the device is not attached successfully or is forcibly disconnected by writing 0 to USBCMD[RS]. 0b - No device present or attached 1b - Device present and attached

51.8.1.33 On-The-Go Status and Control (OTGSC)

Offset

Register	Offset
OTGSC	1A4h

Function

Provides OTG status and control.

This register is available only in the OTG controller core and includes fields for:

- OTG interrupt enables
- OTG interrupt status
- OTG status inputs
- OTG controls

The status inputs are debounced using a 1 ms time constant. Values on the status inputs that do not persist for more than 1 ms do not cause an update of the status input register, or cause an OTG interrupt.

See USB Device Mode (USBMODE) for more information.

NOTE

Each module instance supports a different number of registers.

Instance	Register supported	Register not supported
USB0	OTGSC	—
USB1	—	OTGSC

Diagram

Fields

Field	Function
31 —	Reserved
30 DPIE	Data Pulse Interrupt Enable Enables the data pulse interrupt. Writing 1 to the field enables the interrupt.
29 EN_1MS	1 Millisecond Timer Interrupt Enable Enables the 1 ms timer interrupt. Writing 1 to the field enables the interrupt.
28 BSEIE	B Session End Interrupt Enable Enables the B session end interrupt. Writing 1 to the field enables the interrupt.
27 BSVIE	B Session Valid Interrupt Enable Enables the B session valid interrupt. Writing 1 to the field enables the interrupt.
26 ASVIE	A Session Valid Interrupt Enable Enables the A session valid interrupt. Writing 1 to the field enables the interrupt.
25	A VBUS Valid Interrupt Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
AVVIE	Enables the A VBUS valid interrupt. Writing 1 to the field enables the interrupt.
24 IDIE	USB ID Interrupt Enable Enables the USB ID interrupt. Writing 1 to the field enables the interrupt.
23 —	Reserved
22 DPIS	Data Pulse Interrupt Status Indicates the status of the data pulse interrupt. This field becomes 1 when data bus pulsing occurs on a DP or DM line. Data bus pulsing is detected only when USBMODE[CM] = 11b and PORTSC1[PP] = 0b.
21 STATUS_1MS	1 Millisecond Timer Interrupt Status Indicates the status of the timer interrupt. This field becomes 1 once every millisecond.
20 BSEIS	B Session End Interrupt Status Indicates the status of the B session end interrupt. This field becomes 1 when VBUS has fallen below the B session end threshold.
19 BSVIS	B Session Valid Interrupt Status Indicates the status of the B session valid interrupt. This field becomes 1 when VBUS has either risen above or fallen below the B session valid threshold.
18 ASVIS	A Session Valid Interrupt Status Indicates the status of the A session valid interrupt. This field becomes 1 when VBUS has either risen above or fallen below the A session valid threshold.
17 AVVIS	A VBUS Valid Interrupt Status Indicates the status of the A VBUS valid interrupt. This field becomes 1 when VBUS has either risen above or fallen below the VBUS valid threshold on A device.
16 IDIS	USB ID Interrupt Status Indicates the status of the USB ID interrupt. This field becomes 1 when a change on the ID input is detected.
15 —	Reserved
14	Data Bus Pulsing Status

Table continues on the next page...

Table continued from the previous page...

Field	Function
DPS	Indicates the status of data bus pulsing. If this field is 1, it indicates that data bus pulsing is detected on the port.
13 TOG_1MS	1 Millisecond Timer Toggle Toggles once per millisecond.
12 BSE	B Session End Indicates that VBUS is below the B session end threshold.
11 BSV	B Session Valid Indicates that VBUS is above the B session valid threshold.
10 ASV	A Session Valid Indicates that VBUS is above the A session valid threshold.
9 AVV	A VBUS Valid Indicates that VBUS is above the A VBUS valid threshold.
8 ID	USB ID Indicates the USB ID. 0b - A device 1b - B device
7 HABA	Hardware Assist B-Disconnect to A-connect Enables hardware assist for B-disconnect to A-connect. During HNP, the B-disconnect occurs from the OTG-A Suspended state and within 3 ms, the A-device must enable the pullup on the DP leg in the A-peripheral state. When this field is 1, the host controller port is in Suspend mode, and the device disconnects. Then this hardware assist begins. 0b - Disables 1b - Enables
6 HADP	Hardware Assist Data Pulse Enables starting a data pulse. Writing 1 to this field starts a data pulse of approximately 7 ms in duration and then automatically ceases the data pulsing. During the data pulse, OTGSC[DP] becomes 1 and then becomes 0. This automation relieves software from accurately controlling the data-pulse duration. During the data pulse, HCD can poll to see that the HADP and DP fields have become 0 to recognize the completion of the data pulse, or launch the data pulse and wait to see if a VBUS valid interrupt occurs when the A-side supplies bus power. This field ensures data pulsing meets the OTG requirement of > 5 ms and < 10 ms. 0b - Disables

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enables
5 IDPU	ID Pullup Provides control over the ID pull-up resistor. If this field is 0, the functionality is off and the ID input is not sampled. If this field is 1 (default), the functionality is on and the ID input is sampled.
4 DP	Data Pulsing Controls pullup on the DP line. Writing 1 to this field causes the pullup on the DP line to be asserted for data pulsing during SRP.
3 OT	OTG Termination Controls pulldown on the DM line. This field must be 1 when the OTG device is in Device mode to control the pulldown on the DM line.
2 HAAR	Hardware Assist Auto Reset Enables automatic reset of hardware after a connect event on host port. When this field is 1, the host automatically starts a reset after a connect event. This is a shortcut to the normal process through which you are notified of the connect event to start the reset. Even after receiving a notification of the connect event, you must not write to the reset field when HAAR is 1. You are again notified after the reset is complete via PORTSC1[PTS_1] that causes a port change interrupt. 0b - Disables 1b - Enables
1 VC	VBUS Charge Controls VBUS pulsing during SRP. Writing 1 to this field causes the VBUS line to be charged.
0 VD	VBUS Discharge Discharges VBUS through a resistor. Writing 1 to this field causes VBUS to discharge through a resistor.

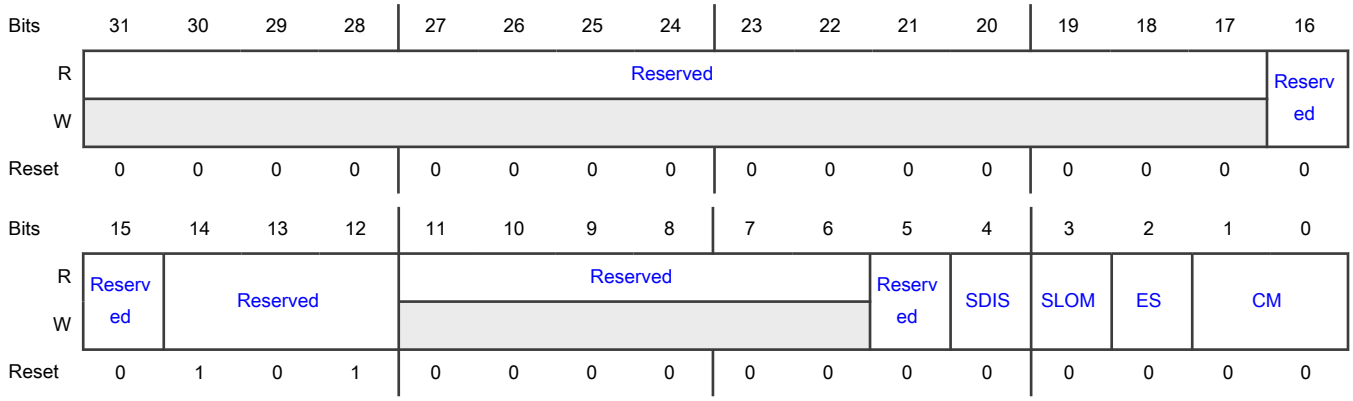
51.8.1.34 USB Device Mode (USBMODE)

Offset

Register	Offset
USBMODE	1A8h

Function
Selects the USB device mode.

Diagram



Fields

Field	Function
31-17 —	Reserved
16 —	Reserved
15 —	Reserved
14-12 —	Reserved
11-6 —	Reserved
5 —	Reserved
4 SDIS	Stream Disable Mode Disables double priming for low-bandwidth systems. In Device mode, writing 1 to this field disables double priming on both RX and TX buffers for low-bandwidth systems. This mode ensures that when the RX and TX buffers are sufficient to contain an entire packet, the standard double buffering scheme is disabled to prevent overruns and underruns in bandwidth limited systems. **NOTE** In HS mode, all packets received are responded to with an NYET handshake when stream disable is active.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	In Host mode, writing 1 to this field ensures that overruns and underruns of the latency FIFO are eliminated for low-bandwidth systems where the RX and TX buffers are sufficient to contain the entire packet. Enabling stream disable also ensures that the TX latency is filled to capacity before the packet is launched onto the USB. **NOTE** The time duration to prefill the FIFO becomes significant when stream disable is active. See TX FIFO Fill Tuning (TXFILLTUNING) to characterize the adjustments needed for the scheduler when using this feature. The use of this feature substantially limits the overall USB performance that can be achieved. 0b - Disables 1b - Enables
3 SLOM	Setup Lockout Mode Specifies whether the setup lockouts are on. In Device mode, this field controls the behavior of the setup lock mechanism. See Control endpoint operation model for more information. The DCD requires you to use the setup data buffer tripwire in USB Command (USBCMD). 0b - On (default) 1b - Off
2 ES	Endian Select Selects the endianness. You can use this field to change the byte alignment of the transfer buffers to match the host microprocessor. The fields in the microprocessor interface and the data structures are unaffected by the value of this field because they are based on the 32-bit word. 0b - Little endian (default) 1b - Big endian
1-0 CM	Controller Mode Specifies the controller mode. The controller mode is defaulted to the proper mode for host-only and device-only implementations. For those designs that contain both host and device capabilities, the controller defaults to an idle state and needs to be initialized to the desired operating mode after reset. For combination host and device controllers, you can write to this register only once after reset. If it is necessary to switch modes, you must reset the controller by writing to USBCMD[RST] before reprogramming this register. 00b - Idle (default for host and device combination) 01b - Reserved 10b - Device controller (default for device-only controller) 11b - Host controller (default for host-only controller)

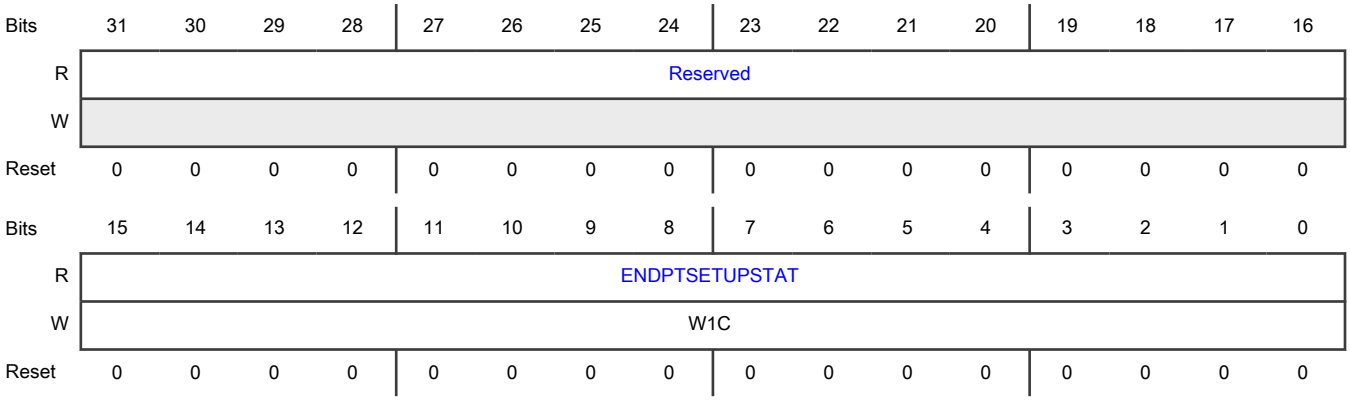
51.8.1.35 Endpoint Setup Status (ENDPTSETUPSTAT)

Offset

Register	Offset
ENDPTSETUPSTAT	1ACh

Function
Indicates the endpoint setup status.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 ENDPTSETUPSTAT	Endpoint Setup Status Flag Indicates the endpoint setup status and whether the setup transaction is received. For every setup transaction that is received, a corresponding bit in this field becomes 1. You must clear or acknowledge the setup transfer by writing 1 to the respective bit after it has read the setup data from the queue head. The response to a setup packet includes many operations in an order. The total response time is crucial to limit bus timeouts if the setup lockout mechanism is engaged. See Managing endpoints in the device operational model. This register is used only in Device mode. **NOTE** This field behaves differently for register reads and writes. When reading 0000_0000_0000_0000b - Not received

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0000_0000_0000_0001b - Received When writing 0000_0000_0000_0000b - No effect 0000_0000_0000_0001b - Clear the flag

51.8.1.36 Endpoint Prime (ENDPTPRIME)

Offset

Register	Offset
ENDPTPRIME	1B0h

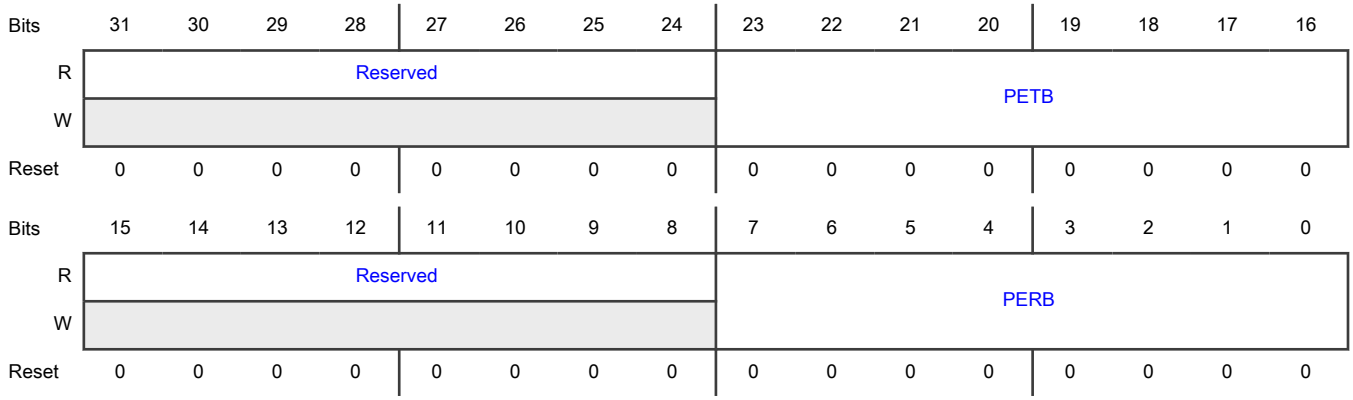
Function

Primes the endpoint.

When you set the prime bit for a given endpoint, the device controller loads the transfer descriptor, pointed to by the queue head, so that the endpoint is ready to transmit or receive when the host sends a request ("In" or "Out" token). The endpoint NAKs all requests from the host until the endpoint is primed. The controller automatically reprimes the endpoint with a new transfer descriptor when one is found via the next_dtd pointer of the current transfer descriptor. Therefore, you must set the prime bit only when a descriptor is added to the queue head.

This register is only used in Device mode.

Diagram



Fields

Field	Function
31-24 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
23-16 PETB	Prime Endpoint Transmit Buffer Parses a new transfer descriptor from the queue head and prepares for a transmit buffer. For each endpoint, a corresponding bit is used to request that a buffer is prepared for a transmit operation to respond to a USB "In" or "Interrupt" transaction. You must write 1 to the corresponding bit when posting a new transfer descriptor to an endpoint queue head. Hardware automatically uses this field to begin parsing for a new transfer descriptor from the queue head and preparing a transmit buffer. Hardware writes 0 to this field when an associated endpoint is successfully primed. PETB[*n*]: Endpoint [*n*], *n* is in 0–7 **NOTE** Hardware temporarily writes 1 to this field during hardware repriming operations when a dTD is retired and the dQH is updated.
15-8 —	Reserved
7-0 PERB	Prime Endpoint Receive Buffer Parses a new transfer descriptor from the queue head and prepares for a receive buffer. For each endpoint, a corresponding bit is used to request that a buffer is prepared for a receive operation when a USB host initiates a USB "Out" transaction. You must write 1 to the corresponding bit when posting a new transfer descriptor to an endpoint queue head. Hardware automatically uses this field to begin parsing for a new transfer descriptor from the queue head and preparing a receive buffer. Hardware writes 0 to this field when an associated endpoint is successfully primed. PERB[*n*]: Endpoint [*n*], *n* is in 0–7 **NOTE** Hardware temporarily writes 1 to this field during hardware repriming operations when a dTD is retired and the dQH is updated.

51.8.1.37 Endpoint Flush (ENDPTFLUSH)

Offset

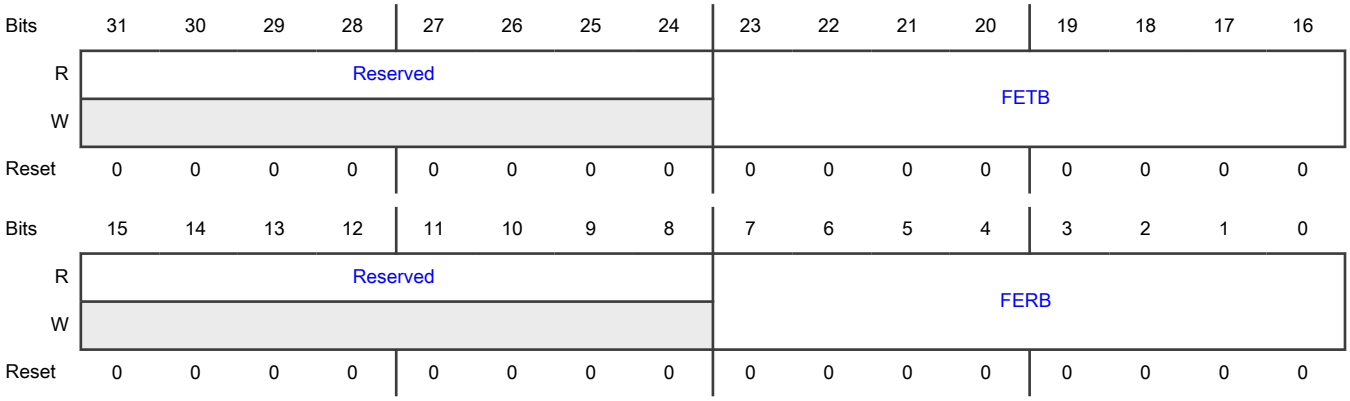
Register	Offset
ENDPTFLUSH	1B4h

Function

Flushes the endpoint.

This register is only used in Device mode.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 FETB	Flush Endpoint Transmit Buffer Clears any primed transmit buffers. When you write 1 to this field, it causes the associated endpoint(s) to clear any primed transfer buffers. If a packet is in progress for one of the associated endpoints, then that transfer continues until completion. Hardware clears this register after the endpoint flush operation is successful. FETB[*n*]: Endpoint [*n*], *n* is in 0–7
15-8 —	Reserved
7-0 FERB	Flush Endpoint Receive Buffer Clears any primed receive buffers. When you write 1 to this field, it causes the associated endpoints to clear any primed receive buffers. If a packet is in progress for one of the associated endpoints, then that transfer continues until completion. Hardware clears this register after the endpoint flush operation is successful. FERB[*n*]: Endpoint [*n*], *n* is in 0–7

51.8.1.38 Endpoint Status (ENDPTSTAT)

Offset

Register	Offset
ENDPTSTAT	1B8h

Function

Indicates endpoint transmit and receive buffer ready status.

This register is only used in Device mode.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-24 —	Reserved
23 TXE	TX Endpoint Enable Enables transmit endpoint. You must enable an endpoint only after it is configured. 0b - Disables 1b - Enables
22-20 —	Reserved
19-18 TXT	TX Endpoint Type Indicates the transmit endpoint type. If this field is 0, endpoint 0 is fixed as a control endpoint.
17 —	Reserved
16 TXS	TX Endpoint Stall Specifies whether the transmit endpoint is stalled. If you write 1 to this field, it forces the endpoint to return a STALL handshake to the host. The field continues returning a STALL response until you write 0 to it or if the field automatically becomes 0 after it receives a new Setup request. After receiving a Setup request, hardware continues to write 0 to this field until the associated endpoint setup status field (ENDPTSETUPSTAT[ENDPTSETUPSTAT]) is cleared. **NOTE** There is a slight delay (a maximum of 50 clocks) between clearing ENDPTSETUPSTAT[ENDPTSETUPSTAT] and the hardware continuing to write 0 to this field. In most systems, it is unlikely for the DCD to observe this delay. However, if DCD observes that this field is not becoming 1, you must continually write to this field until it becomes 1 or until a new setup is received (check ENDPTSETUPSTAT[ENDPTSETUPSTAT] for that). 0b - Endpoint OK 1b - Endpoint stalled
15-8 —	Reserved
7 RXE	RX Endpoint Enable Enables the receive endpoint. Endpoint 0 is always enabled.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disables 1b - Enables
6-4 —	Reserved
3-2 RXT	RX Endpoint Type Indicates the receive endpoint type. If this field is 0, endpoint 0 is fixed as a control endpoint.
1 —	Reserved
0 RXS	RX Endpoint Stall Specifies whether the receive endpoint is stalled. If you write 1 to this field, it forces the endpoint to return a STALL handshake to the host. The field continues returning a STALL response until you write 0 to it or if the field automatically becomes 0 after it receives a new Setup request. After receiving a Setup request, hardware continues to write 0 to this field until the associated endpoint setup status field (ENDPTSETUPSTAT[ENDPTSETUPSTAT]) is cleared. **NOTE** There is a slight delay (a maximum of 50 clocks) between clearing ENDPTSETUPSTAT[ENDPTSETUPSTAT] and the hardware continuing to write 0 to this field. In most systems, it is unlikely for the DCD to observe this delay. However, if DCD observes that this field is not becoming 1, you must continually write to this field until it becomes 1, or until a new setup is received (check ENDPTSETUPSTAT[ENDPTSETUPSTAT] for that). 0b - Endpoint OK 1b - Endpoint stalled

51.8.1.41 Endpoint Control 1 (ENDPTCTRL1)

Offset

Register	Offset
ENDPTCTRL1	1C4h

Function

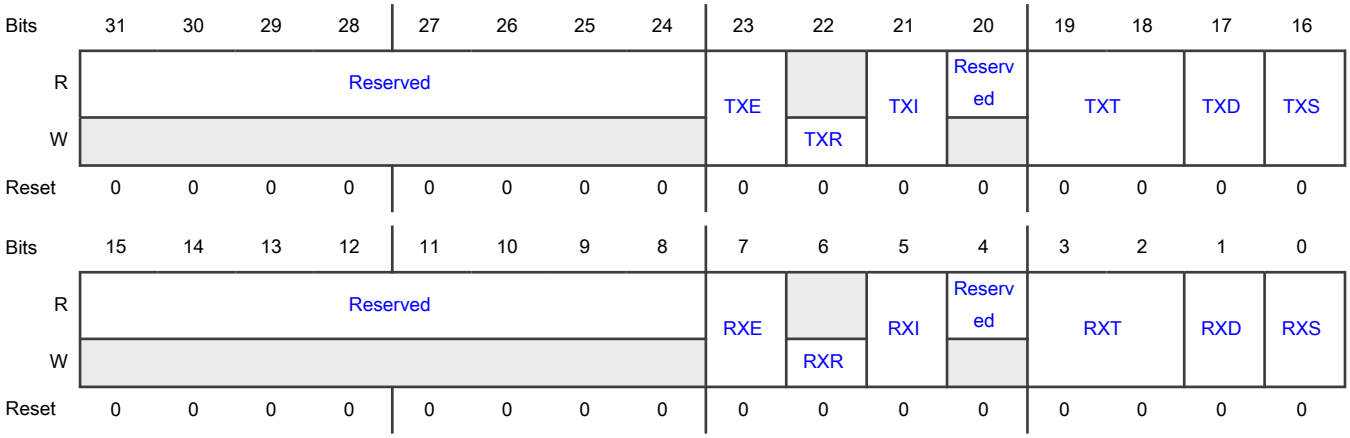
Enables endpoint control 1.

This register is used for endpoint 1 in Device Operation mode.

NOTE

If one endpoint direction is enabled and the paired endpoint of the opposite direction is disabled, then the unused direction type must be changed from the default control type to any other type (bulk type). Leaving an unconfigured endpoint control causes undefined behavior for the data PID tracking on the active endpoint or direction.

Diagram



Fields

Field	Function
31-24 —	Reserved
23 TXE	TX Endpoint Enable Enables transmit endpoint. You must enable an endpoint only after it is configured. 0b - Disables 1b - Enables
22 TXR	TX Data Toggle Reset Resets transmit data toggle. If you write 1 to this field, it resets the PID sequence. When a configuration event is received for this endpoint, you must write 1 to this field to synchronize the data PIDs between the host and device. 0b - Does not reset 1b - Resets
21 TXI	TX Data Toggle Inhibit Inhibits transmit data toggle sequencing. This field is used only for testing; you must always write 0 to it. Writing 1 to this field causes this endpoint to ignore the data toggle sequence and always transmit DATA0 for a data packet.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Allow 1b - Inhibit
20 —	Reserved
19-18 TXT	TX Endpoint Type Indicates the transmit endpoint type. 00b - Control 01b - Isochronous 10b - Bulk 11b - Interrupt
17 TXD	TX Endpoint Data Source Specifies the transmit endpoint data source. This field is 0 by default, which refers to dual port memory buffer and DMA engine. You must always write 0 to this field.
16 TXS	TX Endpoint Stall Specifies whether the transmit endpoint is stalled. This field automatically becomes 1 after receiving a "Setup" request if this endpoint is configured as a control endpoint. Hardware continues to write 0 to this field until the associated endpoint setup status field (ENDPTSETUPSTAT[ENDPTSETUPSTAT]) becomes 0. You can write 1 to this field to force the endpoint to return a STALL handshake to the host. This control continues to stall until you write 0 to this field or if it becomes 0 automatically for control endpoints. **NOTE** Control endpoint only: There is a slight delay (of a maximum of 50 clocks) between the clearing of ENDPTSETUPSTAT[ENDPTSETUPSTAT] and hardware continuing to write 0 to this field. In most systems, it is unlikely the DCD will observe this delay. However, if DCD observes that this field is not becoming 1, you must continually write to this field until it becomes 1, or until a new setup is received (check ENDPTSETUPSTAT[ENDPTSETUPSTAT] for that). 0b - Endpoint OK 1b - Endpoint stalled
15-8 —	Reserved
7 RXE	RX Endpoint Enable Enables the receive endpoint.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	You must enable an endpoint only after it is configured. 0b - Disables 1b - Enables
6 RXR	RX Data Toggle Reset Resets receive data toggle. If you write 1 to this field, it resets the PID sequence. When a configuration event is received for this endpoint, you must write 1 to this field to synchronize the data PIDs between the host and device. 0b - Does not reset 1b - Resets
5 RXI	RX Data Toggle Inhibit Inhibits receive data toggle sequencing. This field is used only for testing; you must always write 0 to it. Writing 1 to this field causes this endpoint to ignore the data toggle sequence and always accept data packets regardless of their data PID. 0b - Allow 1b - Inhibit
4 —	Reserved
3-2 RXT	RX Endpoint Type Specifies the receive endpoint type. 00b - Control 01b - Isochronous 10b - Bulk 11b - Interrupt
1 RXD	RX Endpoint Data Sink Specifies the data sink of the RX endpoint. By default, this field is 0, which refers to dual port memory buffer or DMA engine. You must always write 0 to this field.
0 RXS	RX Endpoint Stall Specifies whether the receive endpoint is stalled. If this endpoint is configured as a control endpoint, this field automatically becomes 1 after receiving a Setup request. Hardware continues to write 0 to this field until the associated endpoint setup status field (ENDPTSETUPSTAT[ENDPTSETUPSTAT]) becomes 0.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	You can write 1 to this field to force the endpoint to return a STALL handshake to the host. This control continues to stall until you write 0 to this field or when it becomes 0 automatically for control endpoints. **NOTE** Control endpoint only: There is a slight delay (a maximum of 50 clocks) between clearing ENDPTSETUPSTAT[ENDPTSETUPSTAT] and hardware continuing to write 0 to this field. In most systems, it is unlikely that the DCD will observe this delay. However, if DCD observes that this field is not becoming 1, you must continually write to this field until it becomes 1, or until a new setup is received (check ENDPTSETUPSTAT[ENDPTSETUPSTAT] for that). 0b - Endpoint OK 1b - Endpoint stalled

51.8.1.42 Endpoint Control 2 (ENDPTCTRL2)

Offset

Register	Offset
ENDPTCTRL2	1C8h

Function

Enables endpoint control 2.

This register is used for endpoint 2 in Device Operation mode.

NOTE

If one endpoint direction is enabled and the paired endpoint of the opposite direction is disabled, then the unused direction type must be changed from the default control type to any other type (bulk type). Leaving an unconfigured endpoint control causes undefined behavior for the data PID tracking on the active endpoint or direction.

Fields

Field	Function
31-24 —	Reserved
23 TXE	TX Endpoint Enable Enables transmit endpoint. You must enable an endpoint only after it is configured. 0b - Disables 1b - Enables
22 TXR	TX Data Toggle Reset Resets transmit data toggle. If you write 1 to this field, it resets the PID sequence. When a configuration event is received for this endpoint, you must write 1 to this field to synchronize the data PIDs between the host and device. 0b - Does not reset 1b - Resets
21 TXI	TX Data Toggle Inhibit Inhibits transmit data toggle sequencing. This field is used only for testing; you must always write 0 to it. Writing 1 to it causes this endpoint to ignore the data toggle sequence and always transmit DATA0 for a data packet. 0b - Allow 1b - Inhibit
20 —	Reserved
19-18 TXT	TX Endpoint Type Indicates the transmit endpoint type. 00b - Control 01b - Isochronous 10b - Bulk 11b - Interrupt
17 TXD	TX Endpoint Data Source Specifies the transmit endpoint data source. This field is 0 by default, which refers to dual port memory buffer and DMA engine. You must always write 0 to this field.

Table continues on the next page...

Table continued from the previous page...

Field	Function
16 TXS	TX Endpoint Stall Specifies whether the transmit endpoint is stalled. This field automatically becomes 1 after receiving a Setup request if this endpoint is configured as a control endpoint. Hardware continues to write 0 to this field until the associated endpoint setup status field (ENDPTSETUPSTAT[ENDPTSETUPSTAT]) becomes 0. You can write 1 to this field to force the endpoint to return a STALL handshake to the host. This control continues to stall until you write 0 to this field or if it becomes 0 automatically for control endpoints. **NOTE** Control endpoint only: There is a slight delay (of a maximum 50 clocks) between the clearing of ENDPTSETUPSTAT[ENDPTSETUPSTAT] and hardware continuing to write 0 to this field. In most systems, it is unlikely the DCD will observe this delay. However, if DCD observes that this field is not becoming 1, you must continually write to this field until it becomes 1, or until a new setup is received (check ENDPTSETUPSTAT[ENDPTSETUPSTAT] for that). 0b - Endpoint OK 1b - Endpoint stalled
15-8 —	Reserved
7 RXE	RX Endpoint Enable Enables receive endpoint. You must enable an endpoint only after it is configured. 0b - Disables 1b - Enables
6 RXR	RX Data Toggle Reset Resets receive data toggle. If you write 1 to this field, it resets the PID sequence. When a configuration event is received for this endpoint, you must write 1 to this field to synchronize the data PIDs between the host and device. 0b - Does not reset 1b - Resets
5 RXI	RX Data Toggle Inhibit Inhibits receive data toggle sequencing. This field is used only for testing; you must always write 0 to it. Writing 1 to this field causes this endpoint to ignore the data toggle sequence and always accept data packets regardless of their data PID. 0b - Allow

51.8.1.43 Endpoint Control 3 (ENDPTCTRL3)

Offset

Register	Offset
ENDPTCTRL3	1CCh

Function

Enables endpoint control 3.

This register is used for endpoint 3 in Device Operation mode.

NOTE

If one endpoint direction is enabled and the paired endpoint of the opposite direction is disabled, then the unused direction type must be changed from the default control type to any other type (bulk type). Leaving an unconfigured endpoint control causes undefined behavior for the data PID tracking on the active endpoint or direction.

52.1.1 Module instances

This device contains one instance of the USBPHY module.

Table 504. USBPHY instance

	USBPHY
Located in	VDD2_MEDIA
Access	CPU0, CPU1, HiFi4, EZH-V, eDMA0, eDMA1, eDMA2, eDMA3
Related USB	USB0

52.1.2 USBPHY0 clock configuration

You can use CLKCTL4.PSCCTL1_MEDIA[USB0] to enable or disable clocks to the USBPHY0. You should also configure the SYSCON4.USBPHY0_CLK_ACTIVE[IPG_CLK_ACTIVE] as below to make the USBPHY0 work normally.

When the USBPHY0 clock is enabled, the SYSCON4.USBPHY0_CLK_ACTIVE[IPG_CLK_ACTIVE] must be configured as 1b (IPG_CLK is active).

When the USBPHY0 clock is gated, the SYSCON4.USBPHY0_CLK_ACTIVE[IPG_CLK_ACTIVE] must be configured as 0b (IPG_CLK is inactive).

52.2 Overview

USBPHY interfaces with the USB host and device system at a low-speed (LS) rate of 1.5 Mbit/s, full-speed (FS) rate of 12 Mbit/s, or USB 2.0 high-speed (HS) rate of 480 Mbit/s. The following sections describe the external and internal interfaces, major blocks, and programmable registers that comprise the integrated USBPHY.

52.2.1 Block diagram

The integrated PHY provides a standard USB transceiver macrocell interface (UTMI). The DP and DN pins (as shown in the following figure) connect directly to a USB connector.

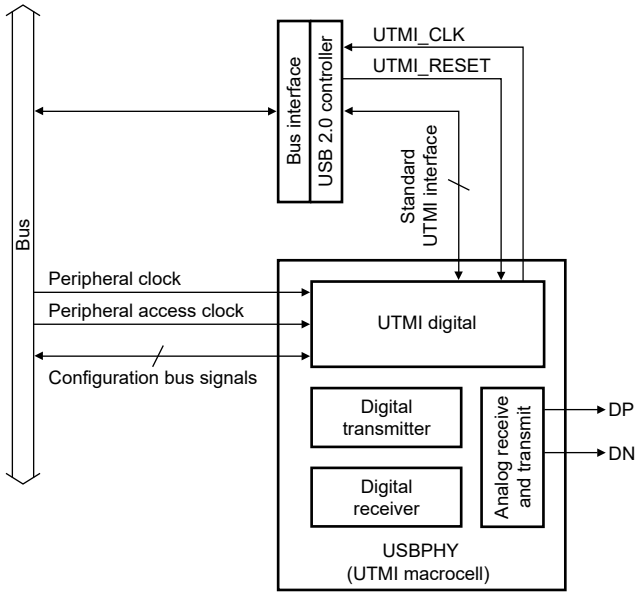

Figure 178. Block diagram

52.2.2 Features

- Supports HS and FS in Device mode
- Supports HS, FS, and LS in Host mode
- Complies with the UTMI+ standard, having a 16-bit data interface to the USB controller
- Provides an integrated 480 MHz PLL
- Provides an integrated USBDCD (see the "USB Device Charger Detection Module (USBDCD)" chapter) with features of *USB Battery Charging Specification, Revision 1.2*

52.3 Functional description

This section covers the USBPHY core components.

- The digital portions of USBPHY include the UTMI, digital transmitter, digital receiver, and programmable registers.
- The analog transceiver comprises an analog receiver and analog transmitter, as shown in Figure 179.

52.3.1 UTMI

The UTMI block handles the LineState bits, reset buffering, suspend distribution, transceiver speed selection, transceiver termination selection, and clock generation logic for the clocks derived from the PHY's USB PLL.

The PLL in USBPHY supplies a 480 MHz clock to the UTMI digital block that divides the clock to generate the 30 MHz clock (UTMI_CLK) used in the interface.

52.3.2 Digital transmitter

The digital transmitter receives a 16-bit transmit data from the USB controller and handles the TX_VALID, TX_VALIDH, and TX_READY handshake. Additionally, it contains the transmit serializer that converts 16-bit parallel words, at a frequency of 30

MHz, to a single bitstream at 480 Mbit/s for HS, 12 Mbit/s for FS, or 1.5 Mbit/s for LS. The digital transmitter does this while implementing the bit-stuffing algorithm and NRZI encoder that you use to remove the DC component from the serial bitstream. The output of this encoder is sent to the LS, FS, or HS drivers in the analog transceiver section's transmitter block.

52.3.3 Digital receiver

The digital receiver receives the raw serial bitstream from the LS differential transceiver, FS differential transceiver, and 480 MHz sampled data from the HS differential transceiver. As the phase of the USB host transmitter shifts relative to the local PLL, the receiver section's HS DLL tracks these changes to give an appropriate sample of the incoming 480 Mbit/s bitstream. Because this sample point shifts relative to the PLL phase that the digital logic uses, a rate-matching elastic buffer is provided to cross this clock domain boundary.

After the bitstream is in the local clock domain, an NRZI decoder and a bit unstuffer restore the original payload data bitstream and pass it to a deserializer and holding register. The RX state machine handles the RX_READY and RX_VALIDH signals, and a handshake with the USB controller. The handshake is not interlocked, with no RX_READY signal coming from the controller, which must take each 16-bit value that the PHY presents. The RX state machine provides an RX_ACTIVE signal to the controller that indicates whether it is inside a valid packet (synchronization detected, for example).

52.3.4 Analog receiver

The following figure illustrates the analog receiver that comprises differential receivers—two single-ended ones, a 9X, and a 480 MHz HS data sampling module.

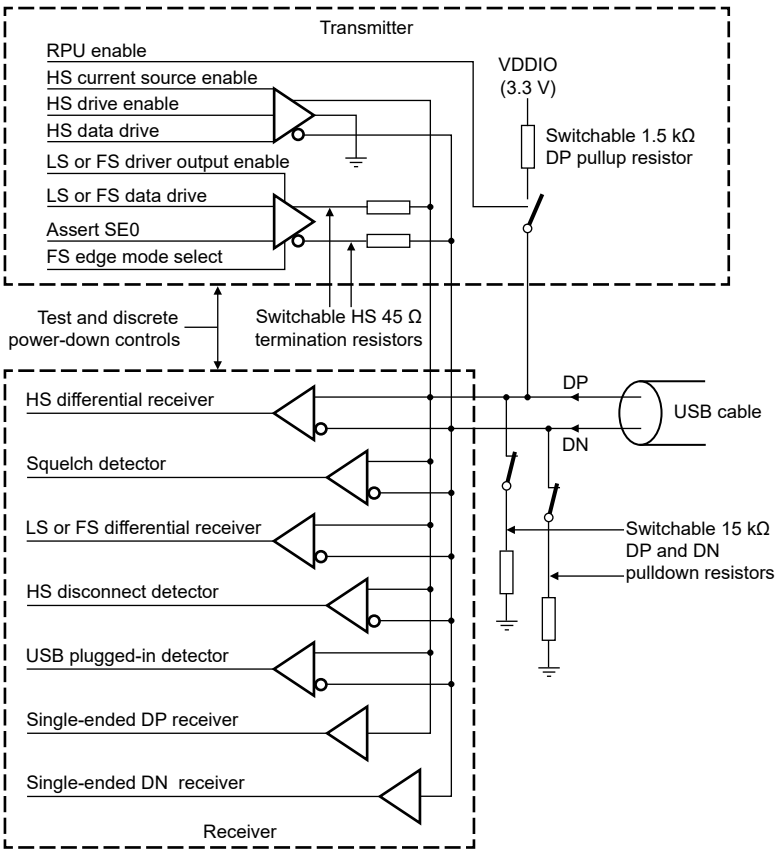

Figure 179. Analog transceiver block diagram

52.3.4.1 HS differential receiver

The HS differential receiver is both a differential analog receiver and threshold comparator. Its output is high (1b) if the differential signal is greater than a 0 V threshold. Otherwise, its output is low (0b). The purpose of the HS differential receiver is to discriminate the ± 400 mV differential voltage resulting from the HS drivers' current flow into the dual 45 Ω terminations found on each pin of the differential pair. The envelope or squelch detector (see Squelch detector) ensures that the differential signal has sufficient magnitude to be valid. The HS differential receiver tolerates up to 500 mV of common mode offset.

52.3.4.2 Squelch detector

The squelch detector is a differential analog receiver and threshold comparator. Its output is high (1b) if the differential magnitude is less than a nominal 100 mV threshold. Otherwise, its output is low (0b). The purpose of the squelch detector is to invalidate the HS differential receiver if the incoming signal is too low for appropriate reception.

52.3.4.3 LS or FS differential receiver

The LS or FS differential receiver is both a differential analog receiver and threshold comparator. The crossover voltage lies between 1.3 V and 2.0 V. Its output is 1 if the DP line is above the crossover point and the DN line is below the crossover point. The digital receiver section decodes the receiver data into the J or K state, according to the speed.

52.3.4.4 HS disconnect detector

The HS disconnect detector is a differential analog receiver and threshold comparator. Its output is high when the differential magnitude is greater than a nominal 575 mV threshold. Otherwise, its output is low.

52.3.4.5 USB plugged-in detector

When operating in Device mode, USBPHY provides the following methods for the local USB device to detect the attachment of a cable to a remote USB host or hub. You must deploy only one of these methods at a time when waiting to identify the cable attachment event, and disable all methods during USB data communication:

- USB plugged-in detector: This method looks for both DP and DN to be high. A large pair of on-chip pullup resistors (200 kΩ) hold both the DP and DN pins high when the USB cable is not attached. The USB plugged-in detector signals a 0 in this case. When operating in Device mode, the upstream port in the host or hub interface contains a 15 kΩ pulldown resistor that could easily override the 200 kΩ pullup resistor. When plugged in, at least one signal in the pair is low, which forces the plugged-in detector's output to become high.

  CTRL[ENDEVPLUGINDETECT] controls the USB plugged-in detector, and you can observe the results through STATUS[DEVPLUGIN_STATUS].

- Data contact detect: This method functions according to *USB Battery Charging Specification, Revision 1.2*. See the "USB Device Charger Detection (USBDCD)" chapter that describes the usage of this method.

52.3.4.6 Single-ended DP receiver

The single-ended DP receiver output is high whenever the DP input is above its nominal 1.8 V threshold.

52.3.4.7 Single-ended DN receiver

The single-ended DN receiver output is high whenever the DN input is above its nominal 1.8 V threshold.

52.3.5 Analog transmitter

The analog transmitter comprises two differential drivers: one for HS signaling and another for FS signaling. It also contains the switchable 1.5 kΩ pullup resistor (see Figure 180).

52.3.5.1 Switchable HS 45 Ω termination resistors

The HS current mode differential signaling requires a 90 Ω differential termination at each end of the USB cable. This results from switching in 45 Ω terminating resistors from each signal line to ground at each end of the cable.

Because each signal is terminated in parallel with 45 Ω at each end, each driver sees a 22.5 Ω load. This load impedance is too low for FS signaling levels, generating the need for switchable HS terminating resistors. Switchable trimming resistors are provided to tune the actual termination resistance for each device, as shown in Figure 180.

TX[TXCAL45DP], for example, allows one of the trimming resistor values to be placed in parallel with the 45 Ω terminator on the DP signal.

52.3.5.2 LS or FS differential driver

The LS or FS differential drivers are essentially a pair of low-impedance pullup and pulldown devices that are switched in a differential mode for most LS or FS signaling. One output is driven high while the other output is driven low to signal the "J" state or the "K" state. Both outputs are driven low for the LS or FS "SE0" state.

52.3.5.3 HS differential driver

The HS differential driver receives a 17.78 mA current from the constant current source (IREF) and essentially steers it down either the DP signal or DN signal, or alternatively to the ground. This current produces an approximately 400 mV drop across the 22.5 Ω termination that the driver sees when it is steered onto one of the signal lines. The approximately 17.78 mA current source is referenced back to the integrated voltage-band-gap (Vbg) circuit.

52.3.5.4 Switchable 1.5 kΩ DP pullup resistor

This chip contains a switchable 1.5 kΩ pullup resistor on the DP signal. You switch the register on to indicate to the host or hub controller that an FS-capable device is on the USB cable, powered on, and ready. You switch this resistor off at POR so that the host does not recognize a USB device until the processor software enables the announcement of an FS device.

52.3.5.5 Switchable 15 kΩ DP and DN pulldown resistors

This chip contains switchable 15 kΩ pulldown resistors on both DP and DN signals. You enable them in Host mode to indicate to the device controller that a host is present.

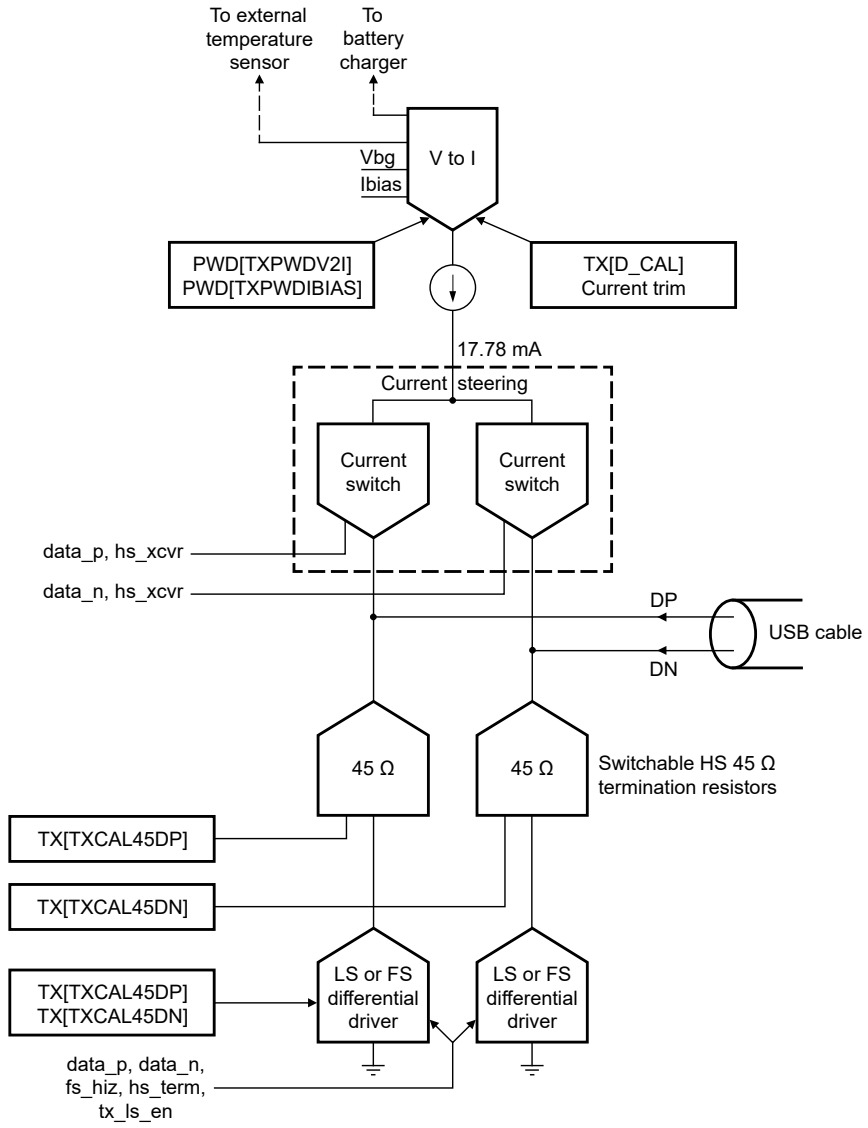

Figure 180. USBPHY transmitter block diagram

52.3.6 Low-Power mode

USBPHY includes a low-power mode (Suspend mode) to save power consumption.

When the USB bus is idle, you can place the transceiver in Low-Power mode (suspend it), after which the clocks to USBPHY can be stopped. The 32 kHz low-power clock must remain active because you need it for wake-up detection.

The USB HS controller monitors USBPHY's entry and exit into Low-Power mode:

- If USB.PORTSC1[SUSP] is 1, the UTMI interface is driven to the FS or LS state.
- If USB.PORTSC1[PHCD] is 1, the UTMI signal "SuspendM" goes low.
- If CTRL[ENAUTOCLR_PHY_PWD] and CTRL[ENAUTOCLR_CLKGATE] are 1, the UTMI clock and PHY transmitter are automatically enabled when the "SuspendM" signal goes high.

- The SW stack must write 1b to PLL_MISC2_CONTROL0 during the USB initialization routine. If PLL_MISC2_CONTROL0 is set, the PLL is auto powered down when in Suspend mode. The PLL is auto enabled after the "SuspendM" signal goes high, and after PLL is locked, USBPHY uses the PLL clock again.

USBPHY enters Low-Power mode under the control of the driver software. See the "Universal Serial Bus Controller (USB)" chapter for details.

52.3.7 Clocking

The following table describes the clock sources for USBPHY. See the chip's clocking chapter for clock setting, configuration, and gating information.

Table 505. USBPHY clocks

Clock name	Description
Peripheral clock	Free running internal register bus (IPS) clock for register configuration
Peripheral access clock	Gated IPS bus clock

52.3.8 Reset

Table 506. USBPHY resets

Reset	How it works
Chip	USBPHY's logic and registers are reset to their default states.
UTMI	UTMI_RESET signal from the USB controller resets the UTMI state machines, FIFO, and so on.
Software	A soft reset (SFTRST) of USBPHY's USBPHY Powerdown (PWD), USBPHY Transmitter Control (TX), USBPHY Receiver Control (RX), USBPHY General Control (CTRL), DEBUG0_STATUS[UTMI_RXERROR_FAIL_COUNT], USBPHY Debug (DEBUG), and UTMI Debug Status 1 (DEBUG1) registers and fields takes place when you write 1 to CTRL[SFTRST]. This also resets state machines in the PHY. Write 0 to CTRL[SFTRST] to release the PHY from reset. **NOTE** A soft reset can take multiple clock periods to complete; therefore, do not write 1 to CTRL[CLKGATE] when writing 1 to CTRL[SFTRST]. The reset process gates the clocks automatically.

52.3.9 Interrupts

Table 507. USBPHY interrupts

Flag or event	Interrupt enable	Description
CTRL[DEVPLUGIN_IRQ]	CTRL[ENIRQDEVPLUGIN]	Indicates nonstandard resistive plugged-in detection

Table continues on the next page...

Table 507. USBPHY interrupts (continued)

Flag or event	Interrupt enable	Description
CTRL[RESUME_IRQ]	CTRL[ENIRQRESUMEDETECT]	Indicates that the host is sending a "resume" signal after a "suspend" signal
CTRL[WAKEUP_IRQ]	CTRL[ENIRQWAKEUP]	Indicates that the USB controller has stopped driving the "SuspendM" signal in its active-low state to the PHY
CTRL[HOSTDISCONDETECT_IRQ]	CTRL[ENIRQHOSTDISCON]	Indicates that the host has detected disconnection of the device in HS mode
USBDCD interrupt	USBDCD interrupt enable	See the "Interrupts" section in the "USB Device Charger Detection Module (USBDCD)" chapter for details

52.4 External signals

Table 508. USBPHY external signals

Signal	Description	Direction
DP	Data positive (D+) pin A didirectional pin that carries USB data to and from USBPHY	Input and output
DN	Data negative (D-) pin A bidirectional pin that carries USB data to and from USBPHY	Input and output
VBUS	USB power supply pin A charge pump external to USBPHY provides power to this pin.	Power

52.5 Initialization

Perform the following procedure to initialize the internal 480 MHz USB PLL clock:

1. Enable the reference clock for USB PLL.
2. Enable the USBPHY PLL regulator.
3. Release the PHY from reset.
4. Power up the PLL.
5. Configure PLL_SIC[PLL_DIV_SEL] appropriately, according to the selected external reference. The system oscillator ranges from 16 MHz to 32 MHz.

52.6 Application information

52.6.1 Recommended register configuration for USB certification

USBPHY has programmability to adjust several transceiver parameters. You can:

- Adjust the TX HS driver termination impedance, FS driver output impedance, and HS driver output currents by using USBPHY Transmitter Control (TX).
- Adjust the HS RX thresholds for the envelope detector or squelch comparator and the host disconnect comparator by using USBPHY Receiver Control (RX).

The default values of the transceiver parametric trim fields are centered with no changes needed for USB certification testing when the chip is used with boards optimized for signal integrity on the HS USB port.

It may be useful to make changes to the parametric trim fields in cases where external components are inserted between the USB DP and DN pins, or compromises are made on USB DP and DN signal routing.

52.6.2 Register macro usage

A read-modify-write (RMW) operation involves updating a field without disrupting the contents of the remaining fields in the register. In this operation, the CPU reads the register, modifies the target field, and then writes the results back to the register. Because of the initial register read, this is an expensive operation in terms of CPU cycles.

To address this issue, you can implement some USBPHY registers as a group, including registers that can be used to either set, clear, or toggle (SCT) individual fields of the primary register. When writing to an SCT register, all fields that are 1 perform the associated operation on the primary register, while all fields that are 0 are not affected. The SCT registers always read back 0, and must have the write-only access type. You cannot implement SCT registers if the primary register has a read-only access type.

With this architecture, you can update one or more fields using only register writes. First, all bits of the target fields are cleared by a write to the associated clear register, and then the desired value of the target fields is written to the set register. This sequence of two writes is referred to as a clear-set (CS) operation.

A CS operation does have a potential drawback—whenever a field is modified, USBPHY sees a value of 0 before you write the final value. For most fields, passing through the 0 state is not a problem. Nonetheless, this behavior is something you must consider when using a CS operation.

Also, you do not require a CS operation for fields that are 1-bit wide. While the CS operation works in this case, it is more appropriate to set or clear the target bit (that is, one write instead of two). A simple set or clear operation is also atomic, while a CS operation is not.

NOTE

All macros for SCT are not atomic. For registers that do not provide hardware support for this functionality, these macros are implemented as a sequence of RMW operations. You must remember this when an atomic operation is required because an unexpected behavior may take place if an interrupt occurs during a critical update sequence.

52.7 USBPHY register descriptions

USBPHY does not generate transfer errors when accessing unimplemented registers in its register space.

Also, the SCT feature is implemented for some registers (see Register macro usage for information about this feature).

52.7.2 USBPHY Powerdown (PWD)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
PWD	0h	USBPHY Powerdown

Table continues on the next page...

Table continued from the previous page...

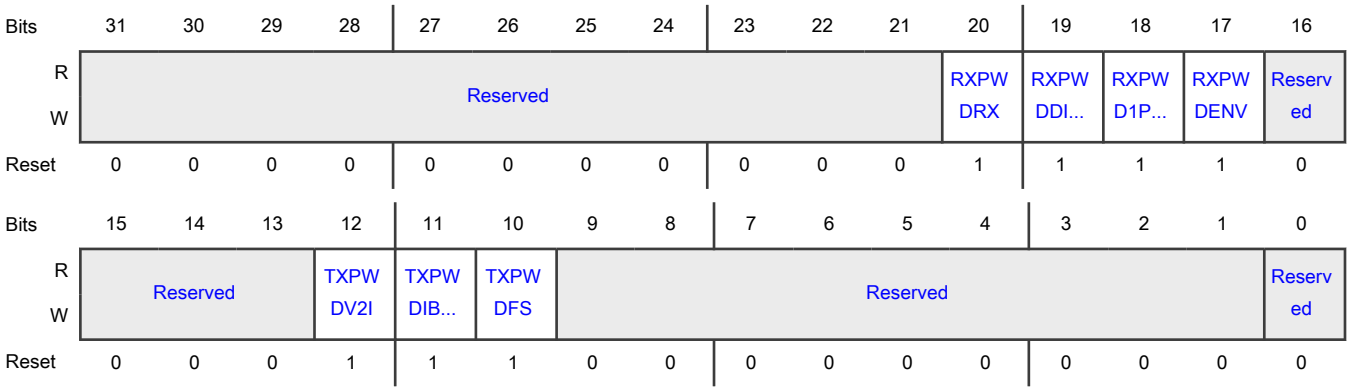
Register	Offset	Description
PWD_SET	4h	Writing 1 to a bit in this register ensures that the corresponding bit in PWD is 1
PWD_CLR	8h	Writing 1 to a bit in this register ensures that the corresponding bit in PWD is 0
PWD_TOG	Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in PWD

Function

Provides an overall control of the PHY power state.

You must enable the PHY clocks before programming this register.

Diagram



Fields

Field	Function
31-21 —	Reserved
20 RXPWDRX	Receiver Powerdown Disables the HS RX differential receiver, HS envelope detector, and HS host disconnect comparator along with their RX current mirror bias circuits. The overall control of the RX current bias block is shared with the battery charge circuit, but this field powers down the other aforementioned RX circuits (the entire USBPHY receiver block) unconditionally, except for the FS differential receiver. This field becomes 0 automatically in case of a wake-up event when USB is suspended while CTRL[ENAUTOCLR_PHY_PWD] is 1. Additionally, this field becomes 1 automatically at the falling edge of the signal from the USB controller that drives CTRL[UTMI_SUSPENDM] to enter the Suspend state. 0b - Enable for normal operation

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Disable or power down RX circuits
19 RXPWDDIFF	HS Receiver Powerdown Disables the USB HS RX differential receiver that is used for data reception in HS operation. This field becomes 0 automatically in case of a wake-up event when USB is suspended while CTRL[ENAUTOCLR_PHY_PWD] is 1. Additionally, this field becomes 1 automatically at the falling edge of the signal from the USB controller that drives CTRL[UTMI_SUSPENDM] to enter the Suspend state. 0b - Enable for normal operation 1b - Disable or power down
18 RXPWD1PT1	FS Receiver Powerdown Disables the USB FS RX differential receiver that is used for data reception in both FS and LS operations. This field does not affect the bias and operation of the FS differential receiver. This field becomes 0 automatically in case of a wake-up event when USB is suspended while CTRL[ENAUTOCLR_PHY_PWD] is 1. Additionally, this field becomes 1 automatically at the falling edge of the signal from the USB controller that drives CTRL[UTMI_SUSPENDM] to enter the Suspend state. 0b - Enable for normal operation 1b - Disable or power down
17 RXPWDENV	Receiver Envelope Powerdown Disables the USB HS RX envelope detector that generates the squelch signal to qualify the HS RX data. The host disconnect comparator is used in Host mode to check for a disconnection from the remote device. This field becomes 0 automatically in case of a wake-up event when USB is suspended while CTRL[ENAUTOCLR_PHY_PWD] is 1. Additionally, this field becomes 1 automatically at the falling edge of the signal from the USB controller that drives CTRL[UTMI_SUSPENDM] to enter the Suspend state. 0b - Enable for normal operation 1b - Disable or power down
16-13 —	Reserved
12 TXPWDV2I	USBPHY TX V-I Converter and Current Mirror Powerdown Disables the USBPHY TX V-I converter that provides currents used in the HS TX drivers. The converter depends on both USBPHY's bias module and the bias current block. This field becomes 0 automatically in case of a wake-up event when USB is suspended while CTRL[ENAUTOCLR_PHY_PWD] is 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Additionally, this field becomes 1 automatically at the falling edge of the signal from the USB controller that drives CTRL[UTMI_SUSPENDM] to enter the Suspend state. 0b - Enable for normal operation 1b - Disable or power down
11 TXPWDIBIAS	Transmitter Bias Powerdown Disables the USBPHY current bias block for the transmitter that provides mirrored currents to track USBPHY's bias module reference current generator for several functions in the TX, RX, and detector sections. Control of the current bias block is shared with the battery charge circuit. Writing 1 to this field does not power down the circuit unless the value of the corresponding field in the battery charge control is also 1 for power down. The field must be 1 only when the USB is in the Suspend bus state. This effectively powers down the entire USB transmit path. The field must become 1 only when the USB is in Suspend mode. This effectively powers down the entire USB transmit path. This field becomes 0 automatically in case of a wake-up event when USB is suspended while CTRL[ENAUTOCLR_PHY_PWD] is 1. Additionally, this field becomes 1 automatically at the falling edge of the signal from the USB controller that drives CTRL[UTMI_SUSPENDM] to enter the Suspend state. **NOTE** These circuits are shared with the battery charge circuit. Writing 1 to this field does not power down these circuits, unless the corresponding field in the battery charger is also configured as 1 for a power down. 0b - Enable for normal operation 1b - Disable or power down
10 TXPWDFS	FS Transmitter Powerdown Disables the USB FS TX drivers that must have their bias enabled during USB data communication, including resume and bus reset signaling. They are used in HS, FS, and LS because pulldown of the FS TX drivers provides local HS termination. If this field is 1, it turns off the current starvation sources and puts the drivers into high-impedance output. This field becomes 0 in case of a wake-up event if USB is suspended when CTRL[ENAUTOCLR_PHY_PWD] is 1. Additionally, this field becomes 1 automatically at the falling edge of the signal from the USB controller that drives CTRL[UTMI_SUSPENDM] to enter the Suspend state. 0b - Provide bias to enable for normal operation 1b - Disable or power down

52.7.3 USBPHY Transmitter Control (TX)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
TX	10h	USBPHY Transmitter Control
TX_SET	14h	Writing 1 to a bit in this register ensures that the corresponding bit in TX is 1
TX_CLR	18h	Writing 1 to a bit in this register ensures that the corresponding bit in TX is 0
TX_TOG	1Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in TX

Function

Allows adjustment of transmit parametric values.

Diagram

52.7.4 USBPHY Receiver Control (RX)

Offset

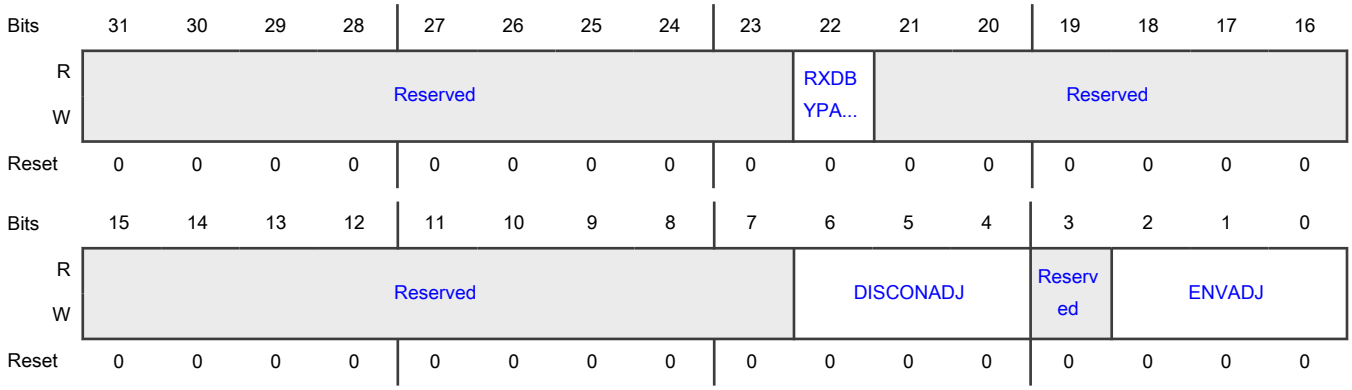
This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
RX	20h	USBPHY Receiver Control
RX_SET	24h	Writing 1 to a bit in this register ensures that the corresponding bit in RX is 1
RX_CLR	28h	Writing 1 to a bit in this register ensures that the corresponding bit in RX is 0
RX_TOG	2Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in RX

Function

Allows adjustment of receive parametric values.

Diagram



Fields

Field	Function
31-23 —	Reserved
22 RXDBYPASS	Differential Receiver Bypass Bypasses the FS differential receiver. If this field is 0, normal operation continues. If this field is 1, the output of the DP single-ended receiver is used instead of the FS differential receiver. 0b - Operate normally 1b - Bypass
21-7 —	Reserved
6-4 DISCONADJ	Disconnect Adjustment Adjusts the trip point (trip-level voltage) for the disconnect detector. 000b - 0.56875 V 001b - 0.55000 V 010b - 0.58125 V 011b - 0.60000 V 1xxb - Reserved
3 —	Reserved
2-0 ENVADJ	Envelope Adjustment

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Adjusts the trip point for the envelope detector. The field values are trip-level voltages in nominal DC settings to indicate the effect of changing these fields. AC values measured during compliance testing are a bit higher. 000b - 0.1000 V 001b - 0.1125 V 010b - 0.1250 V 011b - 0.0875 V 1xxb - Reserved

52.7.5 USBPHY General Control (CTRL)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
CTRL	30h	USBPHY General Control
CTRL_SET	34h	Writing 1 to a bit in this register ensures that the corresponding bit in CTRL is 1
CTRL_CLR	38h	Writing 1 to a bit in this register ensures that the corresponding bit in CTRL is 0
CTRL_TOG	3Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in CTRL

Function

Handles OTG and host controls.

This register also includes interrupt enables, connectivity detect enables, and results.

Diagram

Fields

Field	Function
31 SFTRST	Software Reset Soft-resets USBPHY Powerdown (PWD), USBPHY Transmitter Control (TX), USBPHY Receiver Control (RX), and USBPHY General Control (CTRL). 0b - Release from reset 1b - Reset
30 CLKGATE	Clock Gating Gates UTMI clocks. Write 1 to this field to save power when the USB is not actively used. Retain the configuration state when the clock is gated. **NOTE** This field can automatically become 0 in case of a wake-up event when USB is suspended, if ENAUTOCLR_CLKGATE is 1. 0b - Run clocks 1b - Gate clocks
29 UTMI_SUSPENDM	UTMI Suspend Mode Indicates a power-down state. UTMI_SUSPENDM is negative logic, as the UTMI specification requires it to be. If this field is 0, all powerdown fields in USBPHY Powerdown (PWD) are enabled. If this field is 0, the USB controller enters Suspend mode. 0b - Suspended 1b - Not suspended
28 HOST_FORCE_LS_SE0	FS EOP LS Timing Works with DEBUG[HOST_RESUME_DEBUG] and forces the next FS packet that is transmitted to have an EOP with LS timing. This field is used in Host mode for the resume sequence. After the packet is transferred, the field becomes 0. You can use this function to force the LS SE0 or use UTMI_SUSPENDM to trigger this event when existing the Suspend state. 0b - Do not force the next FS packet 1b - Force the next FS packet
27 —	Reserved
26-25 —	Reserved
24	FSDLL Reset Enable Enables resetting of the FSDLL lock detection logic at the end of each TX packet.

Table continues on the next page...

Table continued from the previous page...

Field	Function
FSDLL_RST_EN	0b - Disables 1b - Enables
23-22 —	Reserved
21 —	This bit must remain at value 0b.
20 ENAUTOCLR_PHY_PWD	PHY PWD Auto Clear Enable Enables automatic writing of 0 to the fields in USBPHY Powerdown (PWD) in case of a wake-up event while USB is suspended. You must write 1 to this field if auto wake-up is required without software interaction. 0b - Disables 1b - Enables
19 ENAUTOCLR_CLKGATE	Clock Gating Auto Clear Enable Enables automatic writing of 0 to CLKGATE in case of a wake-up event while USB is suspended. You must write 1 to this field if auto wake-up is required without software interaction. 0b - Disables 1b - Enables
18 AUTORESUME_EN	Auto Resume Enable Enables the auto resume feature. If this field is 1, USBPHY uses a 32 kHz clock to send resume signaling to respond to the USB device remote wakeup (for Host mode only). The field functionality is useful when PLL is off and the reference clock is powered down. 0b - Disables 1b - Enables
17 WAKEUP_IRQ	Wake-Up Interrupt Specifies whether a wake-up event exists. Reset this field by writing 1 to the clear address space, and not by a general write. 0b - No wake-up event exists 1b - Wake-up event exists
16 ENIRQWAKEUP	Wake-Up Interrupt Enable Enables interrupts for wake-up events. 0b - Disables 1b - Enables
15	UTMI Level 3 Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
ENUTMILEVEL3	Enables UTMI+ level 3 operation for USBPHY. You must write 1 to this field if an embedded host use case needs to support an external FS hub with an LS device connected. 0b - Disables 1b - Enables
14 ENUTMILEVEL2	UTMI Level 2 Enable Enables UTMI+ level 2 operation for USBPHY. You must write 1 to this field if an embedded host use case needs to support an LS device. 0b - Disables 1b - Enables
13 —	The value of this reserved bit must remain 0b.
12 DEVPLUGIN_IRQ	Device Plug-In Interrupt Indicates that the device is connected. Reset this field by writing 1 to the SCT clear address space, and not by a general write. 0b - Not connected 1b - Connected
11 ENIRQDEVPLUGIN	Device Plug-In Interrupt Enable Enables an interrupt for the detection of connectivity to the USB line. 0b - Disables 1b - Enables
10 RESUME_IRQ	Interrupt Resume Specifies whether the host is sending a wake-up signal after suspend signaling. This field also becomes 1 after a reset during Suspend mode. Use this field to wake up the USB device from Suspend mode for either the host resume or host reset case. You must reset this field by writing 1 to the clear address space, and not by a general write. 0b - No resume interrupt 1b - Resume interrupt
9 ENIRQRESUMEDETECT	Resume Detection Interrupt Enable Enables an interrupt for detection of a non-J state on the USB line. You must write 1 to this field only after the USB device has entered Suspend mode. 0b - Disables 1b - Enables
8	RESUME_IRQ Sticky

Table continues on the next page...

Table continued from the previous page...

Field	Function
RESUMEIRQSTICKY	Specifies until when RESUME_IRQ remains 1 during the resume or reset state signaling period. 0b - Remains 1 during the wake-up period 1b - Remains 1 until you write 0 to it
7-6 —	Reserved
5 DEVPLUGIN_POLARITY	Device Plug-In Polarity Specifies whether to trip the interrupt when the USB device is plugged in or when it is unplugged. If this field is 0, it trips the interrupt when the USB cable from the host to the device is plugged in. If this field is 1, it trips the interrupt if the USB cable from the host to the device is unplugged. 0b - Plugged in 1b - Unplugged
4 ENDEVPLUGINDETECT	Nonstandard Resistive Plugged-In Detection Enable Controls connection of nominal 200 kΩ pullup resistors with both the DP and DN pins as a method of detecting, in Device mode, when a USB cable is attached. This field must remain 0 for normal USB data communication, or when using DCD for battery charger detection, according to *USB Battery Charger Specification Revision 1.2* or any other detection mechanism for USB cable plugin. STATUS[DEVPLUGIN_STATUS] reports the results of this detection method. 0b - Disables 1b - Enables
3 HOSTDISCONDETECT_IRQ	Host Disconnect Detection Interrupt Specifies whether the device is disconnected in HS Host mode. Reset this field by writing 1 to the SCT clear address space, and not by a general write. 0b - Connected 1b - Disconnected
2 ENIRQHOSTDISCON	Host Disconnect Interrupt Enable Enables an interrupt for detection of device disconnection when in HS Host mode. You must write 1 to this field after writing 1 to ENDEVPLUGINDETECT. 0b - Disables 1b - Enables
1 ENHOSTDISCONDETECT	Host Disconnect Detection Enable Enables the HS disconnect detector for Host mode. This signal allows the override of detection enabling, which the UTMI controller normally performs. The UTMI controller enables this circuit whenever the host sends a start-of-frame packet.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Write 1 to this field when an HS device is connected. This is suggested during a bus reset. Ensure that this field is not 1 at the end of resume signaling; otherwise, a wrong disconnect status may be detected. 0b - Disables 1b - Enables
0 —	Reserved

52.7.6 USBPHY Status (STATUS)

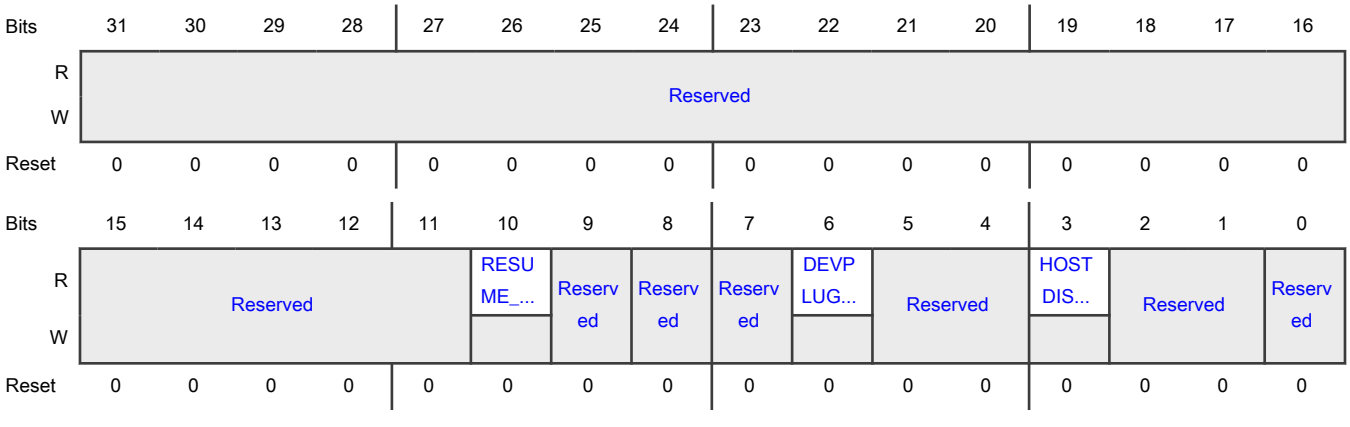
Offset

Register	Offset
STATUS	40h

Function

Holds results of IRQ and other detects.

Diagram



Fields

Field	Function
31-11 —	Reserved
10	Resume Status

Table continues on the next page...

Table continued from the previous page...

Field	Function
RESUME_STATUS	Indicates whether the line state is in J state. This field provides a valid indication of resume signaling only when operating in FS or HS mode, after being in the Suspend bus state. This status field may toggle during USB data packet communication. Also, it does not indicate resume signaling when operating as a host that is directly attached to an LS device. 0b - Is in J state 1b - Is not in J state
9 —	Reserved
8 —	Reserved
7 —	Reserved
6 DEVPLUGIN_STATUS	Status Indicator for Nonstandard Resistive Plugged-In Detection Indicates whether the device is connected on the DP and DN lines using the nonstandard resistive plugged-in detection method that CTRL[ENDEVPLUGINDETECT] controls. When a USB cable attached to a remote host is attached to the local device, the 15 kΩ host pulldowns override the high value resistors used in this detection method. 0b - No attachment detected 1b - Cable attachment detected
5-4 —	Reserved
3 HOSTDISCONDETECT_STATUS	Host Disconnect Detection Status Detects at the local host (downstream) port that the USB cable is disconnected when in HS mode. 0b - Do not detect 1b - Detect
2-1 —	Reserved
0 —	Reserved

52.7.7 USBPHY Debug (DEBUG)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
DEBUG	50h	USBPHY Debug
DEBUG_SET	54h	Writing 1 to a bit in this register ensures that the corresponding bit in DEBUG is 1
DEBUG_CLR	58h	Writing 1 to a bit in this register ensures that the corresponding bit in DEBUG is 0
DEBUG_TOG	5Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in DEBUG

Function

Debugs USBPHY.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	Reserved	CLKGATE	HOST_RE...	SQUELCHRESETLENGTH				ENSQUEL...	Reserved			SQUELCHRESETCOUNT				
W																
Reset	0	1	1	1	1	1	1	1	0	0	0	1	1	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	Reserved			ENTX2RX...	TX2RXCOUNT				Reserved		ENHSTPULLDOWN		HSTPULLDOWN		Reserved	Reserved
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 —	Reserved
30 CLKGATE	Clock Gating Gates the test clocks. To save power while the USB is not being actively used, retain the value of 1 in this field. The configuration state is maintained when the clock is gated. 0b - Run clocks 1b - Gate clocks
29 HOST_RESUME_DEBUG	Host Resume Selects the method used to generate the LS SE0 at the end of host resume signaling. The default method triggers from a change to the UTMI_SUSPENDM signal from the USB controller to the PHY.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	The other method depends on programming CTRL[HOST_FORCE_LS_SE0] at an appropriate time. If this field is 0, it generates LS SE0 at the end of host resume based on CTRL[HOST_FORCE_LS_SE0]. If this field is 1, it generates LS SE0 at the end of host resume based on the state of CTRL[UTMI_SUSPENDM]. 0b - Based on CTRL[HOST_FORCE_LS_SE0] 1b - Based on CTRL[UTMI_SUSPENDM]
28-25 SQUELCHRESETLENGTH	Squelch Reset Length Indicates the number of 480 MHz clock intervals used for the delay time. The changes you make to this field are used only for a specific HS RX debug mode that ENSQUELCHRESET enables. This field adjusts the delay time between the detection of valid HS RX data and release of squelch for that debug mode. The field value indicates the number of 480 MHz clock intervals used for the delay time.
24 ENSQUELCHRESET	Enable Squelch Reset Enables squelch reset. Let the value of this field be 1 to allow normal operation of the squelch state machine for qualification of HS receive data. Writing 0 to this field freezes the functional mode squelch state machine in its reset state, and must be done only for a specific HS RX debug mode. 0b - Disables 1b - Enables
23-21 —	Reserved
20-16 SQUELCHRESETCOUNT	Squelch Reset Count Adjusts the delay time, in 480 MHz clock intervals, between the detection of squelch to the reset of HS RX state machines. Any changes that you make to this field must only be used for a specific HS RX debug mode.
15-13 —	Reserved
12 ENTX2RXCOUNT	Enable Countdown from TX to RX Packets for Debug Enables a countdown to transition between the TX and RX packets for debug. 0b - Disables 1b - Enables
11-8 TX2RXCOUNT	Set Countdown Delay Value from TX to RX Packets for Debug Specifies the delay between the end of transmit to the beginning of receive packets for debug. This is a Johnson counter value and therefore counts to 8.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-6 —	Reserved
5-4 ENHSTPULLDOWN	Enable Host Pulldown Overdrive Mode Selects whether to override the control of DP and DN pins. This field selects Host Pulldown Overdrive mode. Write 1b to bit 5 to override the control of the DP 15 kΩ pulldown, which the USB controller normally performs. Write 1b to bit 4 to override the control of the DN 15 kΩ pulldown, which the USB controller normally performs. Write 00b to both the bits to disable Host Pulldown Overdrive mode and return the control of the pulldown resistors to the USB controller. When in Host Pulldown Overdrive mode, HSTPULLDOWN further controls the connection of the individual pulldown resistors. Both pulldown resistors are also unconditionally enabled when ANACTRL[DEV_PULLDOWN] becomes 1 without considering the value of this field. 00b - Disable Host Pulldown Overdrive mode 01b - Override the control of DN 15 kΩ pulldown 10b - Override the control of DP 15 kΩ pulldown 11b - Override the control of DP and DN 15 kΩ pulldown
3-2 HSTPULLDOWN	Select DP and DN Pulldown Resistors in Host Pulldown Overdrive Mode Selects whether to connect pulldown resistors on the DP and DN pins if Host Pulldown Overdrive mode is enabled through ENHSTPULLDOWN. Write 1b to bit 3 of this field to connect the 15 kΩ pulldown on the DP line, and write 1b to bit 2 to connect the 15 kΩ pulldown on the DN line. Write 00b to both the bits to disconnect the resistors in Host Pulldown Override mode. 00b - Disconnect the resistors 01b - Connect 15 kΩ pulldown on DN 10b - Connect 15 kΩ pulldown on DP 11b - Connect 15 kΩ pulldown on DP and DN
1 —	Reserved
0 —	Reserved

52.7.8 UTMI Debug Status 0 (DEBUG0_STATUS)

Offset

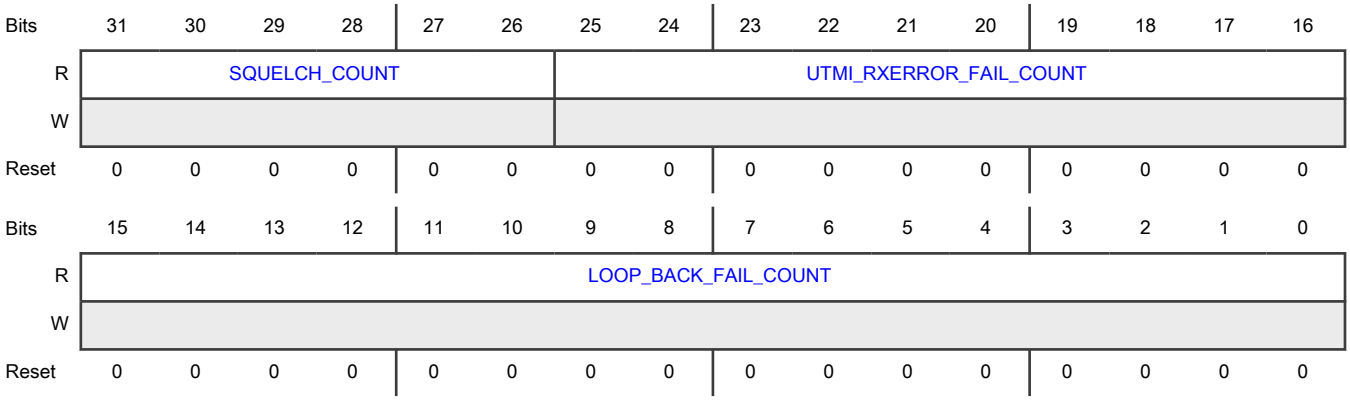
Register	Offset
DEBUG0_STATUS	60h

Function

Holds multiple views for counters and status of state machines.

This field works with DEBUG1[DBG_ADDRESS] to select the function to view. The default settings used to count errors are described in this register.

Diagram



Fields

Field	Function
31-26 SQUELCH_COUNT	Squelch Count Indicates the running count of the squelch reset instead of the normal end for HS RX.
25-16 UTMI_RXERROR_FAIL_COUNT	UTMI Receive Error Fail Count Indicates the running count of UTMI_RXERROR.
15-0 LOOP_BACK_FAIL_COUNT	Loopback Fail Count Indicates the running count of the failed pseudo-random generator loopback. Each time it enters Test mode, the counter goes to 900D and counts up for every detected packet failure in digital and analog loopback tests.

52.7.9 UTMI Debug Status 1 (DEBUG1)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
DEBUG1	70h	UTMI Debug Status 1

Table continues on the next page...

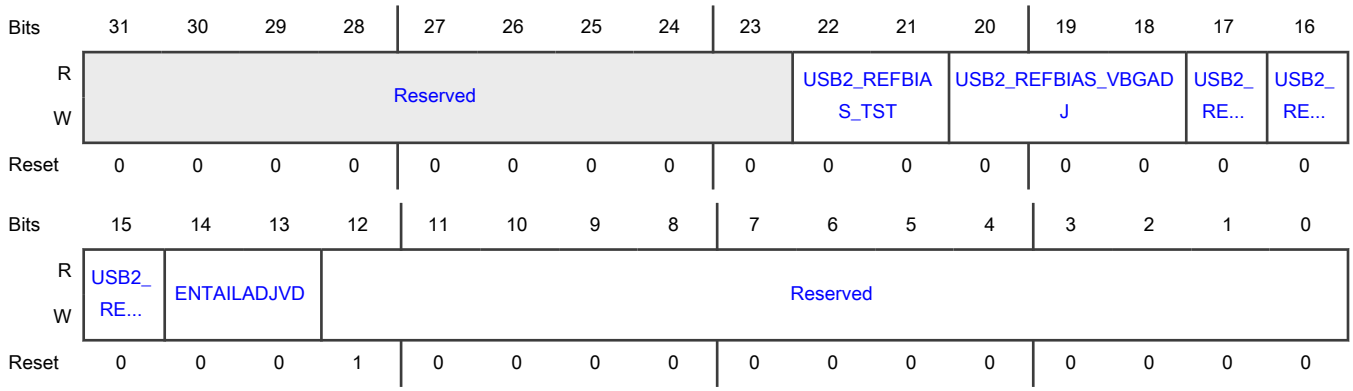
Table continued from the previous page...

Register	Offset	Description
DEBUG1_SET	74h	Writing 1 to a bit in this register ensures that the corresponding bit in DEBUG1 is 1
DEBUG1_CLR	78h	Writing 1 to a bit in this register ensures that the corresponding bit in DEBUG1 is 0
DEBUG1_TOG	7Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in DEBUG1

Function

Selects the muxing of USBPHY Debug (DEBUG) to be indicated in UTMI Debug Status 0 (DEBUG0_STATUS).

Diagram



Fields

Field	Function
31-23 —	Reserved
22-21 USB2_REFBIAS_TST	Bias Current Control Adjustment Specifies the main current trim for the USBPHY bias module current reference generator. Use this field to trim the PHY's current reference when TRIM_OVERRIDE_EN[TRIM_REFBIAS_TST_OVERRIDE] is 1. If TRIM_OVERRIDE_EN[TRIM_REFBIAS_TST_OVERRIDE] becomes 0, the current trim values in TRIM_OVERRIDE_EN[TRIM_USB2_REFBIAS_TST] are used instead. 00b - ≈ 10 µA reference current; nominal 01b - ≈ 0.9x compared to nominal 10b - ≈ 0.8x compared to nominal 11b - ≈ 1.1x compared to nominal

Table continues on the next page...

Table continued from the previous page...

Field	Function
20-18 USB2_REFBIAS_VBGADJ	Bandgap Voltage Adjustment Specifies the voltage adjustment trim on USBPHY bias module bandgap generator. Use this field to trim the PHY's bandgap voltage when TRIM_OVERRIDE_EN[TRIM_REFBIAS_VBGADJ_OVERRIDE] is 1. If TRIM_OVERRIDE_EN[TRIM_REFBIAS_VBGADJ_OVERRIDE] becomes 0, the voltage trim values in TRIM_OVERRIDE_EN[TRIM_USB2_REFBIAS_VBGADJ] are used instead. 000b - Nominal bandgap voltage; flattest temperature coefficient 001b - ≈ +10 mV compared to nominal 010b - ≈ +20 mV compared to nominal 011b - ≈ +30 mV compared to nominal; most-positive temperature coefficient 100b - ≈ -10 mV compared to nominal 101b - ≈ -20 mV compared to nominal 110b - ≈ -30 mV compared to nominal 111b - ≈ -40 mV compared to nominal; most-negative temperature coefficient
17 USB2_REFBIAS_LOWPWR	Reference Bias Low Power Configuration Configures the bias currents in the bandgap reference amplifier in the USBPHY bias module. If this field is 0, the bandgap amplifier for a nominal bias current is configured. If this field is 1, the bandgap amplifier for 50% of the nominal bias current is configured. The field must remain 0 for normal operation. Writing 1 is only intended for lab characterization purposes. 0b - Nominal bias current 1b - 50% of nominal bias current
16 USB2_REFBIAS_PWDVBGUP	Bandgap Voltage Status Comparator Powerdown Disables the VBGUP comparator to save its bias current after the bandgap voltage is valid and stable. The VBGUP comparator monitors the USBPHY bias module bandgap voltage to check that the voltage is in the valid range. If this field is 1, MISC[VBGUP] is also forced to become 1. You cannot detect a bandgap voltage problem if this field is 1, and the PHY does not automatically restore the VBGUP comparator if such a problem occurs. Therefore, it is not recommended to make changes to this field. 0b - Enables 1b - Disables
15 USB2_REFBIAS_SELFBIASOFF	Self-Bias Off for Reference Bias Amplifiers and Comparators Selects the local bias sources to use for the amplifiers and comparators in the USBPHY bias module. If this field is 0, self-bias is used for bias reference amplifier and comparator circuits. If this field is 1, the current reference bias is used for amplifier and comparator circuits.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Self-bias is required at reference generator startup. After the bandgap voltage and reference current generator are stable, bias from the reference generator's own regulated currents can be used instead. You must let the value of this field be 0 during a ramp of the 1.8 V power domain and during any time that the USBPHY bias reference circuit transitions from the disabled to enabled state. Switching to the current reference bias after the bandgap voltage is stable may somehow improve bandgap voltage stability, but could cause problems if the 1.8 V power is interrupted. You must monitor MISC[VBGUP]; intervention is mandatory if the value of this field changes. You must also note the interaction of USB2_REFBIAS_PWDVBGUP and MISC[VBGUP]. 0b - Self-bias 1b - Current reference bias
14-13 ENTAILADJVD	HS RX Squelch Rise Time Delay Trim Adjusts the squelch rise time delay for the squelch signal, from the HS RX envelope detector, when TRIM_OVERRIDE_EN[TRIM_ENV_TAIL_ADJ_VD_OVERRIDE] is 1. If TRIM_OVERRIDE_EN[TRIM_ENV_TAIL_ADJ_VD_OVERRIDE] becomes 0, the squelch rise time trim values in TRIM_OVERRIDE_EN[TRIM_USB_REG_ENV_TAIL_ADJ_VD] are used instead. 00b - Squelch rising edge delay is nominal 01b - +20% delay compared to nominal 10b - -20% delay compared to nominal 11b - -40% delay compared to nominal
12-0 —	The value of this reserved bit must remain 0b.

52.7.10 USBPHY Version (VERSION)

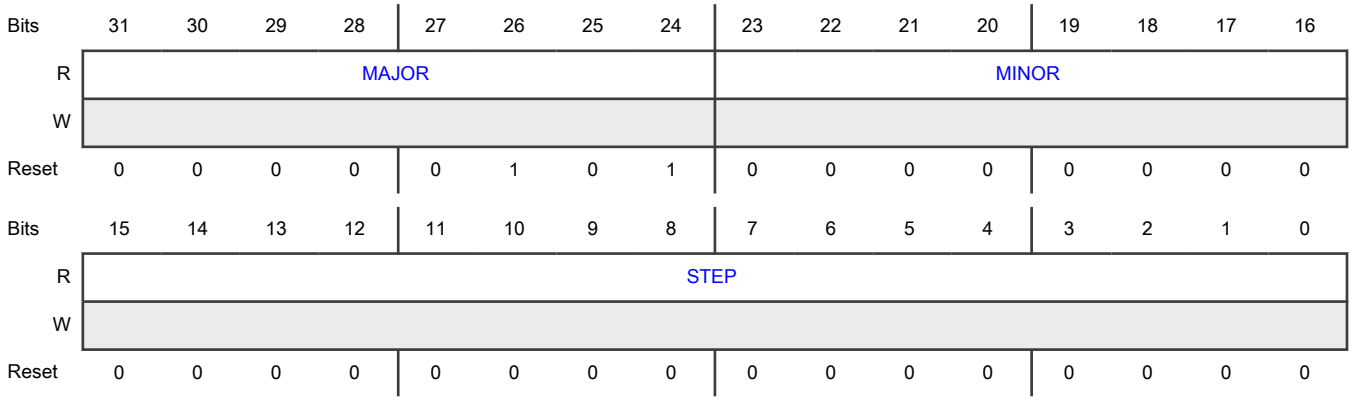
Offset

Register	Offset
VERSION	80h

Function

Indicates the version of USBPHY.

Diagram



Fields

Field	Function
31-24 MAJOR	Major Indicates the "Major" field of the USBPHY version.
23-16 MINOR	Minor Indicates the "Minor" field of the USBPHY version.
15-0 STEP	Step Indicates the stepping of the USBPHY version.

52.7.11 USBPHY PLL Control and Status (PLL_SIC)

Offset

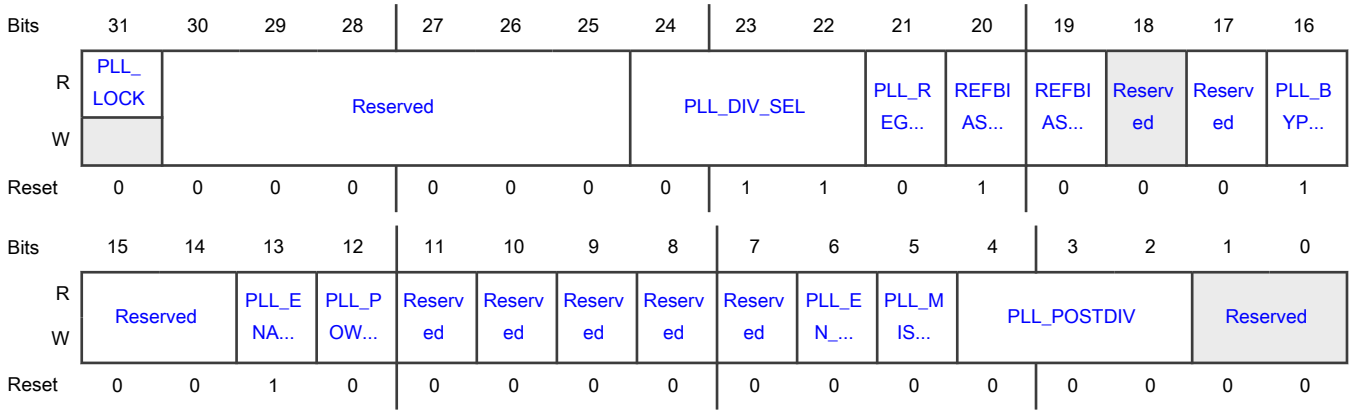
This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
PLL_SIC	A0h	USBPHY PLL Control and Status
PLL_SIC_SET	A4h	Writing 1 to a bit in this register ensures that the corresponding bit in PLL_SIC is 1
PLL_SIC_CLR	A8h	Writing 1 to a bit in this register ensures that the corresponding bit in PLL_SIC is 0
PLL_SIC_TOG	ACh	Writing 1 to a bit in this register inverts the value of the corresponding bit in PLL_SIC

Function

Configures the 480 MHz USBPHY PLL.

Diagram



Fields

Field	Function
31 PLL_LOCK	PLL Lock Indicates the current status of the USB PLL lock. 0b - Not locked 1b - Locked
30-25 —	Reserved
24-22 PLL_DIV_SEL	PLL Divider Selection Controls the USB PLL feedback loop divider. The valid range for divider values is 13–40. (Fout = Fin × div_select). The USB PLL produces a 480 MHz output clock. This field allows the use of different frequency signals for the PLL reference clock input connected to the OSCCLK signal from the system oscillator. If TRIM_OVERRIDE_EN[TRIM_DIV_SEL_OVERRIDE] is 1, the USB PLL uses this register value. 000b - Divide by 13 001b - Divide by 15 010b - Divide by 16 011b - Divide by 20 100b - Divide by 22 101b - Divide by 25 110b - Divide by 30 111b - Divide by 40
21 PLL_REG_ENABLE	PLL Regulator Enable Enables the USB PLL regulator. You must set this field to 15 µs before selecting PLL_POWER to avoid glitches on the PLL output clock. 0b - Disables

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enables
20 REFBIAS_PWD	Reference Bias Powerdown Enables reference bias powerdown. This field is used only when REFBIAS_PWD_SEL is 1. 0b - Disables 1b - Enables
19 REFBIAS_PWD_SEL	Reference Bias Powerdown Selection Selects PLL_POWER or REFBIAS_PWD to control the reference bias. 0b - PLL_POWER 1b - REFBIAS_PWD
18 —	Reserved
17 —	The value of this reserved bit must remain 0b.
16 PLL_BYPASS	PLL Bypass Bypasses the USB PLL. 0b - Do not bypass 1b - Bypass
15-14 —	Reserved
13 PLL_ENABLE	PLL Enable Enables the clock output from the USB PLL (the PLL powerup control also controls the PLL output enable signal). USBPHY disables the PLL output before PLL powerdown, and enables the PLL output after PLL powerup. You must only set it when initializing the PLL. 0b - Disables 1b - Enables
12 PLL_POWER	PLL Power Enables the USB PLL (USBPHY also controls PLL powerup and powers it down when the USB is suspended and not in use). 0b - Disables 1b - Enables
11	The value of this reserved bit must remain 0b for normal operation.

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
10 —	The value of this reserved bit must remain 0b.
9 —	The value of this reserved bit must remain 0b.
8 —	The value of this reserved bit must remain 0b.
7 —	The value of this reserved bit must remain 0b.
6 PLL_EN_USB_CLKS	PLL USB Clocks Enable Enables the USB clock output from USBPHY PLL. 0b - Disables 1b - Enables
5 PLL_MISC2_CONTROL0	PLL_MISC2_CONTROL0 This field together with PLL_POWER determines when USBPHY's 480 MHz PLL is powered up. The SW stack must write 1b to this bit during the USB initialization routine. 0b - Power up PLL without regard to state of "SuspendM" signal 1b - Power down PLL when in Suspend bus state
4-2 PLL_POSTDIV	PLL Post-Divider Output Value Configuration Specifies the integer divide values for PLL post divider. 000b - Disable the output of PLL post divider 001b - Divide value is 1 010b - Divide value is 2 011b - Divide value is 3 100b - Divide value is 4 101b - Divide value is 5 110b - Divide value is 6 111b - Reserved
1-0 —	Reserved

52.7.12 USBPHY VBUS Detect Control (USB1_VBUS_DETECT)

Offset

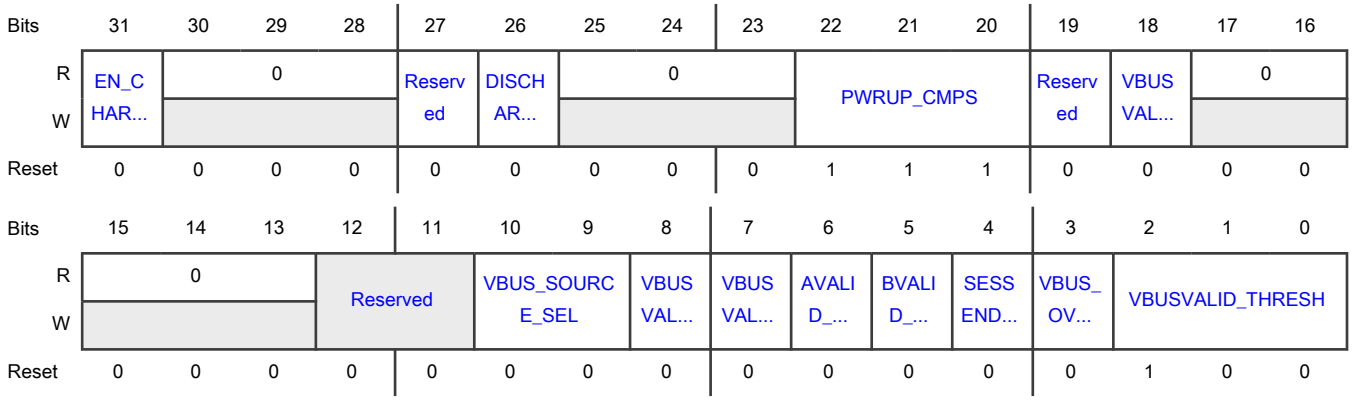
This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
USB1_VBUS_DETECT	C0h	USBPHY VBUS Detect Control
USB1_VBUS_DETECT_SET	C4h	Writing 1 to a bit in this register ensures that the corresponding bit in USB1_VBUS_DETECT is 1
USB1_VBUS_DETECT_CLR	C8h	Writing 1 to a bit in this register ensures that the corresponding bit in USB1_VBUS_DETECT is 0
USB1_VBUS_DETECT_TOG	CCh	Writing 1 to a bit in this register inverts the value of the corresponding bit in USB1_VBUS_DETECT

Function

Defines controls for USB VBUS detect and some additional out-of-band signaling functions.

Diagram



Fields

Field	Function
31 EN_CHARGER_RESISTOR	Charger Resistor Enable Enables a nominal 125 kΩ pullup on DP and a nominal 375 kΩ pulldown on DN. This allows resistive battery charger detection according to *USB Battery Charging Specification Revision 1.0*, which is now obsolete. With this method, you perform the detection of the DN and DP pin states by using USB1_CHRG_DET_STAT[DN_STATE] and USB1_CHRG_DET_STAT[DP_STATE], respectively. This field must remain 0 for normal USB data communication, or when using the DCD for battery charger detection, according to *USB Battery Charger Specification Revision 1.2* or any other detection mechanism for USB cable plugin. 0b - Disables

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enables
30-28 —	Reserved
27 —	Reserved
26 DISCHARGE_VBUS	VBUS Discharge Resistor Controller Enables (controls) a nominal 22 kΩ resistor between the USB1_VBUS pin and the ground that can be used to accelerate the fall of the VBUS signal at the end of a session. 0b - Disables 1b - Enables
25-23 —	Reserved
22-20 PWRUP_CMPS	VBUS_VALID Comparator Enable Enables (powers up) the comparator used for the VBUS_VALID detector. You can reset this field to 0 to save power if the internal VBUS_VALID comparator is not used. The default value is 111b. 000b - Disable the VBUS_VALID comparator 001b - Enable the SESS_VALID comparator 010b - Enable 3V detection
19 —	Reserved
18 VBUSVALID_TO_SESSVALID	VBUS_VALID Comparator Selection Controls the comparator that is used to report the VBUS_VALID results of the VBUS_VALID comparator and session valid comparators, in USB1_VBUS_DETECT[ID_OVERRIDE_EN]. If this field is 0, the VBUS_VALID comparator for the VBUS_VALID results is used. If this field is 1, the session end comparator for the VBUS_VALID results is used. The session end threshold is > 0.8 V and < 4.0 V. The VBUS_VALID comparator is the most accurate and has a programmable threshold that VBUSVALID_THRESH defines. The session valid comparator may be useful in systems using nonstandard VBUS voltages. The mux selection in this field happens before any VBUS_VALID selection controlled by VBUSVALID_SEL and VBUS_SOURCE_SEL. 0b - VBUS_VALID comparator for the VBUS_VALID results

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Session end comparator for the VBUS_VALID results
17-13 —	Reserved
12-11 —	Reserved
10-9 VBUS_SOURCE_SEL	VBUS_VALID Source Selection Selects the source of the VBUS_VALID signal reported to the USB controller. If this field is 0b, by default, the VBUS_VALID comparator results for the signal reported to the USB controller are used. If this field is 1b or 10b, the session valid comparator results for the signal reported to the USB controller are used. The VBUS_VALID source selections in this field take effect only if both VBUSVALID_SEL and VBUS_OVERRIDE_EN are 0. This field does not impact the value of USB1_VBUS_DET_STAT[VBUS_VALID]. 00b - VBUS_VALID comparator results 01b - Session valid comparator results 10b - Session valid comparator result 11b - Reserved; do not use
8 VBUSVALID_SEL	VBUS_VALID Source Selection Selects the source of the VBUS_VALID signal reported to the USB controller. If this field is 0, by default, the VBUS_VALID comparator results for the signal reported to the USB controller are used. If this field is 1, the VBUS_VALID_3V detector results for the signal reported to the USB controller are used. The VBUS_VALID source selection in this field only takes effect if VBUS_VALID is 0 . This field does not impact the value of USB1_VBUS_DET_STAT[VBUS_VALID]. 0b - VBUS_VALID comparator results 1b - VBUS_VALID_3V detector results
7 VBUSVALID_OVERRIDE	Override Value for the VBUS_VALID Signal Provides the value of USB1_VBUS_DET_STAT[VBUS_VALID] reported to the USB controller if the value of VBUS_OVERRIDE_EN is 1. This field does not impact the value of USB1_VBUS_DET_STAT[VBUS_VALID]. 0b - Overridden to 0 1b - Overridden to 1

Table continues on the next page...

Table continued from the previous page...

Field	Function
6 AVALID_OVERRIDE	Override Value for A-Device Session Valid Provides the value for USB1_VBUS_DET_STAT[AVALID] if the value of VBUS_OVERRIDE_EN is 1. 0b - Overridden to 0 1b - Overridden to 1
5 BVALID_OVERRIDE	Override Value for B-Device Session Valid Provides the value for USB1_VBUS_DET_STAT[BVALID] if the value of VBUS_OVERRIDE_EN is 1. 0b - Overridden to 0 1b - Overridden to 1
4 SESSEND_OVERRIDE	Override Value for SESSEND Provides the value for USB1_VBUS_DET_STAT[SESSEND] if the value of VBUS_OVERRIDE_EN is 1. 0b - Overridden to 0 1b - Overridden to 1
3 VBUS_OVERRIDE_EN	VBUS Detect Signal Override Enable Allows you to override the results from VBUS_VALID and session valid comparators using the values in USB1_VBUS_DETECT[7:4]. If this field is 0, by default, the results of the internal VBUS_VALID and session valid comparators for VBUS_VALID, AVALID, BVALID, and SESSEND are used. If this field is 1, the override values for VBUS_VALID, AVALID, BVALID, and SESSEND are used. The VBUS_VALID, AVALID, BVALID, and SESSEND signals sent to the USB controller are affected by these bit selections. The values reported for USB1_VBUS_DET_STAT[AVALID], USB1_VBUS_DET_STAT[BVALID], and USB1_VBUS_DET_STAT[SESSEND] are also affected but the value of USB1_VBUS_DET_STAT[VBUS_VALID] is not affected. This override method may be useful if you do not perform VBUS detection using the internal VBUS_VALID or session end comparators. 0b - Results of VBUS_VALID and session valid comparators for VBUS_VALID, AVALID, BVALID, and SESSEND 1b - Override values for VBUS_VALID, AVALID, BVALID, and SESSEND
2-0 VBUSVALID_THRESH	VBUSVALID Threshold Sets the threshold for the VBUSVALID comparator, which is the most accurate method to determine the presence of 5 V, and includes hysteresis to minimize the need for software debounce of the detection. This comparator has ~50 mV of hysteresis to prevent chattering at the comparator trip point. 000b - 4.0 V 001b - 4.1 V

Table continues on the next page...

Table continued from the previous page...

Field	Function
	010b - 4.2 V 011b - 4.3 V 100b - 4.4 V 101b - 4.5 V 110b - 4.6 V 111b - 4.7 V

52.7.13 USBPHY VBUS Detector Status (USB1_VBUS_DET_STAT)

Offset

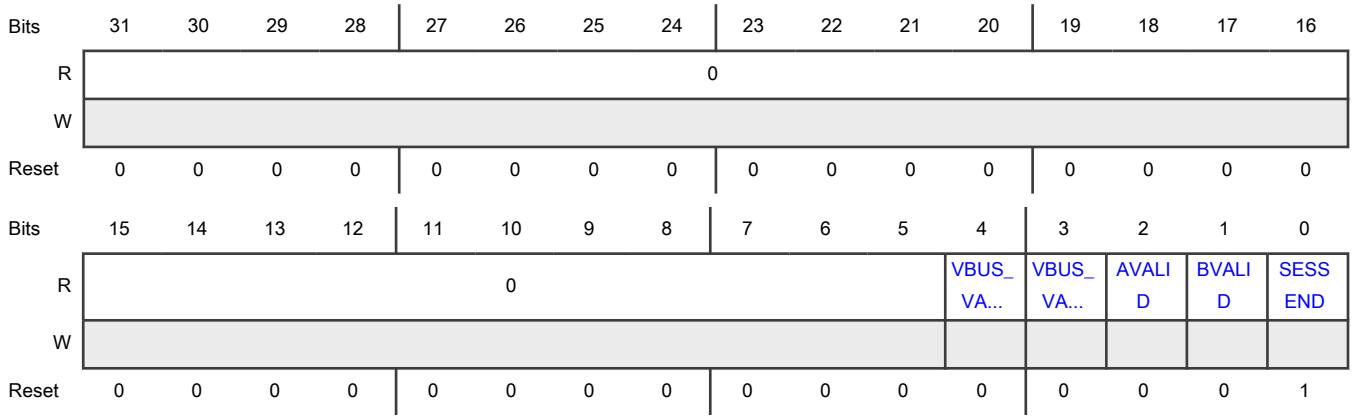
Register	Offset
USB1_VBUS_DET_STAT	D0h

Function

Allows status observation for USB VBUS detect functions.

The APB clock synchronizes the values reported in this register.

Diagram



Fields

Field	Function
31-5 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
4 VBUS_VALID_3V	VBUS_VALID_3V Detector Status Indicates the status of the VBUS_VALID_3V detector. If this field is 0, the VBUS voltage is below the VBUS_VALID_3V threshold. If this field is 1, the VBUS voltage is above the VBUS_VALID_3V threshold. The VBUS_VALID_3V detector has a lower threshold for the voltage on the USB1_VBUS pin than either the session valid or VBUS_VALID comparators. This signal may be useful for applications using a nonstandard VBUS voltage. 0b - Below threshold 1b - Above threshold
3 VBUS_VALID	VBUS Voltage Status Indicates the result of VBUS_VALID detection for the USB1_VBUS pin. If this field is 0, the VBUS voltage is below the comparator threshold. If this field is 1, the VBUS voltage is above the comparator threshold. USB1_VBUS_DETECT[VBUSVALID_TO_SESSVALID] selects the VBUS_VALID comparator used. You cannot overwrite the VBUS_VALID source, which is not affected by the values of USB1_VBUS_DETECT[VBUSVALID_OVERRIDE] and USB1_VBUS_DETECT[VBUS_OVERRIDE_EN]. 0b - Below threshold 1b - Above threshold
2 AVALID	A-Device Session Valid Status Indicates A-device session valid status that the session valid comparator determines. If this field is 0, the VBUS voltage is below the session valid threshold. If this field is 1, the VBUS voltage is above the session valid threshold. The voltage on the USB1_VBUS pin determines the default value of this field. You can overwrite this field by using USB1_VBUS_DETECT[AVALID_OVERRIDE] and USB1_VBUS_DETECT[VBUS_OVERRIDE_EN]. 0b - Below threshold 1b - Above threshold
1 BVALID	B-Device Session Valid Status Indicates B-device session valid status that the session valid comparator determines. If this field is 0, the VBUS voltage is below the session valid threshold. If this field is 1, the VBUS voltage is above the session valid threshold. The voltage on the USB1_VBUS pin determines the default value of this field. You can overwrite this field by using USB1_VBUS_DETECT[BVALID_OVERRIDE] and USB1_VBUS_DETECT[VBUS_OVERRIDE_EN].

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Below threshold 1b - Above threshold
0 SESSEND	Session End Indicator Indicates session end status, the value inverted from the session valid comparator. If this field is 0, the VBUS voltage is above the session valid threshold. If this field is 1, the VBUS voltage is below the session valid threshold. The voltage on the USB1_VBUS pin determines the default value of this field. You can overwrite this field by using USB1_VBUS_DETECT[SESSEND_OVERRIDE] and USB1_VBUS_DETECT[VBUS_OVERRIDE_EN]. 0b - Above threshold 1b - Below threshold

52.7.14 USBPHY Charger Detect Control (USB1_CHRG_DETECT)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
USB1_CHRG_DETECT	E0h	USBPHY Charger Detect Control
USB1_CHRG_DETECT_SET	E4h	Writing 1 to a bit in this register ensures that the corresponding bit in USB1_CHRG_DETECT is 1
USB1_CHRG_DETECT_CLR	E8h	Writing 1 to a bit in this register ensures that the corresponding bit in USB1_CHRG_DETECT is 0
USB1_CHRG_DETECT_TOG	ECh	Writing 1 to a bit in this register inverts the value of the corresponding bit in USB1_CHRG_DETECT

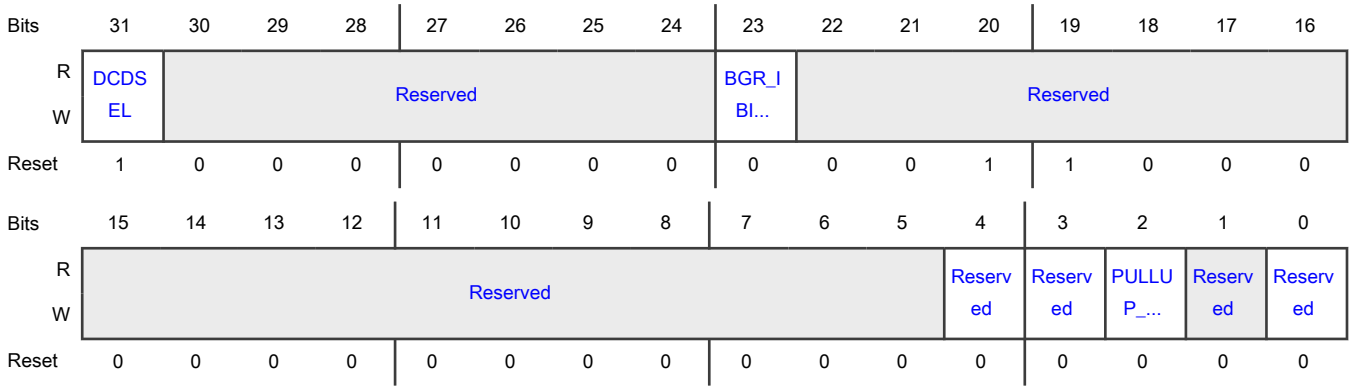
Function

Defines controls for USB battery charging detection functions.

USBDCD controls the USB battery charging detection functions (see the "USB Device Charger Detection Module (USBDCD)" chapter for more information).

You must not change the values of this field except for characterization tasks.

Diagram



Fields

Field	Function
31 DCDSEL	DCD Selection Selects the control source for battery charging detection. If this field is 0, USBPHY Charger Detect Control (USB1_CHRG_DETECT) controls the BC 1.2 functionality. If this field is 1, fields and state machines in USBHSDCD control the BC 1.2 functionality (see the "USB Device Charger Detection Module (USBDCD)" chapter for more information). You can control several of the USBPHY analog circuits associated with the USB battery charging v1.2 functions by either using control fields in USBPHY Charger Detect Control (USB1_CHRG_DETECT) or by using the USBHSDCD module's registers. Use of USBHSDCD is recommended for software simplification, for device mode charger detection because USBHSDCD can auto-sequence through the detection states. 0b - Fields in the USB1_CHRG_DETECT register 1b - Fields and state machines in the USBHSDCD module
30-24 —	Reserved
23 BGR_IBIAS	BGR Bias Selects the bias method deployed for the voltage and current sources used for the analog circuits associated with USB battery charging detection in the USBHSDCD instantiation of USBDCD (see the "USB Device Charger Detection Module (USBDCD)" chapter for more information). If this field is 0, by default, the local bias powered from VBUS for 10 µA reference is used. If this field is 1, the bandgap bias powered from VREGIN0 or VREGIN1 for 10 µA reference is used. The V_{DP_SRC} and V_{DN_SRC} bias is generated from the USB1_VBUS voltage, independent of the value of this field. 0b - Local bias 1b - Bandgap bias
22-5	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
4 —	Reserved The value of this reserved bit must remain 0b.
3 —	The value of this reserved bit must remain 0b.
2 PULLUP_DP	DP Pullup Resistor Enable Override Control Enables FS Device mode operation that is normally controlled using the UTMI bus signals that the USB controller sends to USBPHY. If this field is 1, the pullup resistor is enabled independently of the UTMI signals to the PHY. The USB software stack uses this capability during charger type detection, according to the obsolete *USB Battery Charging Specification Revision 1.1*. For USB battery charging detection and normal USB data communication (associated with the USB battery charging v1.2), retain 0 as the value of this field. 0b - Disables 1b - Enables
1 —	Reserved
0 —	This value of this bit must remain 0b to avoid interference with USB battery charging detection.

52.7.15 USBPHY Charger Detect Status (USB1_CHRG_DET_STAT)

Offset

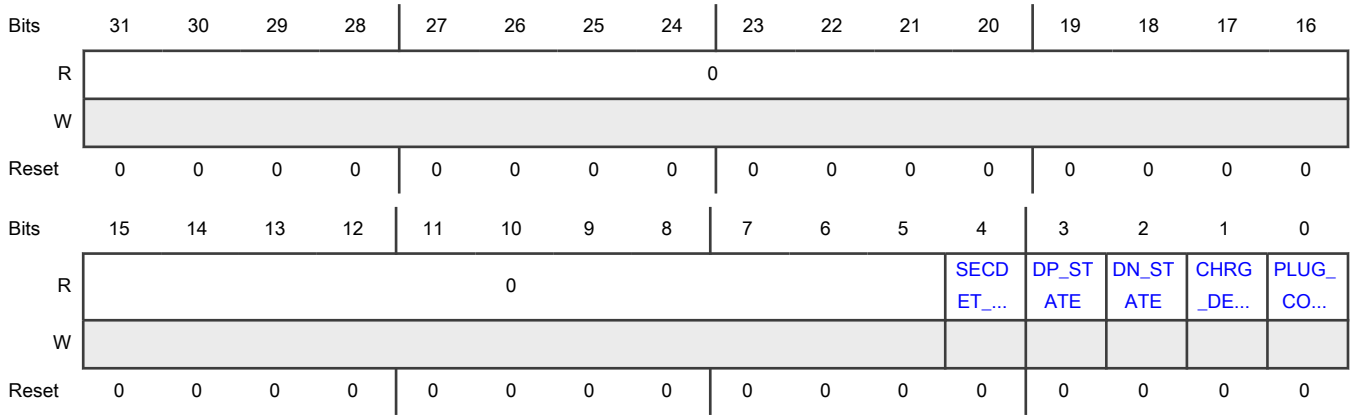
Register	Offset
USB1_CHRG_DET_STAT	F0h

Function

Indicates the USBPHY charger detect status.

Use the USBHSDCD registers for USB battery charging detection functions and standards-based charger detection purposes.

Diagram



Fields

Field	Function
31-5 —	Reserved
4 SECDET_DCP	Battery Charging Secondary Detection Phase Output Indicates the type of charging port detected—charging downstream port (CDP) or downstream charging port (DCP)—during the USB battery charging secondary detection phase, using the USBHSDCD module. 0b - CDP detected 1b - DCP detected
3 DP_STATE	DP State Indicates the single-ended receiver output for the DP pin, from charger detection circuits. 0b - < 0.8 V 1b - > 2.0 V
2 DN_STATE	DN State Indicates the single-ended receiver output for the DN pin, from charger detection circuits. 0b - < 0.8 V 1b - > 2.0 V
1 CHRG_DETECTED	Battery Charging Primary Detection Phase Output Indicates whether a standard downstream port (SDP) or charging port is detected during the USB battery charging primary detection phase. 0b - SDP detected 1b - Charging port detected
0	Battery Charging Data Contact Detection Phase Output

Table continues on the next page...

Table continued from the previous page...

Field	Function
PLUG_CONTACT	Indicates whether an attached USB cable is detected between the remote host and the local device during the data contact detection phase, according to *USB Battery Charging Specification Revision 1.2* (using the USBHSDCD module). 0b - Not detected 1b - Detected

52.7.16 USBPHY Analog Control (ANACTRL)

Offset

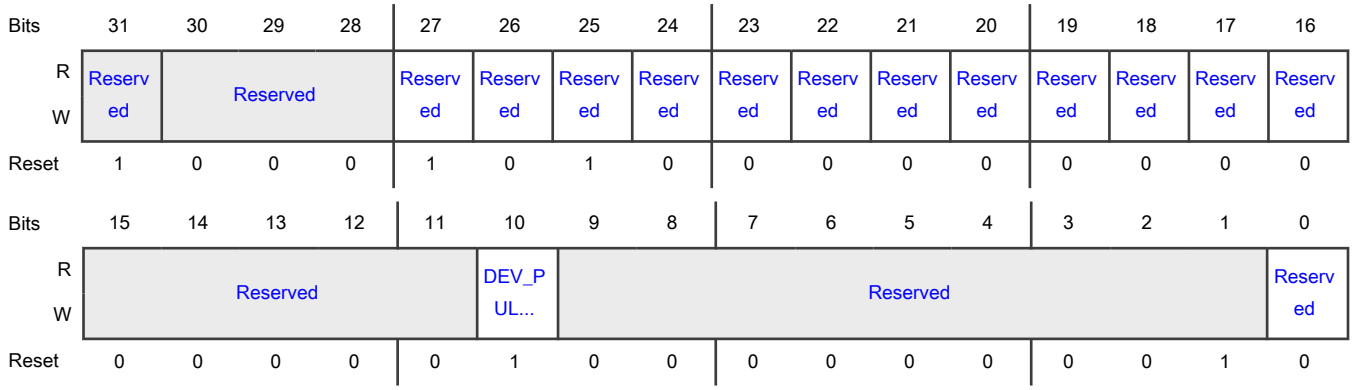
This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
ANACTRL	100h	USBPHY Analog Control
ANACTRL_SET	104h	Writing 1 to a bit in this register ensures that the corresponding bit in ANACTRL is 1
ANACTRL_CLR	108h	Writing 1 to a bit in this register ensures that the corresponding bit in ANACTRL is 0
ANACTRL_TOG	10Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in ANACTRL

Function

Includes fields for adding pre-emphasis to the USB HS TX output drivers.

Diagram



Fields

Field	Function

17 —	This field must remain at value 0b.
16 —	This field must remain at value 0b.
15-11	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
10 DEV_PULLDOWN	Device Pulldown Enables the 15 kΩ pulldown resistors on both DP and DN pins in Device mode. You can use this feature in Device mode, while the USB cable is disconnected, to retain the data pins at known values, avoiding unnecessary interrupts from single-ended receivers. This field must be reset to 0 during normal USB data communication in Device mode, or during battery charger detection, using the USBHSDCD module. 0b - Disables 1b - Enables
9-1 —	Reserved
0 —	The value of this reserved bit must remain 0b for normal operation.

52.7.17 USBPHY Loopback Control and Status (USB1_LOOPBACK)

Offset

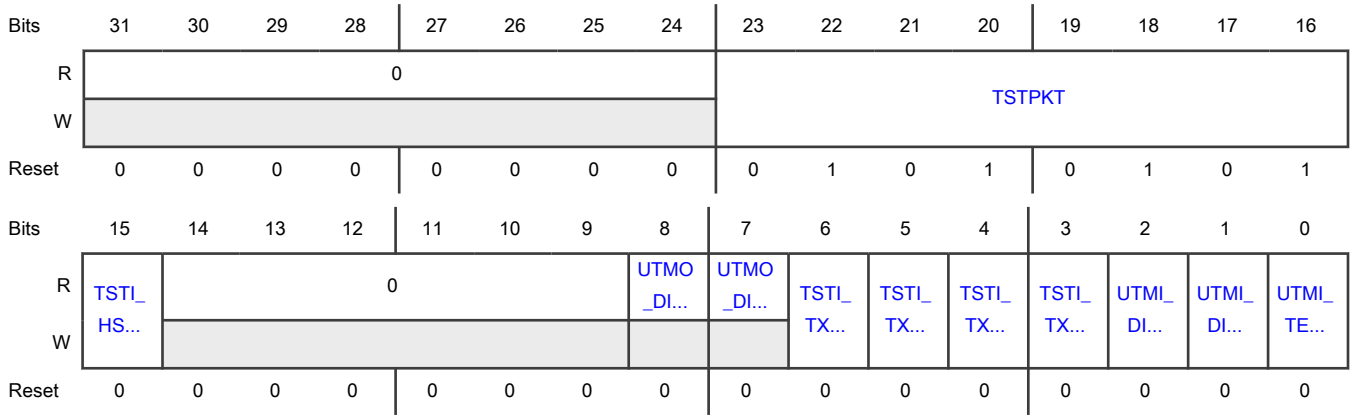
This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
USB1_LOOPBACK	110h	USBPHY Loopback Control and Status
USB1_LOOPBACK_SET	114h	Writing 1 to a bit in this register ensures that the corresponding bit in USB1_LOOPBACK is 1
USB1_LOOPBACK_CLR	118h	Writing 1 to a bit in this register ensures that the corresponding bit in USB1_LOOPBACK is 0
USB1_LOOPBACK_TOG	11Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in USB1_LOOPBACK

Function

Controls loopback testing for USBPHY. Loopback mode is for test purposes only; you cannot use it for normal USB data communication.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 TSTPKT	Testing Packet Selects the packet data byte used for USB loopback testing in Pulse mode. Pulse mode is selected if you write 01b to UTMI_DIG_TST0 and UTMI_DIG_TST1. The default value produces a data inversion at each unit interval.
15 TSTI_HSFS_MODE_EN	Loopback Test HS-FS Mode Enable Enables the loopback test to dynamically change the packet speed. It sends a number of HS packets determined by USB1_LOOPBACK_HSFSCNT[TSTI_HS_NUMBER], followed by a number of FS packets determined by USB1_LOOPBACK_HSFSCNT[TSTI_FS_NUMBER]. 0b - Disables 1b - Enables
14-9 —	Reserved
8 UTMO_DIG_TST1	UTMO Digital Test 1 Indicates USB loopback test results. Test results are only valid when UTMI_TESTSTART is 1. 0b - Not passing 1b - Passing
7 UTMO_DIG_TST0	UTMO Digital Test 0 Indicates USB loopback test results. Test results are only valid when UTMI_TESTSTART is 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Passing 1b - Not passing
6 TSTI_TX_HIZ	Loopback Test Transmit Hi-Z Enables TX Hi-Z for USB loopback test. 0b - Disables 1b - Enables
5 TSTI_TX_EN	Loopback Test Transmit Enable Enables TX for USB loopback test. 0b - Disables 1b - Enables
4 TSTI_TX_LS_MODE	Loopback Test LS Mode Selects the TX mode. 0b - HS or FS (defined by TSTI1_TX_HS) 1b - LS
3 TSTI_TX_HS_MODE	Loopback Test HS Mode Selects HS or FS mode for USB loopback testing. 0b - FS 1b - HS
2 UTMI_DIG_TST1	UTMI Digital Test 1 Selects the mode for USB loopback test 1. If this field is 0, Pulse mode for the loopback test is selected. This field remains 0 when UTMI_DIG_TST0 is 1. If this field is 1, Pseudorandom mode for the loopback test is selected. This field becomes 1 when UTMI_DIG_TST0 is 0. 0b - Pulse mode 1b - Pseudorandom mode
1 UTMI_DIG_TST0	UTMI Digital Test 0 Selects the mode for USB loopback test 0. If this field is 0, Pseudorandom mode for the loopback test is selected. This field remains 0 when UTMI_DIG_TST1 is 1. If this field is 1, Pulse mode for the loopback test is selected. This field becomes 1 when UTMI_DIG_TST1 is 0. 0b - Pseudorandom mode

Table continues on the next page...

Table continued from the previous page...

	1b - Pulse mode
0 UTMI_TESTSTART	UTMI Test Start Enables the USB loopback test. 0b - Disables 1b - Enables

52.7.18 USBPHY Loopback Packet Number Selection (USB1_LOOPBACK_HSFSCNT)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

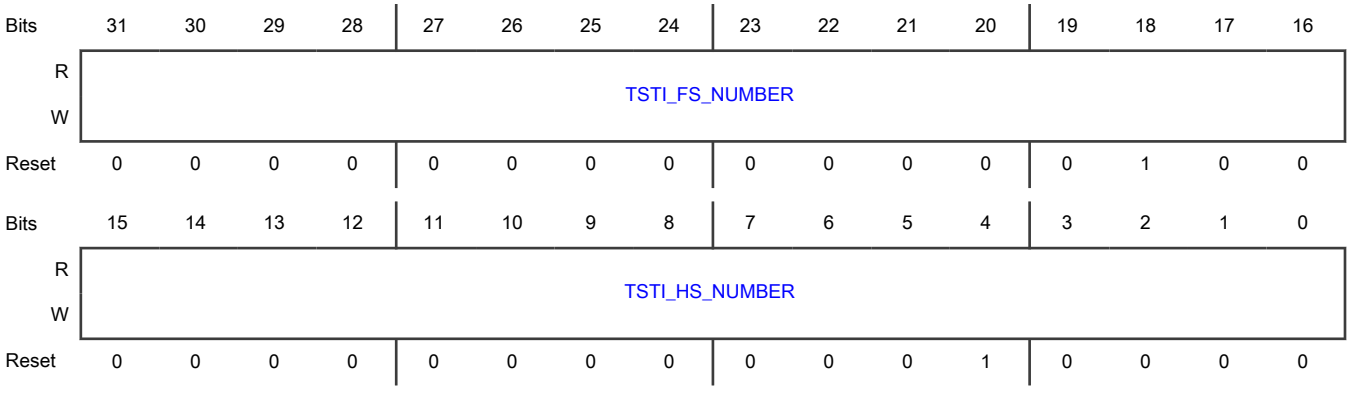
Register	Offset	Description
USB1_LOOPBACK_HSFSCNT	120h	USBPHY Loopback Packet Number Selection
USB1_LOOPBACK_HSFSCNT_SET	124h	Writing 1 to a bit in this register ensures that the corresponding bit in USB1_LOOPBACK_HSFSCNT is 1
USB1_LOOPBACK_HSFSCNT_CLR	128h	Writing 1 to a bit in this register ensures that the corresponding bit in USB1_LOOPBACK_HSFSCNT is 0
USB1_LOOPBACK_HSFSCNT_TOG	12Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in USB1_LOOPBACK_HSFSCNT

Function

Selects the packet counts used for the specific loopback test mode that dynamically alternates the transmit speed.

See USBPHY Loopback Control and Status (USB1_LOOPBACK) for other configuration of this mode.

Diagram



Fields

Field	Function
31-16 TSTI_FS_NUMBER	Loopback Test FS Packet Number Specifies the FS packet number, used when USB1_LOOPBACK[TSTI_HSFS_MODE_EN] is 1.
15-0 TSTI_HS_NUMBER	Loopback Test HS Packet Number Specifies the HS packet number, used when USB1_LOOPBACK[TSTI_HSFS_MODE_EN] is 1.

52.7.19 USBPHY Trim Override Enable (TRIM_OVERRIDE_EN)

Offset

This type of register has supplemental _SET, _CLR, and _TOG registers at adjacent offsets.

Register	Offset	Description
TRIM_OVERRIDE_EN	130h	USBPHY Trim Override Enable
TRIM_OVERRIDE_EN_SET	134h	Writing 1 to a bit in this register ensures that the corresponding bit in TRIM_OVERRIDE_EN is 1
TRIM_OVERRIDE_EN_CLR	138h	Writing 1 to a bit in this register ensures that the corresponding bit in TRIM_OVERRIDE_EN is 0
TRIM_OVERRIDE_EN_TOG	13Ch	Writing 1 to a bit in this register inverts the value of the corresponding bit in TRIM_OVERRIDE_EN

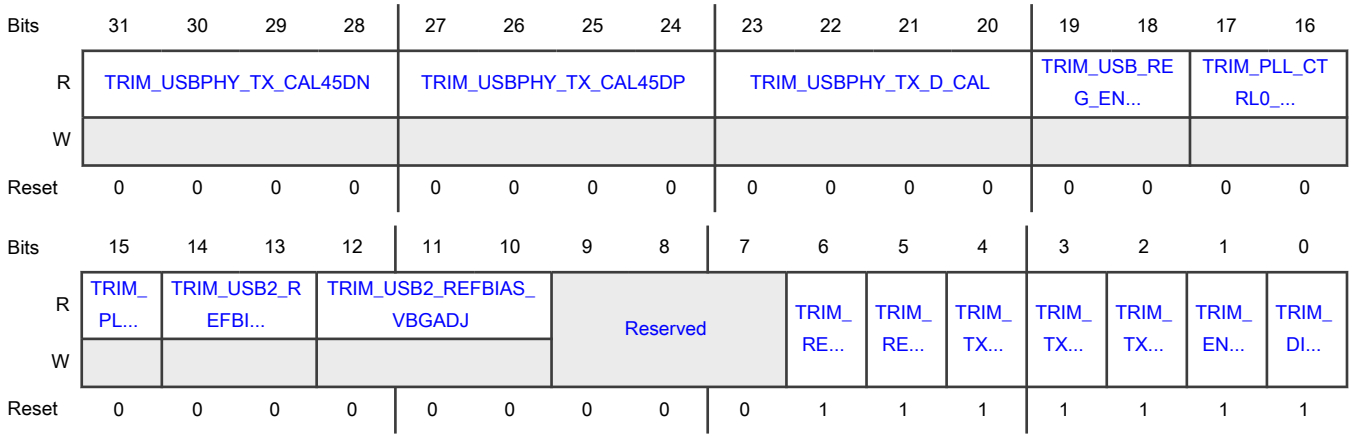
Function

Allows observation of the default IFR settings of the PHY parameters for the following fields:

- TRIM_USBPHY_TX_CAL45DN
- TRIM_USBPHY_TX_CAL45DP
- TRIM_USBPHY_TX_D_CAL
- TRIM_USB_REG_ENV_TAIL_ADJ_VD
- TRIM_PLL_CTRL0_DIV_SEL

Additional fields also determine whether you can overwrite those values by using the settings defined in USBPHY Transmitter Control (TX), UTMI Debug Status 1 (DEBUG1), and USBPHY PLL Control and Status (PLL_SIC).

Diagram



Fields

Field	Function
31-28 TRIM_USBPHY_TX_CAL45DN	DN Series Termination Resistance Trim Bits from Outside USBPHY Trims the termination resistance if TRIM_TX_CAL45DN_OVERRIDE is 0. If TRIM_TX_CAL45DN_OVERRIDE is 1, the resistance trim values in TXCAL45DN are used instead. Decode to trim the nominal 45 Ω series termination resistance to the DN output pin, with values loaded using signals outside USBPHY. The methods used to load the read-only values into this field during reset and boot are chip-specific. The maximum resistance is at value 0000b and minimum resistance is at value 1111b (resistance is centered at value 0111b). For USBPHY, each incrementally increasing trim value decreases the target resistance by approximately 3.5%, compared to the next lower value. Trimming this resistance impacts both the overshoot and undershoot of the FS TX output and the amplitude of the HS TX output. The methods used to load the read-only values into this field during reset and boot are chip-specific.
27-24 TRIM_USBPHY_TX_CAL45DP	DP Series Termination Resistance Trim Bits from Outside USBPHY Trims the termination resistance when TRIM_TX_CAL45DP_OVERRIDE is 0. If TRIM_TX_CAL45DP_OVERRIDE is 1, the resistance trim values in TX[TXCAL45DP] are used instead. Decode to trim the nominal 45 Ω series termination resistance to the DP output pin, with values loaded using signals outside USBPHY. The methods used to load the read-only values into this field during reset and boot are chip-specific. The maximum resistance is 0000b and minimum resistance is 1111b (the resistance is centered at value 0111b). For USBPHY, each incrementally increasing trim value decreases the target resistance by approximately 3.5%, compared to the next lower value. Trimming this resistance impacts both the overshoot and undershoot of the FS TX output and amplitude of the HS TX output. The methods used to load the read-only values into this field during reset and boot are chip-specific.
23-20	HS TX Output Current Trim Bits from Outside USBPHY

Table continues on the next page...

Table continued from the previous page...

Field	Function
TRIM_USBPHY_TX_D_CAL	Trims the output current if TRIM_TX_D_CAL_OVERRIDE is 0. In this case, the current trim values in TX[D_CAL] are used instead. Decode to trim the nominal 17.78 mA current source for the HS TX drivers on DP and DN, with values loaded using signals from outside the PHY. This current is directly proportional to the amplitude of the HS TX eye diagram. The methods used to load the read-only values into this field during reset and boot are chip-specific. 0000b - Maximum current; approximately 19% above nominal 0111b - Nominal 1111b - Minimum current; approximately 19% below nominal
19-18 TRIM_USB_REG_ENV_TAIL_ADJ_VD	HS RX Squelch Rise Time Delay Trim Bits from Outside USBPHY Allows you to adjust the squelch rise time if TRIM_ENV_TAIL_ADJ_VD_OVERRIDE is 0. In this case, the squelch rise time trim values in DEBUG1[ENTAILADJVD] are used instead. This field defines the delay adjustment for the rise time of the squelch signal from the HS RX envelope detector, with values loaded using signals from outside the PHY. The methods used to load the read-only values into this field during reset and boot are chip-specific. See DEBUG1[ENTAILADJVD] to understand the available trims.
17-15 TRIM_PLL_CTRL0_DIV_SEL	PLL Divider Value Configuration Bits from Outside USBPHY Controls the PLL feedback loop divider if TRIM_DIV_SEL_OVERRIDE is 0. USBPHY's PLL produces a 480 MHz output clock. This field allows the use of different frequency signals for the PLL reference clock input connected to the OSCCLK signal from the system oscillator, with values loaded from outside USBPHY. If TRIM_DIV_SEL_OVERRIDE is 0, the PLL divider values in PLL_SIC[PLL_DIV_SEL] are used instead. See the field value descriptions for PLL_SIC[PLL_DIV_SEL] to understand the available input frequency settings. The methods used to load the read-only values into this field during reset and boot are chip-specific.
14-13 TRIM_USB2_REFBIAS_TST	Bias Current Control Adjustment Bits from Outside USBPHY Trims the PHY's current reference when TRIM_REFBIAS_TST_OVERRIDE is 0. If TRIM_REFBIAS_TST_OVERRIDE is 1, the current trim values in DEBUG1[USB2_REFBIAS_TST] are used instead. This field defines the main current trim for the USBPHY bias module current reference generator, with values loaded using signals from outside the PHY.
12-10 TRIM_USB2_REFBIAS_VBGADJ	Bandgap Voltage Adjustment Bits from Outside USBPHY Trims the PHY's bandgap voltage if TRIM_REFBIAS_VBGADJ_OVERRIDE is 0. In this case, the voltage trim values in DEBUG1[USB2_REFBIAS_VBGADJ] are used instead. This field defines voltage adjustment trim on the USBPHY bias module bandgap generator, with values loaded using signals from outside the PHY.

53.1.2 Reset control

Reset control is the same as USBPHY0, see RSTCTL_PRSTCTL1 and PRSTCTL1_SET.

53.1.3 Clock control

The media_main_clock is the clock input for USBDCD, and CLKCTL4_PSCCTL1_MEDIA[USB0] is used to enable or disable this clock.

See .

53.2 Overview

USBDCD works with the USB transceiver to detect whether the USB device is attached to a Charging Port, either a Dedicated Charging Port (DCP) or a Charging Downstream Port (CDP). System software coordinates the detection activities of the module and controls an off-chip integrated circuit that performs the battery charging.

The use of the term "USB transceiver" in this module documentation applies to the USB physical layer instance on the chip, whether it is an Full Speed (FS)/Low Speed (LS) only transceiver or an High Speed (HS)/FS/LS capable PHY.

53.2.1 Block diagram

The following figure is a high-level block diagram of the module.

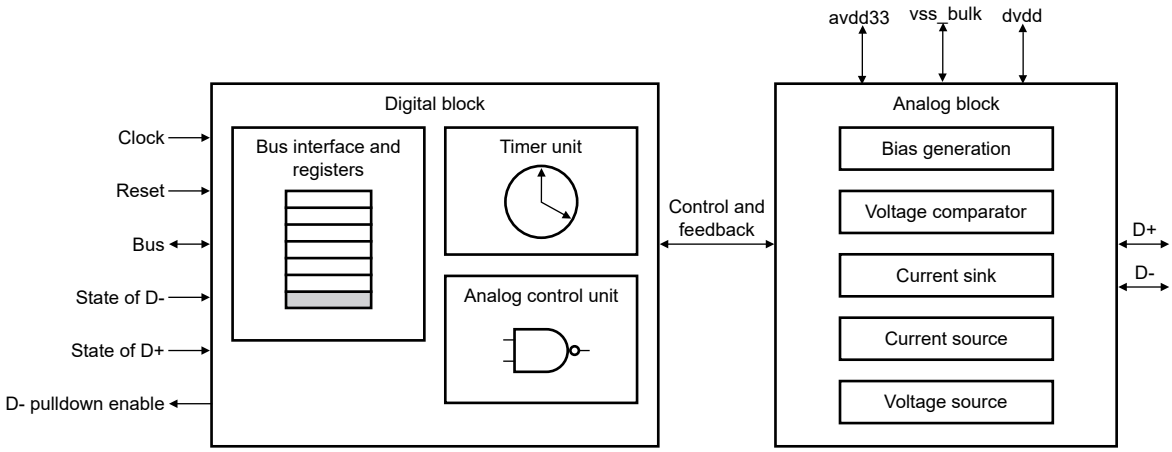

Figure 181. Block diagram

USBDCD consists of two main blocks:

- A Digital block provides the programming interface (memory-mapped registers) and includes the Timer unit and the Analog control unit.
- An Analog block provides the circuitry for the physical detection of the charger that includes the Bias generation, Voltage source, Current source, Current sink, and Voltage comparator circuitry. This block also contains necessary muxes between the source/sink circuits and the D- and D+ pins.

53.2.2 Features

- Compliant with the latest industry-standard specifications: *USB Battery Charging Specification, Revisions 1.1 and 1.2*
- Supports programmable timing parameters:
  - By default set to values required by the industry standards to allow easy configuration. You only need to set the clock frequency before enabling the module.
  - Updates of the standards are programmable.

53.3 Functional description

Several hardware components are involved in the sequence of detecting the presence of the charging port and type of the charging port. System software coordinates this activity. This collection of interacting hardware and software is called USB battery charging subsystem. The following figure shows USBDCD as a component of the subsystem.

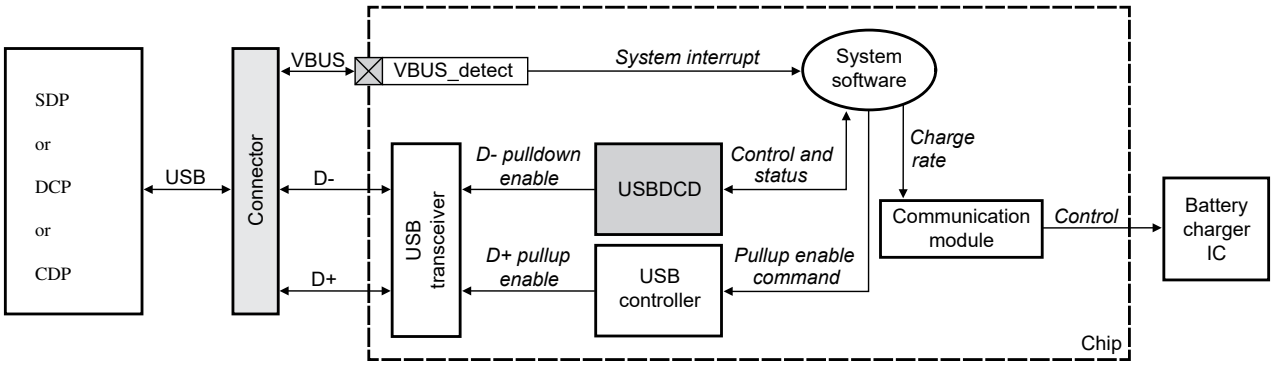

Figure 182. USB battery charging subsystem

The following table describes the components.

Table 511. USB battery charger subsystem components

Component	Description
Battery Charger IC	The external battery charger IC regulates the charge rate to the rechargeable battery. System software is responsible for communicating the appropriate charge rates.

Charger	Maximum current drawn
Standard Downstream Port (SDP)	up to 500 mA (I_{CFG_MAX})[1]
CDP	up to 1500 mA (I_{DEV_CHG})
DCP	up to 1500 mA (I_{DEV_CHG})

1. If a USB SDP host has suspended the USB device, the current drawn by the device has to follow the rules of the Dead Battery Provision in the *USB Battery Charging Specification, Rev. 1.2*.

Comm Module	A communications module on the device can be used to control the charge rate of the battery charger IC.
System software	Coordinates the detection activities of the subsystem.
USB Controller	The D+ pullup enable control signal plays a role during the charger type detection phase. System software must issue a command to the USB controller to assert this signal. After this pullup is enabled, the device is considered to be connected to the USB bus. The host then attempts to enumerate it. **NOTE** In general, the USB controller is used only for USB device applications when using USBDCD. For USB host applications, USBDCD must be disabled.
USB Transceiver	The USB transceiver contains the pullup resistor for the USB D+ signal and the pulldown resistors for the USB D+ and D– signals. The D+ pullup and the D– pulldown are both used during the charger detection sequence in BC1.1, but it is not used during charger detection in

Table continues on the next page...

Table 511. USB battery charger subsystem components (continued)

Component	Description
	BC1.2. The USB transceiver also outputs the digital state of the D+ and D– signals from the USB bus. The pullup and pulldown enable signals are controlled by other modules during the charger detection sequence in BC1.1: The D+ pullup enable is output from the USB controller and is under software control. USBDCD controls the D– pulldown enable.
USBDCD	Detects whether the device has been plugged into either an SDP, a CDP, or a DCP.
VBUS_detect	This interrupt pin connected to the USB VBUS signal detects when the device has been plugged into or unplugged from the USB bus. If the system requires waking up from a low-power mode on being plugged into the USB port, this interrupt should also be a low-power wakeup source. If this pin multiplexes other functions, such as GPIO, the pin can be configured as an interrupt so that the USB plug or unplug event can be detected.

53.3.1 Modes of operation

The operating modes of the USBDCD module are shown in the following table.

Table 512. Module modes and their conditions

Module mode	Description	Conditions when used
Enabled for Charger Detection	The module performs the charger detection sequence.	System software must enable the module only if all of the following conditions are true: • The system is using a rechargeable battery or is otherwise capable of being powered up by an SDP or a Charging Port. • The device is being used in a USB device application. • The device is attached to the USB cable.
Enabled for Signal Overrides	Module bias circuits are enabled for special signaling on DP/DM pins.	See SIGNAL_OVERRIDE[PS].
Disabled	The module is not active and is held in a low-power state.	System software must disable the module when either of the following conditions is true: • The charger detect sequence is complete. • The conditions for being enabled are not met.
Powered Off	The digital supply voltage dvdd is removed.	Low system performance requirements allow putting the device into a very low-power stop mode.

Operating mode transitions are shown in the following table.

Table 513. Entering and exiting module modes

Module mode	Entering	Exiting	Mode after exiting
Enabled	Set CONTROL[START].	Set CONTROL[SR]. [1]	Disabled
Disabled	Take *either* of the following actions: • Set CONTROL[SR].[1] • Reset the module. By default, the module is disabled.	Set CONTROL[START].	Enabled
Powered Off	Perform the following actions: 1. Put the device into very low-power stop mode. 2. Adjust the supply voltages.	Perform the following actions: 1. Restore the supply voltages. 2. Take the device out of very low-power stop mode.	Disabled

1. The effect of setting the CONTROL[SR] field is immediate; that is, the module is disabled even if the sequence has not completed.

53.3.2 The charger detection sequence

The following figure illustrates the charger detection sequence in a simplified timing diagram based on the *USB Battery Charging Specification, Rev. 1.2*.

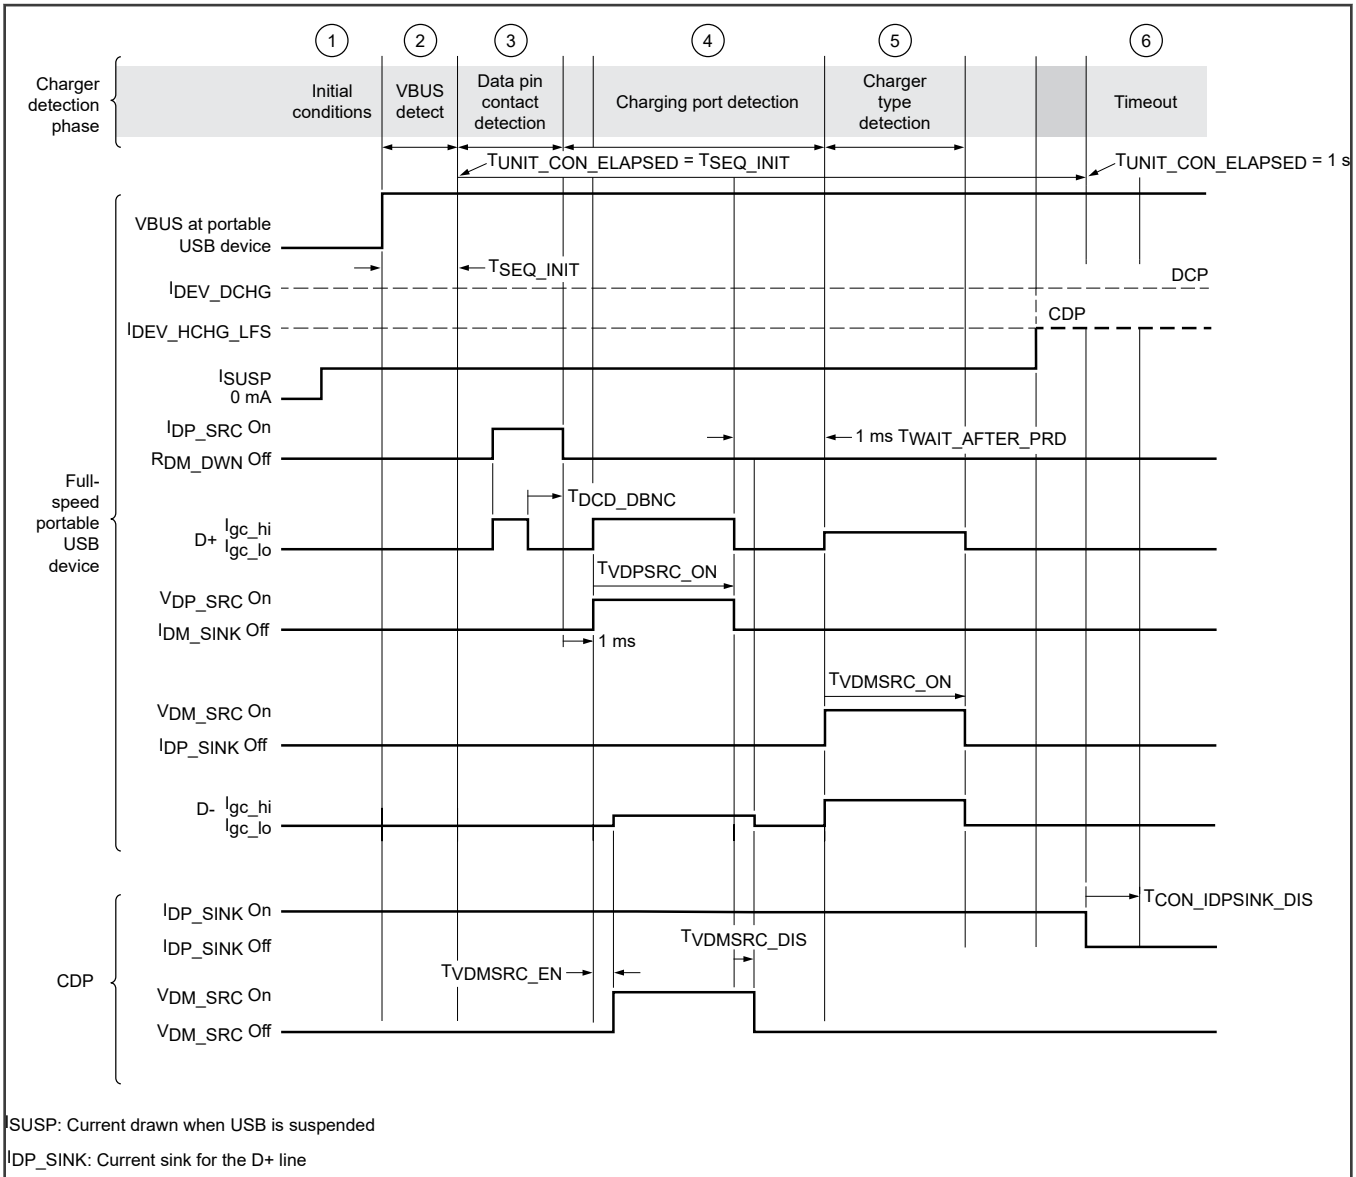

Figure 183. FS charger detection timing for BC1.2

Timing parameter values used in this module for BC1.2 are listed in the following table.

Table 514. Timing parameters for the charger detection sequence for BC1.2

Parameter	USB Battery Charging Spec	Module default	Module programmable range
T_{DCD_DBNC} [1]	10 ms min (no max)	10 ms	0– 1023 ms
T_{VDPSRC_ON} [1]	40 ms min (no max)	40 ms	0 –1023 ms
$T_{WAIT_AFTER_PRD}$	N/A	1 ms	0– 1023 ms
T_{VDMSRC_ON}	40 ms	40 ms	0 –1023 ms

Table continues on the next page...

Table 514. Timing parameters for the charger detection sequence for BC1.2 (continued)

Parameter	USB Battery Charging Spec	Module default	Module programmable range
T_{SEQ_INIT}	N/A	16 ms	0 –1023 ms
T_{UNIT_CON} [1]	1 s	N/A	N/A
T_{VDMSRC_EN} [1]	1– 20 ms	From the USB host	N/A
T_{VDMSRC_DIS} [1]	0 – 20 ms	From the USB host	N/A
$T_{CON_IDPSINK_DIS}$ [1]	0 – 10 ms	From the USB host	N/A

1. This parameter is defined by the *USB Battery Charging Specification, Rev. 1.2*.

The following figure illustrates the charger detection sequence in a simplified timing diagram based on the *USB Battery Charging Specification, Rev. 1.1*.

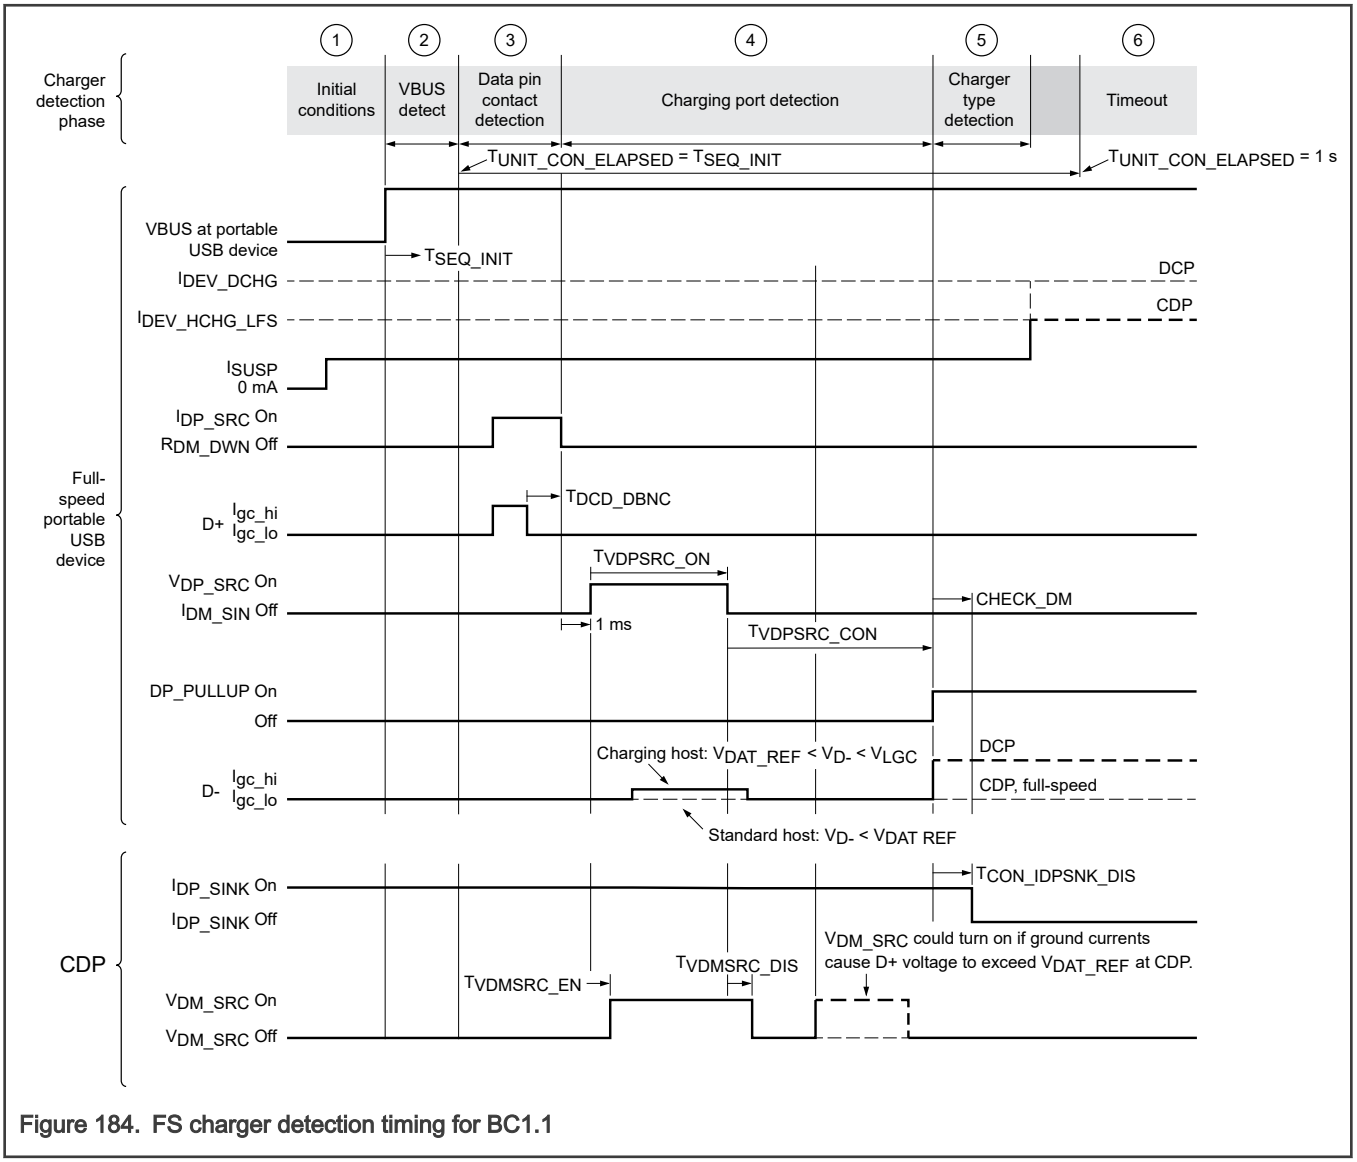

Figure 184. FS charger detection timing for BC1.1

Timing parameter values used in this module for BC1.1 are listed in the following table.

Table 515. Timing parameters for the charger detection sequence for BC1.1

Parameter	USB Battery Charging Spec	Module default	Module programmable range
T_{DCD_DBNC} [1]	10 ms min (no max)	10 ms	0– 1023 ms
T_{VDPSRC_ON} [1]	40 ms min (no max)	40 ms	0 –1023 ms
T_{VDPSRC_CON} [1]	40 ms min (no max)	40 ms	0 –1023 ms
CHECK_DM	N/A	1 ms	0– 15 ms
T_{SEQ_INIT}	N/A	16 ms	0 –1023 ms
T_{UNIT_CON} [1]	1 s	N/A	N/A
T_{VDMSRC_EN} [1]	1– 20 ms	From the USB host	N/A
T_{VDMSRC_DIS} [1]	0 –20 ms	From the USB host	N/A
$T_{CON_IDPSINK_DIS}$ [1]	0– 20 ms	From the USB host	N/A

1. This parameter is defined by the *USB Battery Charging Specification, Rev. 1.1*.

The following table provides an overview description of the charger detection sequence shown in the preceding figure.

Table 516. Overview of the charger detection sequence

Phase		Overview description	Full description
1	Initial conditions	Initial system conditions that need to be met before the detection sequence is initiated.	Initial system conditions
2	VBUS detection	System software detects contact of the VBUS signal with the system interrupt pin VBUS_detect.	VBUS contact detection
3	Data pin contact detection	The USBDCD module detects that the USB data pins D+ and D– have made contact with the USB port.	Data pin contact detection
4	Charging port detection	The USBDCD module detects if the port is an SDP or either type of charging port, that is CDP or DCP.	Charging port detection
5	Charger type detection	The USBDCD module detects the type of charging port, if applicable.	Charger type detection
6	Sequence timeout	The USBDCD module did not finish the detection sequence within the timeout interval. The sequence will continue until halted by software.	Charger detection sequence timeout

53.3.2.1 Initial system conditions

The USBDCD module is intended for use with USB device applications using a rechargeable battery. The module does not have support for interfacing with ACA or ACA-Dock equipment as defined in the *USB Battery Charging Specification, Revision 1.2*. It cannot be used with USB applications that are embedded host or OTG.

In addition, before the USBDCD module's charger detection sequence can be initiated, the system must be:

- Powered-up and in run mode. The USBDCD instantiation of this module for the High-Speed port does not directly depend on the VBUS voltage and can operate as long as the avdd33 supply is in a valid range.
- Recently plugged into a USB port.
- Drawing not more than 2.5 mA total system current from the USB bus, except as allowed by the *USB 2.0 Connect Timing Update ECN*.

Examples of allowable precursors to this set of initial conditions include:

- A powered-down device is subsequently powered-up upon being plugged into the USB bus.
- A device in a low-power mode subsequently enters run mode upon being plugged into the USB bus.

53.3.2.2 VBUS contact detection

Once the device is plugged into a USB port, the VBUS_detect system interrupt is triggered. System software must do the following to initialize the module and start the charger detection sequence:

1. Restore power if the module is powered-off.
2. Set CONTROL[SR] to initiate a software reset.
3. Configure the USBDCD module by programming the CLOCK register and the timing parameters as needed.
4. Set CONTROL[IE] to enable interrupts, or clear CONTROL[IE] if the software polling method is used.
5. Program CONTROL[BC12] based on which revision of the USB Battery Charging Specification is needed.
6. Set CONTROL[START] to start the charger detection sequence.

53.3.2.3 Data pin contact detection

The module must ensure that the data pins have made contact because the detection sequence depends upon the state of the USB D+ and D- signals. USB plugs and receptacles are designed such that when the plug is inserted into the receptacle, the power pins make contact before the data pins make contact. See the following figure.

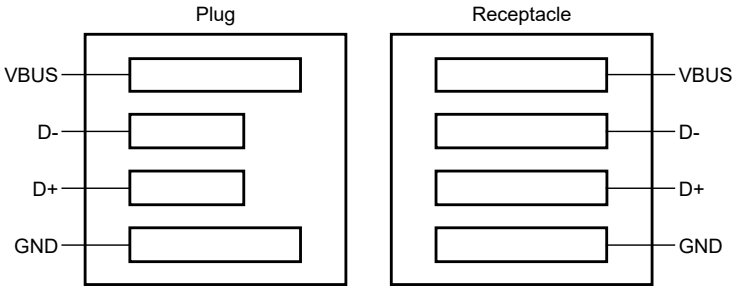

Figure 185. Relative pin positions in USB plugs and receptacles

As a result, when a portable USB device is attached to an upstream port, the portable USB device detects VBUS before the data pins have made contact. The time between power pins and data pins making contact depends on how fast the plug is inserted into the receptacle. Delays of several hundred milliseconds are possible.

53.3.2.3.1 Debouncing the data pin contact

When system software has initiated the charger detection sequence, as described in Initial system conditions, the USBDCD module turns on the I_{DP_SRC} current source and enables the R_{DM_DWN} pulldown resistor. If the data pins have not made contact, the D+ line remains high. After the data pins make contact, the D+ line goes low and debouncing begins.

After the D+ line goes low, the module continuously samples the D+ line over the duration of the T_{DCD_DBNC} debounce time interval. By default, T_{DCD_DBNC} is 10 ms, but it can be programmed in the TIMER0[TDCD_DBNC] field. See the description of TIMER0 for details.

When it has remained low for the entire interval, the debouncing is complete. However, if the D+ line returns high during the debounce interval, the module waits until the D+ line goes low again to restart the debouncing. This cycle repeats until either of the following happens:

- The data pin contact has been successfully debounced (see Success in detecting data pin contact (phase completion)).
- A timeout occurs (see Charger detection sequence timeout).

53.3.2.3.2 Success in detecting data pin contact (phase completion)

After successfully debouncing the D+ state, the module does the following:

- Updates the STATUS register to reflect phase completion (See Table 522 for field values.)
- Directly proceeds to the next step in the sequence: detection of a charging port (See Charging port detection.)

53.3.2.4 Charging port detection

After it detects that the data pins have made contact, the module waits for a fixed delay of 1 ms, and then attempts to detect whether it is plugged into a charging port. The module connects the following analog units to the USB D+ or D– lines during this phase:

- The voltage source V_{DP_SRC} connects to the D+ line
- The current sink I_{DM_SINK} connects to the D– line
- The voltage comparator connects to the USB D– line, comparing it to the voltage V_{DAT_REF}.

After a time of T_{VDPSRC_ON}, the module samples the D– line. The T_{VDPSRC_ON} parameter is programmable and defaults to 40 ms. After sampling the D– line, the module disconnects the voltage source, current sink, and comparator.

The next steps in the sequence depend on the voltage on the D– line as determined by the voltage comparator. See the following table.

Table 517. Sampling D– in the charging port detection phase

If the voltage on D- is...	Then...	See...
Below V_{DAT_REF}	The port is an SDP that does not support using charging currents above I_{CFG_MAX}.	SDP
Above V_{DAT_REF} but below V_{LGC}	The port is a charging port.	Charging port
Above V_{LGC}	This is an error condition.	Error in charging port detection

53.3.2.4.1 SDP

As part of the charger detection handshake with a standard USB host, the module does the following without waiting for the interval ($T_{WAIT_AFTER_PRD}$ or T_{VDPSRC_CON}) to elapse:

- Updates the STATUS register to reflect that an SDP is detected with SEQ_RES = 01b. See Table 522 for field values.
- Sets CONTROL[IF].

- Generates an interrupt if enabled in CONTROL[IE].

At this point, control is passed to system software via the interrupt. The rest of the sequence, which detects the type of charging port, is not applicable, so software must perform the following steps:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Set CONTROL[SR] to issue a software reset to the module.
4. Disable the module.
5. Communicate the appropriate charge rate to the external battery charger IC; see Table 511.

53.3.2.4.2 Charging port

As part of the charger detection handshake with any type of USB host, the module waits until the interval ($T_{WAIT_AFTER_PRD}$ or T_{VDPSRC_CON}) has elapsed before it does the following:

For *USB Battery Charging Specification, Rev. 1.2*:

- Enables V_{DM_SRC}.
- Updates the STATUS register to reflect that a charging port is detected with SEQ_RES = 10b. See Table 522 for field values.
- At this point the detection sequence progresses to Charger type detection without needing software interaction.

For *USB Battery Charging Specification, Rev. 1.1*:

- Updates the STATUS register to reflect that a charging port is detected with SEQ_RES = 10b. See Table 522 for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].
- At this point, control is passed to system software via the interrupt. Software must:
  1. Read the STATUS register.
  2. Set CONTROL[IACK] to acknowledge the interrupt.
  3. Issue a command to the USB controller to pullup the USB D+ line.
  4. Wait for the module to complete the final phase of the sequence. See Charger type detection.

53.3.2.4.3 Error in charging port detection

For this error condition, the module does the following:

- Updates the STATUS register to reflect the error with SEQ_RES = 00b. See Table 522 for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].

Note that in this case the module does not wait for the interval ($T_{WAIT_AFTER_PRD}$ or T_{VDPSRC_CON}) to elapse.

At this point, control has been passed to system software via the interrupt. The rest of the sequence (detecting the type of charging port) is not applicable, so software should:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Set CONTROL[SR] to issue a software reset to the module.
4. Disable the module.

53.3.2.5 Charger type detection

For *USB Battery Charging Specification, Rev. 1.2*:

After the USBDCD module enables the V_{DM_SRC}, the module starts the T_{VDMSRC_ON} timer counting down the time interval programmed into the TIMER2[T_{VDMSRC_ON}] field.

Once the T_{VDMSRC_ON} timer is elapsed, the module samples the USB D+ line to determine the type of charger. See the following table.

Table 518. Sampling D+ in the charger type detection phase (BC1.2)

If the voltage on D+ is...	Then...	See...
High (D+>V_{DAT_REF})	The port is a DCP. [1]	DCP
Low (D+<V_{DAT_REF})	The port is a CDP. [2]	CDP

1. In a DCP, the D+ and D– lines are shorted together through a small resistor.
2. In a CDP, the D+ and D– lines are not shorted.

For *USB Battery Charging Specification, Rev. 1.1*:

After software enables the D+ pullup resistor, the module is notified automatically (via internal signaling) to start the CHECK_DM timer counting down the time interval programmed in the TIMER2[CHECK_DM] field.

After the CHECK_DM time is elapsed, the module samples the USB D– line to determine the type of charger. See the following table.

Table 519. Sampling D– in the charger type detection phase (BC1.1)

If the voltage on D– is...	Then...	See...
High	The port is a DCP. [1]	DCP
Low	The port is a CDP. [2]	CDP

53.3.2.5.1 DCP

For a DCP, the module does the following:

- Updates the STATUS register to reflect that a dedicated charging port is detected with SEQ_RES = 11b. See Table 522 for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE] field.

The *USB Battery Charging Specification, Rev. 1.2* indicates that additionally if the detection sequence determines an attachment to a DCP, then the USB device should signal on the D+ pin by either enabling the D+ pullup resistor or enabling V_{DP_SRC}.

At this point, control has been passed to system software via the interrupt. Software should:

1. Read the STATUS register.
2. Disable the USB controller to prevent transitions on the USB D+ or D– lines from causing spurious interrupt or wakeup events to the system.
3. Set CONTROL[IACK] to acknowledge the interrupt.
4. Set CONTROL[SR] to issue a software reset to the module.
5. Disable the module.

6. Enable signaling on the D+ pin. This can be done by enabling the Transceiver D+ pullup resistor through configuration of the register fields in the USB controller instance for this USB port. For USBHSDCD instantiation of USBDCD, this signaling can alternatively be done by enabling V_{DP_SRC} through setting the SIGNAL_OVERRIDE[PS] field to a value of 010b.
7. Communicate the appropriate charge rate to the external battery charger IC; see Table 511.

53.3.2.5.2 CDP

For a CDP, the module does the following:

- Updates the STATUS register to reflect that a CDP is detected with SEQ_RES = 10b. See Table 522 for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].

At this point, control is passed to system software via the interrupt. Software should:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Set CONTROL[SR] to issue a software reset to the module.
4. Disable the module.
5. Communicate the appropriate charge rate to the external battery charger IC; see Table 511.

53.3.2.6 Charger detection sequence timeout

The maximum time allowed to connect according to the *USB Battery Charging Specification* is one second. If the Unit Connection Timer reaches the one second limit and the sequence is still running as indicated by the STATUS[ACTIVE] field, the module does the following:

- Updates the STATUS register to reflect that a timeout error has occurred. See Table 522 for field values.
- Sets CONTROL[IF].
- Generates an interrupt if enabled in CONTROL[IE].
- The detection sequence continues until explicitly halted by software setting CONTROL[SR].
- The Unit Connection Timer continues counting. See the description of TIMER0.

At this point, control is passed to the system software via the interrupt, which has two options: ignore the interrupt and allow more time for the sequence to complete, or halt the sequence. To halt the sequence, software must:

1. Read the STATUS register.
2. Set CONTROL[IACK] to acknowledge the interrupt.
3. Set CONTROL[SR] to issue a software reset to the module.
4. Disable the module.

This timeout function is also useful in case software does not realize that the USB device is unplugged from USB port during the charger detection sequence. If the interrupt occurs but the V_{BUS_DETECT} input is low, software can disable and reset the module.

System software might allow the sequence to run past the timeout interrupt under these conditions:

1. The USB Battery Charging Spec is amended to allow more time. In this case, software should poll TIMER0[$T_{UNITCON}$] periodically to track elapsed time after 1s; or
2. For debug purposes.

Note that the $T_{UNITCON}$ register field will stop incrementing when it reaches its maximum value so it will not roll over to zero and start counting up again.

53.3.2.7 Dead Battery Provision signaling

If the system needs to operate under the Dead Battery Provision of the *USB Battery Charging Specification, Revision 1.2*, the USBDCD module must be configured to signal V_{DP_SRC} on the USB_DP pin.

For information on Dead Battery Provision conditions and signaling, see the Dead or weak battery later in this chapter.

53.3.3 Clocking

The following table describes the clock sources for the USBDCD module. Refer to the chip's clocking chapter for clock setting, configuration, and gating information.

Note these clocks share same name with the USB PHY.

Table 520. USBDCD clocks

Clock name	Description
MODULE_CLK	Peripheral clock
MODULE_CLK_S	Peripheral access clock

53.3.4 Resets

There are two ways to reset various register contents in this module: hardware resets and a software reset.

53.3.4.1 Hardware resets

Hardware resets originate at the system or device level and propagate down to the individual module level. They include start up reset, low-voltage reset, and all other hardware reset sources.

Hardware resets cause the register contents to be restored to their default state as listed in the register descriptions.

53.3.4.2 Software reset

A software reset re-initializes the module's status information, but leaves configuration information unchanged. The software reset allows software to prepare the module without needing to reprogram the same configuration each time the USB device is plugged into a USB port.

Setting CONTROL[SR] initiates a software reset. The following table shows all register fields that are reset to their default values by a software reset.

Table 521. Software reset and register fields affected

Register	Fields affected	Fields not affected
CONTROL[1]	IF	IE, START
STATUS	All	None
CLOCK	None	All
TIMER*n*	TUNITCON	All other

1. CONTROL[SR] and CONTROL[IACK] are self-clearing.

A software reset also returns all internal logic, timers, and counters to their reset states. If the module is already active (STATUS[ACTIVE] = 1b), a software reset stops the sequence.

NOTE

Software must always initiate a software reset before starting the sequence to ensure the module is in a known state.

53.3.5 Interrupts

The USBDCD module has an interrupt to alert system software of certain events, which are listed in the following table. All events except the Phase Complete event for the Data Pin Detection phase can trigger an interrupt.

Table 522. Events triggering an interrupt by sequence phase

Sequence phase	Event	Event description	STATUS fields [1]	Phase description
Data Pin Detection	Phase Complete	The module has detected data pin contact. *No interrupt occurs*: CONTROL[IF] = 0b.	ERR = 0b SEQ_STAT = 01b SEQ_RES = 00b TO = 0b	VBUS contact detection
Charging Port Detection	Phase Complete	The module has completed the process of identifying if the USB port is a charging port or not. **NOTE:** An interrupt is triggered at completion of this phase for BC 1.1 operation whether an SDP or a Charging port is detected. For BC 1.2 operation, if an SDP is detected an interrupt is triggered but if a Charging port is detected the sequence goes directly to the Charger Type Detection phase.	ERR = 0b SEQ_STAT = 10b SEQ_RES = 01b or 10b TO = 0b	Charging port detection
	Error	The module cannot identify the type of port because the D– line is above the USB's VLGC threshold.	ERR = 1b SEQ_STAT = 10b SEQ_RES = 00b TO = 0b	Error in charging port detection
Charger Type Detection	Phase Complete	The module has completed the process of identifying the charger type detection. **NOTE:** The ERR flag always reads zero because no known error conditions are checked during this phase.	ERR = 0b SEQ_STAT = 11b SEQ_RES = 11b or 10b TO = 0b	Charger type detection
Sequence Timeout	Error	The timeout interval from the time the USB device attaches to a USB port until it connects has elapsed.	ERR = 1b SEQ_STAT = last value [2] SEQ_RES = last value [2] TO = 1b	Charger detection sequence timeout

1. See the description of the Status register for register information.
2. The SEQ_STAT and SEQ_RES fields retain the values held at the time of the timeout error.

53.3.5.1 Interrupt handling

Software reads which event caused the interrupt from the STATUS register during the interrupt service routine.

An interrupt is generated only if CONTROL[IE] is set. The CONTROL[IF] field is always set under interrupt conditions, even if CONTROL[IE] is cleared. In this case, software can poll CONTROL[IF] to determine if an interrupt condition is pending.

Writes to CONTROL[IF] are ignored. To reset CONTROL[IF], set CONTROL[IACK] to acknowledge the interrupt. Writing to CONTROL[IACK] when CONTROL[IF] is cleared has no effect.

53.4 External signals

This section describes the module signals. The following table shows a summary of module signals that interface with the pins of the device.

Table 523. Signal descriptions

Signal	Description	I/O
USB_DM	USB D– analog data signal. The analog block interfaces directly to the D– signal on the USB bus.	I/O
USB_DP	USB D+ analog data signal. The analog block interfaces directly to the D+ signal on the USB bus.	I/O
avdd33 [1]	3.3 V regulated analog supply	POWER
vss_bulk	Digital/Analog ground	POWER
dvdd	Core voltage digital supply	POWER

1. Voltage must be 3.3 V ± 10% for full functionality of the module. That is, the charger detection function does not work when this voltage is below 3.0 V, and the CONTROL[START] field should not be set.

NOTE

The transceiver module also interfaces to the USB_DM and USB_DP signals. Both modules and the USB host/hub use these signals as bidirectional, tristate signals.

Information about the signal integrity aspects of the lines including shielding, isolated return paths, input or output impedance, packaging, suggested external components, ESD, and other protections can be found in the USB 2.0 Specification and in Application information.

53.5 Initialization

This module is designed for minimal configuration while retaining significant programmability. To initialize USBDCD:

1. Initialize the CLOCK register to the actual system clock frequency, unless the default value already matches the system requirements.
2. Reset ANACTRL[DEV_PULLDOWN] to 0b when this module is in use for the proper operation of the USBHSDCD instantiation of USBDCD.

   For more information, see the "USB PHY Analog Control Register (ANACTRL)" section of the "Universal Serial Bus 2.0 Integrated PHY (USB-PHY)" chapter.
3. Do not modify other registers, as they default to the values that comply with the USB Battery Charging Specification.
4. Configure timing parameters to obtain flexibility as per the requirements of a specific system.

All module configuration must occur *before* initiating the charger detection sequence. Configuration changes made *after* setting CONTROL[START] result in undefined behavior.

53.6 Application information

This section provides application information.

53.6.1 External pullups

Any external pullups applied to the USB D+ or D- data lines must be capable of being disabled to prevent incorrect pullup values or incorrect operation of the USB subsystem.

53.6.2 Dead or weak battery

According to the *USB Battery Charging Specification, Revision 1.2*, a USB device with a dead or weak battery that is attached to an SDP can draw charging current from VBUS without connecting for several minutes, until the battery is charged to the point that the USB device can connect. The conditions for this operation are referred to as the Dead Battery Provision.

The *USB Battery Charging Specification, Revision 1.2* limits this charging condition to 100 mA for a duration of 45 minutes. The later *USB 2.0 Connect Timing Update ECN* modifies this charging condition to 500 mA for a duration of 2 minutes. Customers designing systems to take advantage of the Dead Battery Provision should study both specifications closely.

The USBDCD module is compatible with systems that do not check the strength of the battery. Therefore, this module assumes that the battery is good, so the USB device must immediately connect to the USB bus by pulling the USB_DP pin high after the USBDCD module has determined that the device is attached to an SDP or CDP. (By definition, a DCP does not support connection but still requires a signaling event, see DCP.)

The module is also compatible with systems that have other circuitry to check the strength of the battery. In these systems, if it is known that the battery is weak or dead, software can delay connecting to the USB while charging using the Dead Battery Provision. Once the battery is charged to the good battery threshold, software must then connect to the USB host by pulling the USB_DP pin high.

While using the Dead Battery Provision, the USB_DP pin must signal by enabling V_{DP_SRC}. On this product that signaling can be done most simply by setting the SIGNAL_OVERRIDE[PS] field to value 10b.

53.6.3 Handling unplug events

If the device is unplugged from the USB bus during the charger detection sequence, the contents of the STATUS register must be ignored and the USBDCD module must get a Software Reset, as described in Software reset.

53.7 USBDCD register descriptions

53.7.1 USBDCD memory map

USBDCD base address: 4041_4800h

Offset	Register	Width (In bits)	Access	Reset value
0h	Control (CONTROL)	32	RW	0001_0000h
4h	Clock (CLOCK)	32	RW	0000_00C1h
8h	Status (STATUS)	32	R	0000_0000h
Ch	Signal Override (SIGNAL_OVERRIDE)	32	RW	0000_0000h
10h	TIMER0 (TIMER0)	32	RW	0010_0000h
14h	TIMER1 (TIMER1)	32	RW	000A_0028h

Table continues on the next page...

Table continued from the previous page...

Offset	Register	Width (In bits)	Access	Reset value
18h	TIMER2_BC11 (TIMER2_BC11)	32	RW	0028_0001h
18h	TIMER2_BC12 (TIMER2_BC12)	32	RW	0001_0028h

53.7.2 Control (CONTROL)

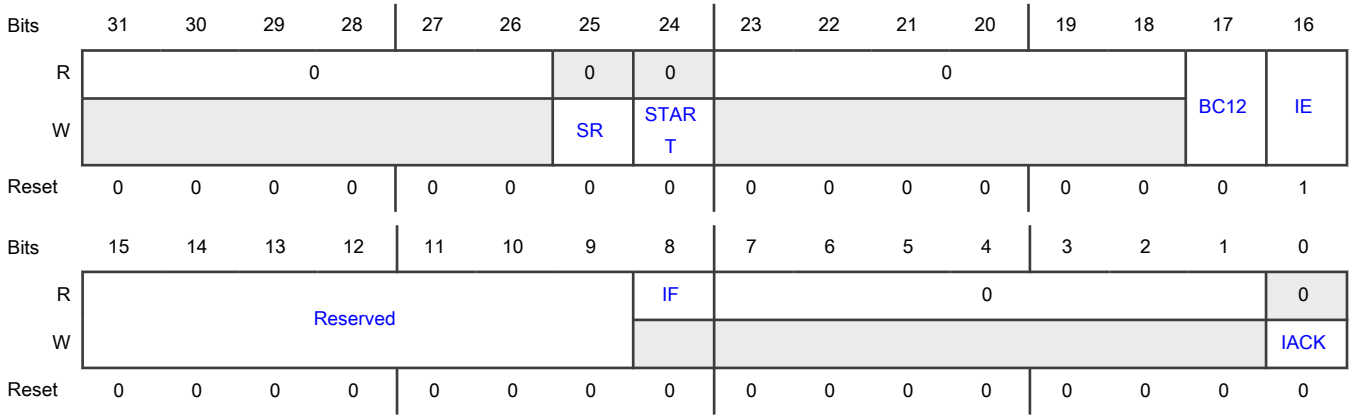
Offset

Register	Offset
CONTROL	0h

Function

Controls various global functions, such as software reset, initiating the charger detection sequence, BC12 compatibility, and interrupt enablement.

Diagram



Fields

Field	Function
31-26 —	Reserved
25 SR	Software Reset Determines whether a software reset is performed. 0b - Do not perform a software reset. 1b - Perform a software reset.

Table continues on the next page...

Table continued from the previous page...

Field	Function
24 START	Start Change Detection Sequence Determines whether the charger detection sequence is initiated. 0b - Do not start the sequence. Writes of this value have no effect. 1b - Initiate the charger detection sequence. If the sequence is already running, writes of this value have no effect.
23-18 —	Reserved
17 BC12	Battery Charging Revision 1.2 Compatibility BC1.2 compatibility. This field cannot be changed after start detection. 0b - Compatible with BC1.1 (default) 1b - Compatible with BC1.2
16 IE	Interrupt Enable Enables/disables interrupts to the system. 0b - Disable interrupts to the system. 1b - Enable interrupts to the system.
15-9 —	Reserved
8 IF	Interrupt Flag Determines whether an interrupt is pending. 0b - No interrupt is pending. 1b - An interrupt is pending.
7-1 —	Reserved
0 IACK	Interrupt Acknowledge Determines whether the interrupt is cleared. 0b - Do not clear the interrupt. 1b - Clear the IF field (interrupt flag).

53.7.3 Clock (CLOCK)

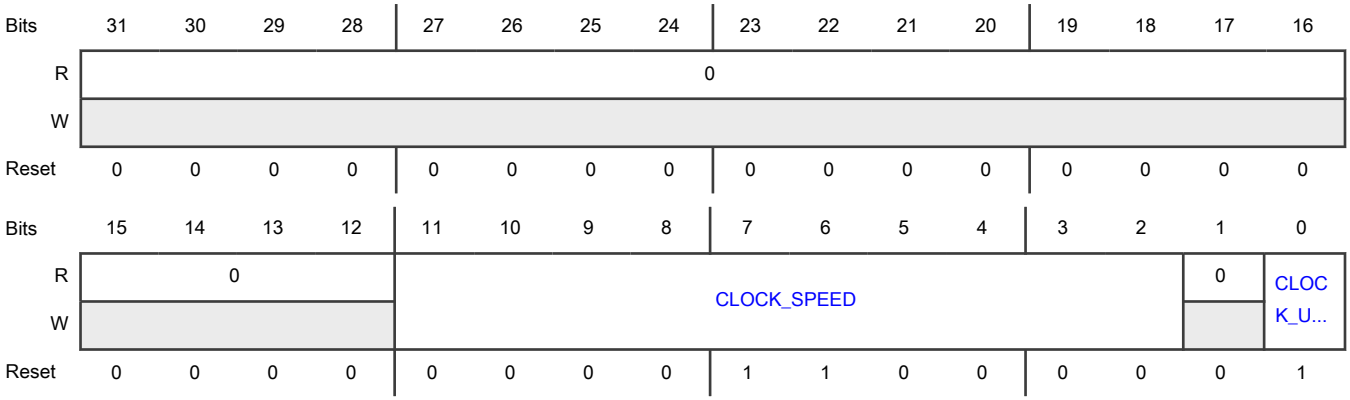
Offset

Register	Offset
CLOCK	4h

Function

Controls the clock speed.

Diagram



Fields

Field	Function
31-12 —	Reserved
11-2 CLOCK_SPEED	Numerical Value of Clock Speed in Binary The unit of measure is programmed in CLOCK_UNIT. The valid range is from 1 to 1023 when the clock unit is MHz and 4 to 1023 when the clock unit is kHz. Examples with CLOCK_UNIT = 1b: • For 48 MHz: 00110000b (48) • For 24 MHz: 00011000b (24) Examples with CLOCK_UNIT = 0b: • For 100 kHz: 01100100b (100) • For 500 kHz: 000111110100b (500)
1 —	Reserved
0	Unit of Measurement Encoding for Clock Speed

Table continues on the next page...

Table continued from the previous page...

Field	Function
CLOCK_UNIT	Specifies the unit of measure for the clock speed. 0b - kHz Speed (between 4 kHz and 1023 kHz) 1b - MHz Speed (between 1 MHz and 1023 MHz)

53.7.4 Status (STATUS)

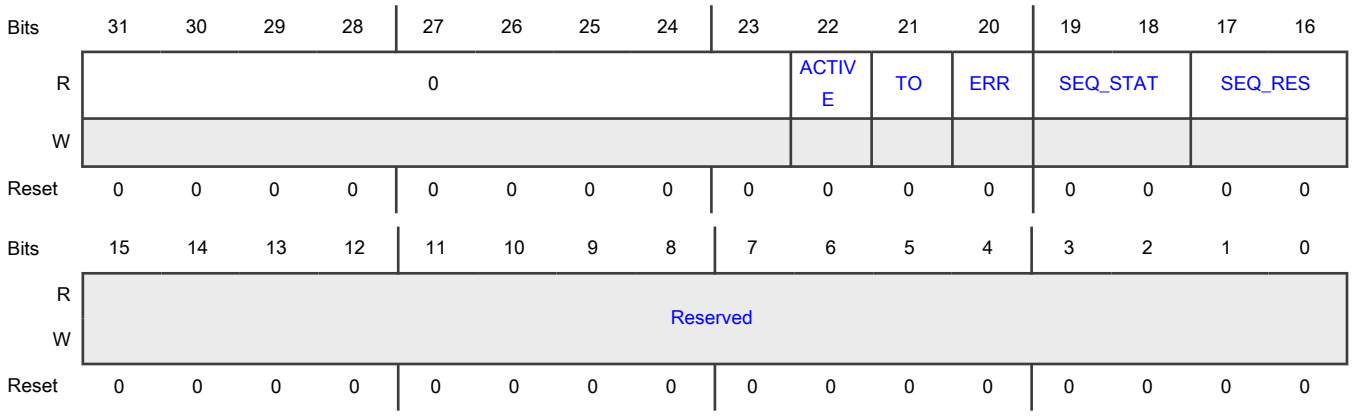
Offset

Register	Offset
STATUS	8h

Function

Stores the current state of the module for system software monitoring.

Diagram



Fields

Field	Function
31-23 —	Reserved
22 ACTIVE	Active Status Indicator Indicates whether the sequence is running. 0b - The sequence is not running. 1b - The sequence is running.
21	Timeout Flag

Table continues on the next page...

Table continued from the previous page...

Field	Function
TO	Indicates whether the detection sequence is passed the timeout threshold. 0b - The detection sequence is not running for over 1 s. 1b - It is over 1 s since the data pin contact was detected and debounced.
20 ERR	Error Flag Indicates whether there is an error in the detection sequence. 0b - No sequence errors. 1b - Error in the detection sequence. See STATUS[SEQ_STAT]to determine the phase in which the error occurred.
19-18 SEQ_STAT	Charger Detection Sequence Status Indicates the status of the charger detection sequence. 00b - The module is either not enabled, or the module is enabled but the data pins have not yet been detected. 01b - Data pin contact detection is complete. 10b - Charging port detection is complete. 11b - Charger type detection is complete.
17-16 SEQ_RES	Charger Detection Sequence Results Reports how the charger detection is attached. 00b - No results to report. 01b - Attached to an SDP. Must comply with USB 2.0 by drawing only 2.5 mA (max) until connected. 10b - Attached to a charging port. The exact meaning depends on the STATUS[SEQ_STAT] field (value 0: Attached to either a CDP or a DCP. The charger type detection has not completed. value 1: Attached to a CDP. The charger type detection has completed.) 11b - Attached to a DCP.
15-0 —	Reserved **NOTE** Fields do not always read as 0.

53.7.5 Signal Override (SIGNAL_OVERRIDE)

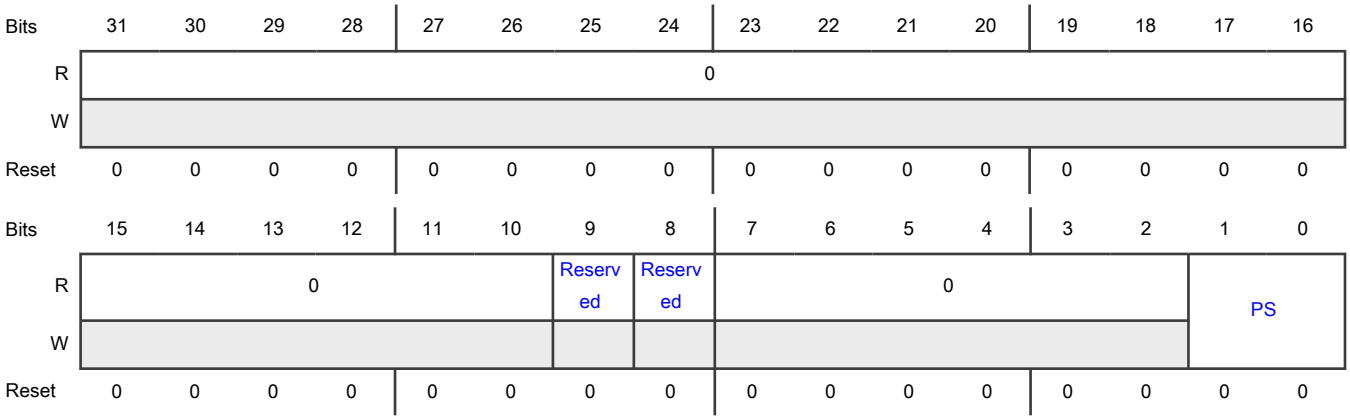
Offset

Register	Offset
SIGNAL_OVERRIDE	Ch

Function

Provides a way for the customer to enable signaling required by the USB BC Rev. 1.2 Specification after the battery charger detection sequences is completed.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 —	Reserved Reserved, not for customer use. The value of this field may change during module operation.
8 —	Reserved Reserved, not for customer use. The value of this field may change during module operation.
7-2 —	Reserved
1-0 PS	Phase Selection Enables specified voltage and current source circuits on the USB_DP and USB_DM pins. Use of the override value below enables the charger detection bias circuits without needing to set CONTROL[START]. Customers may set this field to 10b for required signaling if attached to a Dedicated Charging Port, or during operation under the Dead Battery Provision. 00b - No overrides. Field must remain at this value during normal USB data communication to prevent unexpected conditions on USB_DP and USB_DM pins. (Default) 01b - Reserved, not for customer use. 10b - Enables VDP_SRC voltage source for the USB_DP pin and IDM_SINK current source for the USB_DM pin. 11b - Reserved, not for customer use.

53.7.6 TIMER0 (TIMER0)

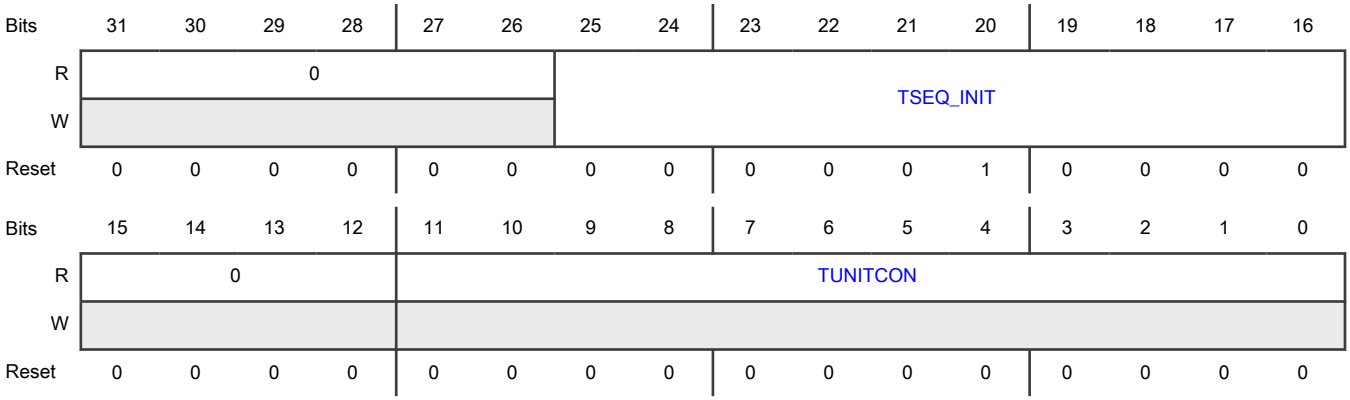
Offset

Register	Offset
TIMER0	10h

Function

Represents the system latency in ms using the TSEQ_INIT field.

Diagram



Fields

Field	Function
31-26 —	Reserved
25-16 TSEQ_INIT	Sequence Initiation Time TSEQ_INIT represents the system latency (in ms) measured from the time VBUS goes active to the time system software initiates the charger detection sequence in the USBDCD module. When software sets CONTROL[START], the Unit Connection Timer (TUNITCON) is initialized with the value of TSEQ_INIT. Valid values are 0-1023, but the USB Battery Charging Specification requires the entire sequence, including TSEQ_INIT, to be completed in 1 s or less. 00_0000_0000b-11_1111_1111b - 0 ms - 1023 ms
15-12 —	Reserved
11-0 TUNITCON	Unit Connection Timer Elapse (in ms) Displays the amount of elapsed time since the event of setting CONTROL[START] plus the value of TSEQ_INIT. The timer is automatically initialized with the value of TSEQ_INIT before starting to count.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	This timer enables compliance with the maximum time allowed to connect T_{UNIT_CON} under the USB Battery Charging Specification. If the timer reaches the one second limit, the module triggers an interrupt and sets the error flag STATUS[ERR]. The timer continues counting throughout the charger detection sequence, even when control has been passed to software. As long as the module is active, the timer continues to count until it reaches the maximum value of FFFh (4095 ms). The timer does not roll over to zero. A software reset clears the timer.

53.7.7 TIMER1 (TIMER1)

Offset

Register	Offset
TIMER1	14h

Function

Contains timing parameters.

NOTE

Register values can be written that are not compliant with the USB Battery Charging Specification, so care should be taken when overwriting the default values.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

31-26 —	Reserved
25-16	Time Period to Debounce D+ Signal

Table continues on the next page...

Table continued from the previous page...

Field	Function
TDCD_DBNC	Sets the time period (ms) to debounce the D+ signal during the data pin contact detection phase. See Debouncing the data pin contact. Valid values are 1-1023, but the USB Battery Charging Specification requires a minimum value of 10 ms. 00_0000_0001b-11_1111_1111b - 1 ms - 1023 ms
15-10 —	Reserved
9-0 TVDPSRC_ON	Time Period Comparator Enabled This timing parameter is used after detection of the data pin. See Charging port detection. Valid values are 1-1023, but the USB Battery Charging Specification requires a minimum value of 40 ms. 00_0000_0001b-11_1111_1111b - 1 ms - 1023 ms

53.7.8 TIMER2_BC11 (TIMER2_BC11)

Offset

Register	Offset
TIMER2_BC11	18h

Function

TIMER2_BC11 contains timing parameters for *USB Battery Charging Specification, Rev 1.1.*

NOTE

Register values can be written that are not compliant with the USB Battery Charging Specification, so care should be taken when overwriting the default values.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

54.1.1 Module instances

This device has one instance of the MIPI_DSI_HOST module.

Table 525. MIPI_DSI_HOST instance

	MIPI_DSI_HOST
Located in	VDD2_MEDIA
Access	CPU0, CPU1, HiFi4, EZH-V, eDMA0, eDMA1, eDMA2, eDMA3

54.1.2 Reset and initialization

NOTE

Initialize the LCDIF module before the MIPI_DSI_HOST module.

Chip-specific Reset and Initialization procedure for the MIPI_DSI_HOST:

- Deassert all resets through RSTCTL3_PRSTCTL0[MIPIDSI].
- Setup MIPI_DSI_HOST related clocks through chip-specific registers provided for this purpose.
- Setup MIPI DSI application by programming all DSI Host Controller and DSI DPHY required parameters (refer to MIPI_DSI_HOST Memory Map/Register for details).

MIPI_DSI_HOST is ready for use.

54.2 Overview

MIPI_DSI_HOST controller is a flexible, high-performance, and easy-to-use digital core that implements all protocol functions defined in the MIPI_DSI_HOST Specification. The MIPI_DSI_HOST controller provides an interface that allows communication with MIPI_DSI_HOST-compliant peripherals.

The MIPI_DSI_HOST D-PHY is a high frequency, low power, low-cost, source-synchronous, physical layer supporting the MIPI Alliance standard for D-PHY.

NOTE

MIPI_DSI_HOST in this chip does not have an embedded PLL, hence disregard any PLL related contents in this chapter.

54.2.1 Features

Key features of the MIPI_DSI_HOST Controller Core include:

- Implements all three DSI Layers (Pixel to Byte packing, Low Level Protocol, Lane Management)
- Support for Command and Video Modes
- Host Version
- Scalable data lane support, 1 to 2 Data Lanes
  - Optional bidirectional support on lane 0
- Supports High Speed and Low Power operation
- Support for all DSI data types and formats
- Virtual Channel support
- Supports ULPS mode
- Full Low-Level Protocol Error and Contention detection and reporting
- Supports continuous and non-continuous Clock Lane operation
- Supports multiple packets per transmission
- Support for all three Video Mode packet sequences
  - Non-Burst Mode with Sync Pulses
  - Non-Burst Mode with Sync Events
  - Burst mode
- Support for bus turnaround signaling
- Flexible packet based user interface
  - APB interface option (status and control)
  - Display Pixel Interface Core (DPI-2) option
  - Display Bus Interface Core (DBI-2) option
- Supports PHY Protocol Interface (PPI) compatible MIPI D-PHYs
- MIPI Alliance Specification for Display Serial Interface Version 1.1 compliant

The following are the key features of the MIPI_DSI_HOST D-PHY:

- 1 Clock lane
- 2 data lanes
- Supports MIPI Standard for D-PHY

- Supports both high speed and low power modes
- High Speed Serializers and Deserializers

54.3 DSI Host Controller Core

The figure below illustrates the DSI Host Controller Core structure. The DSI Host Controller Core operates on the host (transmit) side of a DSI link.

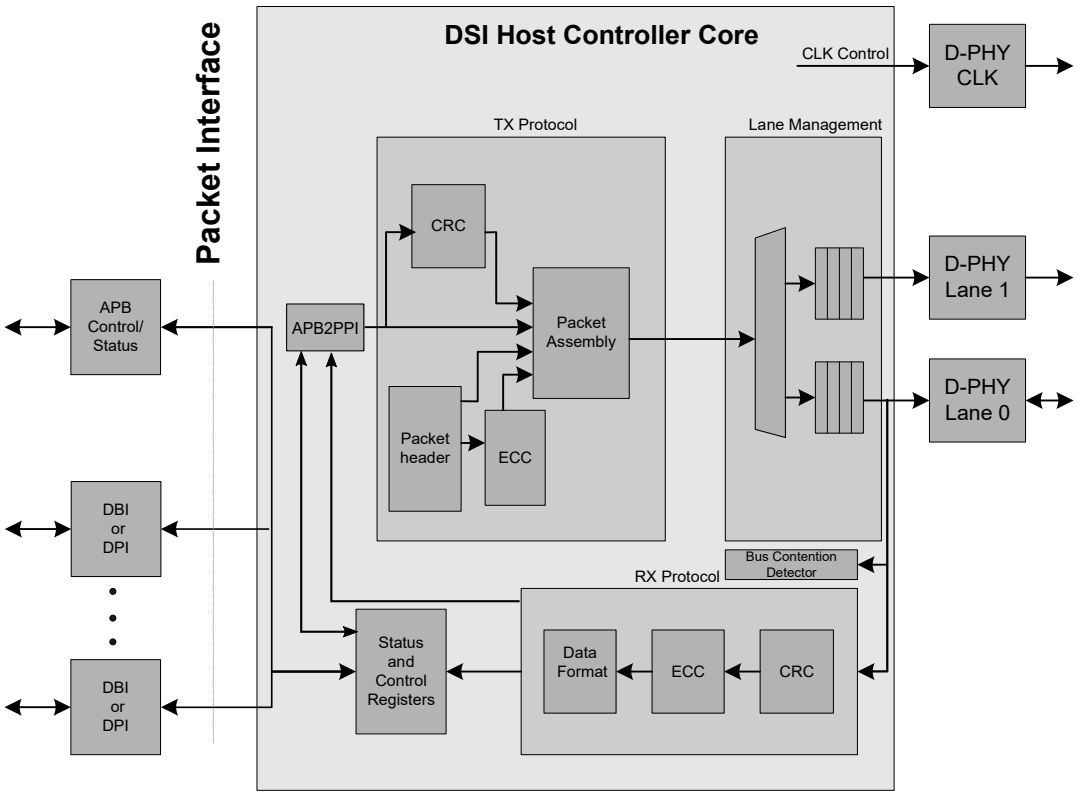

Figure 186. DSI Host Controller Core Block Diagram

The DSI Host Controller Core implements all three layers defined by the DSI Specification: Pixel to Byte Packing in the Application layer, Low Level Protocol, and Lane Management. The DSI Host Controller Core sends and receives DSI commands via the Packet Interface. The Packet Interface can be connected to a DBI/DPI translator or to an APB to PPI gasket.

The D-PHY interface of the DSI Host Controller Core supports up to four PHY Protocol Interface (PPI) compatible MIPI D-PHYs.

The Packet Interface is an easy-to-use data interface that accepts commands and data, and sends it over the DSI link. It supports 1 to 4 virtual channels, and the use of 1-2 D-PHY lanes. The DSI Host Controller Core takes care of all packet formatting details and transmission over the MIPI bus.

The DBI/DPI Translator connects to the DSI Host Controller Core via the Packet Interface. DBI/DPI controllers may connect directly to the DBI/DPI Translator to send commands across the DSI link.

Sending commands and receiving information through the DSI link is also possible through the APB to PPI gasket. See MIPI_DSI_HOST APB PKT IF Memory Map/Register section for details about the DSI registers which allow the APB to PPI setup and communication.

54.3.1 D-PHY Interface

The DSI Host Controller Core D-PHY Interface connects directly to MIPI PPI compliant D-PHYs. The DSI Host Controller Core uses this interface to transmit data, send Escape sequences, receive and transmit triggers, and detect and report D-PHY error conditions.

54.3.1.1 High-Speed Transmit Interface

The High-Speed Transmit interface is used to transmit High-Speed data across the MIPI interface. All signals are synchronous to the PPI TX byte clock, TxByteClkHS, and are PPI compliant.

54.3.1.2 Escape Mode Transmit Interface

The DSI Host Controller Core uses the Escape Mode Transmit Interface to generate Escape sequences on the MIPI Interface via the D-PHY. Escape sequences are used to change the DPHY transmit mode, go into low-power mode, or initiate a bus turnaround. The Controller generates Escape sequence requests when necessary to implement the DSI protocol. These signals are synchronous to the clk_esc.

54.3.2 Packet Interface

The DSI Host Controller Core Packet Interface consists of Transmit, Receive, and Control and Status sections. Through these interfaces, the user application can take complete control of the DSI interface, sending all video timing, sending DSI commands, receiving DSI reads, monitoring the status of the interface and responding to error reporting.

User application may have access to DSI Host Controller Core Packet Interface through DSI_HOST_APB_PKT_IF registers, DSI_HOST_TX_PAYLOAD and DSI_HOST_PKT_CONTROL. For details refer to the section MIPI DSI Host register descriptions

54.3.2.1 Transmit Ports

The Transmit Packet Interface is the mechanism with which the user creates packets to send over the MIPI Interface.

For Long Packets, the user provides the Virtual Channel (VC) number, Data Type (DT), and Word Count (WC) to the controller. The Controller then creates a packet header and pulls the packet data from the Packet Interface and out to the D-PHY to transmit.

For Short Packets, the user provides the Virtual Channel (VC) number, Data Type (DT), and required parameters (if any) to the controller. The Controller then creates the short packet and sends it to the D-PHY to transmit. This interface enables the user application to transmit and receive any type of DSI packet.

The Packet Interface Transmit Interface ports are listed in the table below. Signals are synchronous to the Tx Byte clock.

NOTE

Only a subset of the Packet Interface Signals are accessible by user application through DSI_HOST_APB_PKT_IFx (DSI_HOST_TX_PAYLOAD and DSI_HOST_PKT_CONTROL) registers. For reset_byte_n and reset_esc_n signals, refer to chip-specific MIPI_DSI_HOST information. For tx_payload, tx_cmd_data_type, tx_cmd_vc, and tx_cmd_byte_count signals, refer to DSI_HOST_TX_PAYLOAD register.

Table 526. DSI Host Controller Core Transmit Packet Interface

PORT	TYPE	DESCRIPTION
clk_byte	Input	Byte clock input. The D-PHY PPI interface, the tx_cmd and tx_payload interfaces are synchronous to clk_byte. This clock can be independent and unrelated to clk_esc.
clk_esc	Input	The low-speed D-PHY Escape Mode clock, which becomes TxClkEsc on the D-PHY interface. This clock can be independent and unrelated to clk_byte.
reset_byte_n	Input	Asynchronous reset, active low. This reset applies to all logic in the clk_byte clock domain.
reset_esc_n	Input	Asynchronous reset, active low. This reset applies to all logic in the clk_esc clock domain.
tx_payload[31:0]	Input	Packet data input.

Table continues on the next page...

Table 526. DSI Host Controller Core Transmit Packet Interface (continued)

PORT	TYPE	DESCRIPTION
tx_payload_en	Output	Packet data read enable. This active high signal indicates that the controller requires a valid packet during the next clk_byte period.
tx_payload_en_last	Output	Last packet read enable, active high signals last cycle of tx_payload_en.
tx_cmd_data_type[5:0]	Input	Transmit packet DSI data type. It is written into the command buffer when tx_cmd_ack is asserted high.
tx_cmd_vc[1:0]	Input	Transmit packet command virtual channel. It is written into the command buffer when tx_cmd_ack is asserted high.
tx_cmd_byte_count[15:0]	Input	Transmit packet payload byte count. It is written into the command buffer when tx_cmd_ack is asserted high. For DSI Long packet types, tx_cmd_byte_count defines the number of bytes of packet data to pull from the tx_payload port. For DSI Short packets, the format of tx_cmd_byte_count contains any optional parameters. If the SDI Short packet type does not have any parameters, it is recommended to set tx_cmd_byte_count to all 0s.
tx_cmd_req	Input	Transmit packet command request. This active high signal informs the controller that the packet command is valid. The packet command consists of the ports tx_cmd_data_type, tx_cmd_vc, and tx_cmd_byte_count. The controller will assert tx_cmd_ack when it accepts the command, after which, the user should either update port values for the next transmit packet command or deassert tx_cmd_req.
tx_cmd_ack	Output	Transmit packet command request acknowledge. This active high signal indicates that the controller has accepted the TX packet request and the user logic should either submit a new request or deassert tx_cmd_req on the next rising edge of clk_byte.

54.3.2.2 Receive Ports

The Receive Packet Interface returns data from the Peripheral to the user. The user is provided the Virtual Channel (VC) number, Data Type (DT), Word Count (WC), and Rx Payload Data.

This interface enables the user application to receive any type of DSI packet. These signals are synchronous to the clk_byte clock. The Packet Interface Receive Interface ports are listed in the table below.

NOTE

Only a subset of the Packet Interface signals are accessible by user application through DSI_HOST_APB_PKT_IFx registers and DSI_HOST device registers:

- rx_payload
- rx_cmd_vc
- rx_cmd_data_type
- rx_cmd_byte_count
- ecc_one_bit_error
- ecc_two_bit_error
- ecc_one_bit_error_pos[4:0]
- crc_err

See DSI_HOST_APB_PKT_IFx and DSI_HOST device sections in MIPI DSI Host register descriptions for details.

Table 527. DSI Host Controller Core Receive Packet interface

PORT	TYPE	DESCRIPTION
rx_payload[31:0]	Output	Received packet data output. The Host Receive Packet Interface presents 4 bytes at a time. Bytes are valid in this interface according to the rx_cmd_byte_count signal, beginning with the lowest byte.
rx_payload_valid	Output	Packet data valid. This active high signal indicates that the controller is presenting valid packet during the next clk_byte period.
rx_payload_valid_last	Output	This data is the last of the packet, active high signals last cycle of rx_payload_valid.
rx_cmd_valid	Output	Packet header data is valid on the packet header ports below when this signal is asserted.
rx_cmd_vc[1:0]	Output	Packet virtual channel number, valid when rx_cmd_valid is asserted.
rx_cmd_data_type[5:0]	Output	Packet data type, valid when rx_cmd_valid is asserted. See the MIPI_DSI_HOST-2 specification for a definition of possible values.
rx_cmd_byte_count[15:0]	Output	Packet Word Count (byte count). Contains the number of bytes of data in the received packet. Valid when rx_cmd_valid is asserted.
ecc_one_bit_error	Output	Single bit error in the packet header was detected and corrected. Active high. Valid when rx_cmd_valid is high.
ecc_two_bit_error	Output	Two packet header bit errors were detected and not corrected, active high. Valid when rx_cmd_valid is high.
ecc_one_bit_error_pos[4: 0]	Output	Position of the corrected single bit error in the packet header. Valid when ecc_one_bit_error is high.
crc_err	Output	Asserts high when the CRC calculated on the received data does not reach the end of the packet.

54.3.3 Status Interface Ports

The Status Interface Core provides for reading the Status of the DSI Host Controller Core via a simple interface. All signals in the Status Interface are synchronous to the clk_byte clock. The Status Interface ports are listed in the table below.

NOTE

Only a subset of the Packet Interface signals are accessible by user application through DSI_HOST_APB_PKT_IFx registers and DSI_HOST device registers:

- status_out
- hs_tx_timeout
- lp_rx_timeout

Refer to DSI_HOST_APB_PKT_IFx and DSI_HOST device sections in MIPI DSI Host register descriptions for details.

Table 528. DSI Host Controller Status Interface Port

PORT	TYPE	DESCRIPTION
status_rd	Input	Initiates a read of the status register. Asserting this input high will result in the contents of the status register being presented on status_out[15:0] along with status_out_valid asserting high to indicate that status_out[15:0] contains a valid value.
status_addr[3:0]	Input	When status_rd is asserted, indicates which status register is to be returned. Address 0x0 is a valid address while 0x1-0xF are reserved.
status_out[31:0]	Output	Contains the contents of the addressed status register.
status_out_valid	Output	When asserted high, indicates that the data on status_out is valid.
tx_active	Output	tx_active asserts high when the Host Controller is actively transmitting data or when it has accepted a request from the user but has not yet started transmitting.
hs_tx_timeout	Output	Asserts high for one clk_byte period to indicate that a High Speed transmit has timed out.
lp_rx_timeout	Output	Asserts high for one clk_byte period to indicate that a Low Power RX occurred.

54.3.4 Control and Status Ports

The Control and Status Packet Interface allows the user to control and receive the status of the underlying link between the DSI Host and DSI Peripheral. It works on the same clk_byte clock as the Host Transmit Packet Interface. The Packet Interface Control and Status Interface ports are listed in the table below.

NOTE

Only a subset of the Packet Interface signals may be accessible by user application through DSI_HOST_APB_PKT_IFx registers and DSI_HOST device registers:

- dphy_direction
- tx_hs_mode
- dphy_turnaround

Please refer to DSI_HOST_APB_PKT_IFx and DSI_HOST device sections in MIPI DSI Host register descriptions for details.

Table 529. DSI Host Controller Core Control And Status Packet Interface

PORT	TYPE	DESCRIPTION
tx_hs_mode	Input	Switches the DPHY into High Speed Data Transfer mode or Low Power Data Transfer mode. 1'b1 = request HS mode 1'b0 = request LP mode. The Packet interface will not acknowledge packet commands or data while switching modes.
dphy_turnaround	Input	Requests bus turnaround. 1'b1 = Request reverse direction LP mode, from Host TX to Host RX. 1'b0 = No effect. This signal is ignored if the bus is already in Reverse (Host RX) direction.
dphy_direction	Output	Reports the current bus direction. 1'b1 = Bus is in Reverse direction (Host RX). 1'b0 = Bus is in Forward direction (Host TX).

54.3.5 Interface Cores

There are several interface cores for the DSI Host Controller Core. These interface cores provide industry standard interfaces to the DSI Host Controller Core to simplify interfacing and integration the DSI Host Controller Core to your application. When selected, these interface cores provide additional ports to the DSI Host Controller core.

54.3.5.1 DPI-2 Interface Host Bridge Core

The DPI-2 Interface Host Bridge Core provides a DPI-2 compliant interface to the DSI Host controller. The DPI-2 Interface Host Bridge Core handles converting the DPI-2 interface into a packet format that is compatible with the DSI Host Controller Core's Packet Interface, and that adheres to the DSI specification. The DPI-2 Interface Core handles all pixel-to-byte packing for all DPI data types.

The DSI Host Controller DPI-2 Interface Core provides the following features:

- Support for Type 2,3, and 4 displays
- Support for 16-, 18- and 24- bit Pixel data and all alignment configurations
- Support for 16, 18, 24, and 18 bit loosely packed DSI data types
- Supports DSI video modes
  - Non-Burst Mode with Sync Pulses
  - Non-Burst Mode with Sync Events
  - Burst Mode
- Supports normal or inverted HSYNC and VSYNC signals
- Handles clock domain crossing from DPI Pixel clock to the Host controller TX Byte clock
- Interfaces directly to the Host Controller's DSI Packet Interface
- Comes already integrated with the DSI Host Controller

A block diagram of the DPI-2 Interface Host Bridge Core is shown below. The DPI-2 Host Bridge Core accepts a MIPI compliant DPI-2 set of signals (vsync, hsync, pixel data), creates DSI packets for the video timing events and video data and transmits those packets via the DSI Host Controller's Packet Interface.

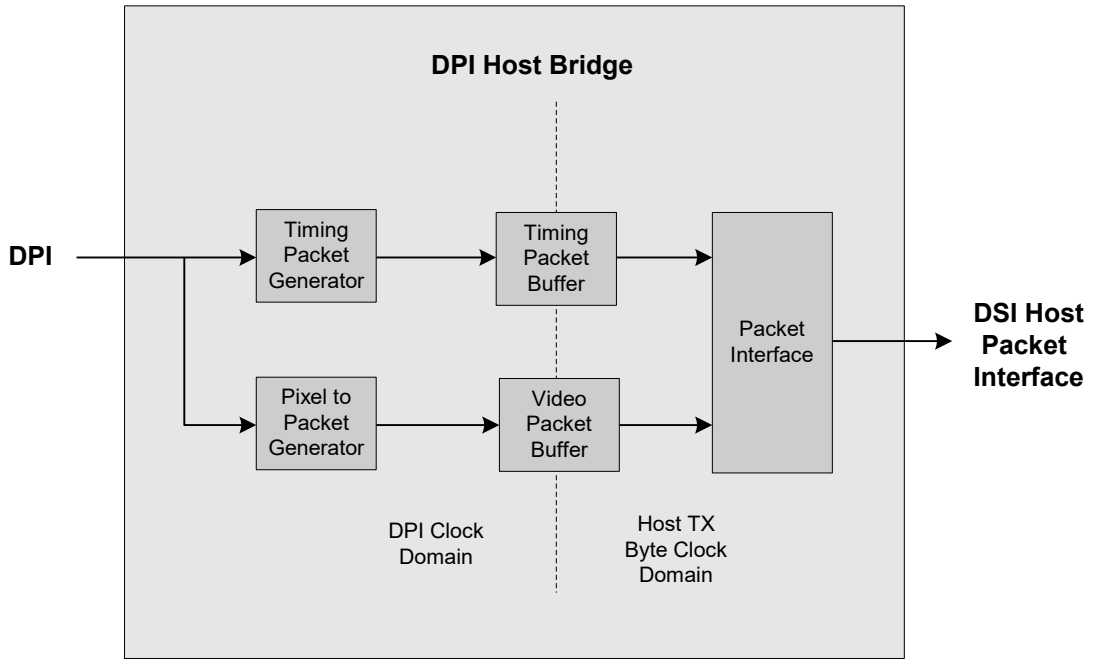

Figure 187. DPI-2 Host Bridge Core Block Diagram

54.3.5.1.1 DPI-2 Interface Ports

The DPI-2 Interface module provides a MIPI compliant DPI-2 interface to the DSI Host Controller Core. In addition to the standard DPI-2 interface signals (prefixed with a dpi_) there are several configuration and status ports that allow the user to adjust the behavior of the DPI-2 Interface module to better suit a particular application.

NOTE

The DPI configuration signals herein described are accessible to User Application through chip-specific registers (please refer to chip-specific MIPI-DSI information section for details) and DSI_HOST_DPI_INTFC device registers (please refer to MIPI_DSI_HOST Memory Map/Register section for details).

Table 530. DSI Host Controller Core Receive Packet interface

PORT	TYPE	DESCRIPTION
dpi_sd	Input	Shut Down – Control to shutdown display (type 4 only) 1'b1= Send shutdown command. 1'b0= No effect
dpi_cm	Input	Color Mode control. 1'b0== Normal Mode 1'b1== Low-color Mode
cfg_dpi_pixel_payload_size [15:0]	Input	Maximum number of pixels that should send as one DSI packet. Recommended to be evenly divisible by the line size (in pixels).
cfg_dpi_pixel_fifo_send_ level[15:0]	Input	In order to optimize DSI utility, the DPI bridge buffers a certain number of DPI pixels before initiating a DSI packet. This configuration port controls the level at which the DPI Host bridge begins sending pixels.

Table continues on the next page...

Table 530. DSI Host Controller Core Receive Packet interface (continued)

PORT	TYPE	DESCRIPTION
cfg_dpi_interface_color_coding[2:0]	Input	Sets the distribution of RGB bits within the 24-bit d bus, as specified by the DPI specification. 0= 16-bit Configuration 1 1= 16-bit Configuration 2 2= 16-bit Configuration 3 3= 18-bit Configuration 1 4= 18-bit Configuration 2 5= 24-bit
cfg_dpi_pixel_format[1:0]	Input	Sets the DSI packet type of the pixels. 0= 16-bit 1= 18-bit 2= 18-bit loosely packed, 3= 24-bit
dpi_host_underrun_err	Output	During DSI Host transmission of DPI data insufficient DPI data was received. This may indicate that DPI_CLK is too slow, or that the cfg_dpi_* parameters are incorrectly set.
cfg_dpi_vsync_polarity	Input	Sets polarity of dpi_vsync input, 0 – active low, 1 active high
cfg_dpi_hsync_polarity	Input	Sets Polarity of dpi_hsync input, 0 – active low, 1 – active high
cfg_host_dpi_video_mode[1:0]	Input	Select DSI video mode that the host DPI module should generate packets for. 2'b00 – Non-Burst mode with Sync Pulses 2'b01 – Non-Burst mode with Sync Events 2'b10 – Burst mode 2'b11 – Reserved, not valid
cfg_host_dpi_hfp[15:0]	Input	Sets the DSI packet payload size, in bytes, of the horizontal front porch blanking packet.
cfg_host_dpi_hbp[15:0]	Input	Sets the DSI packet payload size, in bytes, of the horizontal back porch blanking packet.
cfg_host_dpi_hsa[15:0]	Input	Sets the DSI packet payload size, in bytes, of the horizontal sync active packet.
cfg_enable_mult_packets	Input	Enable Multiple packets per video line. When enabled, cfg_dpi_pixel_payload_size must be set to exactly half the size of the video line. 0 – Video Line is sent in a single packet 1 – Video Line is sent in two packets
cfg_bllp_mode	Input	Optimize bllp periods to Low Power mode when possible 0 – blanking packets are sent during BLLP periods 1 – LP mode is used for BLLP periods

54.3.5.1.2 DPI-2 Video Timing Recreation over DSI

The DSI Host DPI-2 module is designed to preserve the receive video timing by properly spacing the DSI packets that carry the DPI video information and by inserting blanking packets into the packet stream. In order to achieve this goal, the DSI Host controller needs to have the cfg_host_dpi_hfp, cfg_host_dpi_hbp, and cfg_host_dpi_hsa ports properly set. The values of these ports reflect the size of the hfp, hbp, and has in terms of DSI packet bytes, values such that the number of DSI bytes when transmitted takes approximately the same amount of absolute time as the video event took on the DPI interface.

To relate pixel sizes on the DPI interface to DSI packet bytes, use the following relationship:

```
Time of DPI event = time to transmit x number of bytes on the DSI interface
```

```
dpi_event_size * dpi_pclk_period = number_of_dsi_bytes * 8 * dsi_hs_bit_period / cfg_num_lanes
```

Solving for number_of_dsi_bytes:

```
number_of_dsi_bytes = dpi_event_size * dpi_pclk_period * cfg_num_lanes / (8 * dsi_hs_bit_period)
```

number_of_dsi_bytes	value to set the cfg_host_dpi_hfp (hbp, or hsa) port to
dpi_event_size	size of the video event in pixels (hfp, hbp, hsa)
dpi_pclk_period	period of dpi_pclk
dsi_hs_bit_period	bit period of the data lanes in High Speed mode
cfg_num_lanes	host controller setting for number of active lanes (0 = 1 lane, 1 = 2 lanes, 2 = 3 lanes, 3 = 4 lanes)

54.3.5.2 DBI-2 Interface Core

The DBI-2 Interface Core provides a DBI-2 compliant interface that attaches to a Packet Interface Port on the DSI Host controller. The DBI-2 Interface Core handles converting the DBI-2 interface into a packet format that is compatible with the DSI Host Controller Core's Packet Interface and adheres to the DSI specification. The DBI-2 Interface Core handles all pixel-to-byte packing for all DBI data types.

The DSI Host Controller DBI-2 Interface Core provides the following features:

- Support for Type 1, 2, and 3 displays
- Support for DBI-2 Type B and C Interfaces
- Support for 8-, 9- and 16- bit data (Type B)
- Interfaces directly to the Host Controller's Packet Interface
- Comes already integrated with the DSI Host Controller
- Source Code License available (Verilog)
- Provided with expert technical support
- Customization and integration services available

54.3.5.2.1 DBI-2 Host Bridge Module Interface Ports

The DBI-2 Interface module provides a MIPI compliant DBI-2 interface to the DSI Host Controller Core. In addition to the standard DBI-2 interface signals (prefixed with a dbi_) there are several configuration and status ports that allow the user to tune adjust the behavior of the DBI-2 Interface module to better suit a particular application.

Table 531. DSI Host Controller Core Receive Packet interface

PORT	TYPE	DESCRIPTION
dbi_csx	Input	DBI Chip Select, active low.
dbi_wrx	Input	DBI Write enable. Write data/command is registered at the rising edge of dbi_wrx.
dbi_rdx	Input	DBI Read enable. Read data is read at the rising edge of dbi_rdx.
dbi_d_write[15:0]	Input	8-,9- or 16-bit Input Data for Writes
dbi_d_read[15:0]	Output	8-,9- or 16-bit Output Data for Reads
dbi_dcx	Input	Data/Command indicator. 0 – Command cycle 1 – Data cycle
dbi_resx	Input	Active low DBI Display Module reset
dbi_te	Output	Tearing Effect (optional support)

Table continues on the next page...

Table 531. DSI Host Controller Core Receive Packet interface (continued)

PORT	TYPE	DESCRIPTION
dbi_host_underrun_err	Output	During DSI Host transmission of DBI data insufficient DBI data was received. This may indicate that the rate of data received on dbi_d_in was insufficient to keep up with the outgoing data rate on the MIPI interface, or that the cfg_dbi_* parameters are incorrectly set.
cfg_dbi_pixel_payload_size[15:0]	Input	Maximum number of pixels that should send as one DSI packet. Recommended to be evenly divisible by the line size (in pixels).
cfg_dbi_pixel_fifo_send_level[15:0]	Input	In order to optimize DSI utility, the DBI bridge buffers a certain number of DBI pixels before initiating a DSI packet. This configuration port controls the level at which the DBI Host bridge begins sending pixels.

54.3.5.2.2 DBI-2 Host Bridge Module Write and Read Waveforms

The figure below shows a DBI-2 Write transaction. The command portion of the write is registered with the rising edge of dbi_wrx when dbi_dcx and dbi_csx are low. The write data is registered with the rising edge of dbi_wrx when dbi_dcx is high and dbi_csx is low.

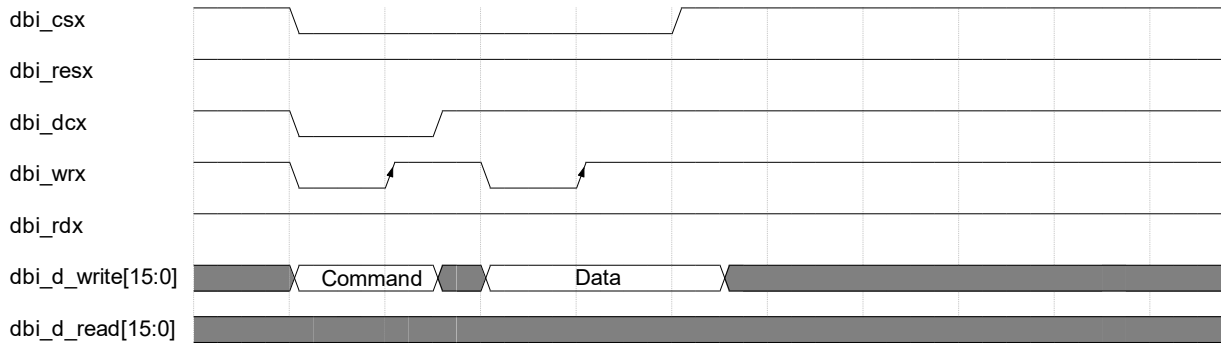

Figure 188. DBI-2 Write Waveform

The figure below shows a DBI-2 Read Transaction. The command portion of the read is registered with the rising edge of dbi_wrx when dbi_dcx and dbi_csx are low. The first cycle of read data is invalid with the first rising edge of dbi_rdx while the second cycle of read data is valid with the rising edge of dbi_rdx.

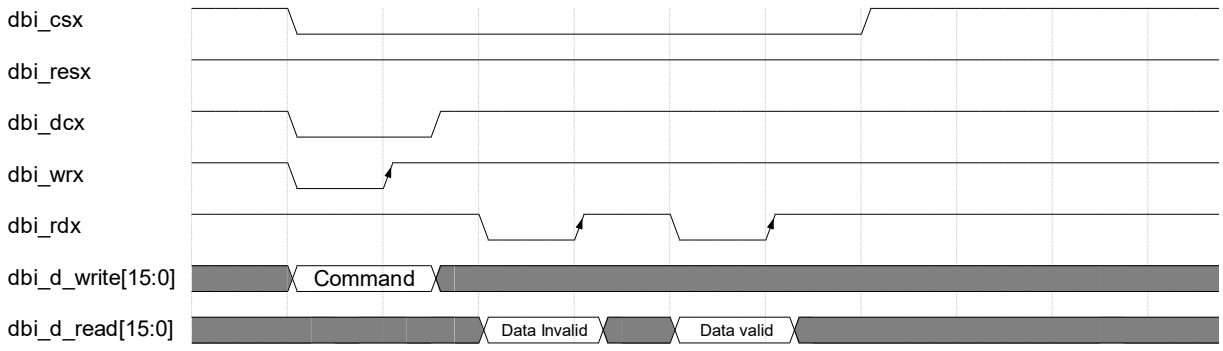

Figure 189. DBI-2 Read Waveform

54.3.6 RAM Usage

The DSI Host Controller Core requires on-chip RAM arrays. These RAM arrays and their corresponding sizes are listed in the table below.

All RAM arrays used in this core are configured as two-port, having the following attributes:

- Two address buses, one for the write port and one for read port
- Two data buses, one for write data on the write port and one for read data on the read port
- Two clock inputs, one for the write port and one for the read port. (Note: In some cases, the core logic will connect the same clock to both the read and write clock inputs of the RAM.)

Ram Purpose	Size (Depth x Width)
DPI Core Pixel Data FIFO	2048 x 32
APB to Packet Interface TX FIFO	64 x 32
APB to Packet Interface RX FIFO	64 x 32

54.3.7 DSI Host Clocking

The DSI Host Controller requires the following clocks:

- Reference clock (ref_clk) - used by the DPHY (DPHY PLL generates byte clock)
- Byte clock (clk_byte) - generated by the DPHY, used for packet generation and transfer to the DPHY
- TX escape mode clock (clk_tx_esc) - for internal LPDT state machines and low-power transmissions;
- Pixel clock (dpi_pclk)
- Serial clock (dbi_c_scl)

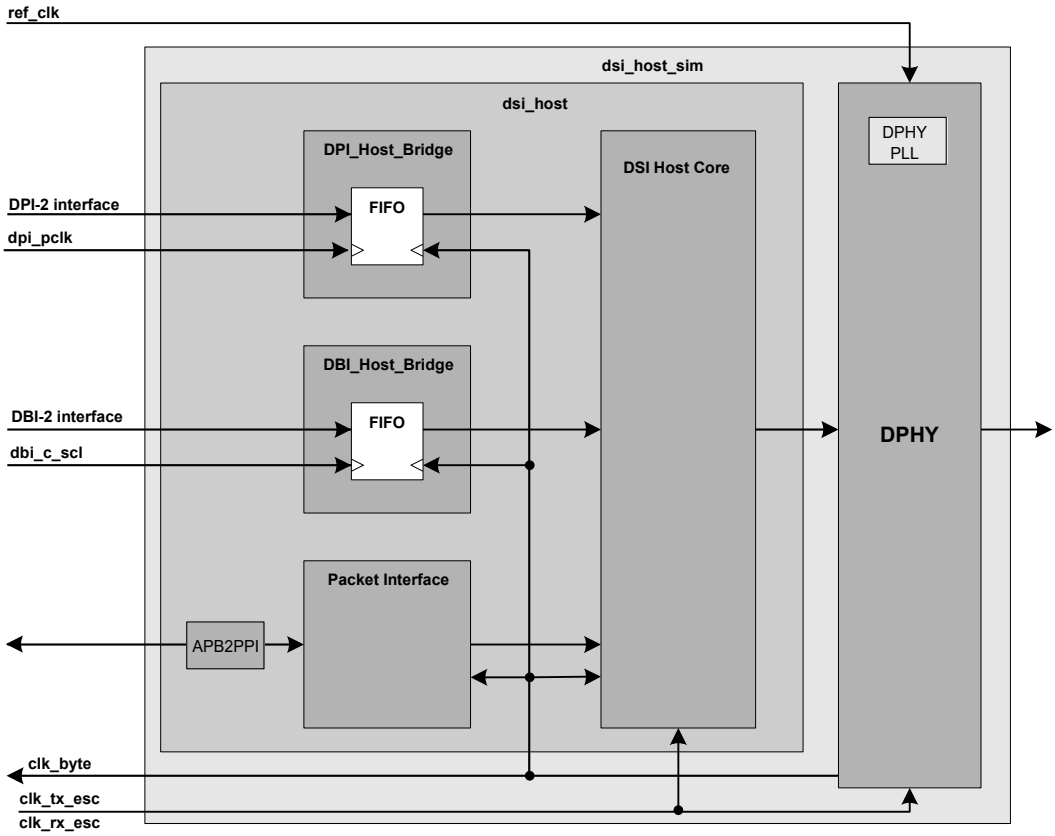

Figure 190. DSI Host Controller Clocking Block Diagram

ref_clk

The reference clock is used by the DPHY (DPHY PLL) to generate the High Speed MIPI clock and High Speed Data Lane signaling. The frequency of the resulting clock generated from DPHY PLL is typically equal to the high speed bit rate of the data lanes. The DPHY will also use this clock to generate the clk_byte clock output used by the Host DSI Controller and user application logic.

The MIPI DPHY PLL must be setup through the MIPI_DSI_HOST_FSL_IP1_DPHY INTFCx registers, prior to starting DSI Host Controller and DPHY operation. For details, please refer to MIPI_DSI_HOST IP1 DPHY INTFC Memory section.

clk_byte

The clk_byte clock is generated by the DPHY (DPHY PLL) and the frequency is 1/8th the data rate of the DPHY Data Lane High Speed data rate. A DPHY configured to generate High Speed data at 1Gbps/lane would generate a 125MHz clk_byte clock.

The clk_byte clock is used by the DSI Host Controller to interface to the MIPI Tx DPHY High Speed PPI interface. The DSI Host Controller's Packet Interface is synchronous to the clk_byte clock.

dpi_pclk

The dpi_pclk clock is used on the Host DPI-2 interface. All of the Host DPI-2 signals are synchronous to this clock. The DSI Host Controller's DPI Bridge module handles transferring video data received in the dpi_pclk clock domain over to the clk_byte clock domain.

The dpi_pclk and clk_byte frequencies are related by the following formula: clk_byte_freq >= dpi_pclk_freq * DPI_pixel_size / (8 * (cfg_num_lanes + 1))

cfg_num_lanes = the configuration port setting that selects the number of active MIPI DPHY data lanes clk_byte_freq = frequency of clk_byte which is 1/8th the High Speed data lane rate. dpi_pclk_freq = frequency of the dpi_pclk clock on the DPI-2 interface. DPI_pixel_size = size of pixels, in bits, on the DPI-2 interface

If the clk_byte frequency does not meet this requirement, the MIPI interface will not be able to keep up with the video stream on the DPI-2 interface resulting in dropped video lines.

clk_tx_esc

The clk_tx_esc clock is used by the MIPI Tx DPHY for state control and low power data transmission. The DSI Host Controller also uses clk_tx_esc for the portion of controller logic that interfaces to the MIPI Tx DPHY that are synchronous to clk_tx_esc. The frequency of clk_tx_esc is defined by the requirements of the MIPI interface and the MIPI Tx DPHY. For details about the clk_tx_esc source, please refer to the chip-specific MIPI-DSI clocking section.

dbi_c_scl

The dbi_c_scl clock is used by the optional DBI-C interface. The MIPI DBI-2 specification defines the minimum period for dbi_c_scl to be 80ns. The DSI Host Controller DBI-2 bridge module handles the clock domain crossing from dbi_c_scl clock domain to the clk_byte clock domain.

54.3.8 Reset and Initialization

Reset and Initialization procedure for the MIPI_DSI_HOST Controller is as follows:

1. Assert all resets through the chip-specific registers provided for this purpose:
   - reset_dpi_n
   - reset_byte_n
   - reset_esc_n
2. Setup MIPI_DSI_HOST related clocks through chip-specific registers provided for this purpose.
3. Setup MIPI_DSI_HOST application by programming all MIPI_DSI_HOST Controller and DSI DPHY required parameters (refer to MIPI_DSI_HOST Memory Map/Register for details).
4. Deassert all remaining resets through the Chip-specific registers provided for this purpose:
   - reset_dpi_n
   - reset_byte_n
   - reset_esc_n
5. DSI Host Controller should be ready for use

54.4 DSI D-PHY

The figure below shows the block diagram of the MIPI_DSI_HOST D-PHY. It consists of a clock lane module and two data lane modules. Each of these PHY Lane Modules communicates through a differential line to a complementary PHY at the other side of the lane interconnect.

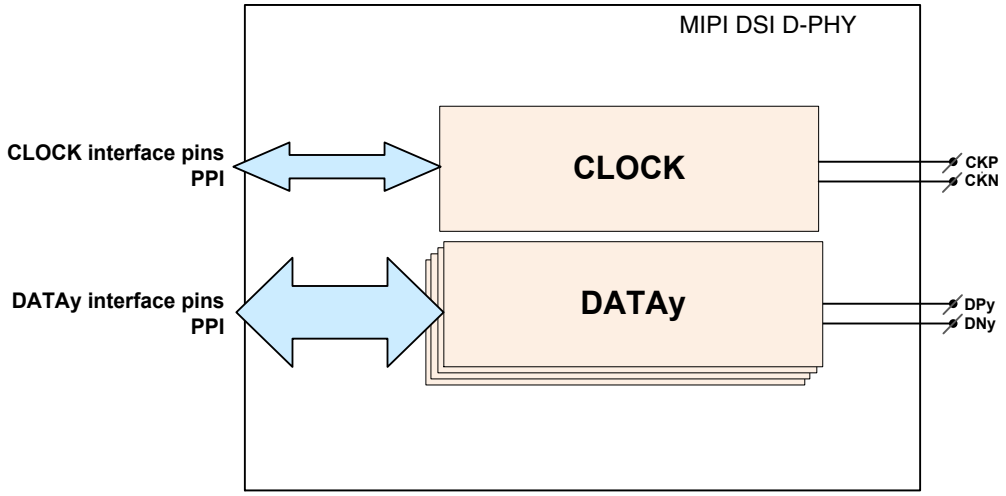

Figure 191. MIPI D-PHY Block Diagram

The figure below shows the D-PHY Lane components:

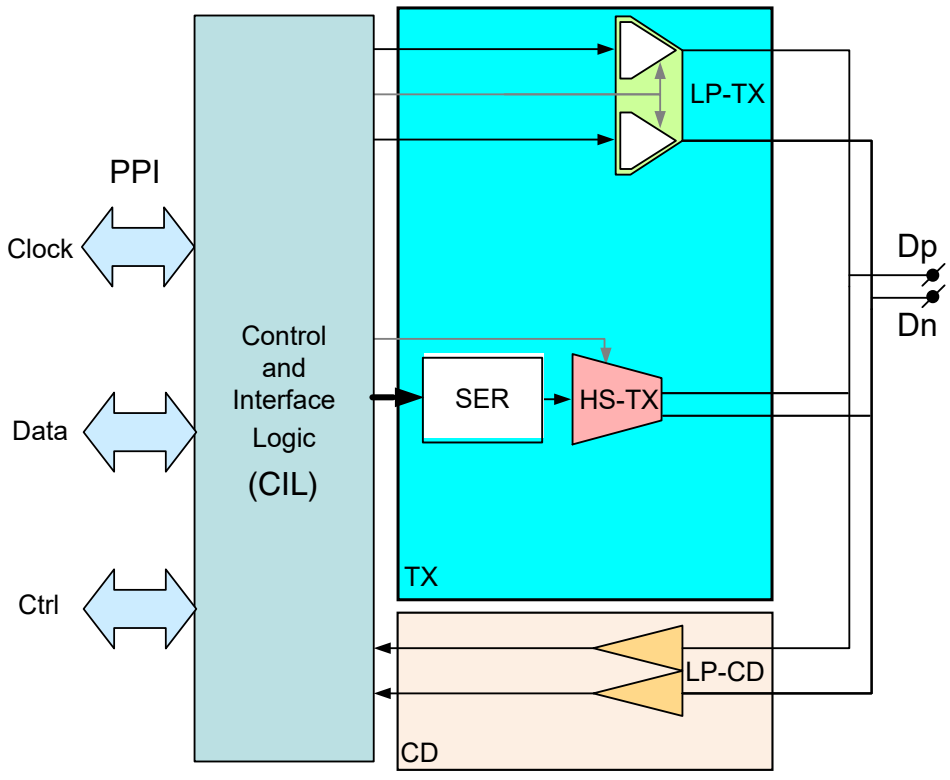

Figure 192. D-PHY Lane Diagram

The DATAy are bidirectional lanes and consist of High-Speed Transmitter (HS-TX), Low-Power Transmitter (LP-TX), Serializer (SER), and Low- Power Contention Detector (LP-CD).

The Clock lane is a bidirectional lane and consists of High-Speed Transmitter (HS-TX), and Low-Power Transmitter (LP-TX).

The Control and Interface Logic (CIL) module interfaces with the Protocol and determines the global operation of the Lane Module. The interface between the D-PHY and the protocol is called the PHY-Protocol Interface (PPI).

During normal operation, a Lane switches between Low-Power and High-Speed mode. Bidirectional Lanes can also switch communication direction. The change of operating mode or direction requires enabling and disabling of certain electrical functions. These enable and disable events do not cause glitches on the Lines that would result in a detection of an incorrect signal level. Therefore, all mode and direction changes are smooth to always ensure a proper detection of the Line signals.

54.4.1 High-Speed Transmitter (HS-TX)

The differential output voltage VOD is defined as the difference of the voltages V_{DP} and V_{DN} at the Dp and Dn pins, respectively.

$VOD = V_{DP} - V_{DN}$

The output voltages V_{DP} and V_{DN} at the Dp and Dn pins will not exceed the high-speed output high voltage V_{OHHS}. The common-mode voltage V_{CMTX} is defined as the arithmetic mean value of the voltages at the Dp and Dn pins:

$V_{CMTX} = (V_{DP} + V_{DN})/2$

V_{OD} and V_{CMTX} are graphically shown in Figure 193 for ideal HS signals. Figure 194 shows single ended HS signals with the possible kinds of distortion of the differential output and common mode voltages. V_{OD} and V_{CMTX} may be slightly different for driving a Differential-1 or a Differential-0 on the pins.

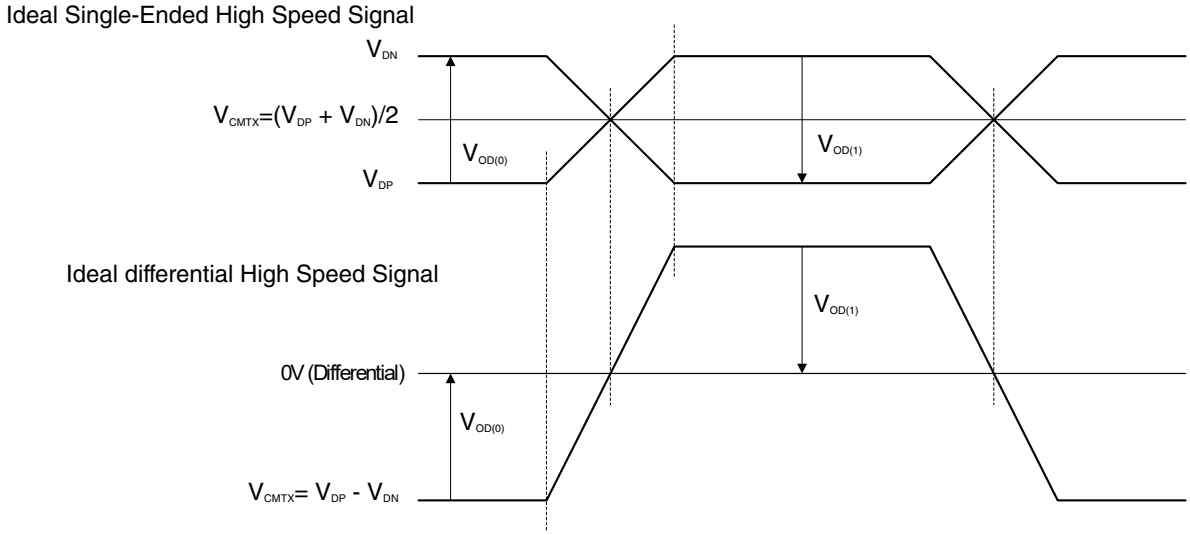

Figure 193. Ideal Single-ended and Resulting Differential HS Signals

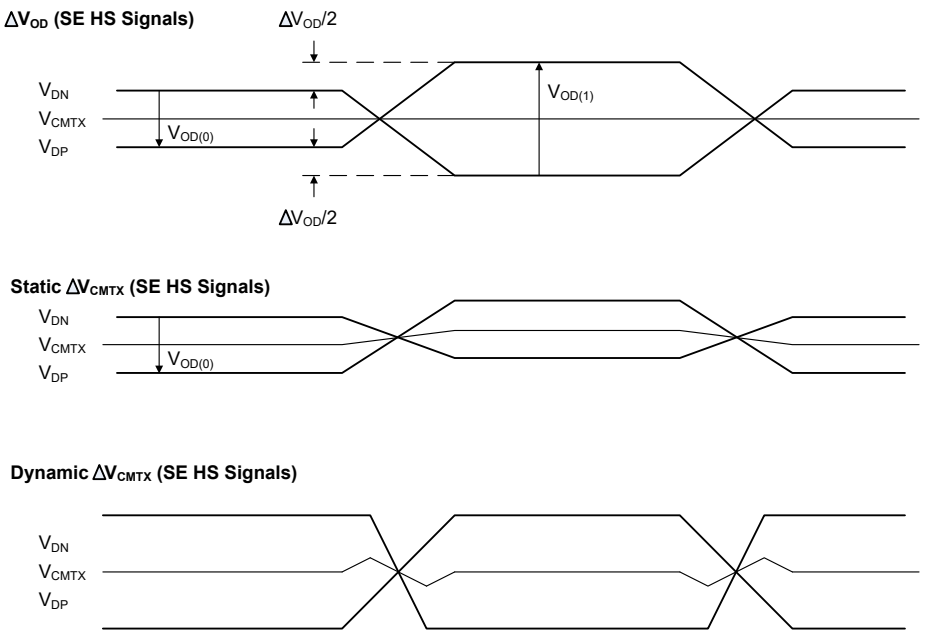

Figure 194. Possible ΔV_{CMTX} and ΔV_{OD} Distortions of the Single-Ended HS Signals

The output differential voltage mismatch ΔV_{OD} is defined as the difference of the absolute values of the differential output voltage in the Differential-1 state $V_{OD}(1)$ and the differential output voltage in the Differential-0 state $V_{OD}(0)$. This is expressed by:

$\Delta V = |V_{OD(1)}| - |V_{OD(0)}|$

If $V_{CMTX(1)}$ and $V_{CMTX(0)}$ are the common-mode voltages for static Differential - 1 and Differential - 0 states respectively, then the common-mode reference voltage is defined by:

$V_{CMTX,\ REF} = (V_{\ CMTX(1)} + V_{\ CMTX(0)})/2$

The transient common-mode voltage variation is defined by:

$\Delta V_{CMTX\ (t)} = V_{CMTX\ (t)} - V_{\ CMTX\ ,REF(t)}$

The static common-mode voltage mismatch between the Differential-1 and Differential-0 state is given by:

$\Delta V_{CMTX\ (1,0\ )} = (V_{CMTX\ (1)} - V_{CMTX\ (0)})/2$

A test circuit for the measurement of V_{OD} and V_{CMTX} is shown:

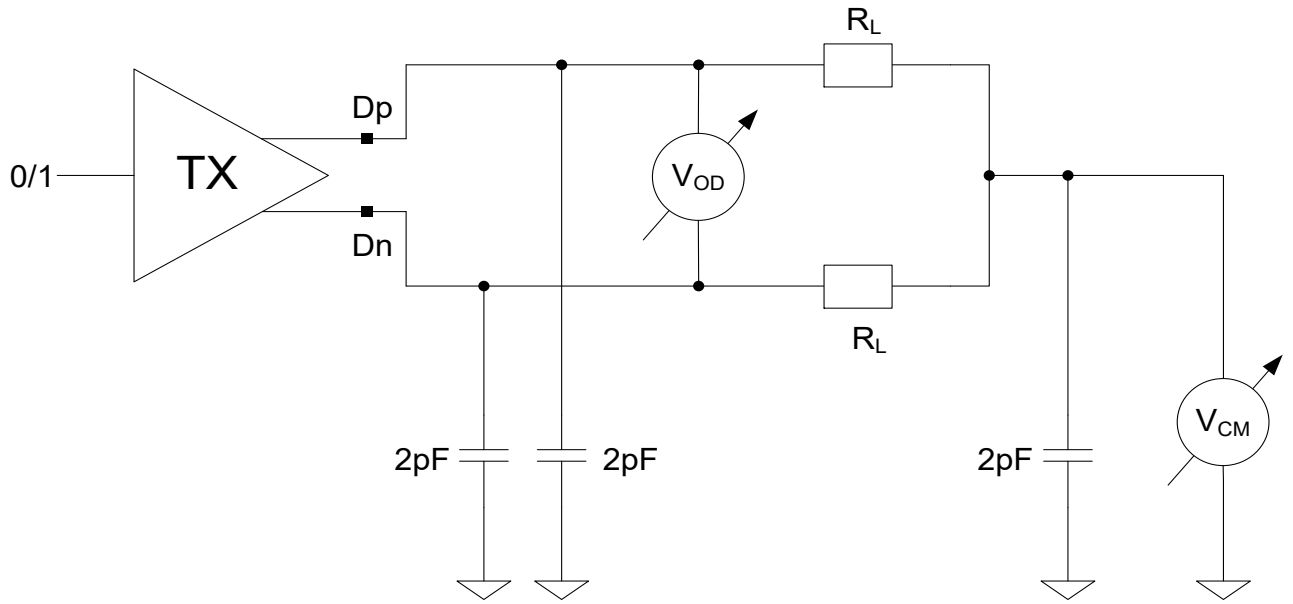

Figure 195. Test Circuit for V_{CMTX} and V_{OD} measurement

The single-ended output impedance of the transmitter at both the Dp and Dn pins is denoted by Z_{OS}. ΔZ_{OS} is the mismatch of the single ended output impedances at the Dp and Dn pins, denoted by Z_{OSDP} and Z_{OSDN} respectively. This mismatch is defined as the ratio of the absolute value of the difference of Z_{OSDP} and Z_{OSDN} and the average of those impedances:

$\Delta Z_{OS} = (2*|Z_{OSDP} - Z_{OSDN}|)/(Z_{OSDP} + Z_{OSDN})$

The output impedance Z_{OS} and the output impedance mismatch ΔZ_{OS} is compliant with High Speed Transmitter DC Specifications for both the Differential-0 and Differential-1 states for all allowed loading conditions. It is recommended the design keep the output impedance during state transitions as close as possible to the steady state value. The output impedance Z_{OS} can be determined by injecting an AC current into the Dp and Dn pins and measuring the peak-to-peak voltage amplitude. The test circuit for such a measurement is shown in the following figure, where R_L are load resistors and $V_{TEST,PP}$ is a test signal applied at the common-mode node via an AC coupling capacitor CAC. The frequency of the test signal is f_{TEST}.

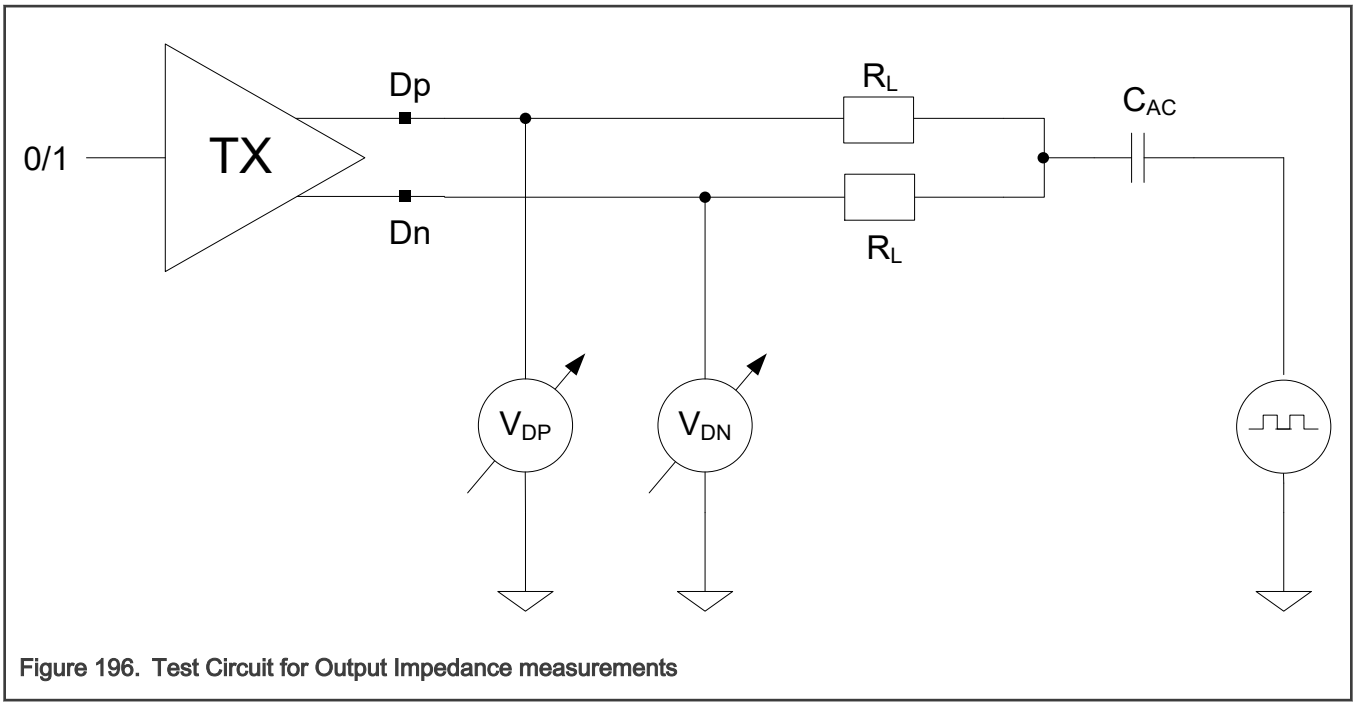

Figure 196. Test Circuit for Output Impedance measurements

Assuming negligible effect of the coupling capacitor, the example circuit gives the following relation between peak-to-peak pin voltage $V_{PIN,PP}$ and Z_{OS}. This equation can be used for both Dn and Dp pins individually.

$Z_{OS} = (V_{PIN,PP} * R_L)/(V_{TEST,PP} – Z_{PIN,PP})$

Where $V_{PIN,PP}$ is the peak-to-peak voltage at the pin Dp or Dn.

54.4.2 Low-Power Transmitter (LP-TX)

The Low-Power transmitter is a slew-rate controlled push-pull driver. It is used for driving the Lines in all Low-Power operating modes. The LP transmitter has been optimized to minimize static power consumption. The slew-rate of signal transitions is bounded in order to keep EMI low. The LP transmitter will not drive the pad pin potential statically beyond the maximum value of V_{OH}. V_{OH} is the thevenin output, high-level voltage in the high-level state, when the pad pin is not loaded. V_{OL} is the thevenin output, low-level voltage in the LP transmit mode. This is the voltage at an unloaded pad pin in the low-level state.

54.4.3 Low-Power Contention Detector (LP-CD)

Contention can be inferred from any of the following conditions:

- LP high fault is detected when the LP transmitter is driving high and the pin voltage is less than VIL.
- LP low fault is detected when the LP transmitter is driving low and the pad pin voltage is greater than VIHCD. An LP low fault will not be detected when the pin voltage is less than VILCD.

The general operation of a contention detector is similar to that of an LP receiver with lower threshold voltages. Although the DC specifications differ, the AC specifications of the LP-CD are defined to match those of the LP receiver. The LP-CD sufficiently filters the input signal to avoid false triggering on short events

The LP-CD threshold voltages (VILCD, VIHCD) are shown along with the normal signaling voltages:

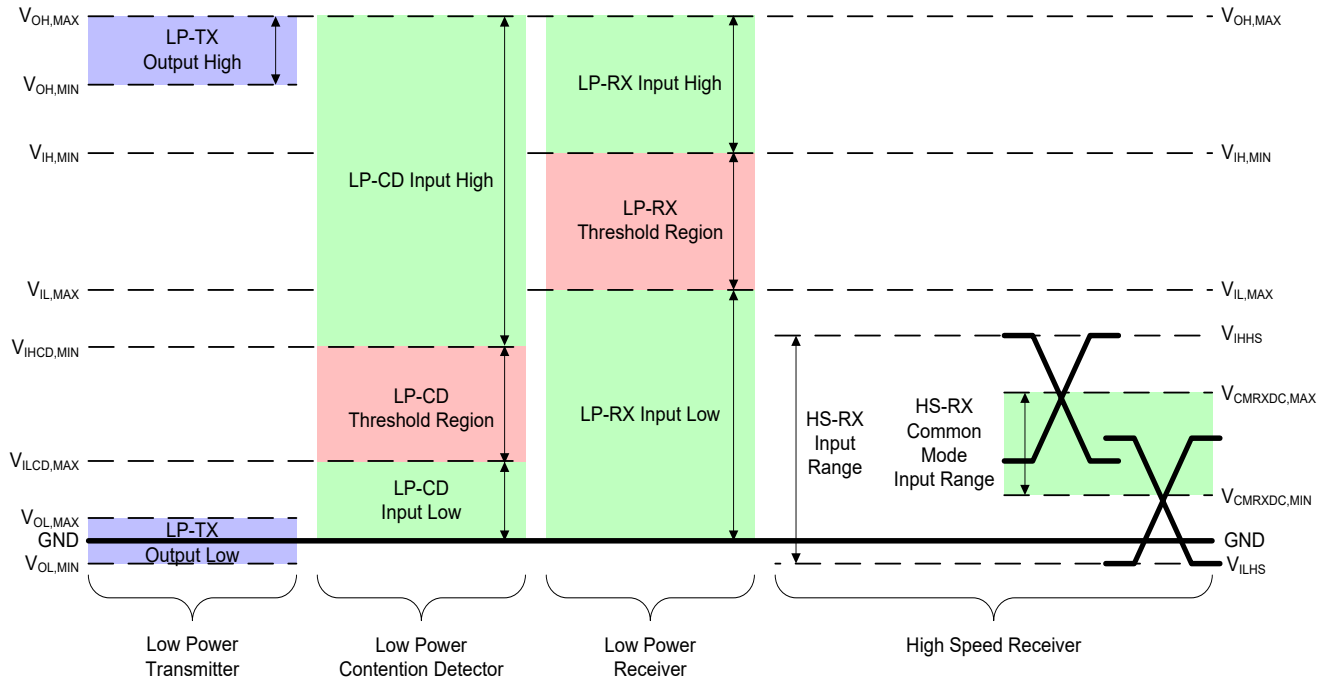

Figure 197. Signaling and MIPI Contention Voltage Levels

54.4.4 Input Characteristics

No structure within the PHY may be damaged when a DC signal that is within the signal voltage range VPIN is applied to a pad pin for an indefinite period of time. $V_{PIN(absmax)}$ is the maximum transient output voltage at the transmitter pin. The voltage on the transmitter's output pin will not excel $V_{PIN,MAX}$ for a period greater than $T_{VPIN(absmax)}$. When the PHY is in the low-power receive mode the pad pin leakage current will be I_{LEAK} when the pad signal voltage is within the signal voltage range of V_{PIN}. The specification of ILEAK assures interoperability of any PHY in the LP mode by restricting the maximum load current of an LP transmitter. The test circuit for leakage current measurement is shown:

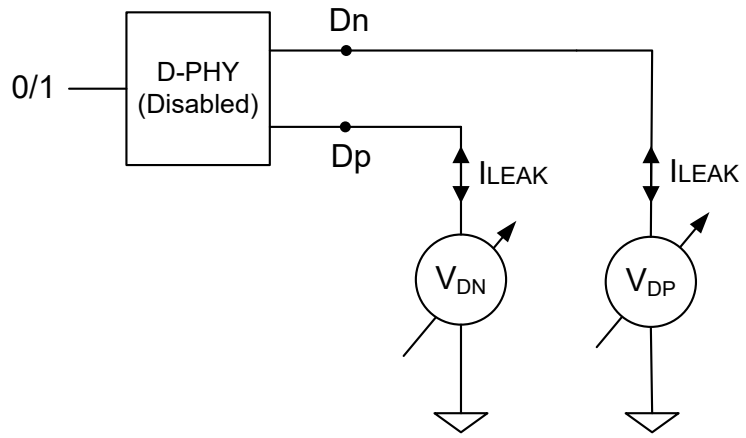

Figure 198. Pin-Leakage Measurement DC specification

54.4.5 High-Speed Serializer

The HS-Serializer converts 8-bits parallel data into 1 bit data stream to be transmitted by HSTX module. The CIL engine should clock out 8-bits parallel data, HSTX_DATA[7:0], on D0_HS_BYTE_CLKS rising edges. Then the Serializer will capture HSTX_DATA[7:0] on D0_HS_BYTE_CLKS rising edges and the signal connected to HSTX_DATA[0] is transmitted first. There is setup timing constraint and hold timing constraint designated to the rising edge of D0_HS_BYTE_CLKS as constrained in the liberty view provided.

The figure shows the relationship between HS_TXCLKP, HS_TXCLKN, HS_SER_LD, HS_BYTE_CLKS and HSTX_DATA[7:0]. It also shows how the 8-bits of parallel bits are mapped into the serial link:

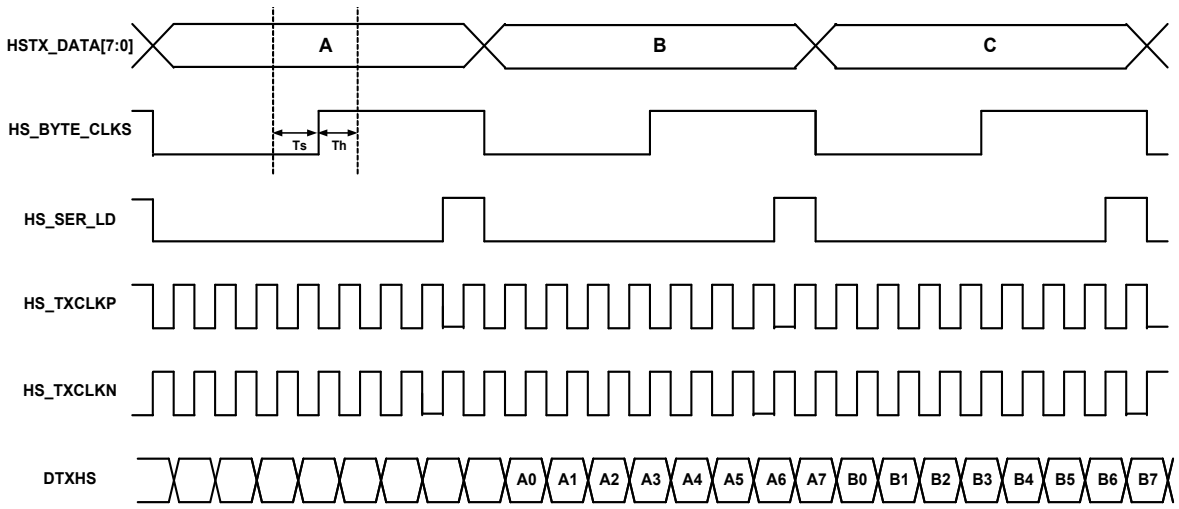

Figure 199. Serializer Timing Diagram

54.4.6 DSI D-PHY Signals

This section details the interface signals for MIPI DSI D-PHY. For detailed signal spec, please refer to the chip data sheet.

Table 532. DSI DPHY PPI Signals

Signal	Type	Description
TxClkEsc	Clock	Escape mode Transmit Clock. This clock is directly used to generate escape sequences. The period of this clock determines the symbol time for low power signals. It is therefore constrained by the normative part of the DPHY specification. **NOTE** The max frequency of TxClkEsc is 20 MHz **NOTE** The Min frequency of TxClkEsc is 12 MHz.

Table continues on the next page...

Table 532. DSI DPHY PPI Signals (continued)

Signal	Type	Description
TxByteClkHS	Clock	High-Speed Transmit Byte Clock. This is used to synchronize PPI signals in the High-Speed transmit clock domain. It is recommended that all transmitting Data Lane Modules share on TxByteClkHS signal. The frequency of TxByteClkHS is exactly 1/8 the High-Speed bit rate.

54.4.7 Operating Modes

54.4.7.1 High-Speed Transmission

The figure shows an example of a High-Speed transmission. While TxRequestHS is low, the Lane Module ignores the value of TxDataHS. To begin transmission, the protocol drives TxDataHS with the first byte of data and asserts TxRequestHS. This data byte is accepted by the PHY on the first rising edge of TxByteClkHS with TxReadyHS also asserted. At this point, the protocol logic drives the next data byte onto TxDataHS. After every rising clock cycle with TxReadyHS active, the protocol supplies a new valid data byte or ends the transmission. After the last data byte has been transferred to the Lane Module, TxRequestHS is driven low to cause the Lane Module to stop the transmission and enter Stop state. The minimum number of bytes transmitted could be as small as one.

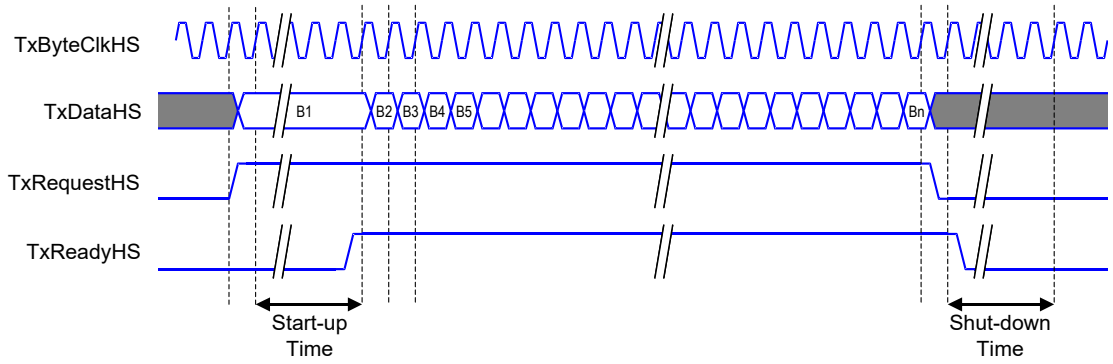

Figure 200. High-Speed Transmission

54.4.7.2 Low-Power Data Transmission

For Low-Power data transmission the TxClkEsc is used. The Protocol directs the Data Lane to enter Low-Power data transmission Escape mode by asserting TxRequestEsc with TxLpdtEsc high. The Low-Power transmit data is transferred on the TxDataEsc lines when TxValidEsc and TxReadyEsc are both active at a rising edge of TxClkEsc. The byte is transmitted in the time after the TxDataEsc is accepted by the Lane Module (TxValidEsc = TxReadyEsc = high). The Protocol knows the byte transmission is finished when TxReadyEsc is asserted. After the last byte has been transmitted, the protocol de-asserts TxRequestEsc to end the Low-Power data transmission. This causes TxReadyEsc to return low. Whenever TxRequestEsc transitions from high-to-low, it always remains in the low state for a minimum of two TxClkEsc clock cycles. The figure shows an example Low-Power data transmission operation.

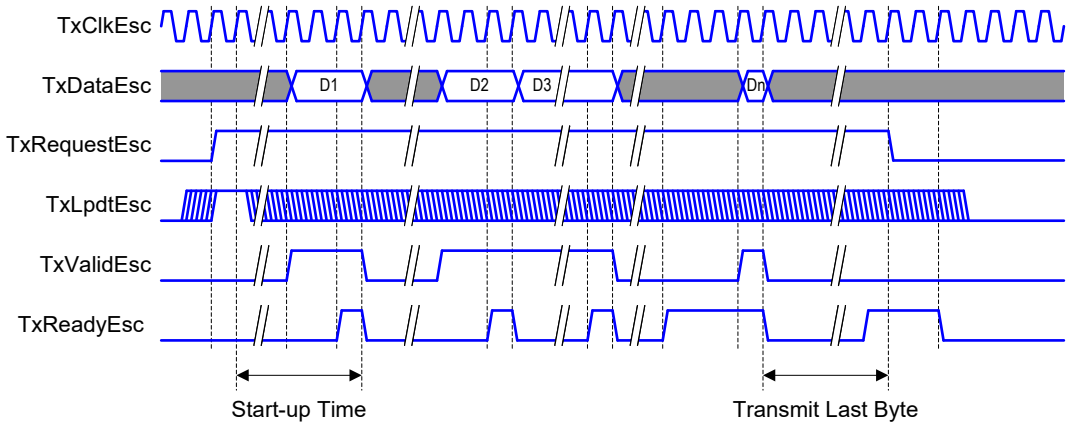

Figure 201. Low-Power Data Transmission

54.4.7.3 Turn-around

If the local side and remote side Lane Modules are both bi-directional, it is possible to turn around the Link for Escape mode signaling. Which side is allowed to transmit is determined by passing a “token” back and forth. That is, the side currently transmitting passes the token to the receiving side. If the receiving side acknowledges the turn-around request, as indicated by driving the appropriate line state, the direction is switched. The figure shows an example of two turn-around events. At the beginning, the local side is the transmitter, as shown by Direction=0. When the protocol on this side wishes to turn the Lane around (i.e. give the token to the other side), it asserts TurnRequest for at least one cycle of TxClkEsc. This initiates the turn around procedure. The remote side acknowledges the turn-around request by driving the appropriate states on the Lines. When this happens, the local Direction signal changes from transmit (0) to receive (1). The remote side initiates a turn-around request, passing the token back to the local side. When this happens, the local Direction signal changes back to transmit (0). The transmitter is in control of the Link direction and decides when to turn the Link around, passing control to the receiver. If the remote side does not acknowledge the turnaround request, the Direction signal does not change.

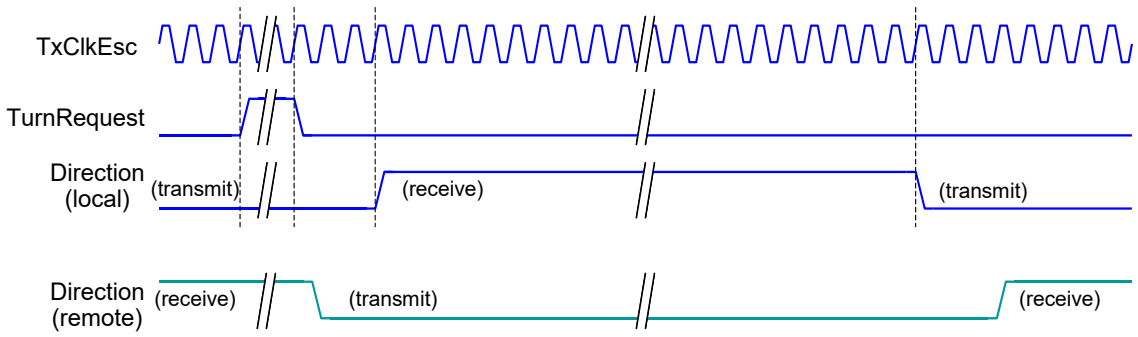

Figure 202. Turn-around Actions Transmit-to-Receive and Back to Transmit

54.5 DPHY Programming

The following sections detail the programming of the MIPI_DSI_HOST DPHY high-speed timers.

High-Speed Prepare Timer ($T_{HS-PREPARE}$)

Calculate the value for clock lane high-speed prepare timer (mc_PRG_HS_PREPARE) using the formula below:

Assuming TxClkEsc = 20 MHz (T_{per} = 50 ns)

When mc_PRG_HS_PREPARE = 0, $T_{CLK\text{-}PREPARE}$= 1 * TxClkEsc Period = 50 ns

When mc_PRG_HS_PREPARE = 1, $T_{CLK\text{-}PREPARE}$ = 1.5 * TxClkEsc Period = 75 ns

Calculate the value for data lane high-speed prepare timer (m_PRG_HS_PREPARE) using the formula below:

Assuming TxClkEsc (TLPX) = 20 MHz (T_{per} = 50 ns)

When m_PRG_HS_PREPARE = 00, $T_{HS\text{-}PREPARE}$ = 1 * TxClkEsc Period = 50 ns

When m_PRG_HS_PREPARE = 01, $T_{HS\text{-}PREPARE}$ = 1.5 * TxClkEsc Period = 75 ns

When m_PRG_HS_PREPARE = 10, $T_{HS\text{-}PREPARE}$ = 2 * TxClkEsc Period = 100 ns

When m_PRG_HS_PREPARE = 11, $T_{HS\text{-}PREPARE}$ = 2.5 * TxClkEsc Period = 125 ns

High-Speed Zero Timer($T_{HS\text{-}ZERO}$)

Calculate the value for clock lane high-speed zero timer (mc_PRG_HS_ZERO) using the formula below:

$T_{CLK\text{-}ZERO}$ = (mc_PRG_HS_ZERO + 4) * (TxByteClkHS Period)

TxByteClkHS = 1/8 Data Rate

When mc_PRG_HS_ZERO = 000110 @ 250 Mb/s, $T_{CLK\text{-}ZERO}$ = (6+4) * 32 ns = 320 ns

When mc_PRG_HS_ZERO = 100000 @ 1 Gb/s, $T_{CLK\text{-}ZERO}$ = (32+4) * 8 ns = 288 ns

Calculate the value for data lane high-speed zero timer (m_PRG_HS_ZERO) using the formula below:

$T_{HS\text{-}ZERO}$ = (m_PRG_HS_ZERO + 6)*(TxByteClkHS Period)

TxByteClkHS = 1/8 Data Rate

When m_PRG_HS_ZERO = 00001 @ 250 Mb/s, $T_{HS\text{-}ZERO}$ = (1+6) * 32 ns = 224 ns

When m_PRG_HS_ZERO = 01001 @ 1 Gb/s, $T_{HS\text{-}ZERO}$ = (9+6) * 8 ns = 120 ns

High-Speed Trail Timer ($T_{HS\text{-}TRAIL}$)

Calculate the value for the high-speed trail timer (PRG_HS_TRAIL) using the formula below:

$T_{HS\text{-}TRAIL}$= (PRG_HS_TRAIL)*(TxByteClkHS Period)

TxByteClkHS = 1/8 Data Rate

When PRG_HS_TRAIL = 0100 @ 250 Mb/s, >$T_{HS\text{-}TRAIL}$ = 4 * 32 ns = 128 ns

When PRG_HS_TRAIL = 1100 @ 1 Gb/s, >$T_{HS\text{-}TRAIL}$ = 12 * 8 ns = 96 ns

54.6 Packet Data and Pixel Formats

The DSI Host Controller Core and the external DSI Peripheral explicitly handle and exchanges 32-bit words encapsulated as packet data. The mapping between pixel formats and pixel data must be done on both sides by user application on both sides of the DSI link. The DSI spec gives many examples of common pixel formats. The DSI Host Controller Core and external DSI Peripheral have no preference or limitation on which pixel formats it will handle. The IP which provides video source packet data through DPI-2 interface (e.g. LCDIF) onto DSI should also be configured by the user application to match the pixel formats expected by the DSI Host Controller.

The DPI-2/DBI-2 interface core handles pixel to byte packing and byte to pixel unpacking according to the MIPI_DSI_HOST specification.

54.7 MIPI_DSI_HOST Memory Map/Register Definition

MIPI_DSI_HOST Controller Register Groups	Offset
DSI_HOST	0x00
DBI_INTFC	0x100
DPI_INTFC	0x200
APB_PKT_IF	0x280

4 ACTIVE4	Data Lane 3 ULPS ACTIVE Shows data lane 3 is in ULPS mode. 0b - ULPS inactive 1b - ULPS active
3 ACTIVE3	Data Lane 2 ULPS ACTIVE Shows data lane 2 is in ULPS mode. 0b - ULPS inactive 1b - ULPS active
2 ACTIVE2	Data Lane 1 ULPS ACTIVE Shows data lane 1 is in ULPS mode. 0b - ULPS inactive 1b - ULPS active
1 ACTIVE1	Data Lane 0 ULPS ACTIVE Shows data lane 0 is in ULPS mode. 0b - ULPS inactive 1b - ULPS active
0 ACTIVE0	Clock Lane ULPS Active Shows clock lane is in ULPS mode. 0b - ULPS inactive 1b - ULPS active

54.7.1.17 High Speed Mode Enable (HS_MODE_ENABLE)

Offset

Register	Offset
HS_MODE_ENABLE	3Ch

Function

Controls transmission mode.

When the APB CSR is delivered as part of the Host Controller HS_MODE_ENABLE register is logically OR with the controller tx_hs_mode input to the controller.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved															ENABLE
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-1 —	Reserved
0 ENABLE	Enable If High Speed (HS) mode is enabled, the APB packet interface always sends packets in HS mode regardless of the setting in Packet Control (PKT_CONTROL). 0b - All transmissions in Low Power Data transmission mode. 1b - All transmissions in High Speed mode.

54.7.1.18 Host Turnaround (HOST_TURNAROUND)

Offset

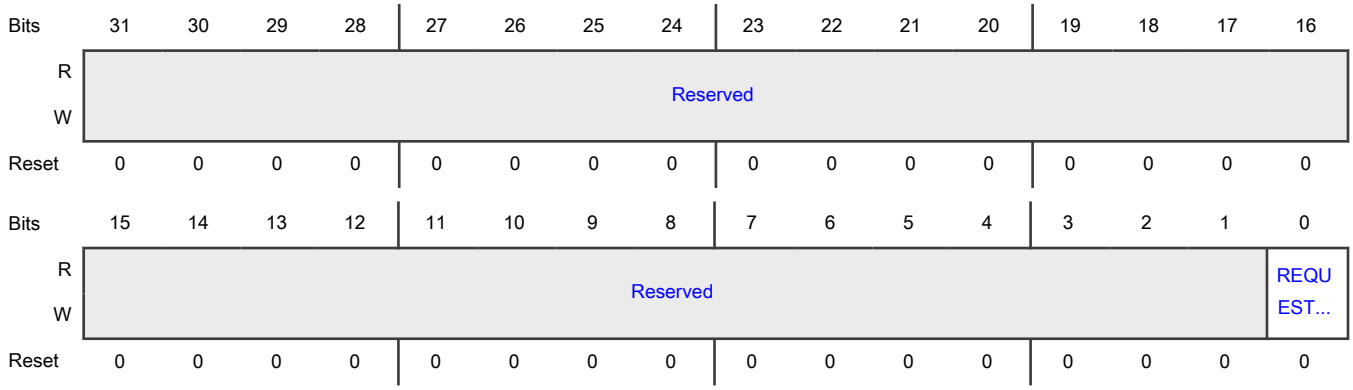
Register	Offset
HOST_TURNAROUND	40h

Function

Controls Bus Turn Around (BTA).

When the APB CSR is delivered as part of the Host Controller, HOST TURNAROUND register is logically OR with the controller dphy_turnaround input to the controller.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 REQUEST_BTA	Request BTA 0b - No Request 1b - Request BTA

54.7.1.19 PHY Direction (PHY_DIRECTION)

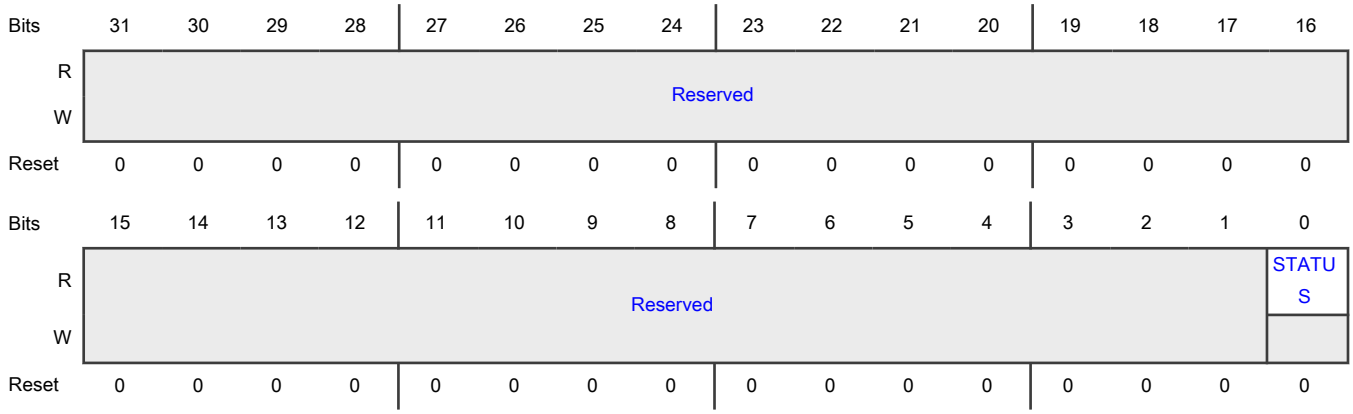
Offset

Register	Offset
PHY_DIRECTION	44h

Function

Shows PHY Status.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 STATUS	PHY Direction 0b - Default PHY direction 1b - Reversed PHY direction

54.7.1.20 PHY Ready (PHY_RDY)

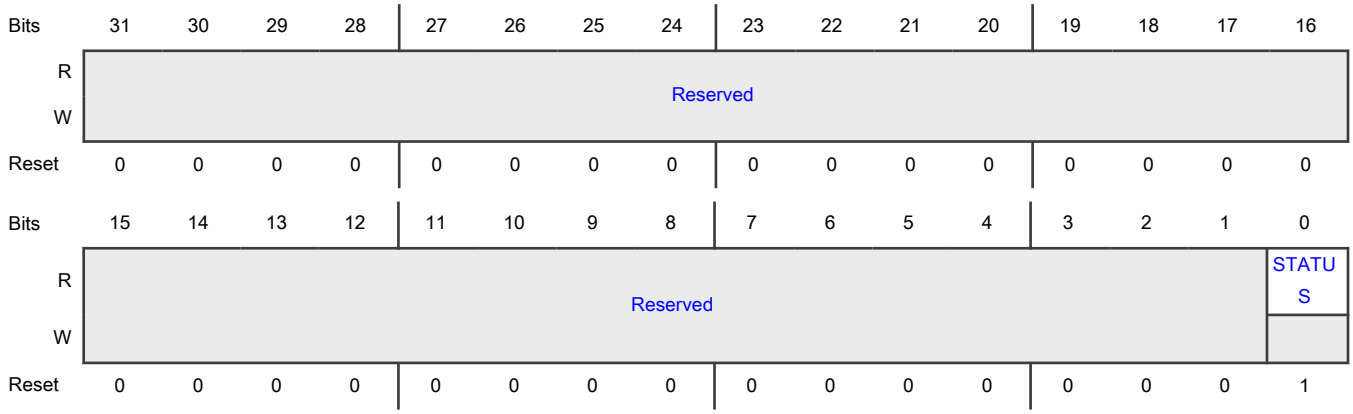
Offset

Register	Offset
PHY_RDY	48h

Function

Indicates Host DPHY ready status.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 STATUS	PHY Ready Status 0b - DPHY not ready 1b - DPHY ready

54.7.1.21 Pixel Payload Size (CFG_DBI_PIXEL_PAYLOAD_SIZE)

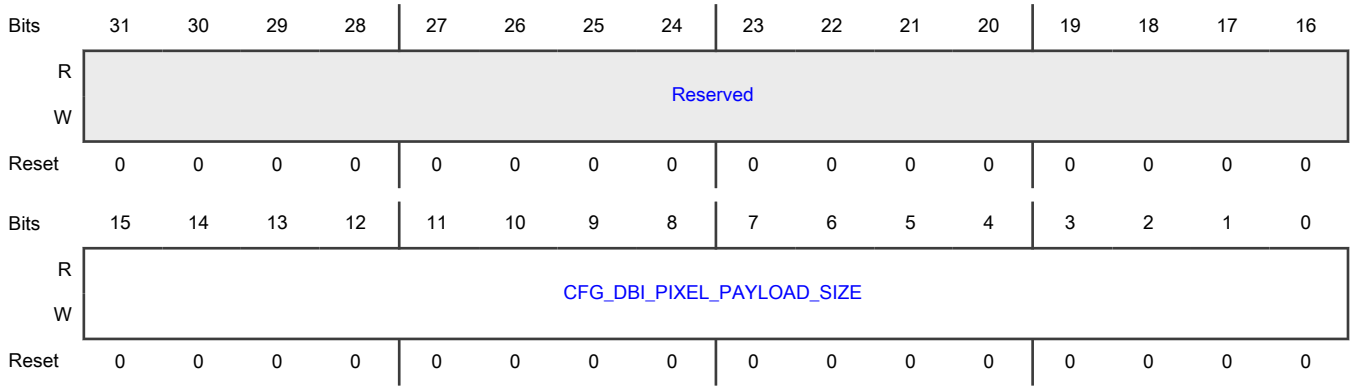
Offset

Register	Offset
CFG_DBI_PIXEL_PAYLOAD_SIZE	100h

Function

Maximum number of pixels that should be sent as one DSI packet.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 CFG_DBI_PIXEL_PAYLOAD_SIZE	Pixel Payload Size Recommended to be evenly divisible by the line size (in pixels).

54.7.1.22 Configure DBI Pixel FIFO Send Level (CFG_DBI_PIXEL_FIFO_SEND_LEVEL)

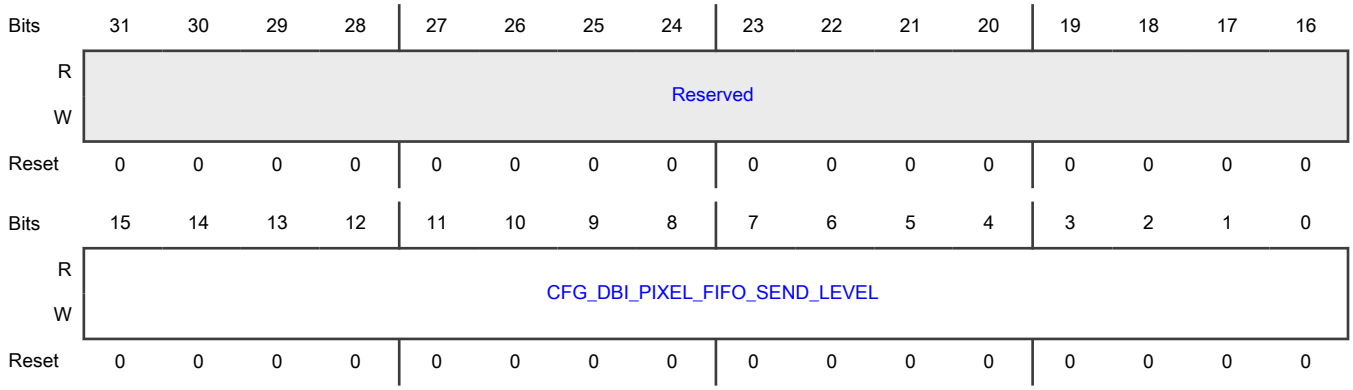
Offset

Register	Offset
CFG_DBI_PIXEL_FIFO_SEND_LEVEL	104h

Function

Controls the level at which the DBI Host bridge begins sending pixels.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 CFG_DBI_PIXEL_FIFO_SEND_LEVEL	Configure DBI Pixel FIFO Send Level In order to optimize DSI utility, the DBI bridge buffers a certain number of DBI pixels before initiating a DSI packet.

54.7.1.23 DBI Pixel Format (CFG_DBI_PIXEL_FORMAT)

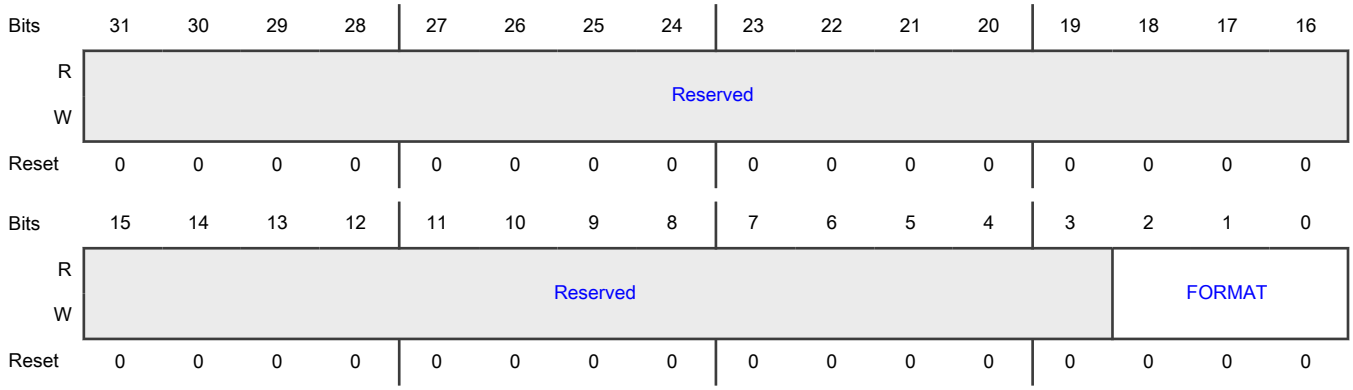
Offset

Register	Offset
CFG_DBI_PIXEL_FORMAT	108h

Function

Configures DBI Pixel Format.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 FORMAT	DBI Pixel Format Options **NOTE** For Option 4: RGB444, both display controller and DSI should work in 8-bit mode, and other configurations should work in 16-bit mode. 000b - Default. No pixel to byte mapping 001b - Option 1: RGB888 010b - Option 2: RGB666 011b - Option 3: RGB565 100b - Option 4: RGB444 101b - Option 5: RGB332 110b-111b - Reserved

54.7.1.24 DBI Underrun Error (DBI_UNDERRUN_ERR)

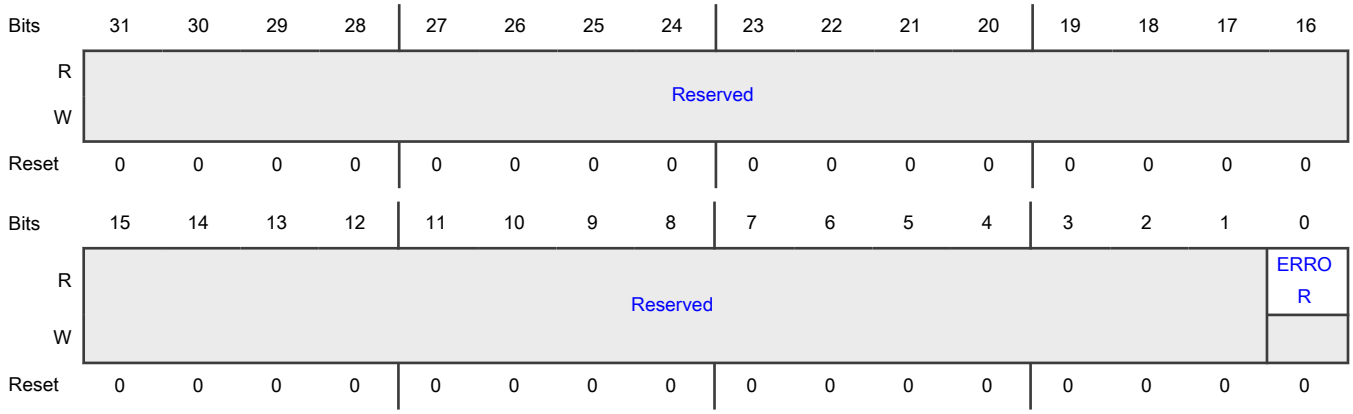
Offset

Register	Offset
DBI_UNDERRUN_ERR	10Ch

Function

Indicates host DBI FIFO underrun error.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 ERROR	Error 0b - No Error 1b - Error

54.7.1.25 DBI Overflow Error (DBI_OVERFLOW_ERR)

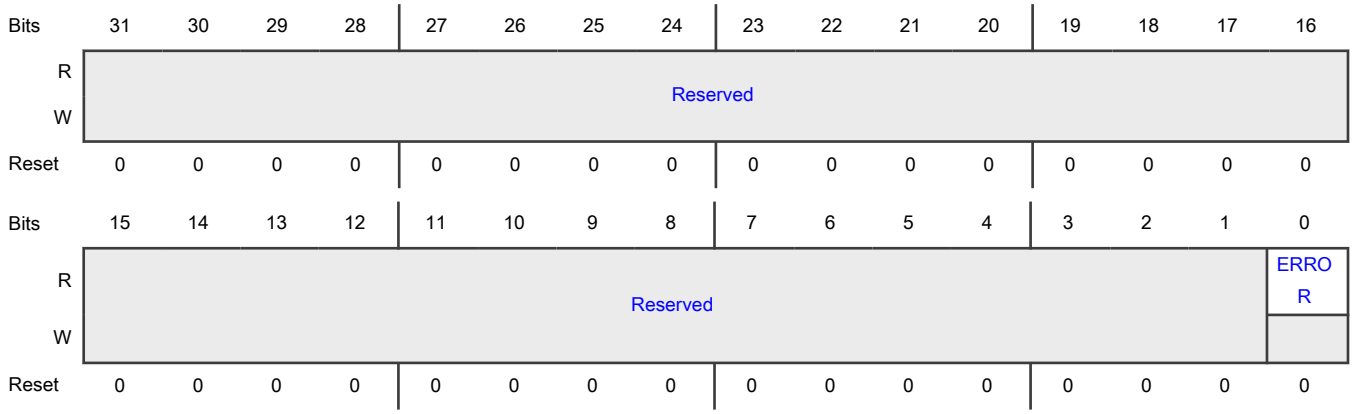
Offset

Register	Offset
DBI_OVERFLOW_ERR	110h

Function

Indicates host DBI FIFO overflow error.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 ERROR	Error 0b - No Error 1b - Error

54.7.1.26 Configure DPI Pixel Payload Size (CFG_DPI_PIXEL_PAYLOAD_SIZE)

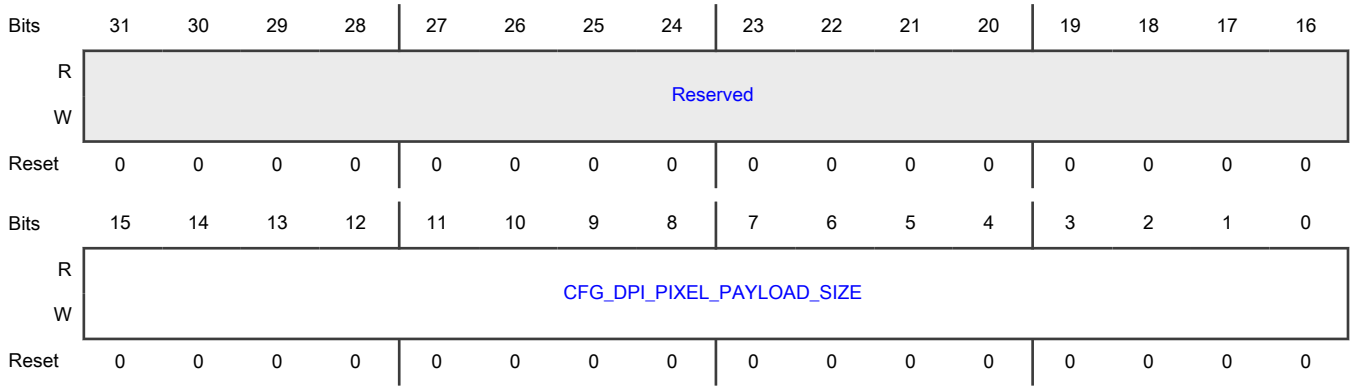
Offset

Register	Offset
CFG_DPI_PIXEL_PAYLOAD_SIZE	200h

Function

Maximum number of pixels that should be sent as one DSI packet.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 CFG_DPI_PIXEL_PAYLOAD_SIZE	Configure DPI Pixel Payload Recommended to be evenly divisible by the line size (in pixels).

54.7.1.27 Configure DPI Pixel FIFO Send Level (CFG_DPI_PIXEL_FIFO_SEND_LEVEL)

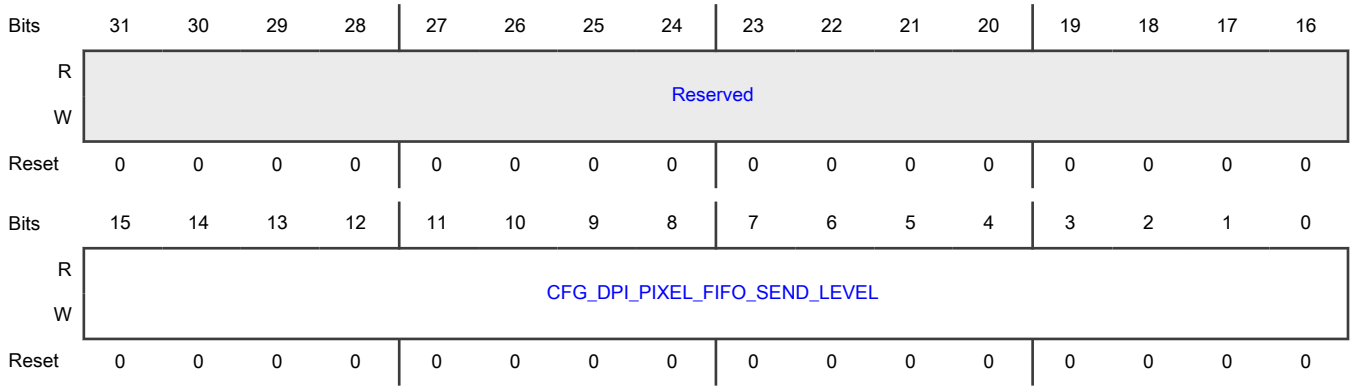
Offset

Register	Offset
CFG_DPI_PIXEL_FIFO_SEND_LEVEL	204h

Function

Controls the level at which the DPI Host bridge begins sending pixels.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 CFG_DPI_PIXEL_FIFO_SEND_LEVEL	Configure DPI Pixel FIFO Send Level In order to optimize DSI utility, the DPI bridge buffers a certain number of DPI pixels before initiating a DSI packet.

54.7.1.28 Configure DPI Interface Color Coding (CFG_DPI_INTERFACE_COLOR_CODING)

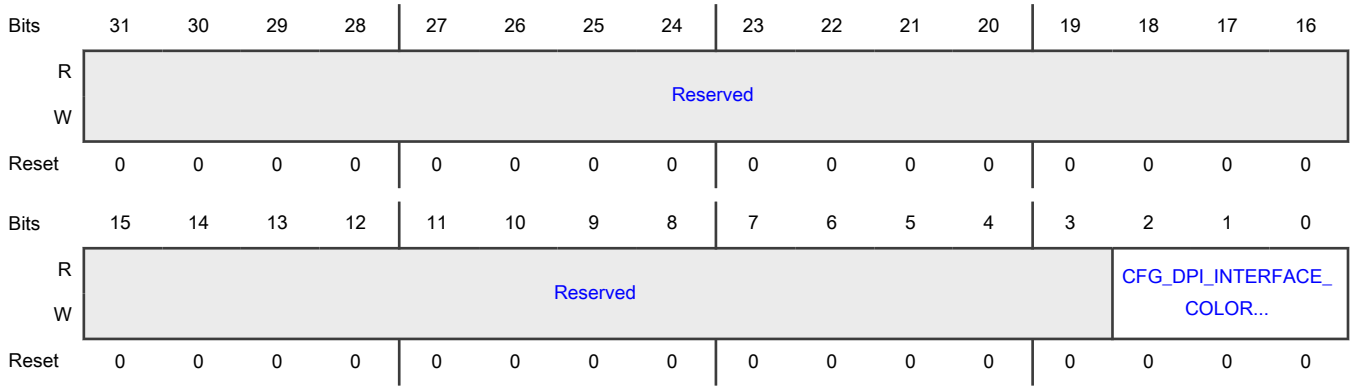
Offset

Register	Offset
CFG_DPI_INTERFACE_COLOR_CODING	208h

Function

Sets the distribution of RGB bits.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 CFG_DPI_INTERFACE_COLOR_CODING	Configure DPI Interface Color Coding Sets the distribution of RGB bits within the 24-bit d bus, as specified by the DPI specification. 0= 16-bit Configuration 1 1= 16-bit Configuration 2 2= 16-bit Configuration 3 3= 18-bit Configuration 1 4= 18-bit Configuration 2 5= 24-bit

54.7.1.29 Configure DPI Pixel Format (CFG_DPI_PIXEL_FORMAT)

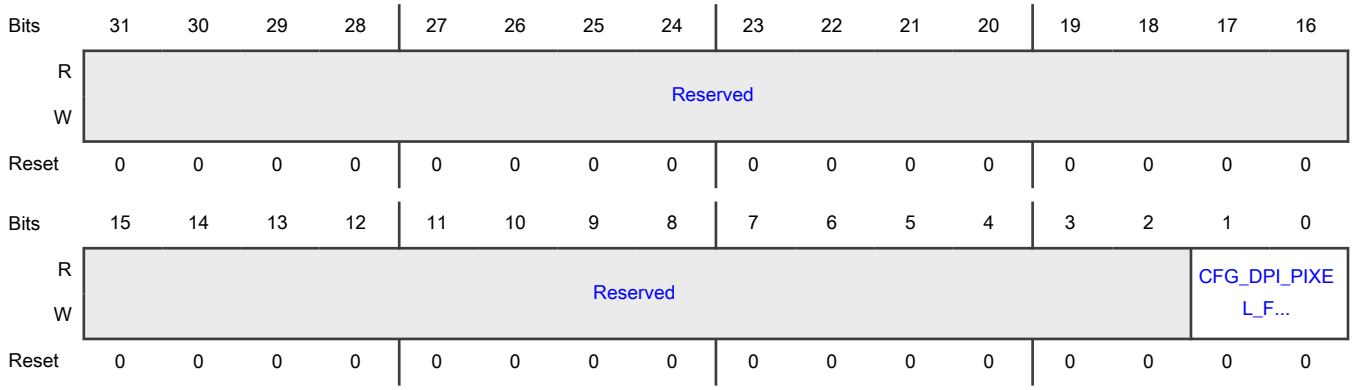
Offset

Register	Offset
CFG_DPI_PIXEL_FORMAT	20Ch

Function

Sets the DSI packet type of the pixels.

Diagram



Fields

Field	Function
31-2 —	Reserved
1-0 CFG_DPI_PIXEL_FORMAT	Configure DPI Pixel Format Sets the DSI packet type of the pixels. 0 - 16 bit 1 - 18 bit 2 - 18 bit loosely packed 3 - 24 bit

54.7.1.30 Configure DPI vsync Polarity (CFG_DPI_VSYNC_POLARITY)

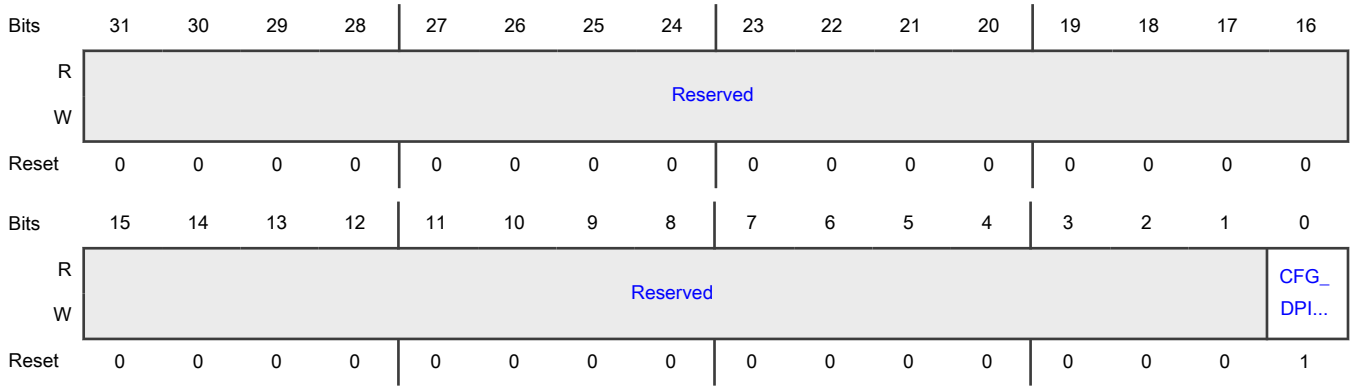
Offset

Register	Offset
CFG_DPI_VSYNC_POLARITY	210h

Function

Sets polarity of dpi_vsync_input

Diagram



Fields

Field	Function
31-1 —	Reserved
0 CFG_DPI_VSYNC_POLARITY	Configure DPI vsync Polarity Sets polarity of dpi_vsync_input. 0 - active low 1 - active high

54.7.1.31 Configure DPI hsync Polarity (CFG_DPI_HSYNC_POLARITY)

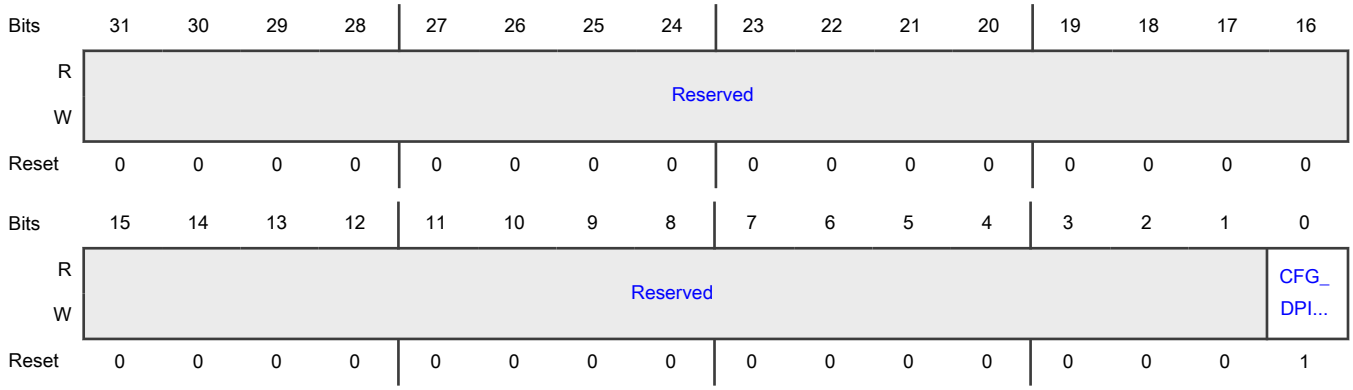
Offset

Register	Offset
CFG_DPI_HSYNC_POLARITY	214h

Function

Sets polarity of dpi_hsync_input.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 CFG_DPI_HSYNC_POLARITY	Configure DPI hsync Polarity Sets polarity of dpi_hsync_input. 0 - active low 1 - active high

54.7.1.32 Configure DPI Video Mode (CFG_DPI_VIDEO_MODE)

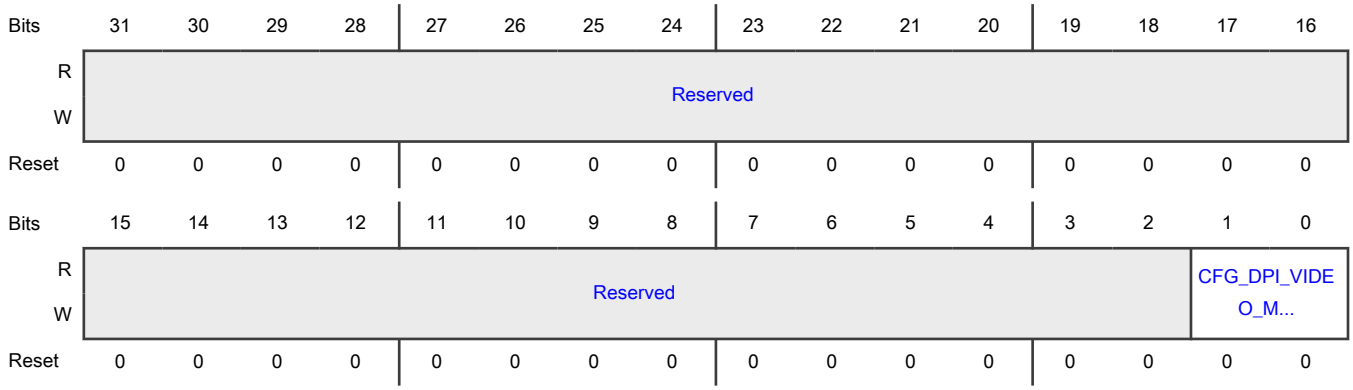
Offset

Register	Offset
CFG_DPI_VIDEO_MODE	218h

Function

Selects DSI video mode for the host DPI module generated packets.

Diagram



Fields

Field	Function
31-2 —	Reserved
1-0 CFG_DPI_VIDEO_MODE	Configure DPI Video Mode Selects DSI video mode for the host DPI module generated packets. 00b - Non-Burst mode with Sync Pulses 01b - Non-Burst mode with Sync Events 10b - Burst mode 11b - Reserved, not valid

54.7.1.33 Configure DPI horizontal front porch (CFG_DPI_HFP)

Offset

Register	Offset
CFG_DPI_HFP	21Ch

Function

Sets the DSI packet payload size for the HFP blanking packet.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CFG_DPI_HFP															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 —	Reserved
15-0 CFG_DPI_HFP	Configure DPI Horizontal Front Porch Sets the DSI packet payload size, in bytes, of the horizontal front porch blanking packet.

54.7.1.34 Configure DPI Horizontal Back Porch (CFG_DPI_HBP)

Offset

Register	Offset
CFG_DPI_HBP	220h

Function

Sets the DSI packet payload size of the HBP blanking packet.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CFG_DPI_HBP															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 —	Reserved
15-0 CFG_DPI_HBP	Configure DPI Horizontal Back Porch Sets the DSI packet payload size, in bytes, of the horizontal back porch blanking packet.

54.7.1.35 Configure DPI Horizontal Sync Width (CFG_DPI_HSA)

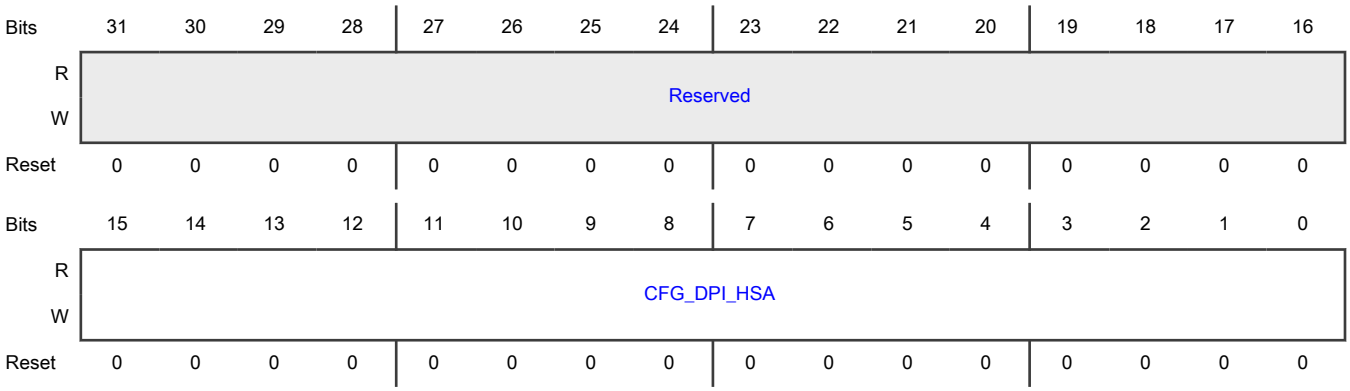
Offset

Register	Offset
CFG_DPI_HSA	224h

Function

Sets the DSI packet payload size of the HSA blanking packet.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 CFG_DPI_HSA	Configure DPI Horizontal Sync Width Sets the DSI packet payload size, in bytes, of the horizontal sync width filler blanking packet.

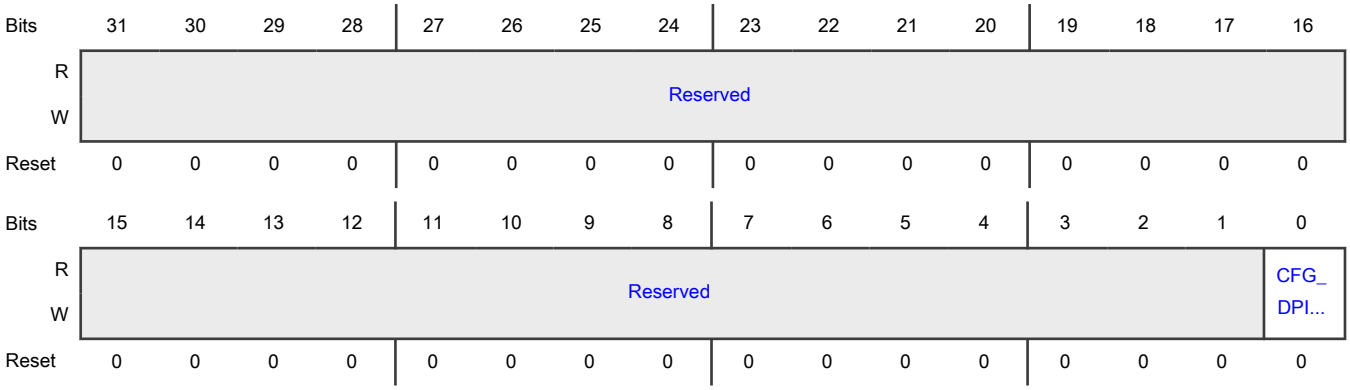
54.7.1.36 Enable Multiple Packets (CFG_DPI_ENABLE_MULT_PKTS)

Offset

Register	Offset
CFG_DPI_ENABLE_MULT_PKTS	228h

Function
Enables video line sent in two packets.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 CFG_DPI_ENABLE_MULT_PKTS	Enable Multiple Packets Per Video Line. When enabled, cfg_dpi_pixel_payload_size must be set to exactly half the size of the video line. 0 - Video Line is sent in a single packet 1 - Video Line is sent in two packets

54.7.1.37 Configure DPI Vertical Back Porch (CFG_DPI_VBP)

Offset

Register	Offset
CFG_DPI_VBP	22Ch

Function
Sets the number of lines in the vertical back porch.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

R W	Reserved				CFG_DPI_VBP											
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-12 —	Reserved
11-0 CFG_DPI_VBP	Configure DPI Vertical Back Porch

54.7.1.38 Configure DPI Vertical Front Porch (CFG_DPI_VFP)

Offset

Register	Offset
CFG_DPI_VFP	230h

Function
Sets the number of lines in the vertical front porch.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	Reserved															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Reserved				CFG_DPI_VFP											
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-12 —	Reserved
11-0 CFG_DPI_VFP	Configure DPI VPP

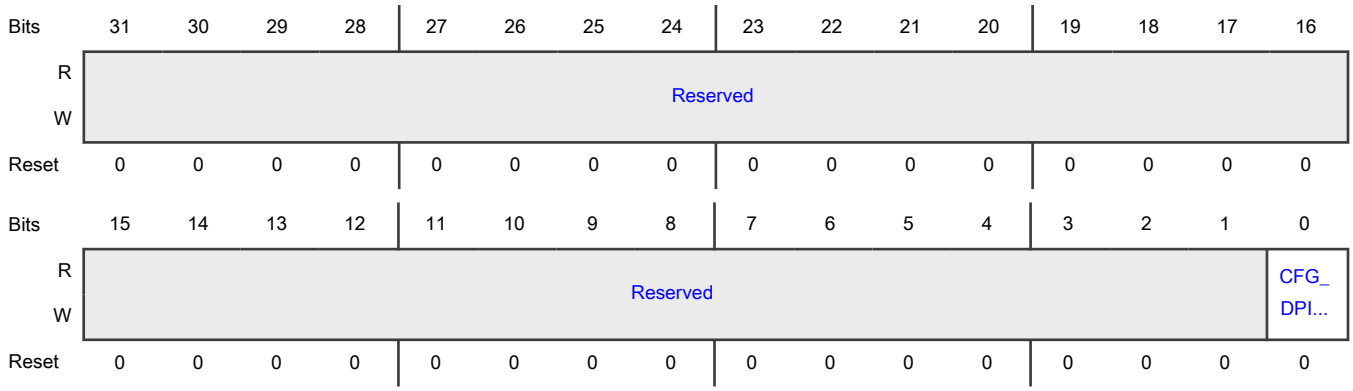
54.7.1.39 Configure DPI BLLP Mode (CFG_DPI_BLLP_MODE)

Offset

Register	Offset
CFG_DPI_BLLP_MODE	234h

Function
Used to optimize bllp periods to Low Power when possible.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 CFG_DPI_BLLP_MODE	Configure DPI BLLP Mode Optimize bllp periods to Low Power mode when possible 0 - blanking packets are sent during BLLP periods 1 - LP mode is used for BLLP periods

54.7.1.40 Configure DPI Blank Packet in BLLP (CFG_DPI_USE_NULL_PKT_BLLP)

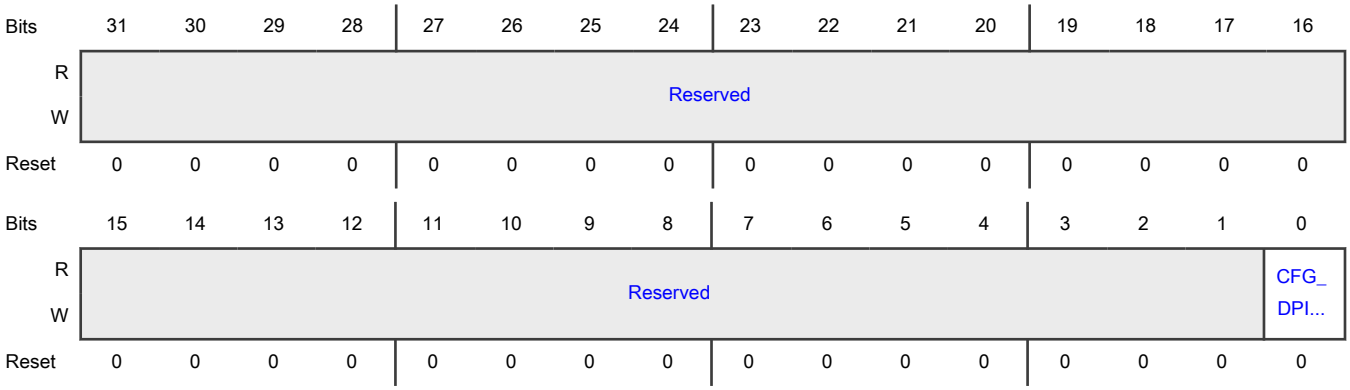
Offset

Register	Offset
CFG_DPI_USE_NULL_PKT_BLLP	238h

Function

Selects type of blanking packet to be sent during bllp region.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 CFG_DPI_USE_NULL_PKT_BLLP	Configure DPI Blank Packet in BLLP Selects type of blanking packet to be sent during bllp region. 0 - Blanking packet used in bllp region 1 - Null packet used in bllp region

54.7.1.41 Configure DPI Vertical Active (CFG_DPI_VACTIVE)

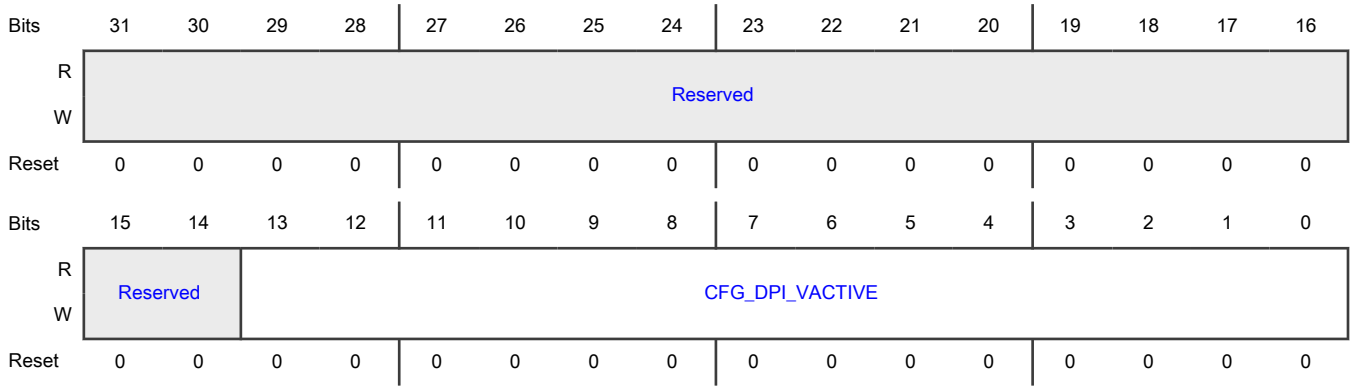
Offset

Register	Offset
CFG_DPI_VACTIVE	23Ch

Function

Sets the number of lines in the Vertical Active.

Diagram



Fields

Field	Function
31-14 —	Reserved
13-0 CFG_DPI_VACTIVE	Configure DPI Vertical Active Sets the number of lines in the vertical active read.

54.7.1.42 Configure DPI Virtual Channel (CFG_DPI_VC)

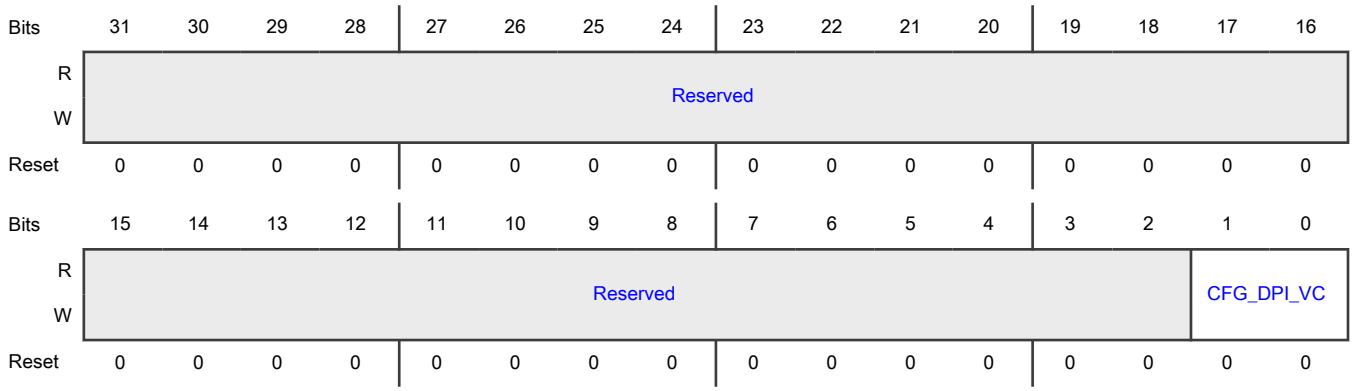
Offset

Register	Offset
CFG_DPI_VC	240h

Function

Sets the Virtual Channel (VC) of packets that will be sent to the receive packet interface.

Diagram



Fields

Field	Function
31-2 —	Reserved
1-0 CFG_DPI_VC	Configure DPI Virtual Channel Packets with VC not equal to this value are discarded and the "DSI VC ID Invalid" bit (bit 12) in the DSI error report is set.

54.7.1.43 DPI Underrun Error (DPI_UNDERRUN_ERR)

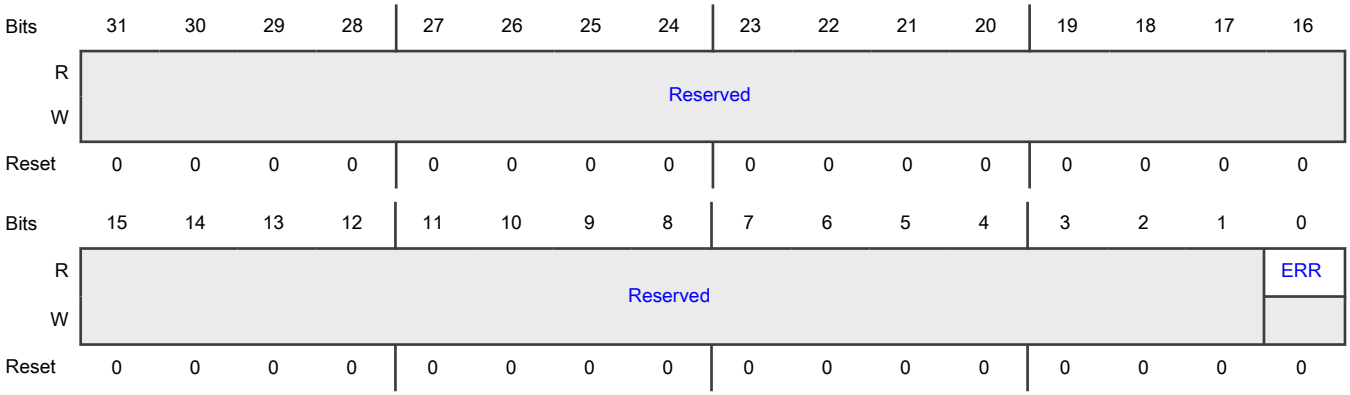
Offset

Register	Offset
DPI_UNDERRUN_ERR	244h

Function

Indicates Host DPI FIFO underrun error detected.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 ERR	Error detected 0b - No error 1b - Error

54.7.1.44 Transmit Payload (TX_PAYLOAD)

Offset

Register	Offset
TX_PAYLOAD	280h

Function

Writes to this registers load the payload fifo with 32 bit values.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	TX_PAYLOAD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	TX_PAYLOAD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 TX_PAYLOAD	Tx Payload Data Write

54.7.1.45 Packet Control (PKT_CONTROL)

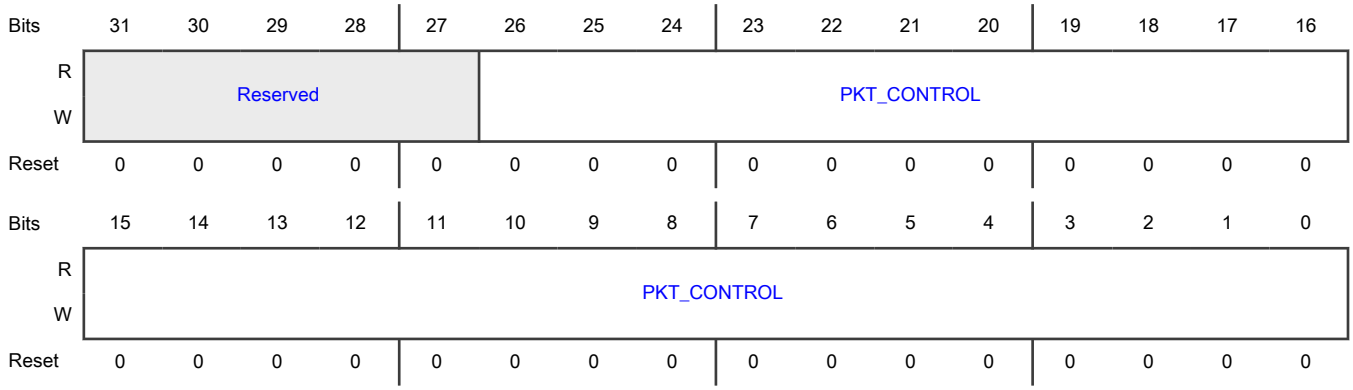
Offset

Register	Offset
PKT_CONTROL	284h

Function

Sets values for packet control.

Diagram



Fields

Field	Function
31-27 —	Reserved
26-0 PKT_CONTROL	Tx Packet Control [15:0] - Packet word count [17:16] - Packet Virtual Channel [23:18] - Packet Header DSI Data Type [24] - LP or HS select. 0 - LP mode, 1 - HS mode [25] - Perform BTA after packet is sent [26] - Perform BTA only, no packet tx

54.7.1.46 Send Packet (SEND_PACKET)

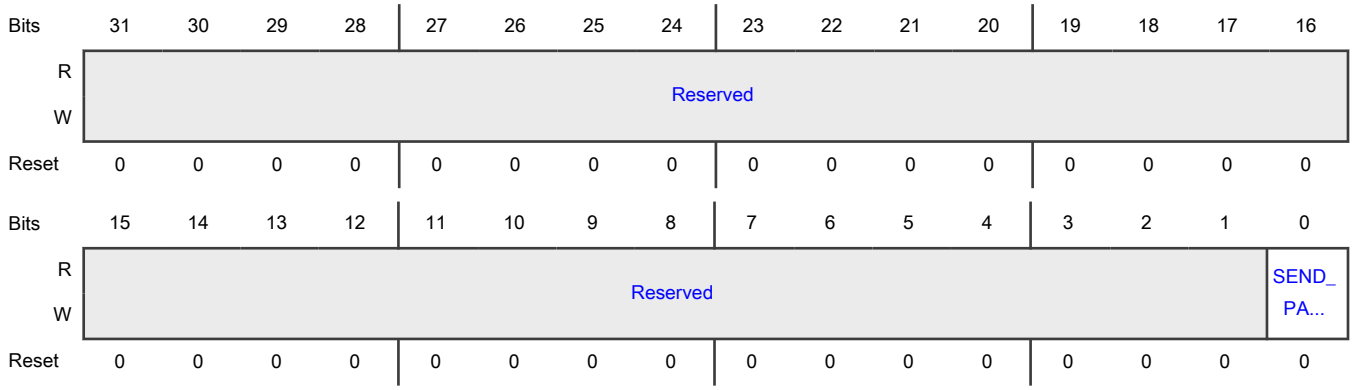
Offset

Register	Offset
SEND_PACKET	288h

Function

Tx send packet, writing to this register causes the packet described in dsi_host_pkt_control to be sent.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 SEND_PACKET	Send Packet

54.7.1.47 Packet Status (PKT_STATUS)

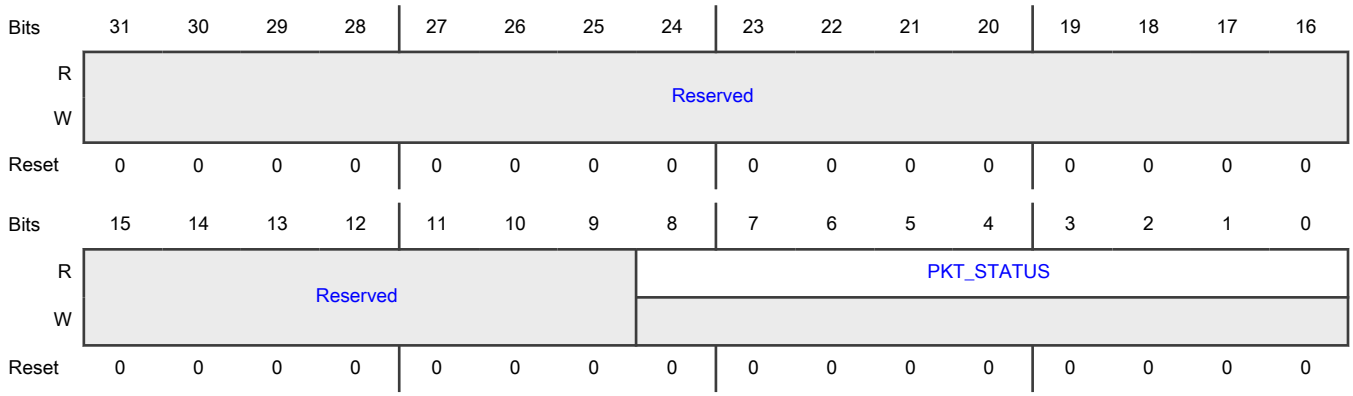
Offset

Register	Offset
PKT_STATUS	28Ch

Function

Status of APB to packet interface

Diagram



Fields

Field	Function
31-9 —	Reserved
8-0 PKT_STATUS	Packet Status [0] - state machine not idle [1] - Tx packet done [2] - dphy direction 0 - tx had control, 1 - rx has control [3] - tx fifo overflow [4] - tx fifo underflow [5] - rx fifo overflow [6] - rx fifo underflow [7] - rx packet header has been received [8] - all rx packet payload data has been received

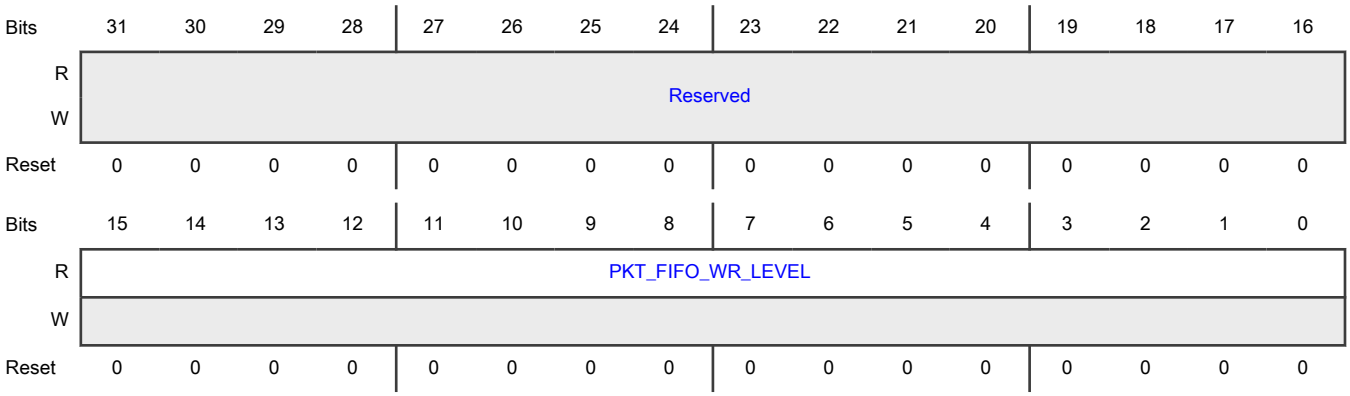
54.7.1.48 Packet FIFO Write (PKT_FIFO_WR_LEVEL)

Offset

Register	Offset
PKT_FIFO_WR_LEVEL	290h

Function
Write level of APB to pkt interface fifo.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 PKT_FIFO_WR_LEVEL	Packet FIFO Write Level

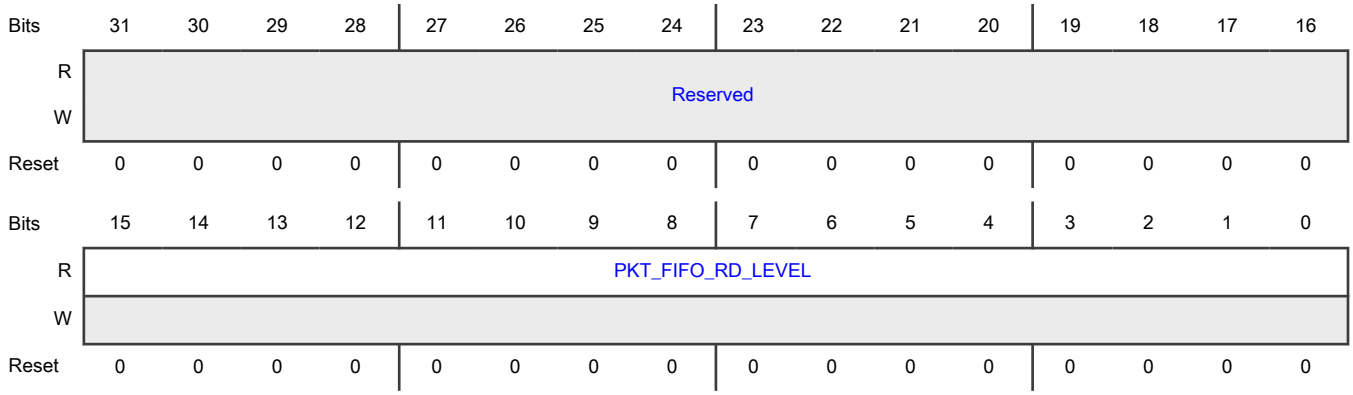
54.7.1.49 Packet FIFO Read (PKT_FIFO_RD_LEVEL)

Offset

Register	Offset
PKT_FIFO_RD_LEVEL	294h

Function
Read level of APB to pkt interface fifo.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 PKT_FIFO_RD_LEVEL	Packet FIFO Read Level

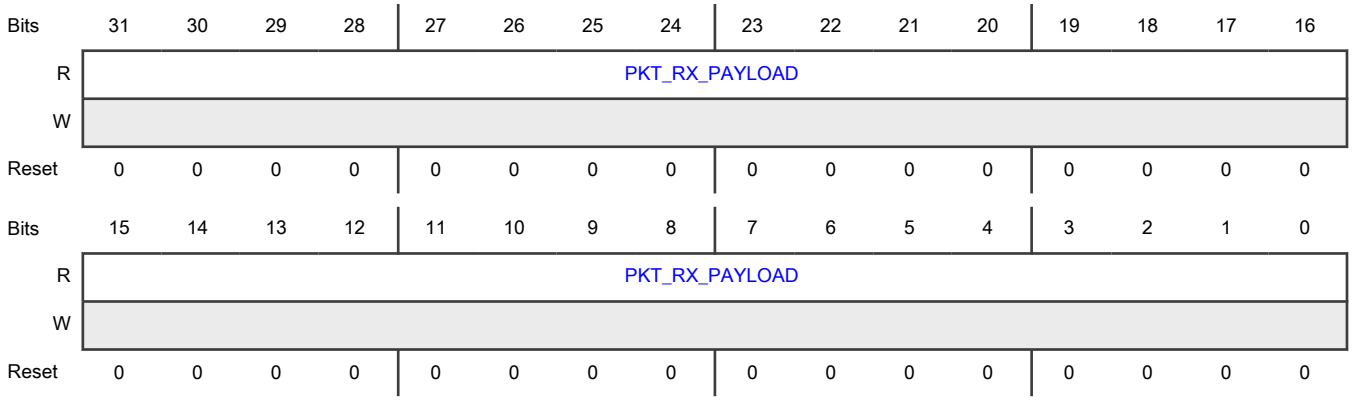
54.7.1.50 Packet Rx Payload (PKT_RX_PAYLOAD)

Offset

Register	Offset
PKT_RX_PAYLOAD	298h

Function
APB to pkt interface rx payload read.

Diagram



Fields

Field	Function
31-0 PKT_RX_PAYLOAD	Packet Rx Payload

54.7.1.51 Packet Rx Packet Header (PKT_RX_PKT_HEADER)

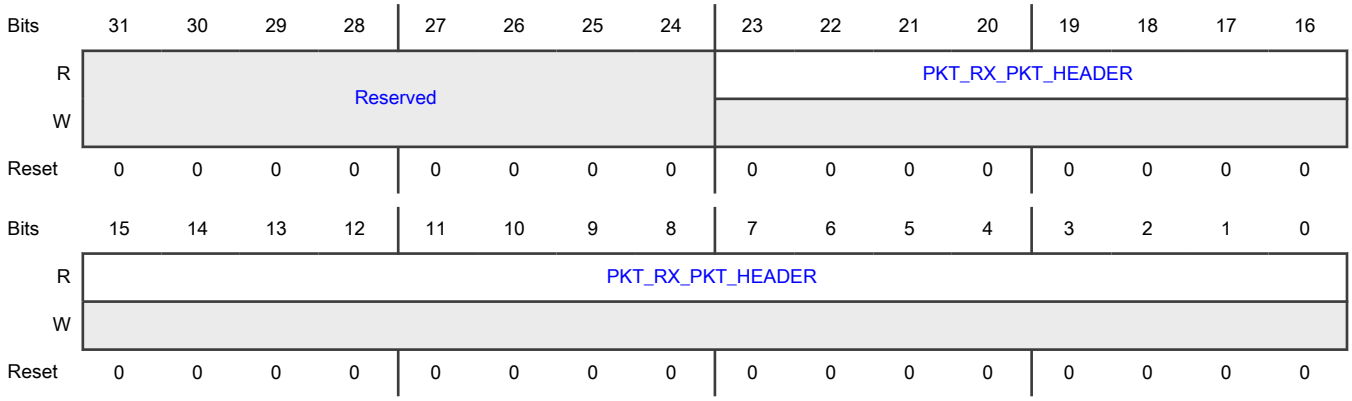
Offset

Register	Offset
PKT_RX_PKT_HEADER	29Ch

Function

APB to pkt interface rx packet header

Diagram



Fields

Field	Function
31-24 —	Reserved
23-0 PKT_RX_PKT_HEADER	Packet Rx Packet Header APB to pkt interface rx packet header [15:0] word count [21:16] data type [23:22] Virtual Channel

54.7.1.52 Interrupt Status (IRQ_STATUS)

Offset

Register	Offset
IRQ_STATUS	2A0h

Function

Status of APB to packet interface

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	IRQ_STATUS															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 IRQ_STATUS	Interrupt Status Status of APB to packet interface [0] - state machine not idle [1] - Tx packet done [2] - dphy direction 0 - tx had control, 1 - rx has control [3] - tx fifo overflow [4] - tx fifo underflow [5] - rx fifo overflow [6] - rx fifo underflow [7] - rx packet header has been received [8] - all rx packet payload data has been received [28:9] - map directory to dsi host controller status_out port bit descriptions [29] - host bta timeout, host controller host_bta_timeout port [30] - low power rx timeout, host controller lp_rx_timeout port [31] - high speed tx timeout, host controller hs_tx_timeout port

54.7.1.53 Interrupt Status 2 (IRQ_STATUS2)

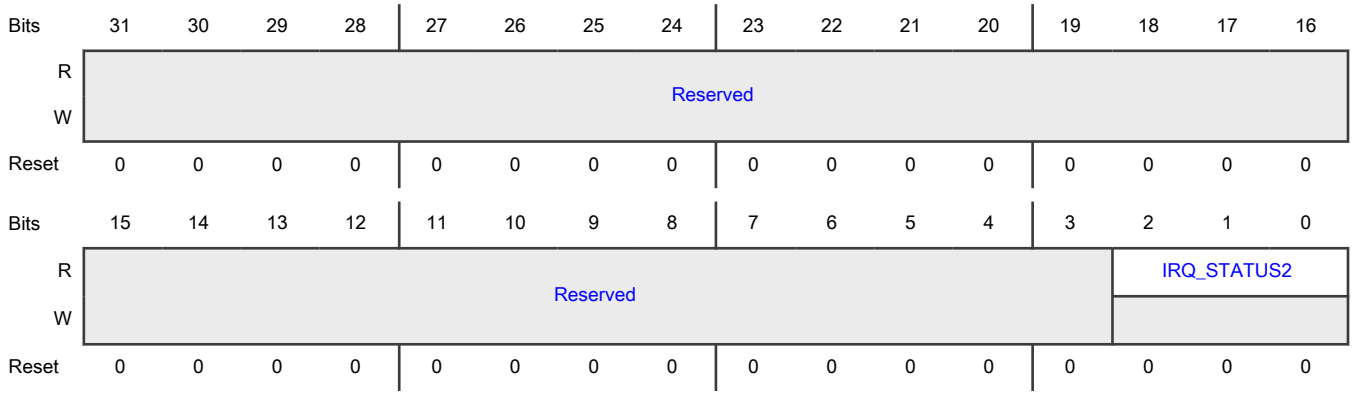
Offset

Register	Offset
IRQ_STATUS2	2A4h

Function

Status of APB to packet interface part 2, read part 2 first then dsi_host_irq_status.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 IRQ_STATUS2	Interrupt Status 2 Reading dsi_host_irq_status will clear both status and status2 [0] - single bit ecc error [1] - multi bit ecc error [2] - crc error

54.7.1.54 Mask Interrupt (IRQ_MASK)

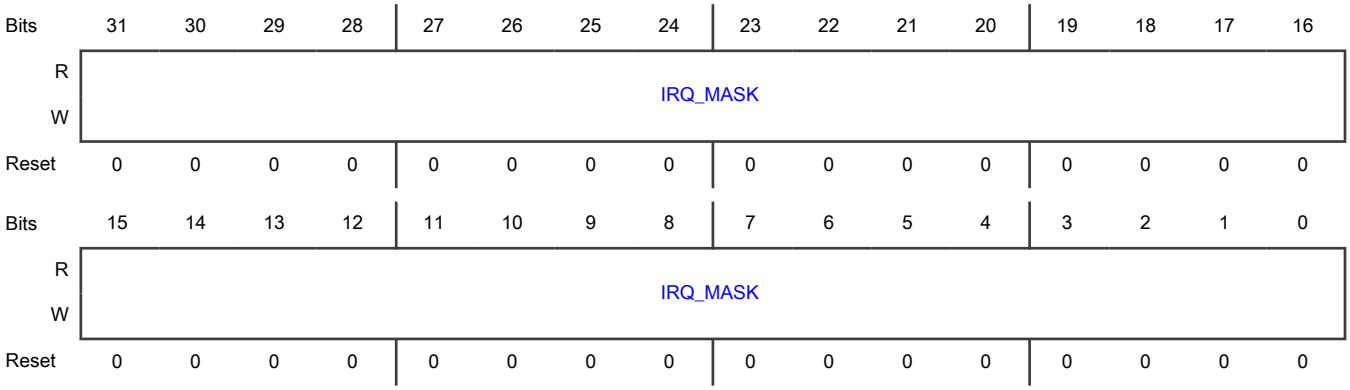
Offset

Register	Offset
IRQ_MASK	2A8h

Function

Contains various mask interrupts.

Diagram



Fields

Field	Function
31-0 IRQ_MASK	Mask Interrupt irq mask [0] - state machine not idle [1] - Tx packet done [2] - dphy direction 0 - tx had control, 1 - rx has control [3] - tx fifo overflow [4] - tx fifo underflow [5] - rx fifo overflow [6] - rx fifo underflow [7] - rx packet header has been received [8] - all rx packet payload data has been received [28:9] - map directory to dsi host controller status_out port bit descriptions [29] - host bta timeout, host controller host_bta_timeout port [30] - low power rx timeout, host controller lp_rx_timeout port [31] - high speed tx timeout, host controller hs_tx_timeout port

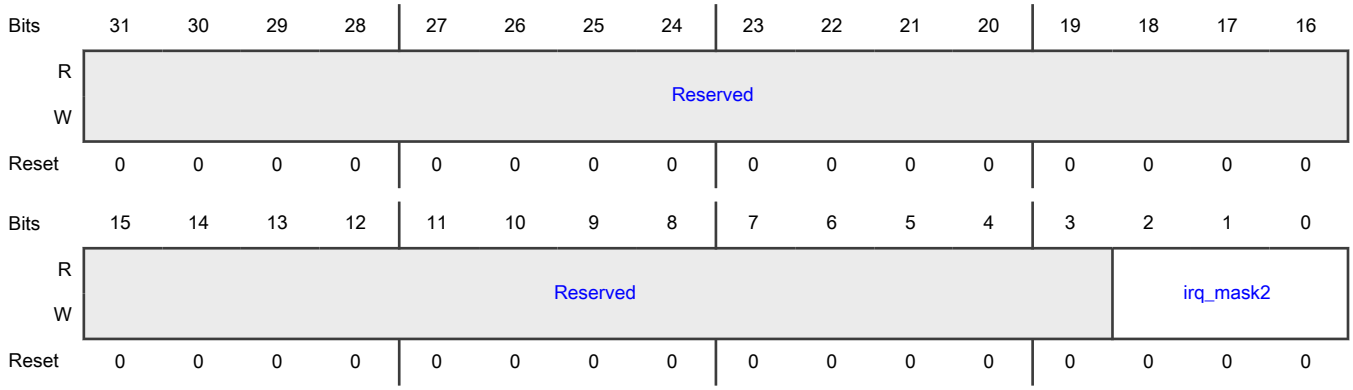
54.7.1.55 Interrupt Mask 2 (IRQ_MASK2)

Offset

Register	Offset
IRQ_MASK2	2ACh

Function
Contains various mask interrupts.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 irq_mask2	Interrupt Mask 2 irq mask 2 [0] - single bit ecc error [1] - multi bit ecc error [2] - crc error

54.7.1.56 DPHY Power Down (PD_DPHY)

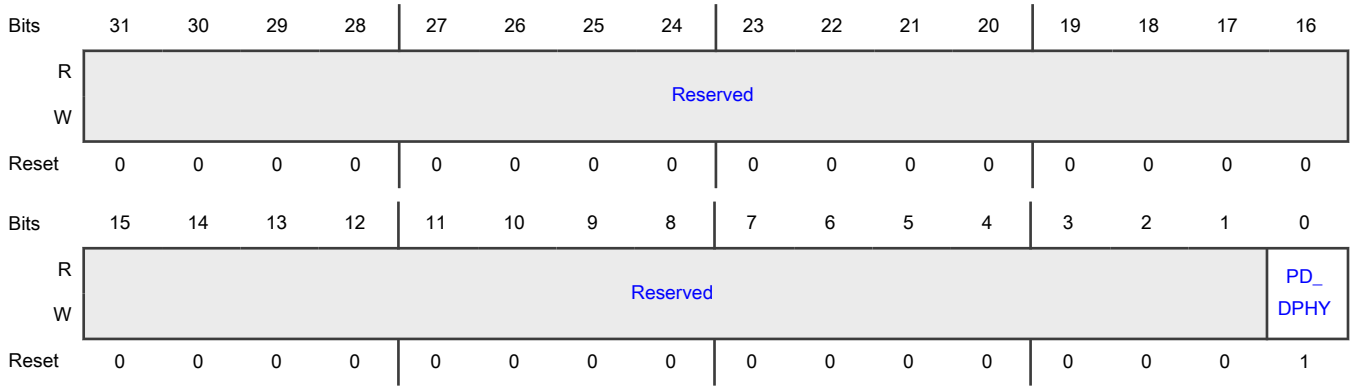
Offset

Register	Offset
PD_DPHY	300h

Function

Power Down Input for D-PHY

Diagram



Fields

Field	Function
31-1 —	Reserved
0 PD_DPHY	Power Down Input for D-PHY 0b - Power up 1b - Power down

54.7.1.57 Program T_HS_PREPARE (M_PRG_HS_PREPARE)

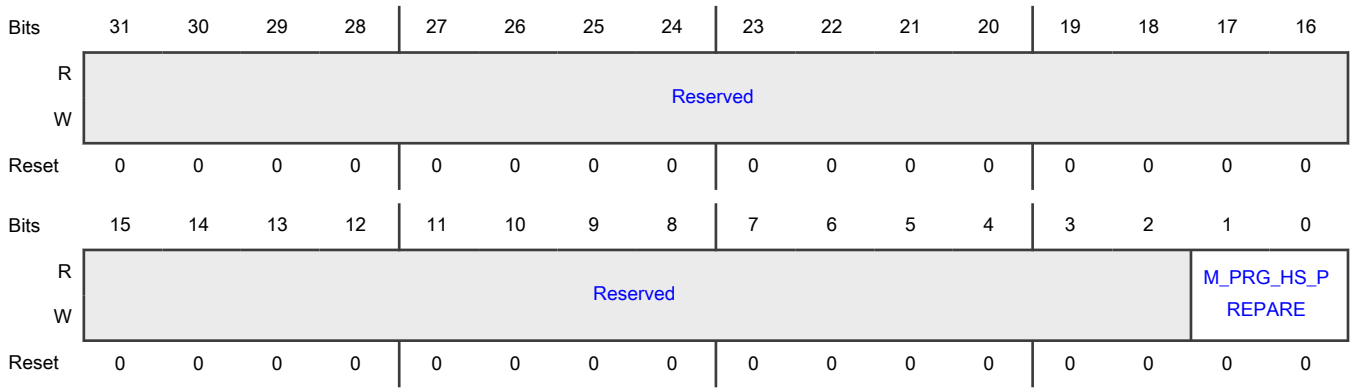
Offset

Register	Offset
M_PRG_HS_PREPARE	304h

Function

Used to program T_HS_PREPARE time.

Diagram



Fields

Field	Function
31-2 —	Reserved
1-0 M_PRG_HS_PREPARE	DPHY m_PRG_HS_PREPARE Input Bits used to program T_HS_PREPARE time in the beginning of high speed transmission mode. For more details on how to program this field, see DPHY Programming.

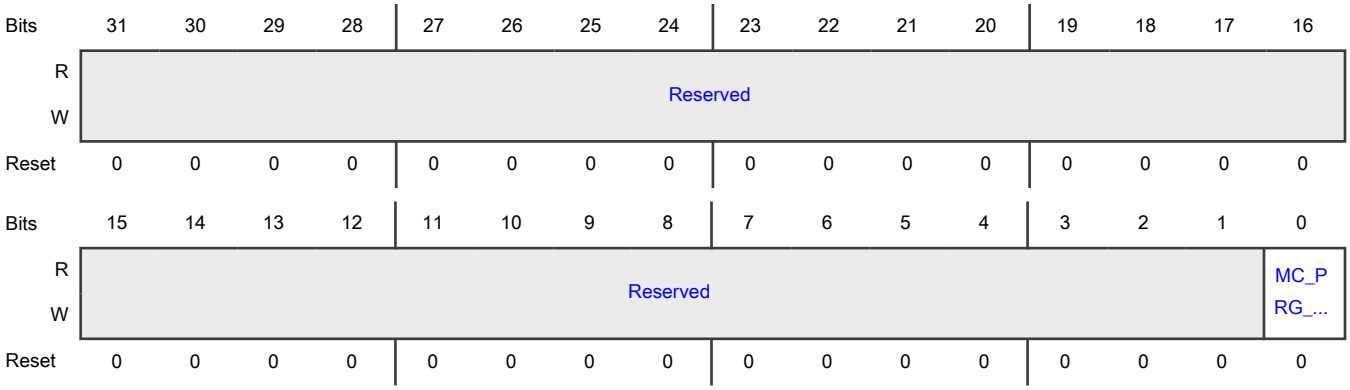
54.7.1.58 Program HS T_CLK_PREPARE (MC_PRG_HS_PREPARE)

Offset

Register	Offset
MC_PRG_HS_PREPARE	308h

Function
Used to program T_CLK_PREPARE time.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 MC_PRG_HS_PREPARE	DPHY mc_PRG_HS_PREPARE input Bits used to program T_CLK_PREPARE time in the beginning of high speed transmission mode. For more details on how to program this field, see DPHY Programming.

54.7.1.59 Program T_HS_ZERO (M_PRG_HS_ZERO)

Offset

Register	Offset
M_PRG_HS_ZERO	30Ch

Function
Used to program T_HS_ZERO time.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

55.2 Overview

NOTE

This chapter describes the Vivante® IP DC8000Nano and contains copyright material disclosed with permission of VeriSilicon.

LCDIF is a high-performance, low-power display processor unit (DPU). It outputs video and graphic streams from a single output panel. The single output panel can connect to either a display pixel interface (DPI) device or a display bus interface (DBI) device to support RGB output.

NOTE

The terminology in this chapter has been updated to align with NXP's inclusive language standards, as shown in the table below.

Table 535. Updated terms

Updated term	Deprecated term

55.2.1 Block diagram

Figure 203 shows the function blocks.

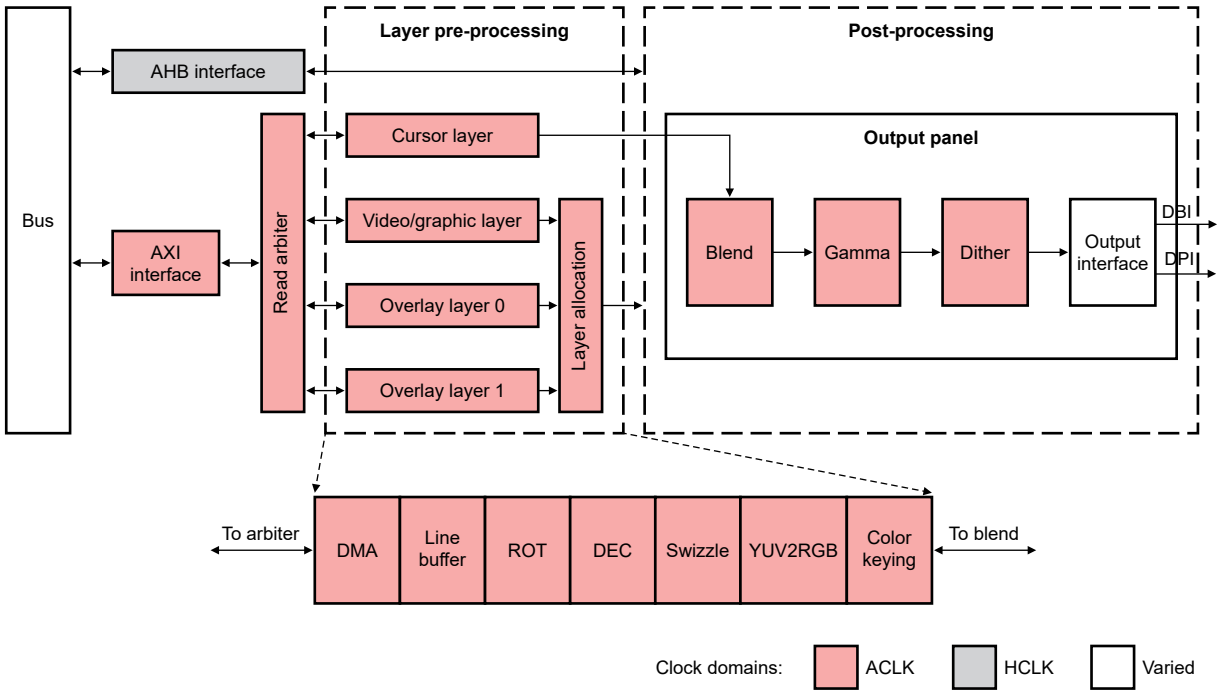

Figure 203. Block diagram

Table 536 summarizes the LCDIF submodules.

Table 536. Submodules

Module name	Description
AHB interface	Provides register access
AXI interface	Provides external memory access and reading of frame buffer data
Cursor	Includes one cursor layer to provide hardware cursor functionality
Layer	Supports: • One layer for video or graphics (VG layer) • Two overlay layers Each of these has DMA to support these pre-processing tasks: • Line buffer • Rotation or flip (ROT) • DECNano decompression and ETC2 decompression (DEC) • Swizzle • YUV-to-RGB color space conversion (YUV2RGB), except for overlay layer 1 • Color keying
Output panel	Provides post-processing computing functions, including:

Table continues on the next page...

Table 536. Submodules (continued)

Module name	Description
	• Alpha blending • Gamma • Dither
Output interface	Provides DPI or DBI for display output. LCDIF uses the DBI interface by default. The supported DBI types include: • Type A (Fixed E mode or Clocked E mode) • Type B These output interfaces reside in different clock domains.

55.2.2 Features

- One AXI initiator interface
  - 64-bit data bus and 32-bit address bus
  - RGB and YUV input formats in linear or tiled mode
- One AHB target interface with a 32-bit data bus and a 32-bit address bus
- One cursor layer
  - 32 × 32 cursor size
  - ARGB8888 and masked cursor formats
- Layers
  - One VG layer with a 4 × 1K - pixel line buffer
  - Two overlay layers (overlay 0 and overlay 1); overlay 0 has a 4 × 1K - pixel line buffer
  - Each layer supports:
    - Rotation and flip
    - DEC
    - Swizzle
    - Color keying
    - YUV-to-RGB conversion (except for overlay layer 1)
  - Post-processing for pixel composition
    - Alpha blending
    - Gamma correction with three separate lookup tables
    - Dither with one lookup table
  - Output interface
    - Single output panel supporting DPI and DBI (default) with RGB output
    - DBI types A and B support RGB swizzle
    - Display resolution at 60 fps:
      - 1024 × 768 in Tiled mode

- 1280 × 720 in Linear mode

— Double-buffered register support for display

— Power management with clock gating for RAM and layers

— Video timing generation with HSYNC, VSYNC, Data Enable (DE) signals programmable timers

55.3 Functional description

55.3.1 Interface features

LCDIF provides AXI and AHB as input interfaces, and supports interfaces to both DPI and DBI at the output.

55.3.1.1 Input formats

LCDIF supports various RGB and YUV input formats for the VG and overlay layers to read data. You can use linear or tiled reads:

- Linear reads access the buffer from left to right and from top to bottom, line by line.
- Tiled reads access the buffer tile by tile. This optimizes space and data readability.

NOTE

Overlay 1 does not support tiled reads.

The following table lists the supported input formats. One layer supports 2 KB of requests before data is returned.

Table 537. Input formats and alignments

Read type	Input format	AXI burst length (bytes)	Maximum read OTs per layer	Stride alignment (bytes)	Base address alignment (bytes)
Linear	RGB888	48	32	64	64
Linear	RGB888 compressed	8, 16, 24, or 32	32	64	64
Linear	ARGB8888	64	32	64	64
Linear	ARGB8888 compressed	8, 16, 24, 32, or 40	32	64	64
Linear	ARGB1555	64	32	64	64
Linear	RGB565	64	32	64	64
Linear	A8RGB565	48	32	64	64
Linear	ARGB4444	64	32	64	64
Tiled	Tiled RGB888	48 (3 bytes × 16 pixels)	32	64	64
Tiled	Tiled RGB888 compressed	16	32	64	64
Tiled	Tiled ARGB8888	64 (4 bytes × 16 pixels)	32	64	64
Tiled	Tiled ARGB8888 compressed	8, 16, 24	32	64	64

Table continues on the next page...

Table 537. Input formats and alignments (continued)

Read type	Input format	AXI burst length (bytes)	Maximum read OTs per layer	Stride alignment (bytes)	Base address alignment (bytes)
Tiled	Tiled A8RGB565	48	32	64	64
Tiled	Tiled YUY2	64 [2 bytes × (16+16) pixels]	32	64	64
Tiled	Tiled NV12	32	64	Y: 64 UV:32	Y: 64 UV:32

NOTE

The total number of read OTs for all the VG and overlay layers cannot exceed 64.

55.3.1.1.1 Linear formats

The pixel data in linear format is stored in the memory line by line, from left to right, and from top to bottom. You can store only RGB formats in Linear mode.

- For the 16-bpp RGB format data, 64 bytes are stored in 32×1 Linear mode
- For the 24-bpp RGB format data, 48 bytes are stored in 16×1 Linear mode
- For the 32-bpp RGB format data, 64 bytes are stored in 16×1 Linear mode.

Figure 204. 16-bpp RGB data stored in 32×1 Linear mode

Figure 205. 24-bpp or 32-bpp RGB pixel data stored in 16×1 Linear mode

55.3.1.1.2 Tiled ARGB8888/RGB888/A8RGB565 and tiled YUY2 formats

The ARGB8888/RGB888/A8RGB565 tiled format and the tiled YUY2 format use the 4×4 tile. The request bursts of the two formats fetch tiles in different ways:

- For the tiled ARGB8888/RGB888/A8RGB565 format, one burst fetches one tile. See Figure 206.

  Each tile is 4×4 with pixel data in 4×4 which are placed in the consecutive addresses as shown in the right diagram below in Figure 206. For ARGB8888, one 4×4 tile takes consecutive 64-byte memory space.

  Figure 206 illustrates n bursts to fetch the first 4 lines, with each burst fetching one tile.

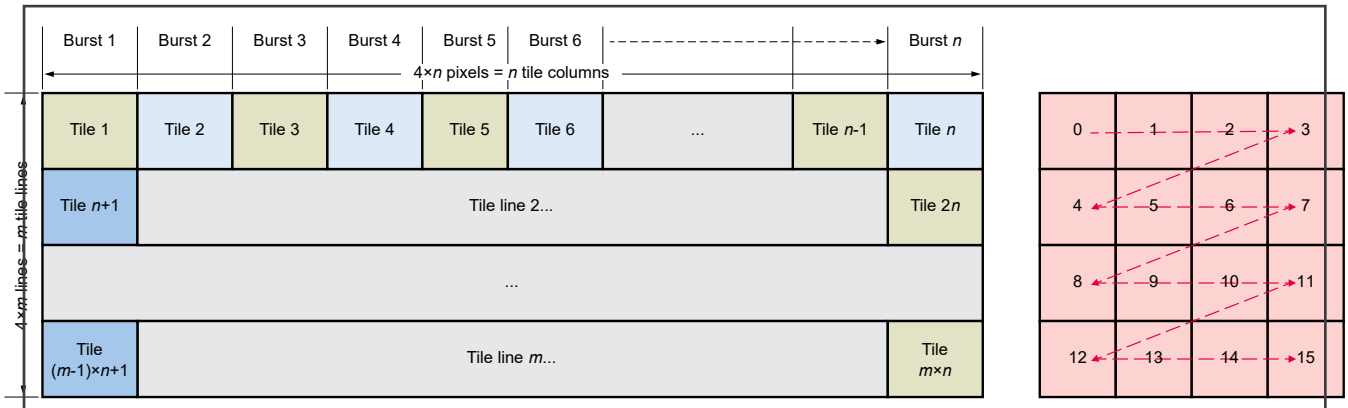

Figure 206. Screen space view: Request burst of the tiled ARGB8888 format (left) and pixel data read inside one 4×4 tile (right)

Although both of linear and tiled formats, LCDIF fetches pixels in consecutive addresses. Since LCDIF output is always linear, it needs to reorder the pixels in tiled format, and ultimately generates the linear output.

- For the tiled YUY2 format, one burst fetches two continuous tiles in the horizontal direction. The horizontal tile number for one frame of the YUY2 tiled format must be an even number. See Figure 207.

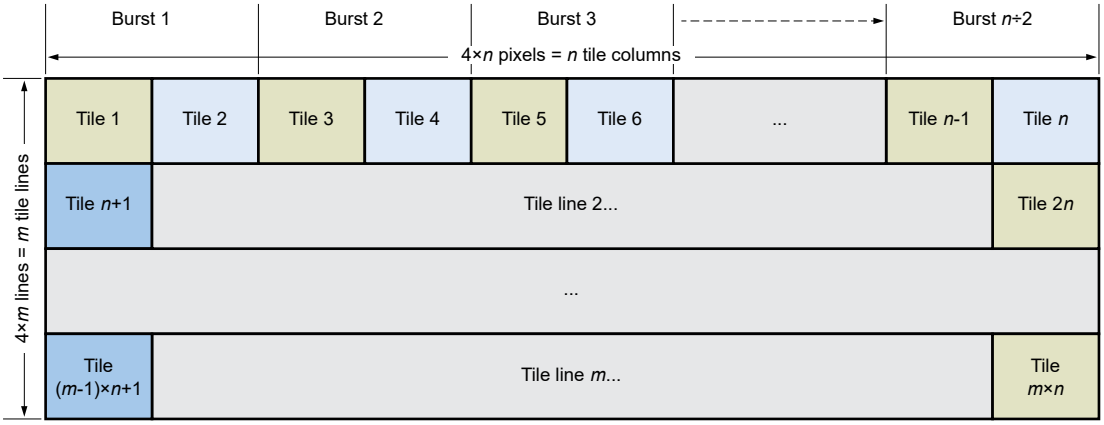

Figure 207. Screen space view: Request burst of the tiled YUY2 format

55.3.1.1.3 Tiled NV12 formats

The tiled NV12 format uses the 8×8 tile for the Y plane and the 4×4 tile for the UV plane. The AXI burst length is 32 bytes for both the Y and UV data.

For the Y plane, one burst fetches half the Y tile (8×4). Figure 208 shows that two bursts are used to fetch one entire 8×8 tile for the Y plane—one is the upper 8×4 part, and the other is the lower 8×4 part. Figure 209 and Figure 210 show the request bursts in one tile line and the tile arrangement, respectively.

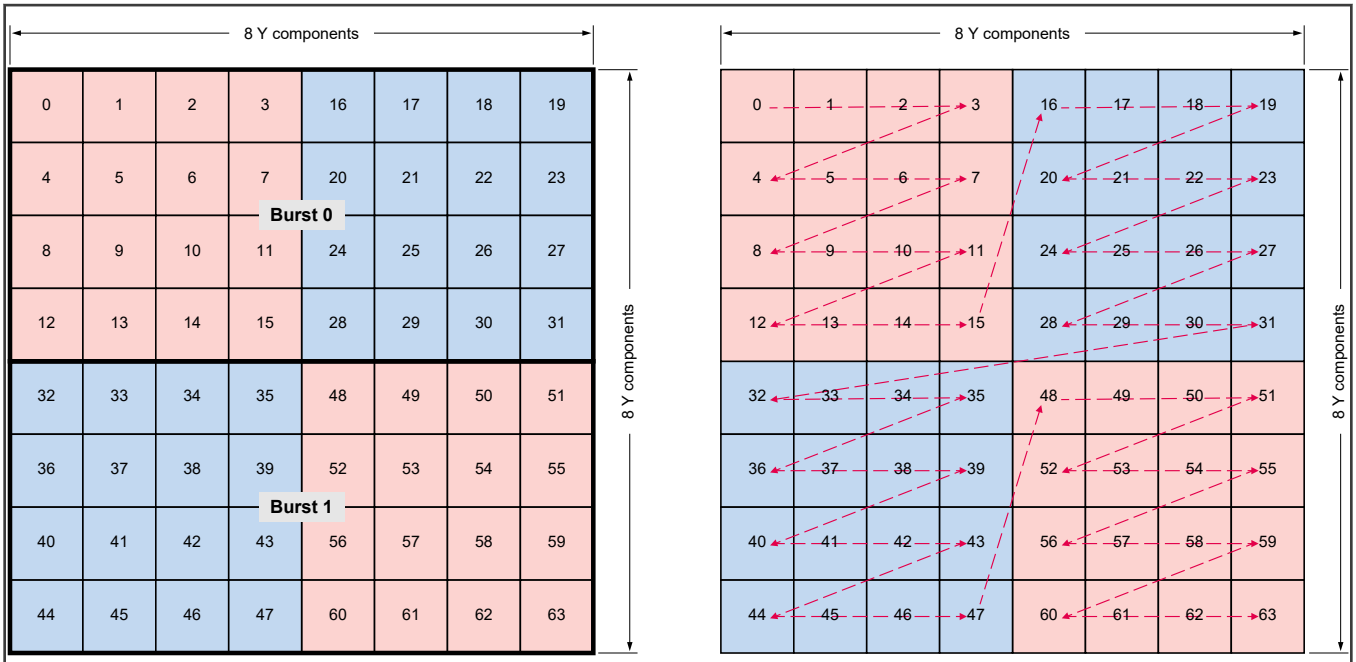

Figure 208. Request burst division and pixel data read inside one 8×8 tile of tiled NV12 Y plane

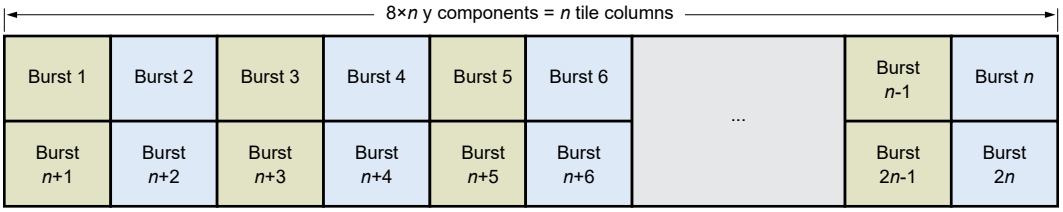

Figure 209. Request burst in one tile line for tiled NV12 Y plane

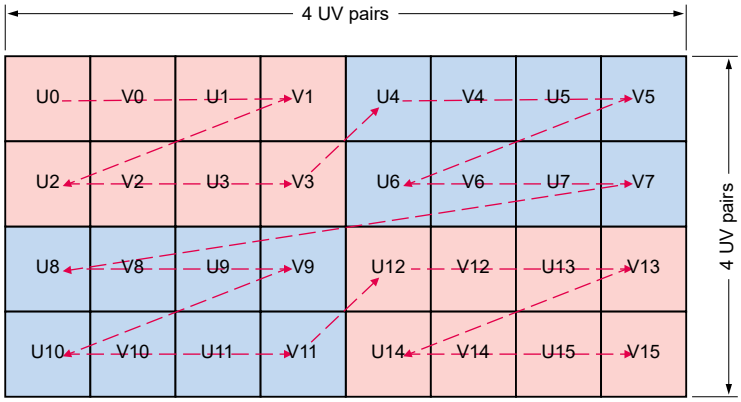

Figure 210. Pixel data read inside one 4×4 tile for tiled NV12 UV plane

For the UV plane, one burst fetches one UV tile, as shown in Figure 212 and Figure 211.

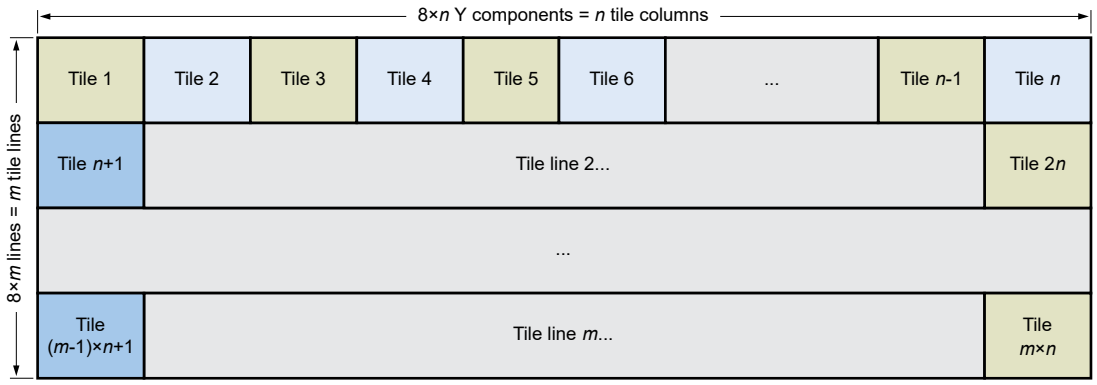

Figure 211. Screen space view: Tile arrangement for tiled NV12 Y plane

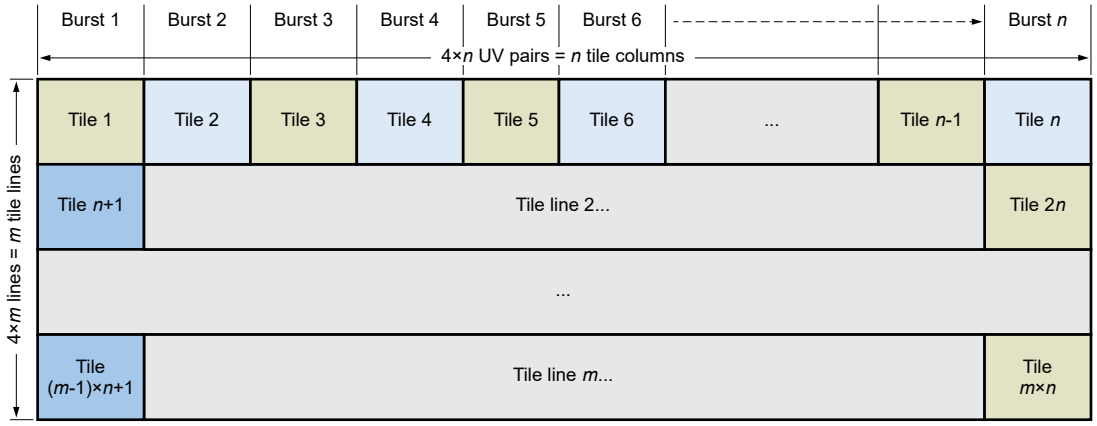

Figure 212. Screen space view: Request burst of tiled NV12 UV plane

55.3.1.1.4 Stride alignment

Stride alignment adds bytes to the end of each pixel line or tile line. This ensures that the data pattern meets the hardware requirement.

For data in linear format, the stride is used to align each pixel line. If one linear-format frame is not aligned to 64 bytes in width, you must pad the frame with dummy data after each pixel line to make it 64-byte aligned.

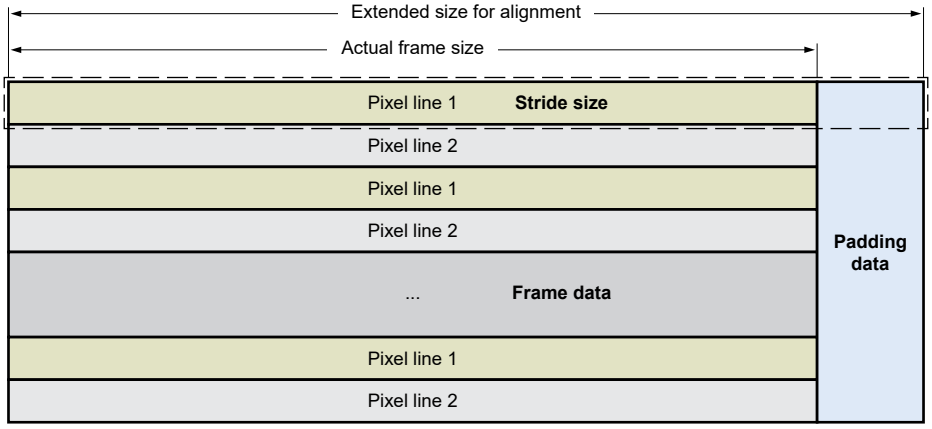

Figure 213. Stride alignment example for a frame in Linear mode

For data in tiled format, the stride is used to align each tile line. If one tiled-format frame is not aligned to the requested stride in the tile line, software pads dummy data after each tile line to make it aligned to the requested value.

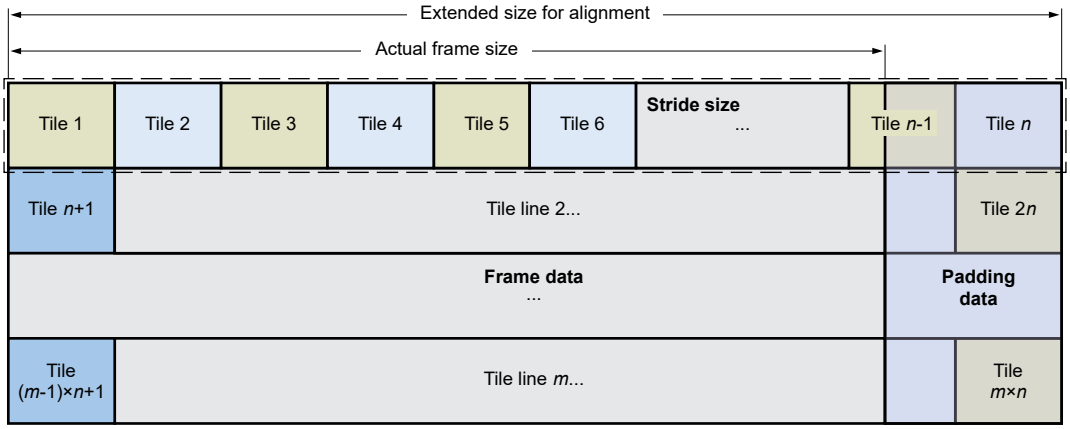

Figure 214. Stride alignment example for a frame in Tiled mode

When the input format is RGB888 or A8RGB565, you must set the stride to be the same as when the input format is ARGB8888. LCDIF then automatically calculates each tile address.

55.3.1.2 Output formats

The DPI interface supports RGB formats in 24-bit data signals. The DBI interface supports RGB formats in 8-bit, 9-bit, and 16-bit data signals.

The following sections describe the supported output formats with data bit maps.

55.3.1.2.1 DPI output formats

Figure 215 shows multiple RGB formats that the DPI interface supports.

RGB format	D23	D22	D21	D20	D19	D18	D17	D16	D15	D14	D13	D12	D11	D10	D9	D8	D7	D6	D5	D4	D3	D2	D1	D0

*Default format

Figure 215. RGB formats for DPI output

DpiConfig0[DPI_DATA_FORMAT] specifies the DPI output format.

55.3.1.2.2 DBI output timing

The method of programming DBI timing varies with DBI types. Table 538 lists the timing registers used to set AC information (such as when to assert or de-assert a signal) for each DBI type. The display controller uses t_{unit} to drive control and data signals and calculate the write period time, which defines:

- Time unit of the ACLK cycle number for DBI Type A and Type B

t_{unit} = DbiConfig0[DBI_AC_TIME_UNIT] + 1 and the minimum value of the register field is 0.

MIPI DBI has defined different AC characteristics for each DBI type, and the timing register configuration must follow corresponding AC characteristics. The following sections describe the output timing configuration and constraints for each DBI type.

Table 538. DBI timing configuration register fields

Timing Register Field	DBI Type A Fixed E Mode	DBI Type A Clocked E Mode	DBI Type B
DbiConfig0[DBI_AC_TIME_UNIT]	Time unit factor of the ACLK cycle number	Time unit factor of the ACLK cycle number	Time unit factor of the ACLK cycle number
DbiWrChar10[DBI_WR_CS_ASSERT]	CSX assert timing	NA	NA
DbiWrChar10[DBI_WR_EOR_WR_ASSERT]	NA	E and D[15:0] assert timing	WRX and D[15:0] assert timing
DbiWrChar10[DBI_WR_PERIOD]	Total ACLK cycle number in a single write period = Register field value x t_{unit}		
DbiWrChar20[DBI_WR_EOR_WR_DE_ASRT]	NA	E de-assert timing	WRX de-assert timing
DbiWrChar20[DBI_WR_CS_DE_ASRT]	CSX de-assert timing	NA	NA

55.3.1.2.2.1 DBI Type A output timing configuration

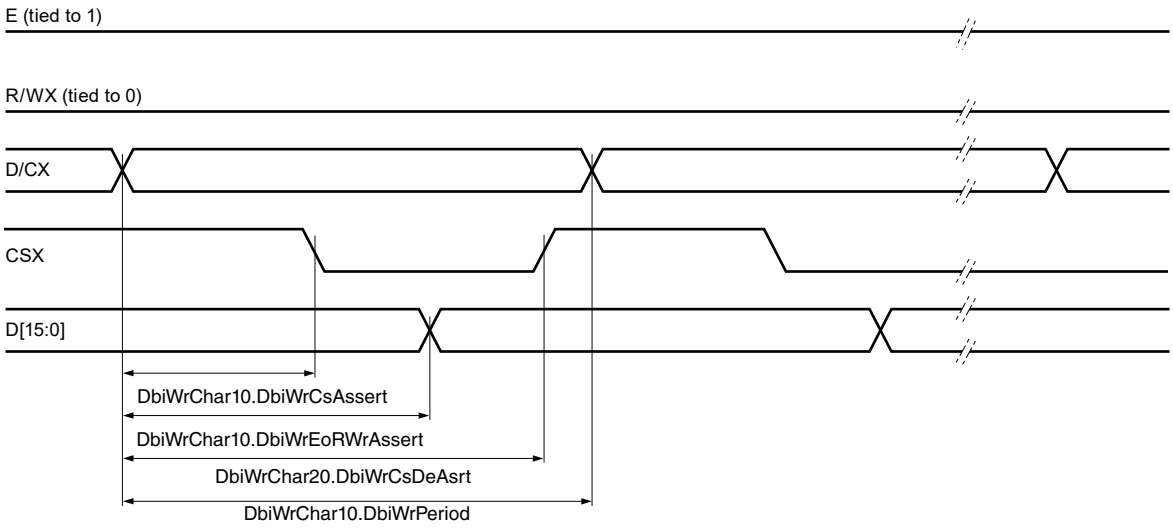

Figure 216. Output timing definition for DBI Type A fixed E mode

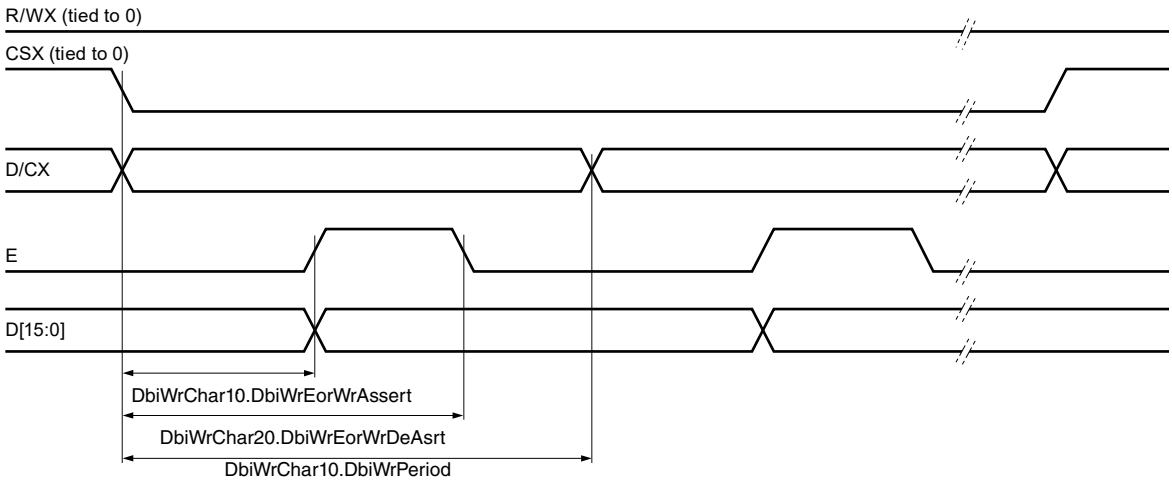

Figure 217. Output timing definition for DBI Type A clocked E mode

Table 539 shows the DBI signals used in output timing.

Table 539. DBI signals

signal	DBI Signal	Width	I/O	Description
CSX	dbiTypeab_csx	1	OUT	Chip Select for DBI Type A or B Display module is selected when low. It is set to 0 for DBI Type A in Clocked E mode.
D[15:0]	dbiTypeab_data	16	OUT	Information signal for DBI Type A or B
OE	dbiTypeab_oe	1	OUT	Data output enable for DBI Type A or B
D/CX	dbiTypeab_dcx	1	OUT	Data/Command indicator for DBI Type A or B Command is active when low.
R/WX for Type A RDX for Type B	dbiTypeab_rwx_or_rdx	1	OUT	For DBI Type A, specifies whether the current cycle is for read (1) or write (0) and set to 0. For DBI Type B, specifies whether the current cycle is for read (0) or write (1) and set to 1. For DBI Type A and Type B, read is not supported.
WRX	dbiTypeab_wrx	1	OUT	Write signal for DBI Type B Host processor writes data at falling edge.
E	dbiTypeaE	1	OUT	E clock for DBI Type A It is set to 1 for DBI Type A in Fixed E mode.

Table 540 describe the timing registers used for DBI Type A.

Table 540. Type A timing configuration register fields

DBI Type A timing register field	Description for fixed E mode	Description for clocked E mode
DbiWrChar10[DBI_WR_CS_ASSERT]	CSX assert timing	NA
DbiWrChar10[DBI_WR_EOR_WR_ASSERT]	D[15:0] assert timing	E and D[15:0] assert timing
DbiWrChar20[DBI_WR_EOR_WR_DE_ASRT]	NA	E de-assert timing
DbiWrChar20[DBI_WR_CS_DE_ASRT]	CSX de-assert timing	NA
DbiWrChar10[DBI_WR_PERIOD]	Single write period duration	Single write period duration

- The assert and de-assert register fields together with t_{unit} decide the ACLK cycle duration after which the corresponding signals are asserted or de-asserted.
  - For Fixed E mode: If DbiWrChar10[DBI_WR_CS_ASSERT] = 4, ACLK cycle number = 4 x t_{unit}. This means the CSX signal is asserted after (4 x t_{unit}) ACLK cycles.
  - For Clocked E mode: If DbiWrChar10[DBI_WR_EOR_WR_ASSERT] = 4, ACLK cycle number = 4 x t_{unit}. This means the E or D[15:0] signal is asserted after (4 x t_{unit}) ACLK cycles.
- DbiWrChar10[DBI_WR_PERIOD] decides the total ACLK cycle number in a single write period. The display controller includes a write period counter to manage signal driving. This register field configures the maximum value of this counter.

  Total cycle number in a single write period = DbiWrChar10[DBI_WR_PERIOD] x t_{unit}

  The write period counter starts from 0 for each signal. When it increments to the assert or de-assert timing configured by the assert or de-assert timing register fields, the corresponding signal is asserted or de-asserted.

55.3.1.2.2.2 DBI Type A output timing constraints

Figure 218, Figure 219 and Table 541 show the AC characteristics of DBI Type A defined in MIPI DBI.

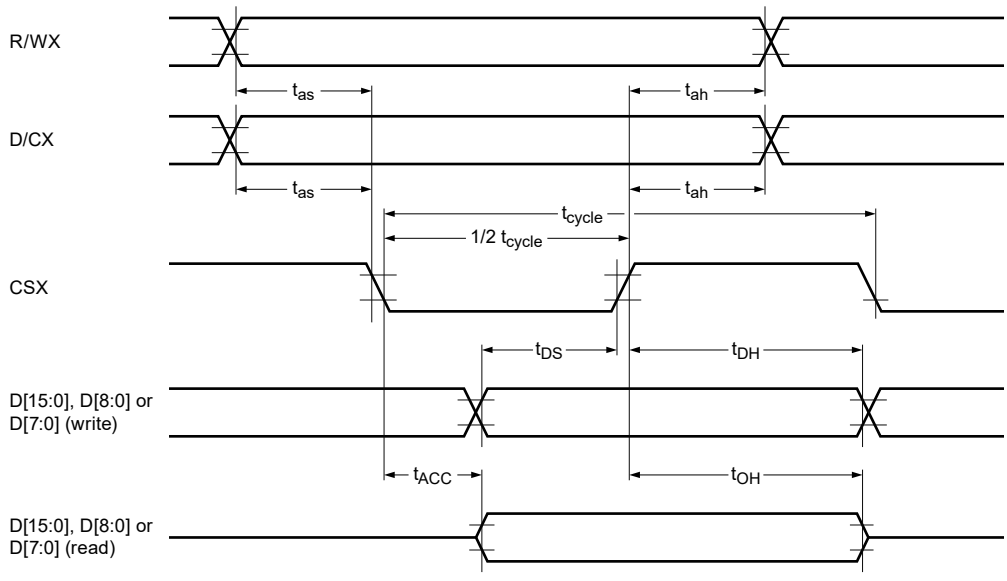

Figure 218. AC characteristics of DBI Type A fixed E mode

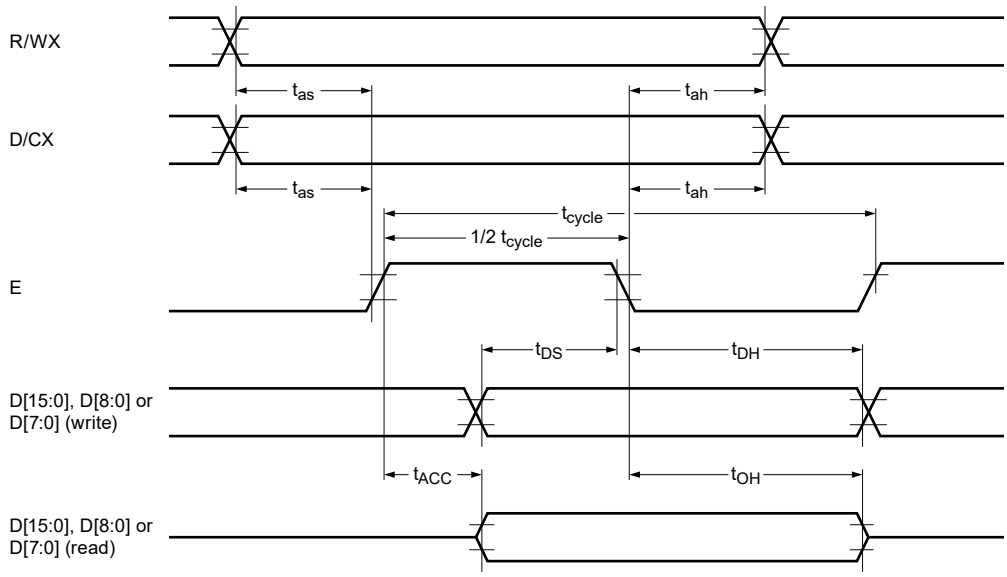

Figure 219. AC characteristics of DBI Type A clocked E mode

Table 541. AC characteristics description of DBI Type A

Signal	Symbol	Parameter	Min	Max	Unit	Description
R/WX or D/CX	t_{as}	Address setup time	T	NA	ns	
	t_{ah}	Address hold time(Write/ Read)	T	NA	ns	
CSX or E	t_{cycle}	System clock cycle time	5xT	79xT	ns	
D[15:0], D[8:0], or D[7:0]	t_{PS}	Data setup time	15	NA	ns	For maximum C_L = 30pF For minimum C_L = 8pF
	t_{PH}	Data hold time	25	NA	ns	
	t_{ACC}	Data access time	10	NA	ns	
	t_{OH}	Output hold time	10	NA	ns	

NOTE

- Ta = -30 to 70 °C, V_{DDI} range: according to Logic High level input voltage classification. GND = 0V, T = 10 ± 0.5 ns
- Does not include signal rise and fall times.

The timing register configuration for DBI Type A must meet the following requirements to ensure output timing follows the defined AC characteristics:

- For Fixed E mode:
  - DbiWrChar10[DBI_WR_CS_ASSERT] ≥ 1

    The time when the CSX signal is asserted is calculated using the following formula: DbiWrChar10[DBI_WR_CS_ASSERT] x t_{unit} x Single ACLK cycle duration.

As required by AC characteristics for DBI Type A Fixed E mode in Figure 218 and Table 541, CSX should be asserted after one t_{as}. One t_{as} lasts one T with 10 ns as the time unit for T. Therefore, the calculated CSX assert timing must be greater than or equal to 10 ns.

— DbiWrChar10[DBI_WR_CS_ASSERT] < DbiWrChar20[DBI_WR_CS_DE_ASRT] < DbiWrChar10[DBI_WR_PERIOD]

— DbiWrChar10[DBI_WR_PERIOD] ≥ 3

If the value of DbiWrChar10[DBI_WR_PERIOD] is less than 3, the display controller always changes it to 3.

- For Clocked E mode:

— DbiWrChar10[DBI_WR_EOR_WR_ASSERT] ≥ 1

The time when the E signal is asserted is calculated using the following formula:
DbiWrChar10[DBI_WR_EOR_WR_ASSERT] x t_{unit} x Single ACLK cycle duration.

As required by AC characteristics for DBI Type A Clocked E mode in Figure 219 and Table 541, E should be asserted after one t_{as}. One t_{as} lasts one T with 10 ns as the time unit for T. Therefore, the calculated E assert timing must be greater than or equal to 10 ns.

— DbiWrChar10[DBI_WR_EOR_WR_ASSERT] < DbiWrChar20[DBI_WR_EOR_WR_DE_ASRT] < DbiWrChar10[DBI_WR_PERIOD]

— DbiWrChar10[DBI_WR_PERIOD] ≥ 3

If the value of DbiWrChar10[DBI_WR_PERIOD] is less than 3, the display controller always changes it to 3.

55.3.1.2.2.3 DBI Type B output timing configuration

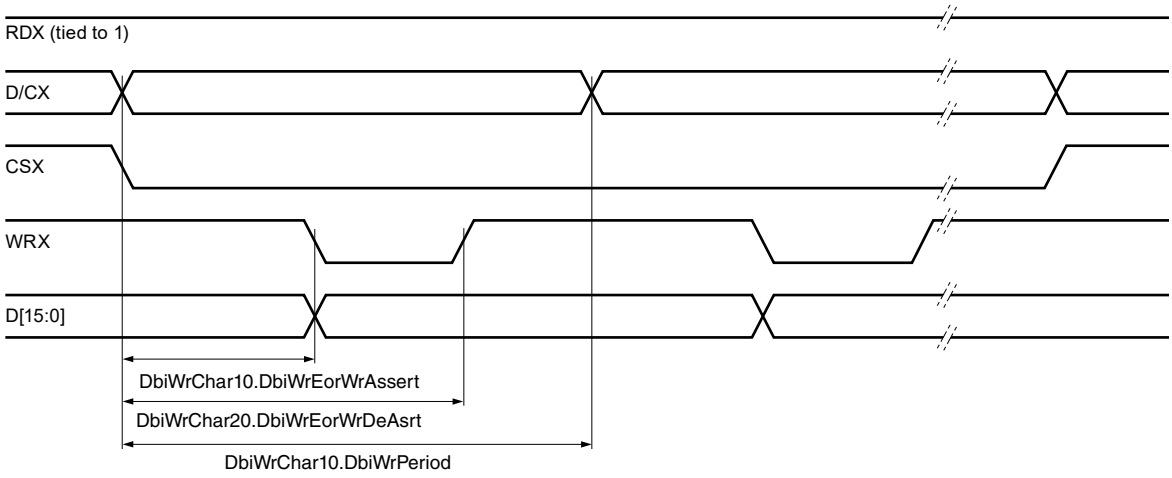

Figure 220. Output timing definition for DBI Type B

For details of DBI signals used for output timing, see Table 539.

Table 542 describe the timing registers used for DBI Type B.

Table 542. Type B timing configuration register fields

DBI Type B timing register field	Description for DBI Type B
DbiWrChar10[DBI_WR_EOR_WR_ASSERT]	WRX and D[15:0] assert timing
DbiWrChar20[DBI_WR_EOR_WR_DE_ASRT]	WRX de-assert timing
DbiWrChar10[DBI_WR_PERIOD]	Single write period duration

- The assert and de-assert register fields together with t_{unit} decide the ACLK cycle duration after which the corresponding signals are asserted or de-asserted.

  If DbiWrChar10[DBI_WR_EOR_WR_ASSERT] = 4, the WRX or D[15:0] signal is asserted after (4 × t_{unit}) ACLK cycles.

- DbiWrChar10[DBI_WR_PERIOD] decides the ACLK cycle number in a single write period.

  Total cycle number in a single write period = DbiWrChar10[DBI_WR_PERIOD] x t_{unit}

  The display controller includes a write period counter to manage signal driving. This register field configures the maximum value of this counter.

  The write period counter starts from 0 for each signal. When it increments to the assert or de-assert timing configured by the assert or de-assert timing register fields, the corresponding signal is asserted or de-asserted.

55.3.1.2.2.4 DBI Type B output timing constraints

Figure 221 and Table 543 show the AC characteristics of DBI Type B defined in MIPI DBI.

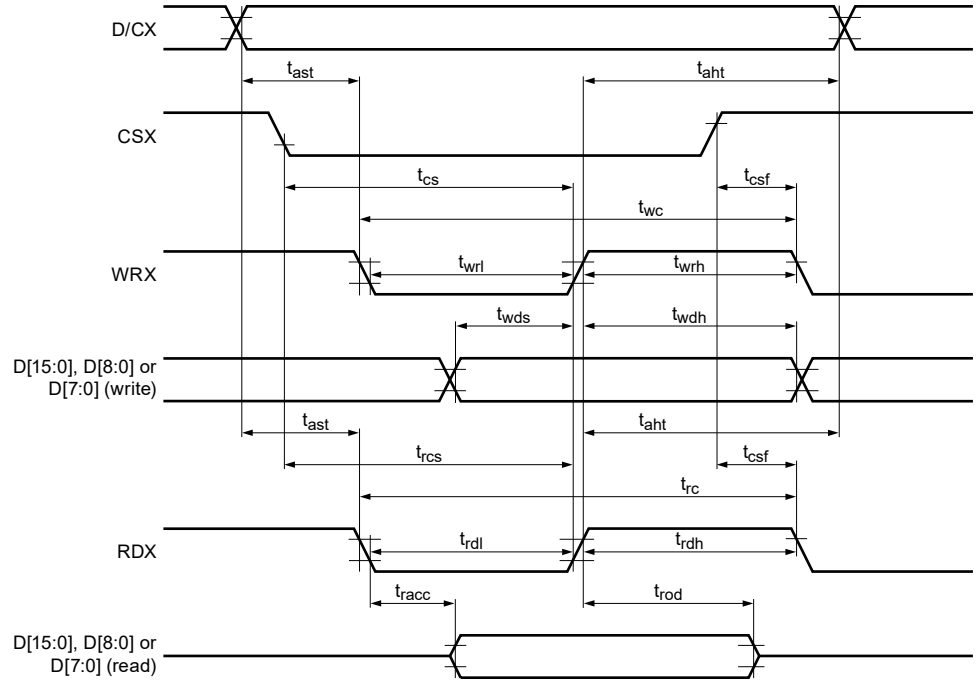

Figure 221. AC characteristics of DBI Type B

Table 543. AC characteristics description of DBI Type B

Signal	Symbol	Parameter	Min	Max	Unit	Description

	t_{aht}	Address hold time(Write/ Read)	T	NA	ns	
CSX or E	t_{cs}	Chip Select setup time (Write)	2xT	NA	ns	(2xT, 3xT, …, 16xT)

Table continues on the next page...

Table 543. AC characteristics description of DBI Type B (continued)

Signal	Symbol	Parameter	Min	Max	Unit	Description
	t_{rcs}	Chip Select setup time (Read)	2xT	NA	ns	(2xT, 3xT, …, 16xT)
	t_{csf}	Chip Select wait time (Write/ read)	20	NA	ns	NA
WRX	t_{wc}	Write cycle	5xT	79xT	ns	(5xT, 6xT, …, 79xT)
	t_{wrh}	Write Control pulse H duration	3xT	63xT	ns	(5xT, 6xT, …, 79xT)
	t_{wrl}	Write Control pulse L duration	2xT	16xT	ns	(2xT, 3xT, …, 16xT)
RDX	t_{rc}	Read cycle	5xT	79xT	ns	(5xT, 6xT, …, 79xT)
	t_{rdh}	Read Control pulse H duration	3xT	63xT	ns	(5xT, 6xT, …, 79xT)
	t_{rdl}	Read Control pulse L duration	2xT	16xT	ns	(2xT, 3xT, …, 16xT)
D[15:0], D[8:0], or D[7:0]	t_{wds}	Write data setup time	15	NA	ns	For maximum C_L = 30pF For minimum C_L = 8pF
	t_{wdh}	Write data hold time	25	NA	ns	
	t_{racc}	Read access time	10	NA	ns	
	t_{rod}	Read output disable time	10	NA	ns	

NOTE

- Ta = -30 to 70 °C, V_{DDI} range: according to Logic High level input voltage classification. GND = 0V, T = 10 ± 0.5 ns
- Does not include signal rise and fall times.

The timing register configuration for DBI Type B must meet the following requirements to ensure output timing follows the defined AC characteristics:

- DbiWrChar10[DBI_WR_EOR_WR_ASSERT] ≥ 1

  The time when the WRX signal is asserted is calculated using the following formula: DbiWrChar10[DBI_WR_EOR_WR_ASSERT] x t_{unit} x Single ACLK cycle duration.

  As required by AC characteristics for DBI Type B in Figure 221 and Table 543, WRX should be asserted after one t_{ast}. One t_{ast} lasts one T with 10 ns as the time unit for T. Therefore, the calculated WrX assert timing must be greater than or equal to 10 ns.
- DbiWrChar10[DBI_WR_EOR_WR_ASSERT] < DbiWrChar20[DBI_WR_EOR_WR_DE_ASRT] < DbiWrChar10[DBI_WR_PERIOD]
- DbiWrChar10[DBI_WR_PERIOD] ≥ 3

If the value of DbiWrChar10[DBI_WR_PERIOD] is less than 3, the display controller always changes it to 3.

55.3.1.2.3 DBI Type A and Type B output formats

DBI Type A and Type B support swizzle for RGB formats.

Figure 222 shows the RGB formats for DBI type-A and type-B output without swizzle.

RGB format	Cycle	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R3G3B2*										R			G			B	
D8R4G4B4	0									R0				G0			
	1									B0				R1			
	2									G1				B1

	1	R0								B1							
	2	G1								R1							
D16R8G8B8 option2	0									B							
	1	G								R							

*Default format

Figure 223. RGB formats for DBI type-A and type-B output with swizzle

DbiConfig[DBI_DATA_FORMAT] specifies an output format for DBI types A and B. Valid values of DBI_DATA_FORMAT for these types are 0h to Ch.

55.3.2 Layer features

55.3.2.1 Hardware cursor

LCDIF provides one cursor layer. A cursor is tracked through the top-left point of the cursor layer and the hotspot of the cursor.

55.3.2.1.1 Top-left point

The address of this point is used as the base address of the cursor, which you can configure using Cursor Base Address (CursorAddress).

This point varies with the cursor layer location:

- If a cursor layer is fully displayed in a display image, this point is the top-left point of the cursor image.

- If a cursor layer has an entire line outside the vertical boundary of a display image, the top-left point is the top point of the leftmost covered cursor layer line. Pixels in the uncovered cursor layer are not fetched from DMA.
- If a cursor layer has an entire line outside the horizontal boundary of a display image, the top-left point is still the top-left of the cursor layer. Pixels in the uncovered cursor layer are dropped after alpha blending.
- If a cursor layer has entire lines outside both the vertical and horizontal boundaries of a display image, the top-left point is the top point of the covered leftmost cursor layer line. Pixels in the uncovered cursor layer are dropped after alpha blending.

55.3.2.1.2 Hotspot

This is the point used in a search for a screen coordinate when someone makes a selection—for example, by pressing the "Enter" key on a keyboard or clicking the left button on a mouse.

The hotspot location determines the cursor position in a display image.

55.3.2.1.3 Cursor layer fully displayed

Figure 224 shows a cursor layer fully displayed in a display image. Table 544 shows the coordinates used in the figure and this section.

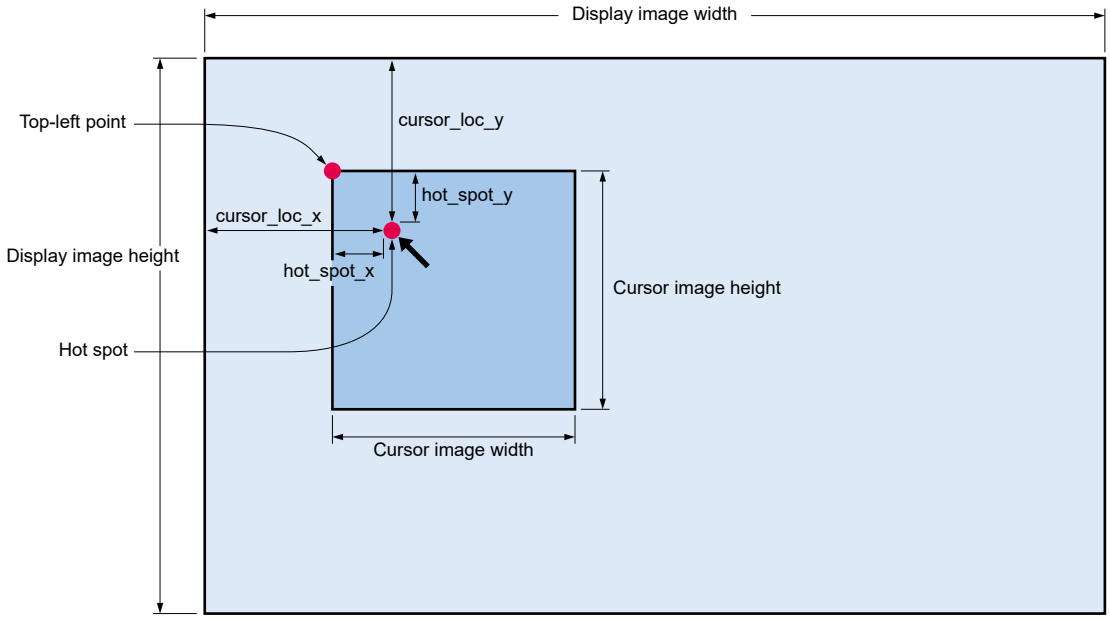

Figure 224. Cursor layer fully displayed

Table 544. Coordinates

Coordinate	Description	Field that specifies the coordinate
cursor_loc_x	Horizontal cursor location	CursorLocation[X]
cursor_loc_y	Vertical cursor location	CursorLocation[Y]
hot_spot_x	Horizontal offset to the cursor hotspot	CursorConfig[HOT_SPOT_X]
hot_spot_y	Vertical offset to the cursor hotspot	CursorConfig[HOT_SPOT_Y]

The hotspot and cursor locations must meet the following requirements to ensure a cursor layer is fully displayed:

- 0 ≤ cursor_loc_x ≤ Display image width

- 0 ≤ cursor_loc_y ≤ Display image height
- 0 ≤ hot_spot_x ≤ Cursor image width
- 0 ≤ hot_spot_y ≤ Cursor image height

55.3.2.1.4 Cursor layer partially displayed

The following figure shows some special cases where a cursor layer is partially displayed in a display image.

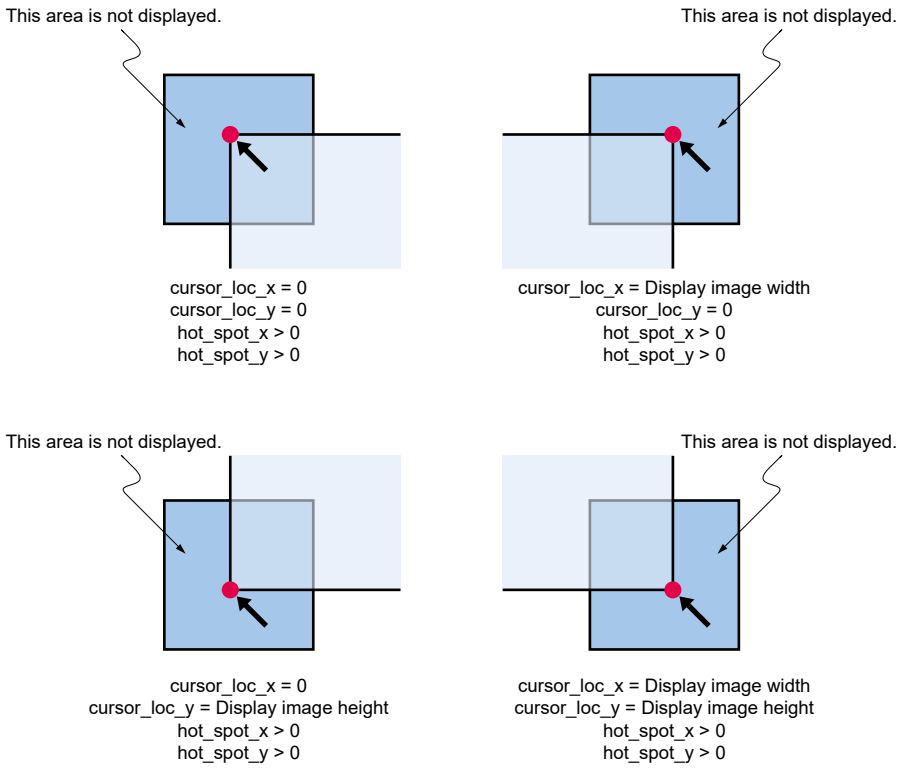

Figure 225. Cursor layer partially displayed

55.3.2.1.5 Cursor formats

The cursor image can be:

- Up to 32×32 pixels in size.
- In either ARGB8888 or masked format.

In the ARGB8888 cursor format, the ARGB values that are fetched from memory determine the color of the cursor.

In the masked cursor format, the mask values of the AND and XOR bits determine the color of one cursor pixel. The following table lists the color values for different bit configurations. Cursor Foreground Color (CursorForeground) and Cursor Background Color (CursorBackground) specify the foreground and background colors, respectively.

Table 545. Color values for different bit configurations

Bit AND	Bit XOR	Color value
0	0	Background color
0	1	Foreground color

Table continues on the next page...

Table 545. Color values for different bit configurations (continued)

Bit AND	Bit XOR	Color value
1	0	Not used
1	1	Bit inversed foreground color

55.3.2.2 Rotation and flip

LCDIF supports 180-degree rotation and flipping (along the X axis, Y axis, or both X and Y axes) of the VG and overlay layers. A 180-degree rotation is equivalent to a flip along the X and Y axes.

You cannot perform a rotation and flip simultaneously.

Use the following fields to control rotation or flip for each layer:

- OverlayConfig[ROT_ANGLE] for overlay layer 0
- OverlayConfig1[ROT_ANGLE] for overlay layer 1

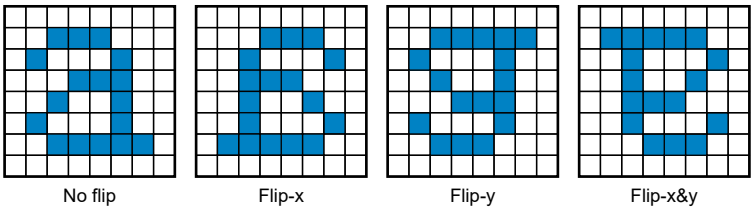

Figure 226. Flip

55.3.2.3 Decompression

Each layer except for the cursor layer provides these types of decompression to decompress input data:

- DECNano decompression supporting linear or tiled ARGB8888 and RGB888 formats
- ETC2 decompression supporting only tiled ARGB8888 format

The following table lists the supported modes of the decompression types. Use FrameBufferConfig0[DEC_MODE] to select the decompression mode.

Table 546. Decompression modes

Decompression type	Decompression mode	Compression ratio	Supported input format	AXI burst length (bytes)
DECNano	Nonsample	8:5	Linear ARGB8888	8, 16, 24, 32, or 40
DECNano	Nonsample	6:4	Linear RGB8888	32
DECNano	H sample	8:4	Linear ARGB8888	32
DECNano	H sample	6:3	Linear RGB8888	8, 16, or 24
DECNano	HV sample	8:3	Tiled ARGB8888	8, 16, or 24
DECNano	HV sample	6:2	Tiled RGB8888	16
ETC2		8:2	Tiled ARGB8888	16

NOTE

HV sample is illegal when the input data is in linear format.

The AXI burst length for compressed formats varies with the compression ratio, but the AXI outstanding request (OT) number is not affected.

You must change the stride and base address alignments for compressed formats according to the decompression modes as follows:

- If you enabled DECNano decompression for the ARGB8888 or RGB888 format, use the same stride as when decompression is disabled. In this case, LCDIF calculates each tile address based on the compression ratio of the decompression mode.
- If you enabled ETC2 decompression, set the stride to 25% of the original image's stride.

55.3.2.4 Swizzle

The components of one color format may be stored in the memory in different orders. To accommodate this possibility, LCDIF can swizzle an input pixel at the VG and overlay layers to align the component order. LCDIF supports swizzle for both RGB and YUV formats.

55.3.2.4.1 RGB swizzle

For RGB formats, the input pixel may be in any of the following format orders:

- ARGB
- RGBA
- ABGR
- BGRA

LCDIF assumes the initial input of ARGB data is in ARGB order, which means A is in the upper bits while B is in the lower bits. If the input is not in ARGB order, LCDIF uses swizzle to reshape the data. For example, if the input format is in BGRA order, you must use the following fields to configure the swizzle to handle the BGRA format:

- FrameBufferConfig0[SWIZZLE]
- OverlayConfig[SWIZZLE]
- OverlayConfig1[SWIZZLE]

The following figure shows the expected input order for the RGB format. If the input RGB data is not in this order, swizzle is required.

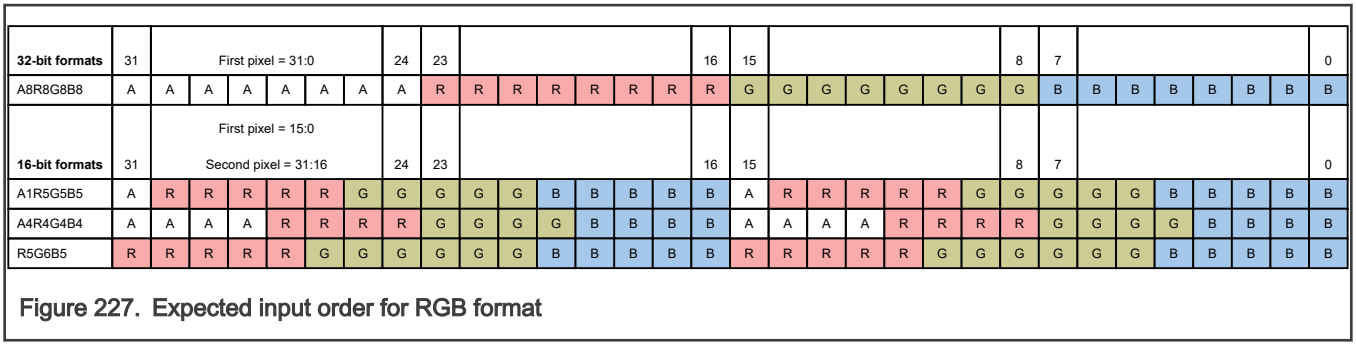

Figure 227. Expected input order for RGB format

55.3.2.4.2 Semi-planar YUV swizzle

For YUV formats, especially for UV mixed formats, the U and V pixels may be placed in different positions. LCDIF assumes that for each UV pair, U is in the lower bits while V is in the upper bits. If the input is not in this order, LCDIF uses UV-swizzle to reshape the input data. Use the following fields to configure the swizzle:

- FrameBufferConfig0[UV_SWIZZLE]
- OverlayConfig[UV_SWIZZLE]

55.3.2.5 YUV-to-RGB conversion

LCDIF supports YUV-to-RGB color space conversion for the VG and overlay 0 layers.

The conversion standard can be either BT.601 or BT.709. Use DcTileInCfg[YUV_STANDARD] and DcOverlayTileInCfg[YUV_STANDARD] to specify the standard.

In the YUV-to-RGB conversion, LCDIF uses an 8-bit pipeline to convert the YUV data into an RGB format with 8 bits for each of the R, G, and B components.

55.3.2.6 Color keying

LCDIF provides overlay and transparency effects by using color keys at the VG and overlay layers. With color keying, LCDIF filters out a special color in a source image and replaces the color with another designated color of the destination image.

Color keying is usually performed before alpha blending and is supported only in ARGB format.

Typical application scenarios include:

- Displaying an interesting scene—such as a weather map—behind people
- Creating special effects—such as floating a car on the ocean

55.3.2.6.1 Color-keying process

LCDIF performs color keying on every two of the VG and overlay layers, together with one background layer in an ascending layer order. If any of the VG or overlay layers are disabled, LCDIF does not apply color keying to the disabled layer.

The following figure shows the default layer arrangement—which is, in descending order:

4) Overlay layer 1

3) Overlay layer 0

2) VG layer

1) Background layer

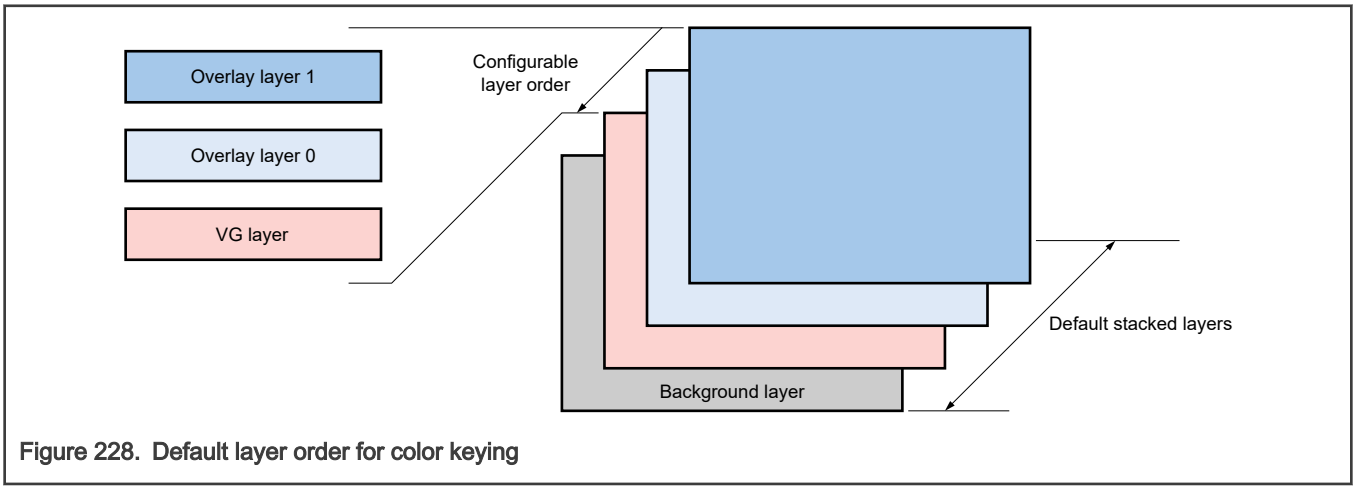

Figure 228. Default layer order for color keying

You can reconfigure the layer ordering using Blend Stack Order (BlendStackOrder). You can also specify the color of the background layer using Frame Buffer Background (FrameBufferBackground).

When color keying is enabled and the default layer order is used, LCDIF performs color keying on the paired layers in the following sequence:

1. Color keying for background and VG layers

   The VG layer is the source layer and the background layer is the destination layer.

   LCDIF replaces the selected special color of the VG layer with the background color.

LCDIF then treats the color-keyed VG layer as the destination layer for the color keying of the overlay 0 layer and the VG layer.

2. Color keying for the overlay 0 layer and the VG layer

   Overlay layer 0 is the source layer and the color-keyed VG layer is the destination layer.

   LCDIF replaces the selected special color of the overlay 0 layer with the pixel color of the color-keyed VG layer.

   LCDIF then treats the color-keyed overlay layer 0 as the destination layer for the color keying of the overlay 1 and overlay 0 layers.

3. Color keying for overlay 0 and overlay 1 layers

   Overlay layer 1 is the source layer and the color-keyed overlay layer 0 is the destination layer.

   LCDIF replaces the selected special color of overlay layer 1 with the pixel color of the color-keyed overlay 0 layer.

55.3.2.6.2 Color-keying implementation

In a typical case, you have at least one source layer (foreground) and one destination layer (background), with the source layer displayed in front of the destination layer. The source layer contains a solid color (typically, blue or green).

LCDIF performs color keying as follows:

1. Compare the component value of each pixel color of the source layer (R, G, B, or A of the color) with the color key range defined in the following registers, which are 32 bits of the ARGB8888 format. See also Figure 229.
   - Frame Buffer Color Keying Start Address (FrameBufferColorKey)
   - Frame Buffer Color Key End Address (FrameBufferColorKeyHigh)
   - Overlay Color Keying Start Address (OverlayColorKey)
   - Overlay Color Keying End Address (OverlayColorKeyHigh)
   - Overlay Layer 1 Color Keying Start Address (OverlayColorKey1)
   - Overlay Layer 1 Color Keying End Address (OverlayColorKeyHigh1)
2. When all of the components of the pixel color are in the range, LCDIF treats it as a special color and filters it out.
3. When the two layers are blended, LCDIF uses the color of the destination layer to replace the special solid color in the source layer.

Color format	31							24	23						16	15							8	7							0
A8R8G8B8	A	A	A	A	A	A	A	A	R	R	R	R	R	R	R	G	G	G	G	G	G	G	G	B	B	B	B	B	B	B	B

Figure 229. Configuration for the color-key registers

Figure 230 shows an example of the blending result after color keying.

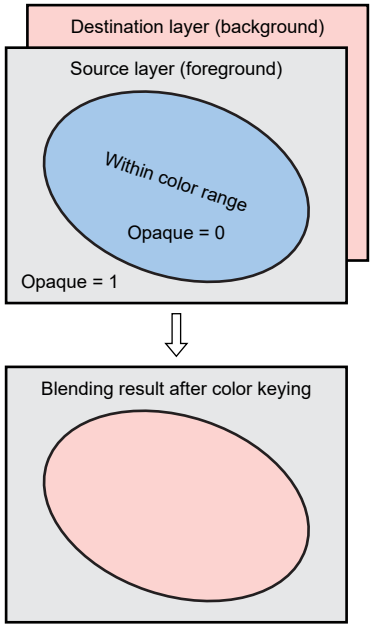

Figure 230. Blending result after color keying

55.3.3 Post-processing features

55.3.3.1 Alpha blending

LCDIF supports alpha blending for the cursor, VG, and overlay layers, together with one background layer.

Figure 231 shows the default order for alpha blending. The cursor layer is always topmost and the background layer with a pure color is bottommost. You can change the order of the VG and overlay layers using Blend Stack Order (BlendStackOrder).

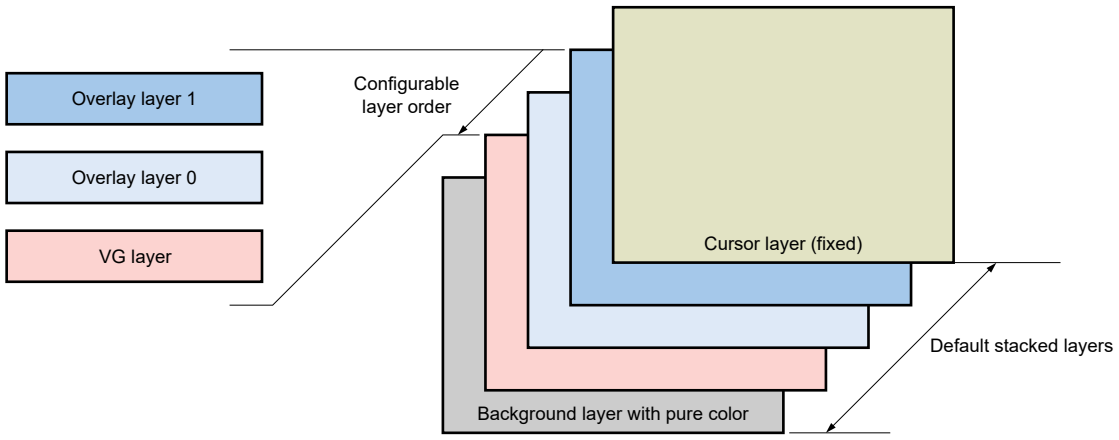

Figure 231. Default layer order for alpha blending

LCDIF performs blending from bottom to top, similar to the color-keying process. If any of the cursor, VG, or overlay layers are disabled, you must not apply alpha blending to the disabled layer. For details about the color-keying process, see Color-keying process.

Because the background layer with a pure color is used, the VG and overlay layers do not need to fill the whole screen. The VG and overlay layers can cover the screen only partially. To configure the necessary screen coordinates:

Table 547. Configuring screen coordinates

Step	Purpose	Programming
1	Specify the top-left coordinates.	Write the coordinates to: • Video Top Left Coordinate (VideoTL) • Overlay Top Left (OverlayTL) • Overlay Layer 1 Top Left (OverlayTL1)
2	Specify the layer size.	Write the size to: • Frame Buffer Size (FrameBufferSize) • Overlay Size (OverlaySize) • Overlay Layer 1 Size (OverlaySize1)
3	Verify that the bottom-right coordinates do not exceed the screen size.	Calculate the bottom-right coordinates from the values in steps 1 and 2.

55.3.3.1.1 Alpha blending algorithm

Figure 232 and Table 548 describe the stages in which LCDIF performs alpha blending.

Table 548. Alpha-blending stages

#	Stage	Description
1	Transparent or opaque conversion	The incoming alpha (independent of source or destination) can be inverted if the internal alpha rule must be followed. Internally, alpha = 0 means transparent and alpha = FFh means opaque. External content may follow the opposite rule. The output of the block is either: • `As` or `1-As` for source • `Ad` or `1-Ad` for destination
2	Global value substitution	You can use a global alpha value from a register to substitute or scale the incoming alpha. This allows any of the following operations for the incoming alpha `As`: • Pass through • `Ags` (global alpha) directly substitutes for `As` • The global alpha value (`As`×`Ags`) scales `As` The source and destination have distinct global alpha values.
3	Blending factor generation	LCDIF generates the blending factors for source and destination alpha. Depending on the blending mode, each alpha can be: • 0 • 1 • A • 1–A
4	Final blending	LCDIF implements the operations described in Alpha blending equations.

NOTE

See VideoAlphaBlendConfig, OverlayAlphaBlendConfig, and OverlayAlphaBlendConfig1 for more details on alpha blending settings.

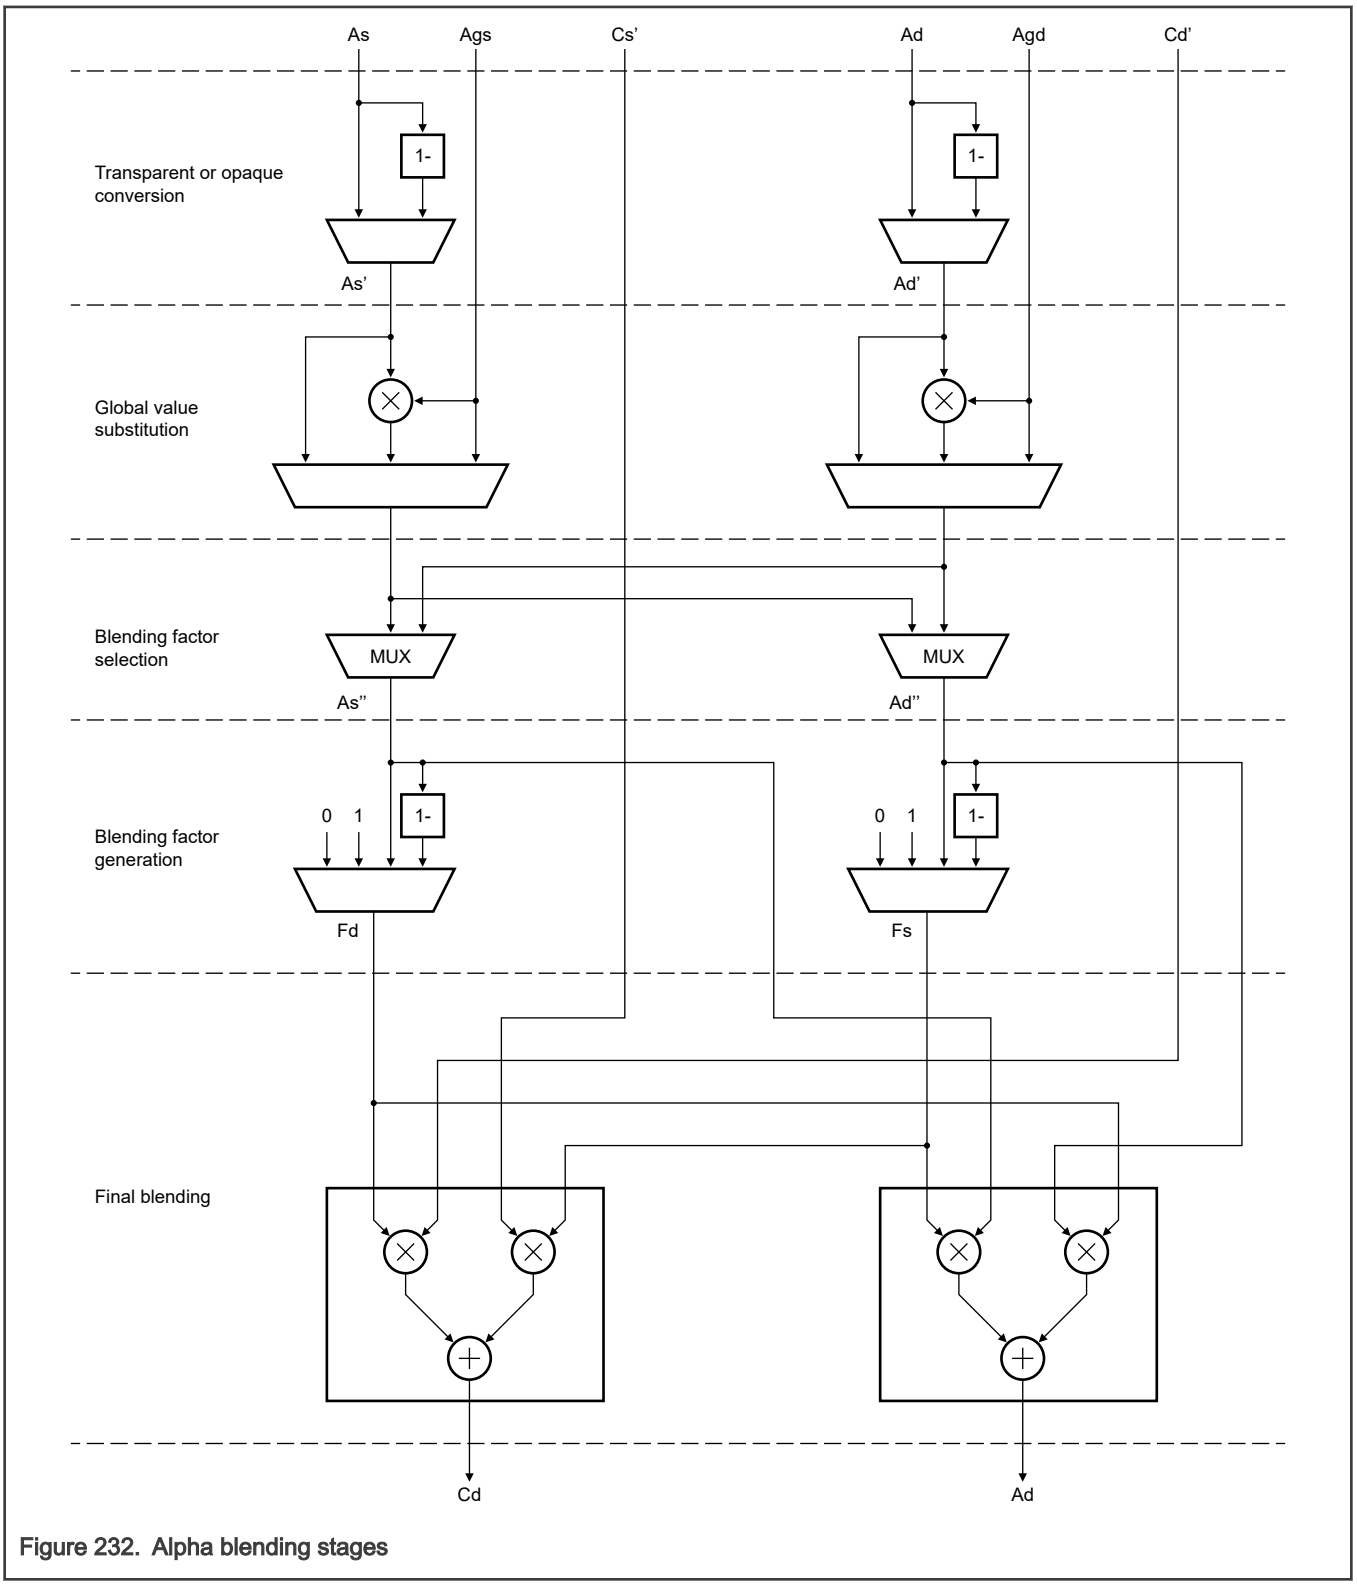

Figure 232. Alpha blending stages

55.3.3.1.2 Alpha blending equations

$$Cd = Fs \times Cs' + Fd \times Cd'$$

$$Ad = Fs \times As'' + Fd \times Ad''$$

Equation 6. Equations

Table 549. Terms

Term	Description
Cd	Destination color after blending
Fs	Source blending factor
Cs'	Source color component
Fd	Destination blending factor
Cd'	Destination color component
Ad	Destination alpha after blending
As''	Modified source alpha component
Ad''	Modified destination alpha component

55.3.3.2 Gamma correction

LCDIF provides gamma correction in the output panel. The gamma correction lookup tables (LUTs) have three separate sets—red, green, and blue. You configure these LUTs using the gamma-related registers.

If you describe gamma correction as LUT index or LUT entry data, you can set a gamma LUT sequentially based on color values, starting from the smallest value and ending at the largest value.

Use Gamma Index (GammaIndex0) and Gamma Data (GammaData0) to configure the LUT index and the LUT entry data, respectively.

If you want to perform gamma correction using the following sequence:

(0, 0)

(1, 2)

(2, 5)

(3, 6)

...

perform the following procedure:

Table 550. Gamma correction for example sequence

Step	Purpose	Programming
1	Specify that gamma correction starts from 0.	Write 0 to GammaIndex0[INDEX].
2	Fill the entire LUT.	Write 0, 2, 5, 6, ... for 256 times to Gamma Data (GammaData0).

55.3.3.3 Dither

In an image where color intensities change slowly, noticeable jumps in intensity levels may occur between pixels. You can use LCDIF's dither feature to diffuse the intensity across neighboring pixels. With this feature, LCDIF scans pixels in order and

distributes (that is, diffuses) errors in calculating a pixel's intensity to neighboring pixels. This keeps the overall intensity of the image closer to the input intensity.

55.3.3.3.1 Dither lookup table

The display controller requires a lookup table of 4 x 4 entries of 4 bits to implement dithering. This 64-bit table is located by the 32-bit registers DisplayDitherTableLow and DisplayDitherTableHigh. The dither lookup table needs to be indexed by the two least significant bits X[1:0] and Y[1:0] of the display controller.

55.3.3.3.2 Dither configuration

The following describes the dither configuration process with RedColor[3:0] as an example:

1. Create a lookup table by setting registers DisplayDitherTableLow and DisplayDitherTableHigh.
   - The lookup table includes 16 entries, 4 bits for each.
   - The lookup table provides a value U[3:0] through the indexes X[1:0] and Y[1:0].
2. Compare the color value RedColor[3:0] with this U[3:0].
   - If RedColor[3:0] > U[3:0] and RedColor[7:4] is not 4’b1111, then the final color value is NewRedColor = RedColor[7:4] + 1’b1.
   - If RedColor[3:0] is less than or equal to U[3:0], then NewRedColor = RedColor[7:4].

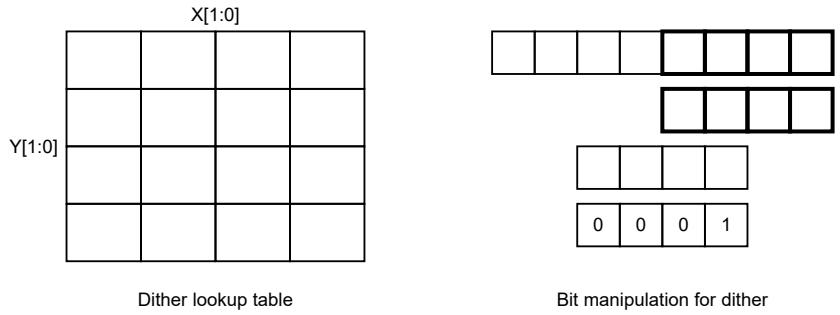

Figure 233. Dither diagram

55.3.4 Miscellaneous features

55.3.4.1 Video timing generation

Video timing generation (VTG) includes a timer corresponding to the pixel clock. Through the timer, VTG generates digital RGB output, including HSYNC, VSYNC, and Data Enable (DE). DE is asserted with Active display zone, and enables the Active display zone to be shown, as illustrated in the following figure.

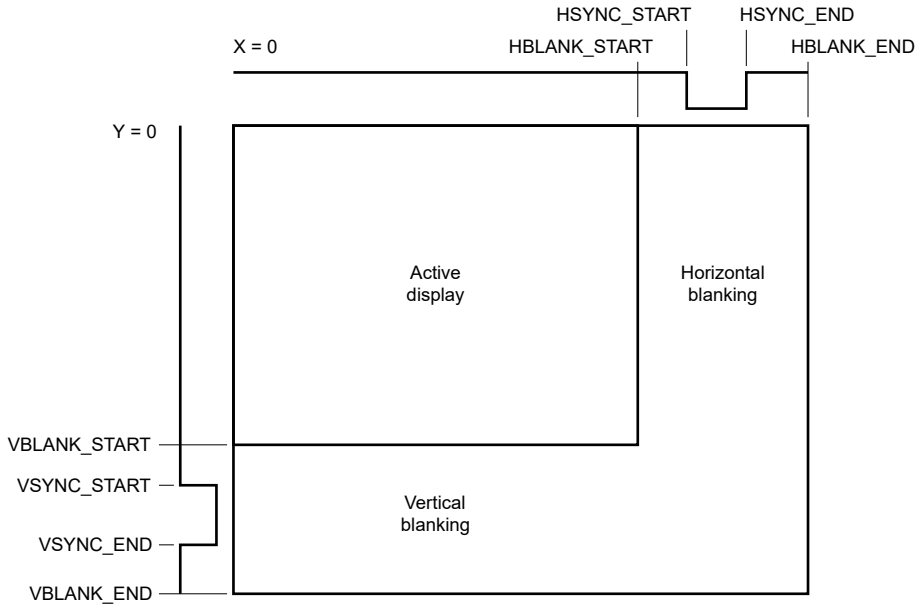

Figure 234. Timing diagram

55.3.4.2 Power management

LCDIF supports clock gating for:

- RAMs when no read/write operations are in progress.
- The VG and overlay layers when in Idle state.

Use DcControl[RAM_CLOCK_GATING] and the fields in Layer Clock Gating (LayerClockGate) to disable clock gating.

55.3.4.3 Double-buffered registers

Most LCDIF registers are double-buffered. Figure 235 shows the double-buffering mechanism:

- The AHB interface accesses shift registers and fields pertaining to set 0.
- The double-buffered registers and fields pertaining to set 1 output data for display use.
- The shift and double-buffered registers and fields share the same addresses.
- LCDIF transmits data from shift registers and fields to the double-buffered registers and fields at frame pulses.
- The shift registers and fields pertaining to set 0 are the only ones that you can read back.

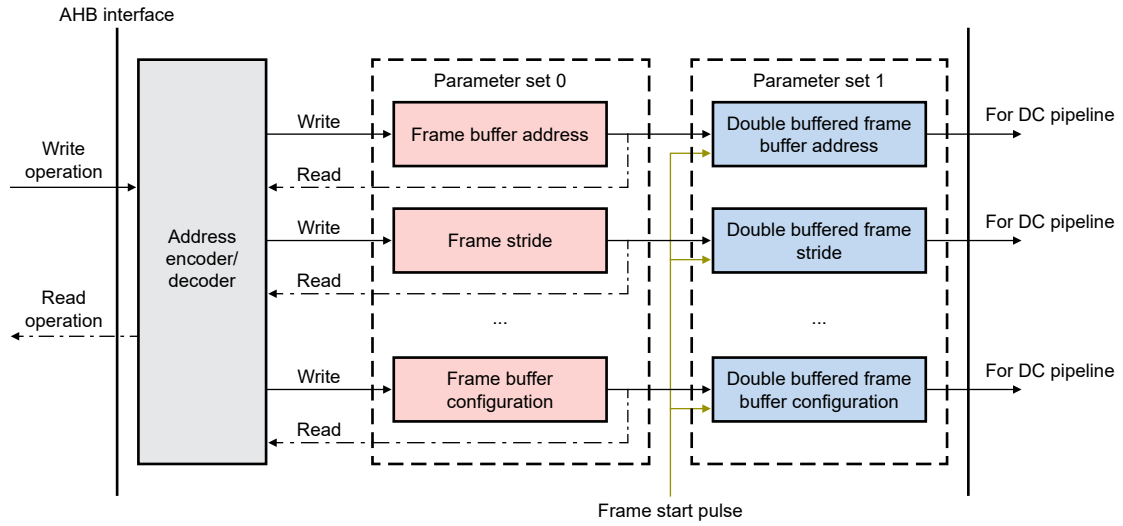

Figure 235. Double-buffered data flow

55.3.5 Clocking

LCDIF uses the following clock signals.

Table 551. Clock signals

Signal	Description	Input or output
ACLK	AXI bus clock or DC core clock	Input for DBI types A and B
HCLK	AHB interface clock	Input
pixelClk	Pixel clock from the display device	Usually input; also used as an output signal to the display

55.3.6 Reset

LCDIF uses the following reset signals to reset the AXI interface, AHB interface, and the display core either simultaneously or individually.

- ARESETn for AXI reset and display core: ensure no AXI transactions are in progress and all the display controller blocks are idle.
- HRESETn for AHB reset: ensure no AHB transactions are in progress.

Reset signals are synchronized to their corresponding clock domains—ACLK and HCLK. Their reset requirements include:

- During a reset, keep the corresponding reset signal asserted for a minimum of 32 slowest clock cycles.
- After deasserting the reset signal, wait for 128 slowest clock cycles before starting new activities.
- When the reset signals are not deasserted together, use the clock of the last reset (preferably the ACLK) for the 128-cycle wait. All deassertions except the last must comply with the 32-cycle assertion time.

55.3.7 Interrupts

The LCDIF interrupt signal is DC_INTR. It indicates LCDIF's interrupt events. When the system receives the DC_INTR signal, read Display Interrupt (DisplayIntr) to identify which of the following interrupt events occurred:

Table 552. Interrupts

Interrupt	Associated DisplayIntr field	LCDIF asserts this interrupt when:
Frame end	DISP0	One frame finishes displaying (see also Frame end interrupt)
DBI configuration error	DISP0_DBI_CFG_ERROR	The DBI command is illegal
Panel underflow	PANEL_UNDERFLOW	The data supply is insufficient
Soft reset done	SOFT_RESET_DONE	A soft reset is completed
AXI bus error	BUS_ERROR	An AXI bus transfer error occurs

55.3.7.1 Frame end interrupt

The following sequence illustrates the handling of a frame-end interrupt:

1. DC_INTR asserts at the last pixel of the visible area in a frame and remains asserted until you read DisplayIntr[DISP0].
2. Register configurations take effect.
3. After you have read DisplayIntr, DC_INTR deasserts automatically and the CPU configures the LCDIF registers—such as Frame Buffer Base Address (FrameBufferAddress0) and Cursor Base Address (CursorAddress)—for the next frame.
4. From the next frame, the LCDIF DMA starts fetching data from the system.

55.4 External signals

The following table lists the signals of LCDIF.

Table 553. External signals

Signal	Description	Direction
LCD_D[23:0]	Display color	OUT
LCD_VSYNC	Display vertical synchronization	OUT
LCD_HSYNC	Display vertical synchronization	OUT
LCD_DOTCLK	Display pixel clock	OUT
LCD_ENABLE	Display enable	OUT
LCD_DBI-D[15:0]	Information signal for DBI Type A or B	OUT
LCD_DBI_CSX_AB	Chip select for DBI Type A or B Display module is selected when low. It is set to 0 for DBI Type A in Clocked E mode.	OUT
LCD_DBI_DCX-AB	Data/Command indicator for DBI Type A or B Command is active when low.	OUT
LCD_DBI_WRX	Write signal for DBI Type B Host processor writes data at falling edge.	OUT
LCD_DBI_RWDX	For DBI Type A, specifies whether the current cycle is for read (1) or write (0) and set to 0.	OUT

Table continues on the next page...

Table 553. External signals (continued)

Signal	Description	Direction
	For DBI Type B, specifies whether the current cycle is for read (0) or write (1) and set to 1. For DBI Type A and Type B, read is not supported.	
LCD_DBI_E	E clock for DBI Type A It is set to 1 for DBI Type A in Fixed E mode.	OUT
LCD_DBI_DATA_OEN	Data output enable for DBI Type A or B	OUT

55.5 Initialization

55.5.1 DPI frame transfer action flow

The following provides the basic steps for setting the display output and frame data for DPI mode transfer.

1. Set the timing parameters according to the specifications for the target panel.
   - HDisplay0
   - HSync0
   - VDisplay0
   - VSync0
2. Set registers for the cursor, gamma, or dither function (if required).
   - Cursor*
   - Gamma*
   - DisplayDither*
   - PanelFunction[GAMMA]
   - PanelFunction[DITHER]
3. Set the frame buffer address, overlay address, stride, layer size, and location.
   - FrameBufferAddress0
   - OverlayAddress
   - OverlayAddress1
   - FrameBufferStride0
   - OverlayStride
   - OverlayStride1
   - DcTileUvFrameBufferAdr0
   - DcTileUvFrameBufferStr0
   - DcTileUvOverlayAdr
   - DcTileUvOverlayStr
   - VideoTL
   - FrameBufferSize

- OverlayTL
- OverlaySize
- OverlayTL1
- OverlaySize1

For tiled formats, any of the stride register values = One-line stride x tile height.

- FrameBufferStride0
- OverlayStride
- OverlayStride1
- DcTileUvFrameBufferStr0
- DcTileUvOverlayStr

4. Set the output bus mode to DPI.

   DbiConfig0[BUS_OUTPUT_SEL] = 0

5. Configure the panel and panel timing requirements.

   PanelConfig

6. Configure the data format of the frame buffer and enable the layer.
   - PanelFunction[OUTPUT] = 1 indicates output panel is enabled.
   - FrameBufferConfig0[ENABLE] = 1 indicates the video/graphic layer is enabled.
   - OverlayConfig[ENABLE] = 1 indicates overlay layer 0 is enabled.
   - OverlayConfig1[ENABLE] = 1 indicates overlay layer 1 is enabled.
   - Registers used to configure the tiled ARGB8888, YUY2, and NV12 formats:
     — DcTileIncfg
     — DcOverlayTileIncfg

     When the linear ARGB8888, ARGB1555, RGB565, ARGB4444 format, RGB888, or A8RGB565 is expected, the tiled format field of these registers must be set to NONE.
   - Register fields used to configure the linear ARGB8888, ARGB1555, RGB565, ARGB4444, RGB888, and A8RGB565 formats:
     — FrameBufferConfig0[FORMAT]
     — OverlayConfig[FORMAT]
     — OverlayConfig1[FORMAT]
7. Start the interface mode transfer.

   PanelWorking[WORKING] = 1

8. Update parameters for the next frame.

   PanelControl[VALID] =1 indicates the next frame configuration is completed.

9. Wait for the interrupt signal when the transfer is completed, or check the interrupt register status.
   - DisplayIntr
   - DisplayIntrEnable
10. (Optional) To write a single frame in DPI command mode, set DpiConfig0[DPI_COMMAND_MODE] = 1.
11. Repeat the preceding steps for each succeeding frame as needed.

55.5.2 DBI frame transfer action flow

The following sections provide the basic steps of setting the display output and frame data for DBI mode transfer in the action flows of initialization, refresh of panel frame buffer, and partial refresh of panel frame buffer.

Initialization

DBI initialization should be done after the panel is powered on. Figure 236 shows the DBI initialization timing:

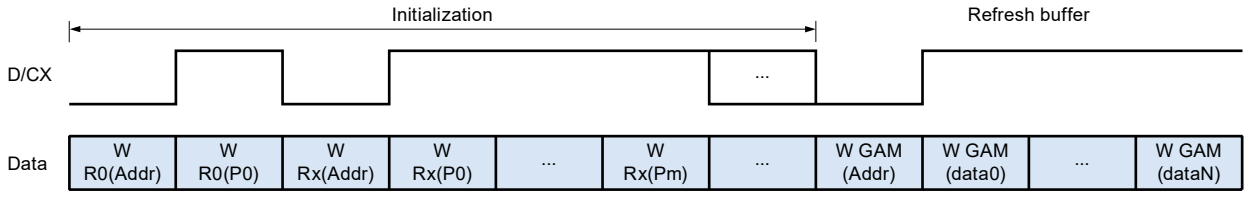

Figure 236. DBI initialization timing

1. Set PanelConfig[CLOCK] = 0. This setting is mandatory for the DBI mode.

   In DBI mode, the display controller ignores the values of any other bits in the PanelConfig register.

2. Set the output bus mode to DBI.

   DbiConfig0[BUS_OUTPUT_SEL] = 1

3. Set the DBI type for output.

   DbiConfig0[DBI_TYPE] = Type A Fixed E, Type A Clocked E, Type B.

4. Set the DBI bus in idle state.

   DbiIfReset[DBI_IF_LEVEL_RESET] = 1

5. Set the DBI output timing parameters and the AC timing specifications of the panel.

   Registers for DBI Type A or Type B:

   - DbiWrChar10
   - DbiWrChar20

6. Configure the interface output or input speed through the DbiConfig0[DBI_AC_TIME_UNIT] register field.
7. Write the DbiCmd register to send configuration data. Commands must be entered one by one.
   - DbiCmd0[DBI_COMMANDFLAG] = 0 indicates writing an address to the panel. The address to be sent to the DBI port is stored in DbiCmd0[DBI_CCOMMAND_WORD].
   - DbiCmd0[DBI_COMMANDFLAG] = 2 indicates writing one parameter to the panel. The parameter is stored in DbiCmd0[DBI_COMMAND_WORD].

Refresh of panel frame buffer (single frame example)

1. Set timing parameters according to the actual panel specifications. Parameters are set before the first frame refresh, and then are ignored after that.
   - HDisplay.TOTAL = Panel width
   - HDisplay.DISPLAY_END = Panel width
   - HSync.START = 0
   - HSync.END = Panel width
   - VDisplay.TOTAL = Panel height + 1

     The extra value 1 is used for waiting for the data FIFO to be filled. This extra value should be 2 for the tile data format.
   - VDisplay.DISPLAY_END = Panel height

- VSync.START = 0
- VSync.END = Panel height

2. Set the registers for the cursor, gamma, or dither function (if required).
   - Cursor*
   - Gamma*
   - DisplayDither*
   - PanelFunction.GAMMA
   - PanelFunction.DITHER
3. Set the frame buffer address or overlay address, stride, layer size, and location.
   - FrameBufferAddress
   - OverlayAddress
   - OverlayAddress1
   - FrameBufferStride
   - OverlayStride
   - OverlayStride1
   - DcTileUvFrameBufferAdr
   - DcTileUvFrameBufferStr
   - DcTileUvOverlayAdr
   - DcTileUvOverlayStr
   - VideoTL
   - FrameBufferSize
   - OverlayTL
   - OverlaySize
   - OverlayTL1
   - OverlaySize1

   For tiled formats, any of the following stride register values = One-line stride x Tile height:
   - FrameBufferStride
   - OverlayStride
   - OverlayStride1
   - DcTileUvFrameBufferStr
   - DcTileUvOverlayStr
4. Configure the data format of the frame buffer and enable the layer.
   - PanelFunction.OUTPUT = 1 indicates the output panel is enabled.
   - FrameBufferConfig.Enable = 1 indicates the video/graphic layer is enabled.
   - OverlayConfig.Enable = 1 indicates overlay layer 0 is enabled.
   - OverlayConfig1.Enable = 1 indicates overlay layer 1 is enabled.
   - Registers used to configure the tiled ARGB8888, YUY2, and NV12 formats: DcTileIncfg and DcOverlayTileIncfg

If the linear ARGB8888, ARGB1555, RGB565, ARGB4444, RGB888, or A8RGB565 format is expected, the tiled format fields of these registers must be set to NONE.

- Registers used to configure the linear ARGB8888, ARGB1555, RGB565, ARGB4444, RGB888, and A8RGB565 formats:
  - FrameBufferConfig
  - OverlayConfig
  - OverlayConfig1

5. Write the DbiCmd register to send configuration data. Commands are entered one by one. DbiCmd.DBI_COMMANDFLAG=1 indicates writing to the DBI bus. For this flag setting, the value of DbiCmd.DBI_COMMAND_WORD is ignored.
6. Wait for the interrupt signal when the write is completed, or check the interrupt register status.
   - DisplayIntr
   - DisplayIntrEnable
7. Repeat the preceding steps for each succeeding frame as needed.

Partial refresh of panel frame buffer (single frame example)

1. Set timing parameters according to the actual panel specifications. Parameters are set before the first frame refresh, and then ignored after that.
   - HDisplay.TOTAL = Partial window width
   - HDisplay.DISPLAY_END = Partial window width
   - HSync.START = Actual clipped window x start
   - HSync.END = Actual clipped window x end
   - VDisplay.TOTAL = Partial window height + 1

     The extra value 1 is used for waiting for the data FIFO to be filled. This extra value should be 2 for the tile data.
   - VDisplay.DISPLAY_END = Partial window height
   - VSync does not require setting for the linear format. For tiled data:
     - VSync.START = Actual clipped window y start
     - VSync.END = Actual clipped window y end
2. Set the registers for the cursor, gamma, or dither function (if required).
   - Cursor*
   - Gamma*
   - DisplayDither*
   - PanelFunction.GAMMA
   - PanelFunction.DITHER
3. Set the frame buffer address, overlay address, stride, layer size, and location.
   - FrameBufferAddress
   - OverlayAddress
   - OverlayAddress1
   - FrameBufferStride
   - OverlayStride

- OverlayStride1
- DcTileUvFrameBufferAdr
- DcTileUvFrameBufferStr
- DcTileUvOverlayAdr
- DcTileUvOverlayStr
- VideoTL
- FrameBufferSize
- OverlayTL
- OverlaySize
- OverlayTL1
- OverlaySize1

For tiled formats, any of the following stride register values = One-line stride x Tile height:

- FrameBufferStride
- OverlayStride
- OverlayStride1
- DcTileUvFrameBufferStr
- DcTileUvOverlayStr

4. Configure the data format of the frame buffer and enable the layer.
   - PanelFunction.OUTPUT = 1 indicates the output panel is enabled.
   - FrameBufferConfig.Enable = 1 indicates the video/graphic layer is enabled.
   - OverlayConfig.Enable = 1 indicates overlay layer 0 is enabled.
   - OverlayConfig1.Enable = 1 indicates overlay layer 1 is enabled.
   - Registers used to configure the tiled ARGB8888, YUY2, and NV12 formats: DcTileIncfg and DcOverlayTileIncfg

     If the linear ARGB8888, ARGB1555, RGB565, ARGB4444, RGB888, or A8RGB565 format is expected, the tiled format fields of these registers must be set to NONE.
   - Registers used to configure the linear ARGB8888, ARGB1555, RGB565, ARGB4444, RGB888, and A8RGB565 formats:
     - FrameBufferConfig
     - OverlayConfig
     - OverlayConfig1
5. Write the DbiCmd register to send configuration data for the partial window. Commands are entered one by one.

   DbiCmd.DBI_COMMANDFLAG=1 indicates writing to the DBI bus.

   For this flag setting, the value of DbiCmd.DBI_COMMAND_WORD is ignored.
6. Wait for the interrupt signal when the write is completed, or check the interrupt register status.
   - DisplayIntr
   - DisplayIntrEnable
7. Repeat the preceding steps for each succeeding frame as needed.

55.6 LCDIF register descriptions

55.6.1 LCDIF memory map

LCDIF base address: 4048_0000h

55.6.2 Frame Buffer Configuration (FrameBufferConfig0)

Offset

Register	Offset
FrameBufferConfig0	2024h

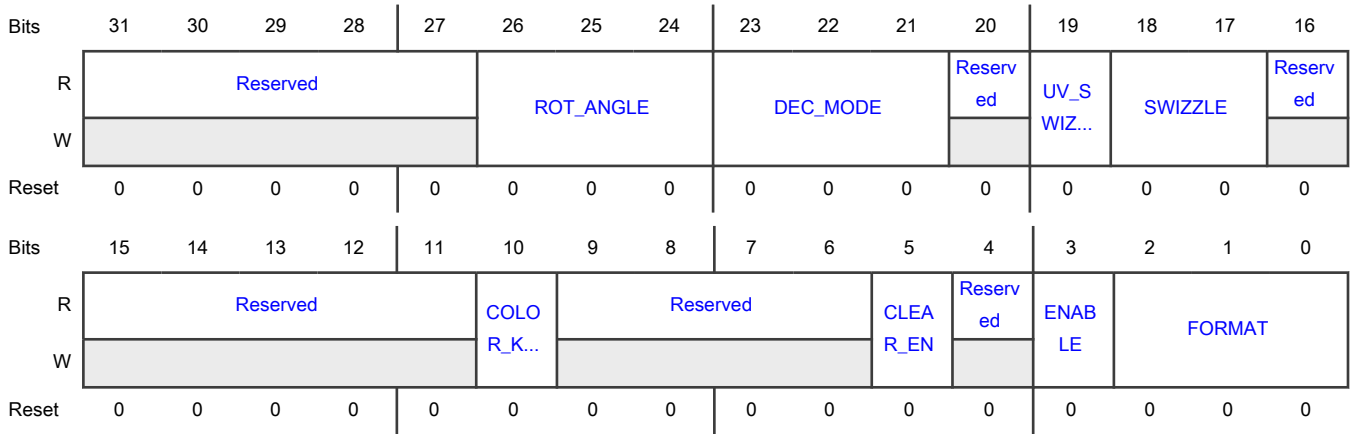
Function

Controls the frame buffer and timing.

NOTE

This register is double-buffered.

Diagram



Fields

Field	Function
31-27 —	Reserved
26-24 ROT_ANGLE	Rotation Angle Specifies the rotation angle for the source surface. FrameBufferSize[HEIGHT] specifies the height of the surface in pixels. 000b - Sets the rotation angle to 0 degree. 010b - Sets the rotation angle to 180 degree. 100b - Flips horizontal 101b - Flips vertical All other values are reserved.
23-21 DEC_MODE	Decompression Mode Specifies the video decompression mode. 000b - Decompression disabled 001b - Non-Subsample 010b - Horizontal Subsample 011b - Horizontal and Vertical Subsample 100b - ETC2 All other values are reserved.
20 —	Reserved
19 UV_SWIZZLE	Swizzle for UV Reshapes the input data if U is not in the lower bits and V is not in the upper bits.
18-17 SWIZZLE	Swizzle for RGB Specifies the input format of a pixel for swizzling at the video, graphic, and overlay layers to switch the component position in the pixel data. 00b - ARGB 01b - RGBA 10b - ABGR 11b - BGRA
16-11 —	Reserved
10	Enable Color Keying

Table continues on the next page...

Table continued from the previous page...

Field	Function
COLOR_KEY_EN	0b - Disable 1b - Enable
9-6 —	Reserved
5 CLEAR_EN	Enable Clear 0b - Disable 1b - Enable
4 —	Reserved
3 ENABLE	Enable Layer Enables this layer. 0b - Disable 1b - Enable
2-0 FORMAT	Frame Buffer Format Specifies the format of the frame buffer. 000b - None; no frame buffer exists and LCDIF does not produce any output 001b - A4R4G4B4 010b - A1R5G5B5 011b - R5G6B5 100b - A8R8G8B8 101b - R8G8B8 110b - A8R5G6B5 All other values are reserved.

55.6.3 Frame Buffer Base Address (FrameBufferAddress0)

Offset

Register	Offset
FrameBufferAddress0	2028h

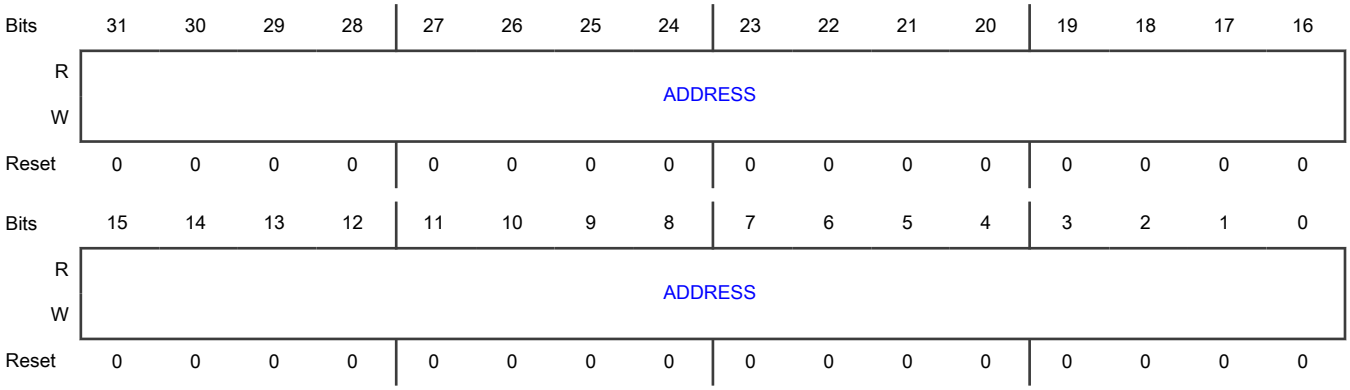
Function

Specifies the starting address of the frame buffer.

NOTE

This register is double-buffered.

Diagram



Fields

Field	Function
31-0 ADDRESS	Starting Address Specifies a 32-bit starting address.

55.6.4 Frame Buffer Stride (FrameBufferStride0)

Offset

Register	Offset
FrameBufferStride0	202Ch

Function

Specifies the stride of the frame buffer, in bytes.

NOTE

This register is double-buffered.

Diagram

31-17 —	Reserved
16-0 STRIDE	Frame Buffer Stride Specifies the number of bytes from the start of one line to the next line.

55.6.5 Tile Input Configuration (DcTileInCfg0)

Offset

Register	Offset
DcTileInCfg0	2034h

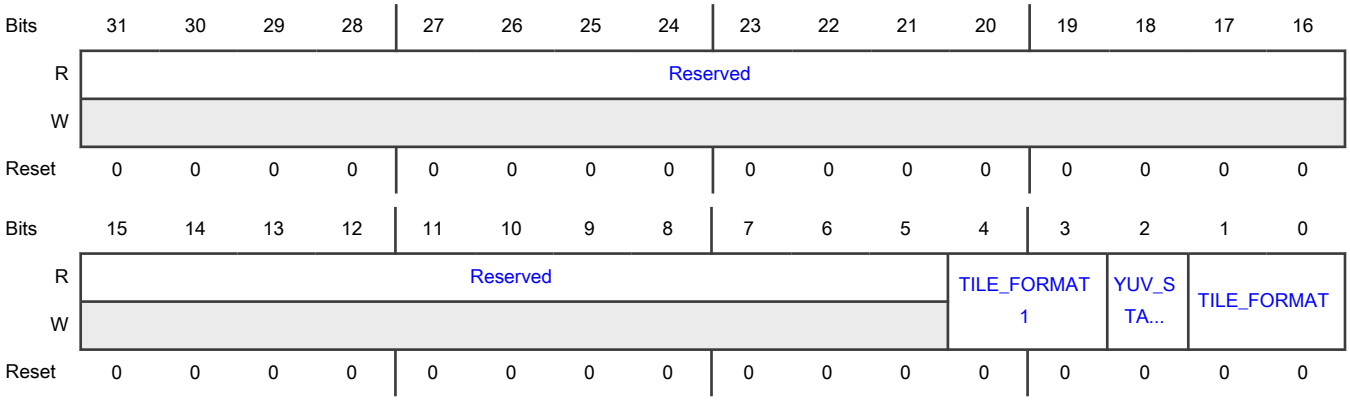
Function

Configures the tile input.

NOTE

This register is double-buffered.

Diagram



Fields

Field	Function
31-5 —	Reserved
4-3 TILE_FORMAT 1	Tile Format 1 Selects high bit of tile format. • {Tile_Format1,Tile_Format} = 0x4, RGB888 • {Tile_Format1,Tile_Format} = 0x5 A8RGB565 **NOTE** This field is double buffered. It needs to be combined with Tile_Format in the form of {Tile_Format1, Tile_Format}
2 YUV_STANDARD	YUV Standard Specifies the YUV standard. 0b - BT601 1b - BT709
1-0 TILE_FORMAT	Tile Input Format Specifies the tile input format. 00b - No tile input. See DcTileInCfg0[TILE_FORMAT1]. 01b - ARGB8888 10b - YUY2 11b - NV12

55.6.6 Frame Buffer Tiled UV Base Address (DcTileUvFrameBufferAdr0)

Offset

Register	Offset
DcTileUvFrameBufferAdr0	2038h

Function

Specifies the UV frame buffer address when tile input is used.

NOTE

This register is double-buffered.

Diagram

23-16 RED	Red Red color **NOTE** This field is double buffered.
15-8 GREEN	Green Green color **NOTE** This field is double buffered.
7-0 BLUE	Blue Blue color **NOTE** This field is double buffered.

55.6.9 Frame Buffer Color Keying Start Address (FrameBufferColorKey)

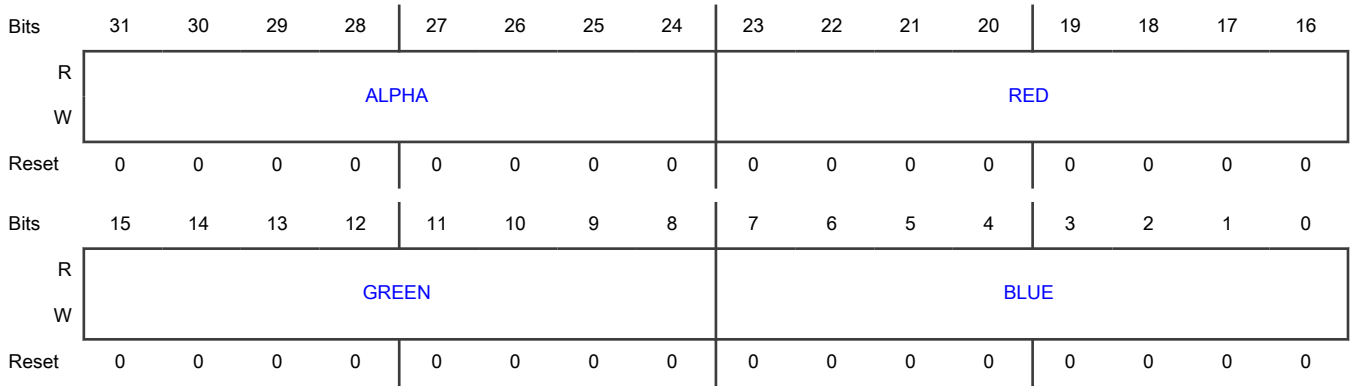
Offset

Register	Offset
FrameBufferColorKey	205Ch

Function

Sets the start address of the color keying range of frame buffer.

Diagram



Fields

Field	Function
31-24 ALPHA	Alpha 8-bit alpha value
23-16 RED	Red 8-bit red color
15-8 GREEN	Green 8-bit green color
7-0 BLUE	Blue 8-bit blue color

55.6.10 Frame Buffer Color Key End Address (FrameBufferColorKeyHigh)

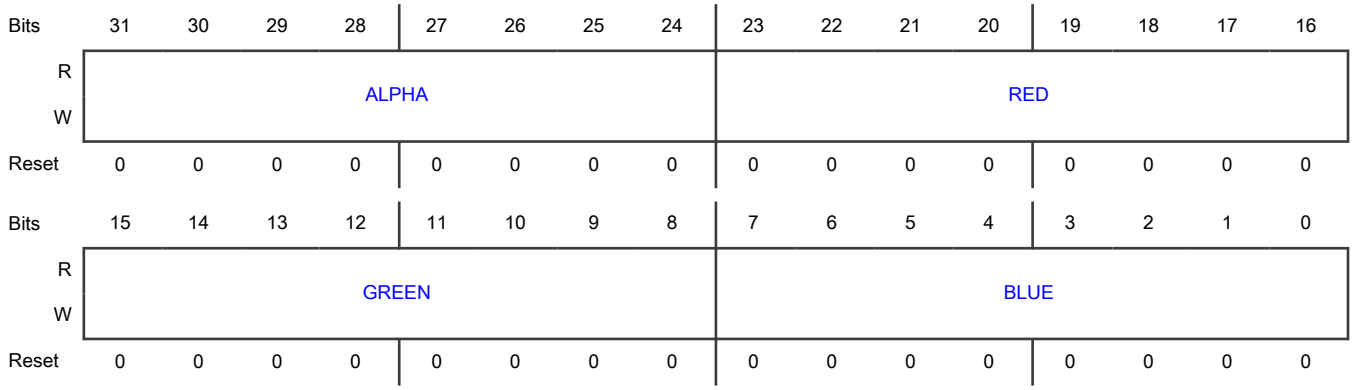
Offset

Register	Offset
FrameBufferColorKeyHigh	2060h

Function

Sets the end address of the color key range of frame buffer.

Diagram



Fields

Field	Function
31-24 ALPHA	Alpha 8-bit alpha value
23-16 RED	Red 8-bit red color
15-8 GREEN	Green 8-bit green color
7-0 BLUE	Blue 8-bit blue color

55.6.11 Frame Buffer Clear Value (FrameBufferClearValue)

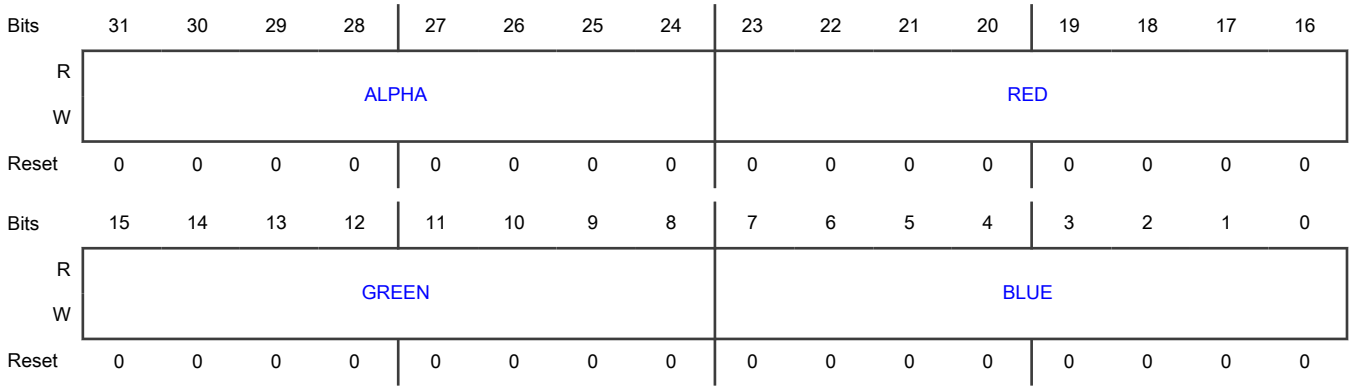
Offset

Register	Offset
FrameBufferClearValue	2064h

Function

Sets the clear value when FrameBufferConfig0[CLEAR_EN] is enabled in the format of A8R8G8B8.

Diagram



Fields

Field	Function
31-24 ALPHA	Alpha 8-bit alpha value
23-16 RED	Red 8-bit red color
15-8 GREEN	Green 8-bit green color
7-0 BLUE	Blue 8-bit blue

55.6.12 Video Top Left Coordinate (VideoTL)

Offset

Register	Offset
VideoTL	2068h

Function

Sets the top left coordinate of panel pixel where the video must start. Note that there is no panning inside the video.

NOTE

This register is double buffered.

Diagram

Fields

Field	Function
31-28 —	Reserved
27-16 HEIGHT	Video Height Video height of frame buffer **NOTE** This field is double buffered.
15-12 —	Reserved
11-0 WIDTH	Video Width Video width of frame buffer **NOTE** This field is double buffered.

55.6.14 Video Global Alpha (VideoGlobalAlpha)

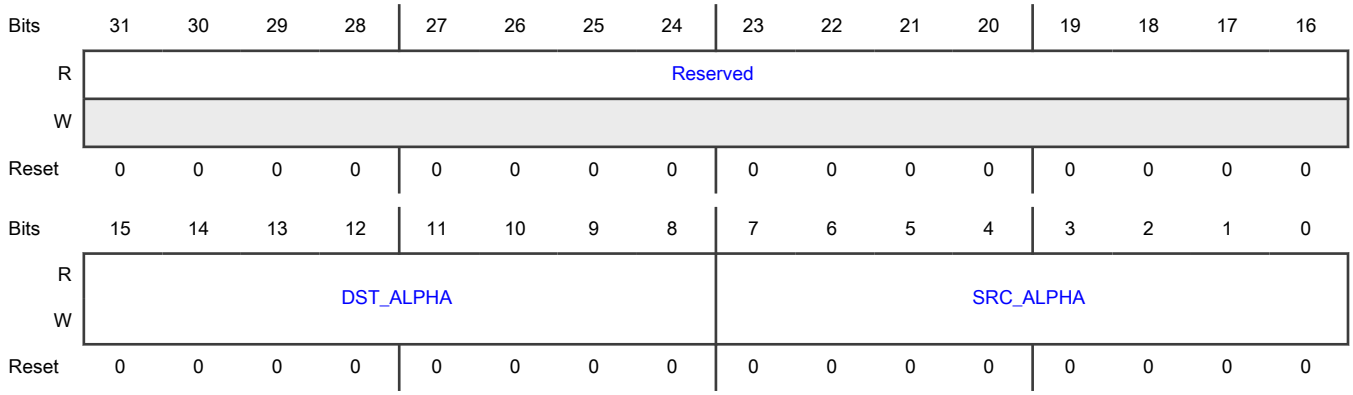
Offset

Register	Offset
VideoGlobalAlpha	2070h

Function

Sets the global alpha information for the video of frame buffer.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 DST_ALPHA	Destination Alpha Sets the destination alpha for video. **NOTE** This field is double buffered.
7-0 SRC_ALPHA	Source Alpha Sets the source alpha for video. **NOTE** This field is double buffered.

55.6.15 Blend Stack Order (BlendStackOrder)

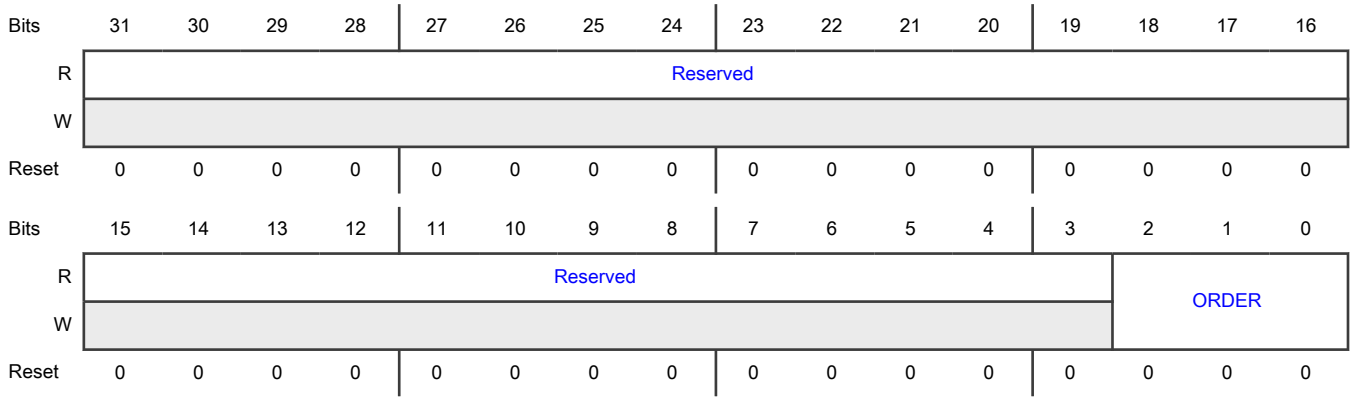
Offset

Register	Offset
BlendStackOrder	2074h

Function

Sets the order of VG, overlay 0, and overlay 1 layers for blending, in which the first layer is the lowest layer, the second layer is the middle layer, and the third layer is the highest layer.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 ORDER	Stack Order Stack order of video, overlay 0, and overlay 1 layers for blending. **NOTE** This field is double buffered. 000b - In the order of VG, Overlay 0 and Overlay 1 layers. 001b - In the order of VG, Overlay 1 and Overlay 0 layers. 010b - In the order of Overlay 0, VG and Overlay 1 layers. 011b - In the order of Overlay 0, Overlay 1, and VG layers. 100b - In the order of Overlay 1, VG and Overlay 0 layers. 101b - In the order of Overlay 1, Overlay 0, and VG layers.

55.6.16 Alpha Blending Configuration (VideoAlphaBlendConfig)

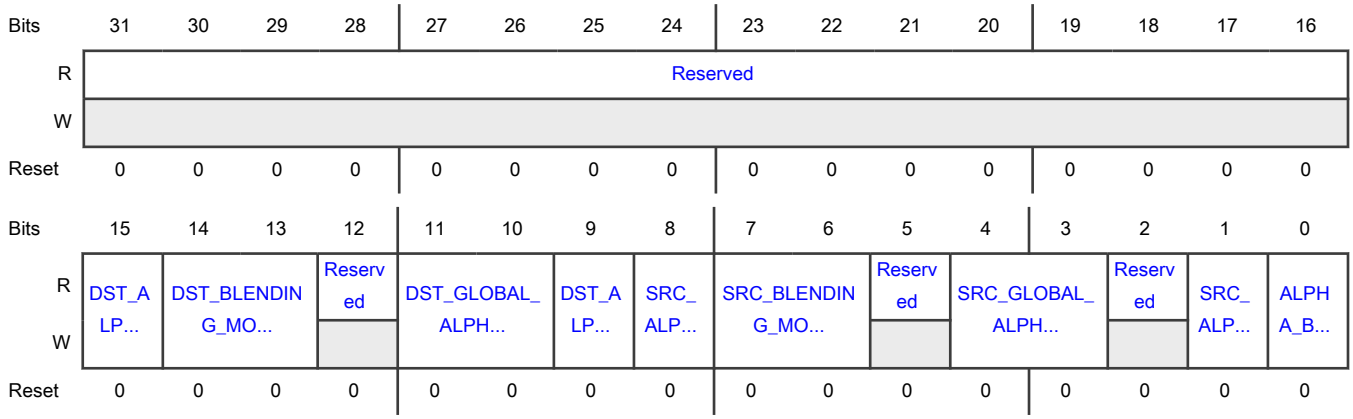
Offset

Register	Offset
VideoAlphaBlendConfig	2078h

Function

The display controller supports alpha blending for the cursor, VG, and overlay layers, together with one background layer.

Diagram



Fields

Field	Function
31-16 —	Reserved
15 DST_ALPHA_FACTOR	Destination Alpha Factor Generates the blending factor for destination alpha. **NOTE** This field is double buffered. 0b - Do not generate the blending factor for destination alpha. 1b - Generates the blending factor for destination alpha.
14-13 DST_BLENDING_MODE	Destination Alpha Blending Mode Sets the blending mode for destination alpha. **NOTE** This field is double buffered. 00b - Each component of the color is multiplied by (0, 0, 0,0). 01b - Each component of the color is multiplied by (1, 1, 1,1). 10b - Normal as the result color is the destination color 11b - Not affected by the color of the underlying pixel
12 —	Reserved
11-10 DST_GLOBAL_ALPHA_MODE	Destination Global Alpha Mode Sets the global destination alpha mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field is double buffered. 00b - Normal destination alpha mode 01b - Global destination alpha mode 10b - Scaled (by the global alpha value) destination alpha mode
9 DST_ALPHA_MODE	Destination Alpha Mode Sets the destination alpha mode. **NOTE** This field is double buffered. 0b - Normal destination alpha mode 1b - Inversed alpha mode if the internal alpha rule needs to be followed
8 SRC_ALPHA_FACTOR	Source Alpha Factor Generates the blending factor for source alpha. **NOTE** This field is double buffered. 0b - Do not generate the blending factor. 1b - Generates the blending factor.
7-6 SRC_BLENDING_MODE	Source Blending Mode Sets the blending mode for source alpha. **NOTE** This field is double buffered. 00b - Each component of the color is multiplied by (0, 0, 0,0). 01b - Each component of the color is multiplied by (1, 1, 1,1). 10b - Normal as the result color is the source color 11b - Not affected by the color of the underlying pixel
5 —	Reserved
4-3 SRC_GLOBAL_ALPHA_MODE	Source Global Alpha Mode Sets the global alpha mode to substitute or scale the source alpha. **NOTE** This field is double buffered.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b - Normal source alpha mode 01b - Global source alpha mode 10b - Scaled (by the global alpha value) source alpha mode
2 —	Reserved
1 SRC_ALPHA_MODE	Source Alpha Mode Sets the source alpha mode for blending. **NOTE** This field is double buffered. 0b - Normal source alpha mode 1b - Inversed alpha mode if the internal alpha rule needs to be followed
0 ALPHA_BLEND	Alpha Blending Enables alpha blending for video and graphics from the bottom layer to the top layer. If any of the cursor, VG, or overlay layers is disabled, alpha blending is not applied to the disabled layer. **NOTE** This field is double buffered. 0b - Disables alpha blending for video. 1b - Enables alpha blending for video.

55.6.17 Overlay Configuration (OverlayConfig)

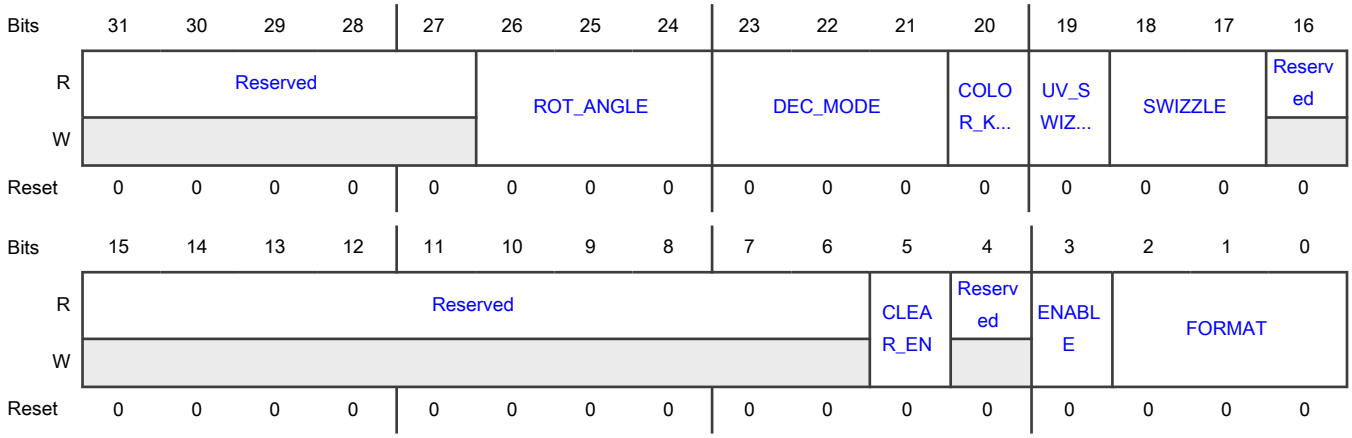
Offset

Register	Offset
OverlayConfig	207Ch

Function

Sets overlay control.

Diagram



Fields

Field	Function
31-27 —	Reserved
26-24 ROT_ANGLE	Rotation Angle Specifies the rotation angle or flip for the source surface. Height field specifies the height of the surface in pixels. **NOTE** This field is double buffered. 000b - Sets the rotation angle to 0 degree. 010b - Sets the rotation angle to 180 degree. 100b - Flips horizontal 101b - Flips vertical All other values are reserved.
23-21 DEC_MODE	Decompression Mode Sets decompression mode on 0verlay 0. **NOTE** This field is double buffered. 000b - Disables decompression. 001b - Non Subsample. Enables non_subsample decompression mode. 010b - Horizontal Subsample. Enables horizontal subsample decompression mode. 011b - Horizontal Vertical Subsample. Enables horizontal and vertical subsample decompression mode. 100b - ETC2. Enables ETC2 decompression mode.

Table continues on the next page...

Table continued from the previous page...

Field	Function
20 COLOR_KEY_EN	Color Keying Enables or disables color keying. **NOTE** This field is double buffered. 0b - Disables color keying. 1b - Enables color keying.
19 UV_SWIZZLE	UV Swizzle Swizzles an input pixel for UV formats at the VG and overlay layers to align the component order. **NOTE** This field is double buffered.
18-17 SWIZZLE	RGB Swizzle Swizzles an input pixel for RGB formats at the VG and overlay layers to align the component order. **NOTE** This field is double buffered. 00b - Input pixel in ARGB format 01b - Input pixel in RGBA format 10b - Input pixel in ABGR format 11b - Input pixel in BGRA format
16-6 —	Reserved
5 CLEAR_EN	Clear Enables or disables clearing the overlay layer. **NOTE** This field is double buffered. 0b - Disables clearing the overlay layer. 1b - Enables clearing the overlay layer.
4 —	Reserved
3 ENABLE	Enable Enables or disables this overlay layer.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	NOTE This field is double buffered. 0b - Disables this overlay layer. 1b - Enables this overlay layer.
2-0 FORMAT	Overlay Format Sets the overlay format. None means there is no overlay. **NOTE** This field is double buffered. 000b - No overlay 001b - Overlay format is A4R4G4B4. 010b - Overlay format is A1R5G5B5. 011b - Overlay format is R5G6B5. 100b - Overlay format is A8R8G8B8. 101b - Overlay format is A8R5G6B5.

55.6.18 Overlay Address (OverlayAddress)

Offset

Register	Offset
OverlayAddress	2080h

Function

Sets the starting address of the overlay.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 ADDRESS	Starting Address A 32-bit address.

55.6.19 Overlay Stride (OverlayStride)

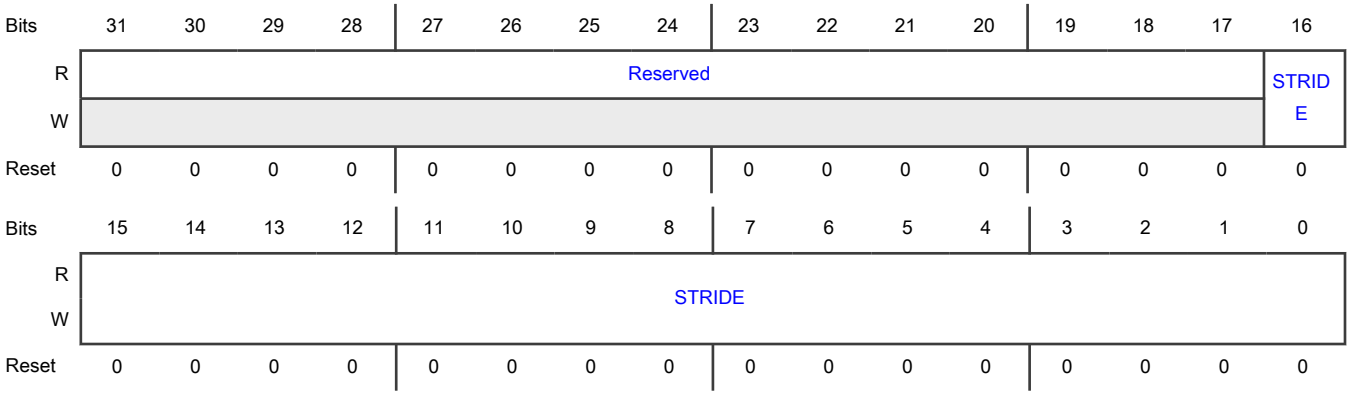
Offset

Register	Offset
OverlayStride	2084h

Function

Sets the stride of the overlay in bytes.

Diagram



Fields

Field	Function
31-17 —	Reserved
16-0 STRIDE	Stride Number of bytes from start of one line to next line.

55.6.20 Tile Input Configuration (DcOverlayTileInCfg)

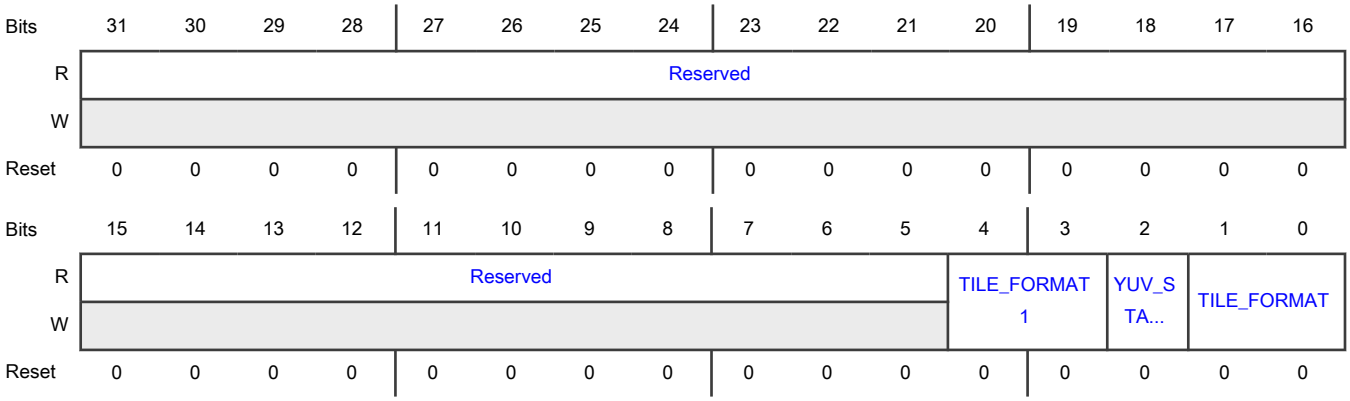
Offset

Register	Offset
DcOverlayTileInCfg	2088h

Function

Sets the tile input format for the overlay.

Diagram



Fields

Field	Function
31-5 —	Reserved
4-3 TILE_FORMAT 1	Tile Format 1 Selects high bit of tile format. • {Tile_Format1,Tile_Format} = 0x4, RGB888 • {Tile_Format1,Tile_Format} = 0x5 A8RGB565 **NOTE** This field is double buffered. It needs to be combined with Tile_Format in the form of {Tile_Format1, Tile_Format}
2 YUV_STANDARD	YUV Standard Selects YUV standard. **NOTE** This field is double buffered.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Selects the YUV standard BT601. 1b - Selects the YUV standard BT709.
1-0 TILE_FORMAT	Tile Input Format Sets the tile input format. **NOTE** This field is double buffered. 00b - No tile input. See DcOverlayTileInCfg[TILE_FORMAT1]. 01b - Sets the tile input format to ARGB8888. 10b - Sets the tile input format to YUY2. 11b - Sets the tile input format to NV12.

55.6.21 Tile Uv Overlay Address (DcTileUvOverlayAdr)

Offset

Register	Offset
DcTileUvOverlayAdr	208Ch

Function

Sets the starting overlay address of the tiled UV plane.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Fields

Field	Function
31-0 ADDRESS	Starting Overlay Address A 32-bit address.

55.6.22 Tile Uv Overlay Stride (DcTileUvOverlayStr)

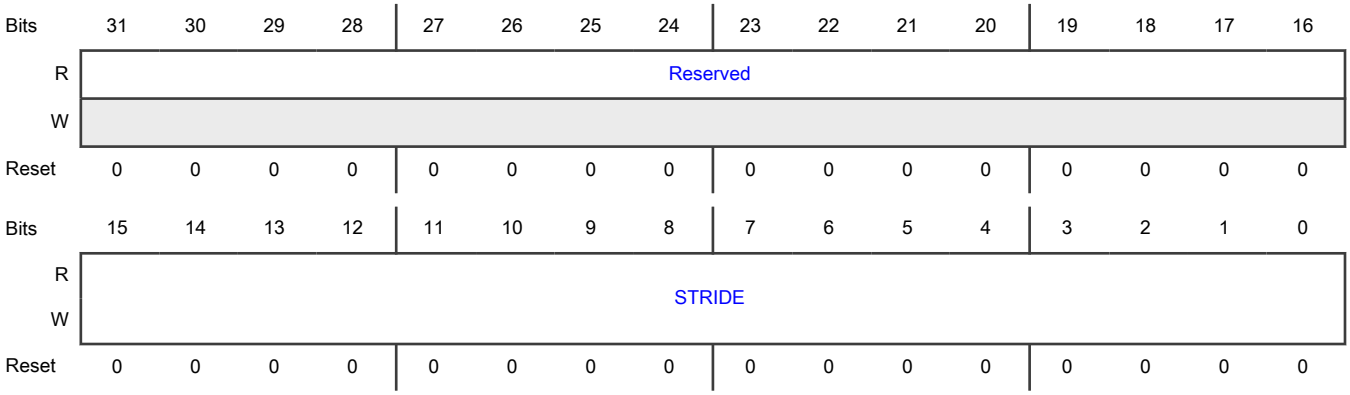
Offset

Register	Offset
DcTileUvOverlayStr	2090h

Function

Sets the stride of the overlay of the tiled UV plane in bytes.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-0 STRIDE	Overlay Stride Number of bytes from start of one line to next line. **NOTE** This field is double buffered.

55.6.23 Overlay Top Left (OverlayTL)

Offset

Register	Offset
OverlayTL	2094h

Function

Sets the top left coordinate of panel pixel where the overlay starts. Note that there is no panning inside the overlay.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

27-16 Y	Top Boundary Sets the top boundary of overlay window.
15-12 —	Reserved
11-0 X	Left Boundary Sets the left boundary of overlay window.

55.6.24 Overlay Size (OverlaySize)

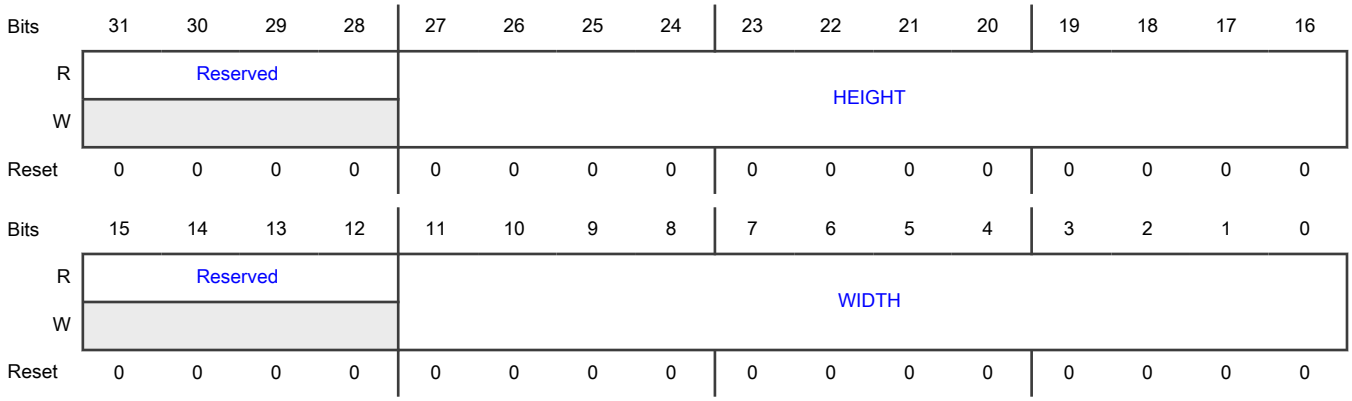
Offset

Register	Offset
OverlaySize	2098h

Function

Sets the overlay size.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-16 HEIGHT	Height Sets the overlay height.
15-12 —	Reserved
11-0 WIDTH	Width Sets the overlay width.

55.6.25 Overlay Color Keying Start Address (OverlayColorKey)

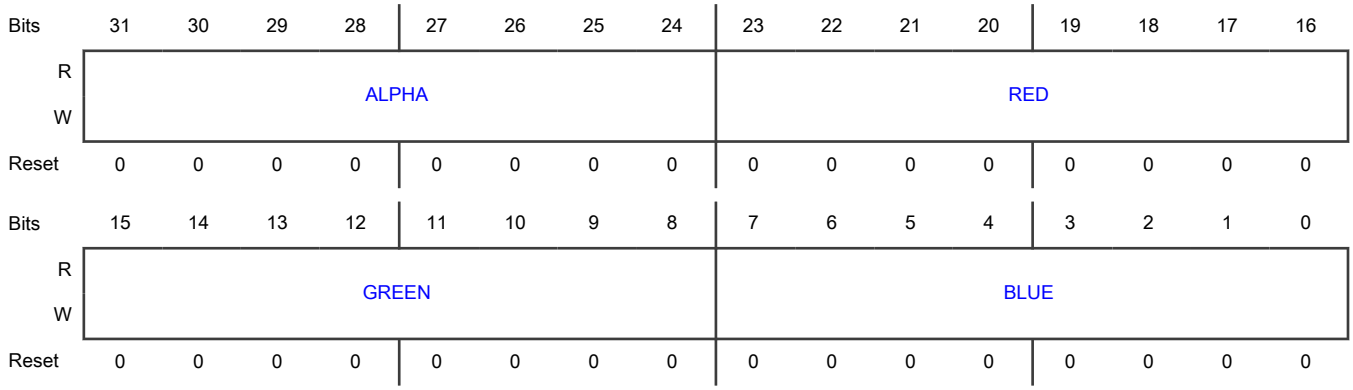
Offset

Register	Offset
OverlayColorKey	209Ch

Function

Sets the start of color keying range for overlay.

Diagram



Fields

Field	Function
31-24 ALPHA	Alpha 8-bit alpha value
23-16 RED	Red 8-bit red color
15-8 GREEN	Green 8-bit green color
7-0 BLUE	Blue 8-bit blue color

55.6.26 Overlay Color Keying End Address (OverlayColorKeyHigh)

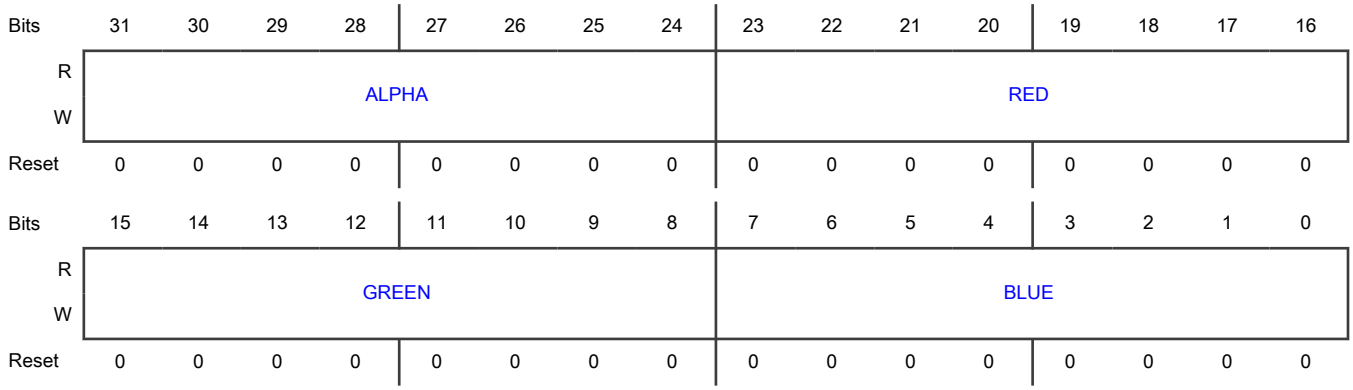
Offset

Register	Offset
OverlayColorKeyHigh	20A0h

Function

Sets the end of color keying range for overlay.

Diagram



Fields

Field	Function
31-24 ALPHA	Alpha 8-bit alpha value
23-16 RED	Red 8-bit red color
15-8 GREEN	Green 8-bit green color

8 SRC_ALPHA_FACTOR	Source Alpha Factor Generates the blending factor for source alpha for the overlay layer. **NOTE** This field is double buffered. 0b - Do not generate the blending factor. 1b - Generates the blending factor.
7-6 SRC_BLENDING_MODE	Source Blending Mode Sets the blending mode for source alpha. **NOTE** This field is double buffered. 00b - Each component of the color is multiplied by (0, 0, 0,0). 01b - Each component of the color is multiplied by (1, 1, 1,1). 10b - Normal as the result color is the source color 11b - Not affected by the color of the underlying pixel
5 —	Reserved
4-3 SRC_GLOBAL_ALPHA_MODE	Source Global Alpha Mode Sets the global alpha mode to substitute or scale the source alpha. 00b - Normal source alpha mode 01b - Global source alpha mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
	10b - Scaled (by the global alpha value) source alpha mode
2 —	Reserved
1 SRC_ALPHA_MODE	Source Alpha Mode Sets the source alpha mode for blending. 0b - Normal alpha mode 1b - Inversed alpha mode if the internal alpha rule needs to be followed
0 ALPHA_BLEND	Alpha Blend Enables alpha blending for overlay from the bottom layer to the top layer. **NOTE** This field is double buffered. 0b - Disables alpha blending for overlay. 1b - Enables alpha blending for overlay.

55.6.28 Overlay Global Alpha (OverlayGlobalAlpha)

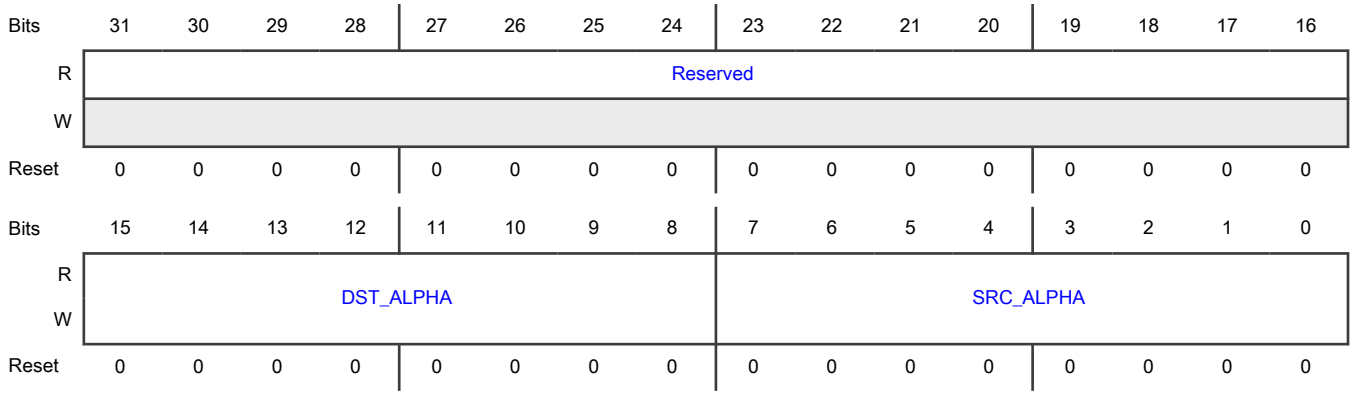
Offset

Register	Offset
OverlayGlobalAlpha	20A8h

Function

Sets the global alpha for overlay.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 DST_ALPHA	Destination Alpha Sets the destination global alpha for overlay. **NOTE** This field is double buffered.
7-0 SRC_ALPHA	Source Alpha Sets the source global alpha for overlay. **NOTE** This field is double buffered.

55.6.29 Overlay Clear Value (OverlayClearValue)

Offset

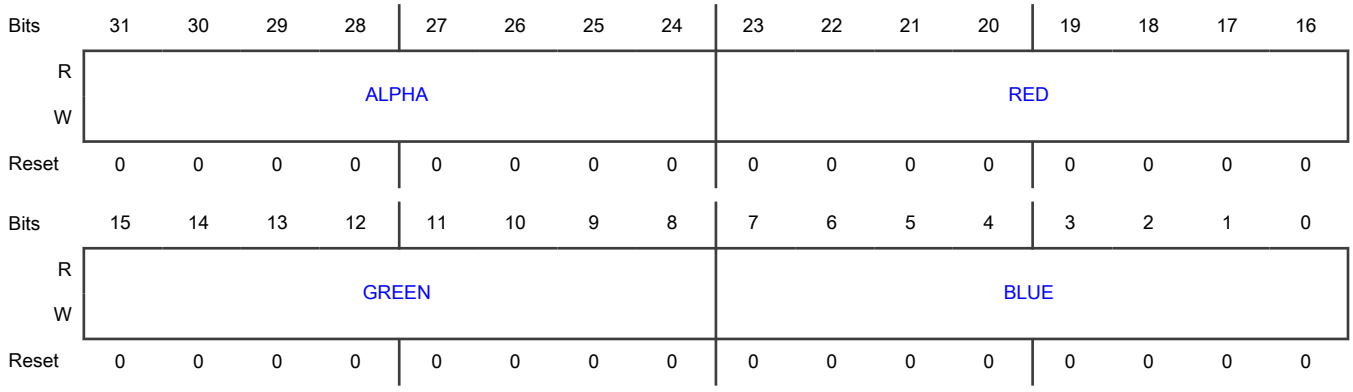
Register	Offset
OverlayClearValue	20ACh

Function

Sets the clear value for overlay, which is used when OverlayConfig[CLEAR_EN] is enabled in the format of A8R8G8B8.

This register is double buffered.

Diagram



Fields

Field	Function
31-24 ALPHA	Alpha 8-bit alpha value
23-16 RED	Red 8-bit red color
15-8 GREEN	Green 8-bit green color
7-0 BLUE	Blue 8-bit blue color

55.6.30 Overlay Layer 1 Configuration (OverlayConfig1)

Offset

Register	Offset
OverlayConfig1	20B0h

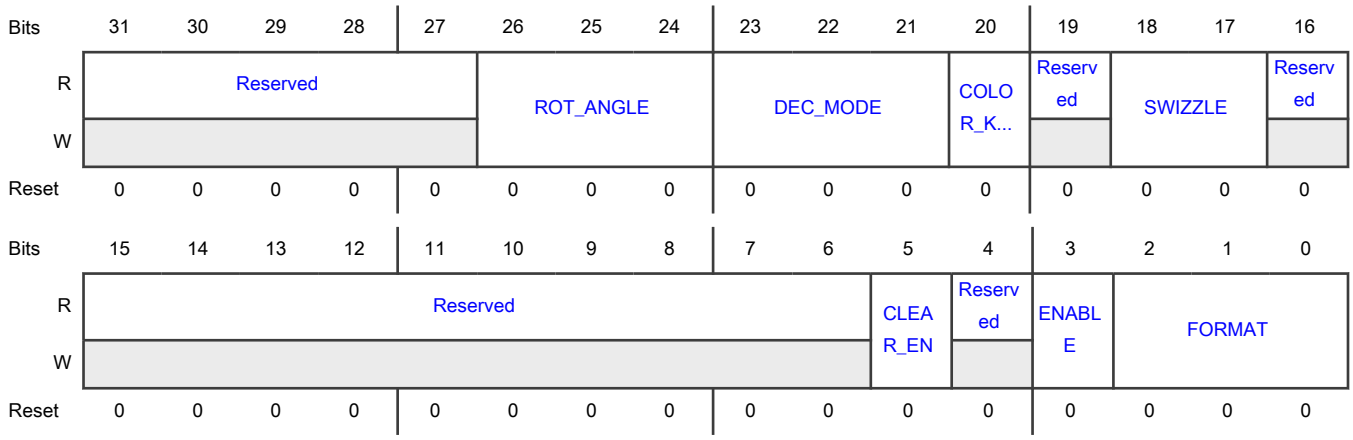
Function

Configures the overlay layer 1 for control.

NOTE

This register is double buffered.

Diagram



Fields

Field	Function
31-27 —	Reserved
26-24 ROT_ANGLE	Rotation Angle Sets the rotation angle for source surface. Height field specifies the height of the surface in pixels. **NOTE** This field is double buffered. 000b - Sets the rotation angle to 0 degree. 010b - Sets the rotation angle to 180 degree. 100b - Flips horizontal 101b - Flips vertical
23-21 DEC_MODE	Decompression Mode Enables or disables decompression mode on the overlay layer 1. **NOTE** This field is double buffered. 000b - Disables decompression. 001b - Enables non_subsample decompression mode. 010b - Enables horizontal subsample decompression mode. 011b - Enables horizontal and vertical subsample decompression mode. 100b - Enables ETC2 decompression mode.
20 COLOR_KEY_EN	Enable Color Keying Enables or disables color keying on the overlay layer 1. **NOTE** This field is double buffered. 0b - Disables color keying. 1b - Enables color keying.
19 —	Reserved
18-17 SWIZZLE	RGB Swizzle Swizzles an input pixel for RGB formats at the overlay layer 1 to align the component order. **NOTE** This field is double buffered.

Table continues on the next page...

7-6 SRC_BLENDING_MODE	Source Blending Mode Sets the source alpha blending mode for the overlay layer 1. **NOTE** This field is double buffered. 00b - Each component of the color is multiplied by (0, 0, 0,0). 01b - Each component of the color is multiplied by (1, 1, 1,1). 10b - Normal as the result color is the source color 11b - Not affected by the color of the underlying pixel
5 —	Reserved
4-3 SRC_GLOBAL_ALPHA_MODE	Source Global Alpha Mode Sets the source global alpha mode for blending for the overlay layer 1. **NOTE** This field is double buffered.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	00b - Normal source alpha mode 01b - Global source alpha mode 10b - Scaled (by the global alpha value) source alpha mode
2 —	Reserved
1 SRC_ALPHA_MODE	Source Alpha Mode Sets the source alpha mode for blending for the overlay layer 1. **NOTE** This field is double buffered. 0b - Normal alpha mode 1b - Inversed alpha mode if the internal alpha rule needs to be followed
0 ALPHA_BLEND	Alpha Blend Enables alpha blending for the overlay layer 1 from the bottom layer to the top layer. **NOTE** This field is double buffered. 0b - Disables alpha blending for the overlay layer 1. 1b - Enables alpha blending for the overlay layer 1.

55.6.38 Overlay Layer 1 Global Alpha (OverlayGlobalAlpha1)

Offset

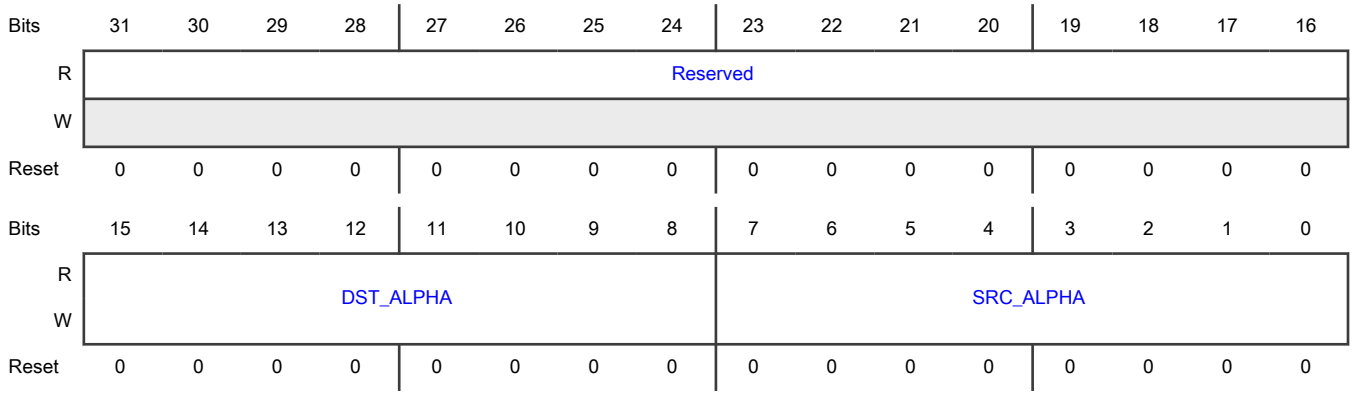
Register	Offset
OverlayGlobalAlpha1	20D0h

Function

Sets the global alpha value for the overlay layer 1.

NOTE
This field is double buffered.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 DST_ALPHA	Destination Alpha Sets the destination global alpha for the overlay layer 1.
7-0 SRC_ALPHA	Source Alpha Sets the source global alpha for the overlay layer 1.

55.6.39 Overlay Layer 1 Clear Value (OverlayClearValue1)

Offset

Register	Offset
OverlayClearValue1	20D4h

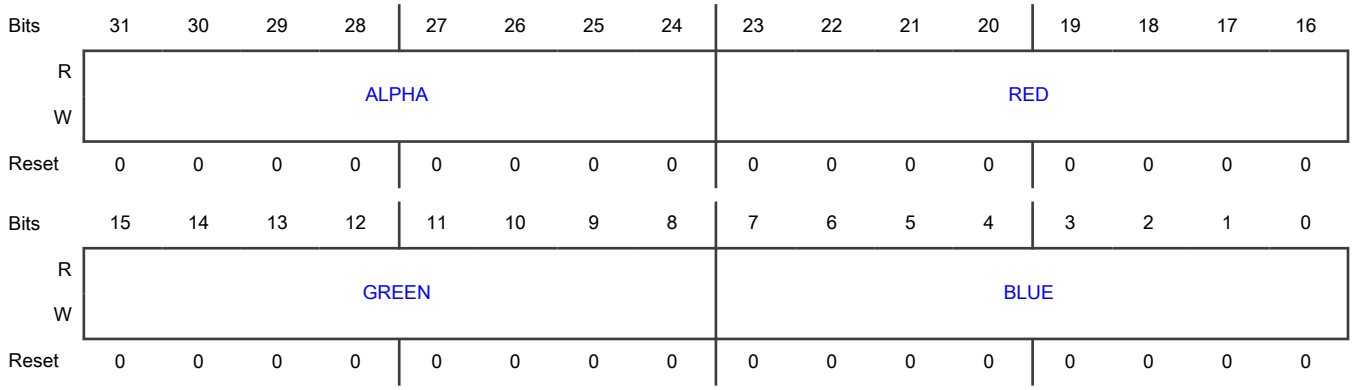
Function

Sets the clear value of the overlay layer 1 when OverlayConfig1[CLEAR_EN] is enabled in the format of A8R8G8B8.

NOTE

This field is double buffered.

Diagram



Fields

Field	Function
31-24 ALPHA	Alpha 8-bit alpha value
23-16 RED	Red 8-bit red color
15-8 GREEN	Green 8-bit green color
7-0 BLUE	Blue 8-bit blue color

55.6.40 Dither Lookup Table Low Threshold (DisplayDitherTableLow0)

Offset

Register	Offset
DisplayDitherTableLow0	20E0h

Function

Sets the lower threshold for creating a dither lookup table.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Y0_X3				Y0_X2				Y0_X1				Y0_X0			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-28 Y1_X3	Y1_X3 Sets the low threshold value to x,y=3,1.
27-24 Y1_X2	Y1_X2 Sets the low threshold value to x,y=2,1.
23-20 Y1_X1	Y1_X1 Sets the low threshold value to x,y=1,1.
19-16 Y1_X0	Y1_X0 Sets the low threshold value to x,y=0,1.
15-12 Y0_X3	Y0_X3 Sets the low threshold value to x,y=3,0.
11-8 Y0_X2	Y0_X2 Sets the low threshold value to x,y=2,0.
7-4 Y0_X1	Y0_X1 Sets the low threshold value to x,y=1,0.
3-0 Y0_X0	Y0_X0 Sets the low threshold value to x,y=0,0.

55.6.41 Dither Lookup Table High Threshold (DisplayDitherTableHigh0)

Offset

Register	Offset
DisplayDitherTableHigh0	20E4h

Function

Sets the high threshold for creating a dither lookup table.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-28 Y3_X3	Y3_X3 Sets the high threshold value to x,y=3,3.
27-24 Y3_X2	Y3_X2 Sets the high threshold value to x,y=2,3.
23-20 Y3_X1	Y3_X1 Sets the high threshold value to x,y=1,3.
19-16 Y3_X0	Y3_X0 Sets the high threshold value to x,y=0,3.
15-12 Y2_X3	Y2_X3 Sets the high threshold value to x,y=3,2.
11-8 Y2_X2	Y2_X2 Sets the high threshold value to x,y=2,2.
7-4 Y2_X1	Y2_X1 Sets the high threshold value to x,y=1,2.
3-0 Y2_X0	Y2_X0 Sets the high threshold value to x,y=0,2.

55.6.42 Panel Configuration (PanelConfig0)

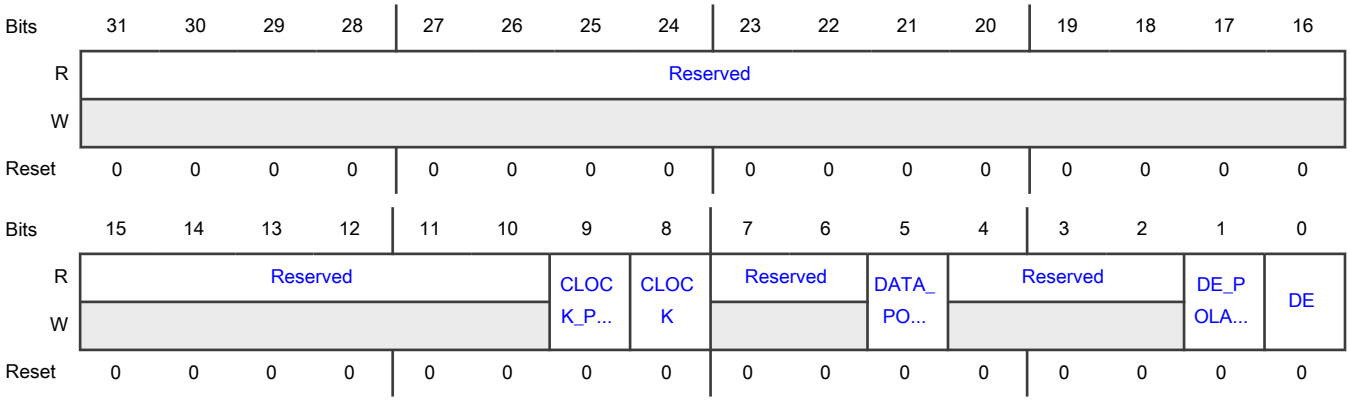
Offset

Register	Offset
PanelConfig0	20E8h

Function

Sets output panel and panel timing.

Diagram



Fields

Field	Function
31-10 —	Reserved
9 CLOCK_POLARITY	Clock Polarity Sets the clock polarity. 0b - Sets the clock polarity to positive. 1b - Sets the clock polarity to negative.
8 CLOCK	Clock Enables or disables clock. 0b - Disables clock. 1b - Enables clock.
7-6 —	Reserved
5	Data Polarity

Table continues on the next page...

Table continued from the previous page...

Field	Function
DATA_POLARITY	Sets the data polarity. 0b - Sets the data polarity to positive. 1b - Sets the data polarity to negative.
4-2 —	Reserved
1 DE_POLARITY	Data Enable Polarity Sets the polarity of data enabled. 0b - Sets the polarity of data enabled to positive. 1b - Sets the polarity of data enabled to negative.
0 DE	Data Enable Enables or disables data. 0b - Disables data. 1b - Enables data.

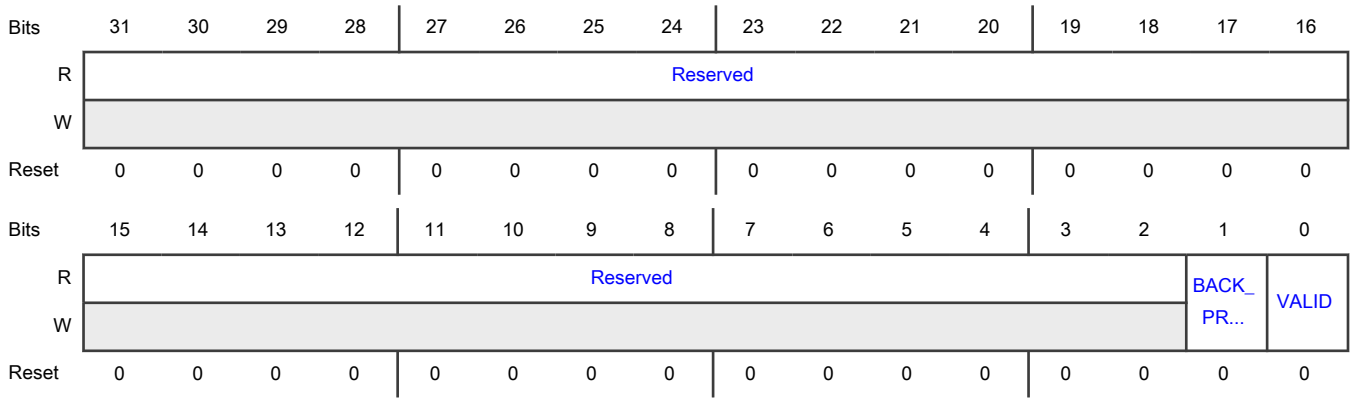
55.6.43 Panel Control (PanelControl)

Offset

Register	Offset
PanelControl	20ECh

Function
Updates parameters for the next frame.

Diagram



Fields

Field	Function
31-2 —	Reserved
1 BACK_PRESSURE_DISABLE	Back Pressure Disable Enables or disables back pressure. 0b - Enables back pressure. 1b - Disables back pressure.
0 VALID	Valid Defines whether you can copy a new set of registers at the next VBLANK or not. This ensures a frame always starts with a valid working set if this register is programmed last, which reduces the need for software to wait for the start of a VBLANK signal in order to ensure all states are loaded before the next VBLANK. 0b - Pending 1b - Copies a set of registers at the next VBLANK.

55.6.44 Panel Function (PanelFunction)

Offset

Register	Offset
PanelFunction	20F0h

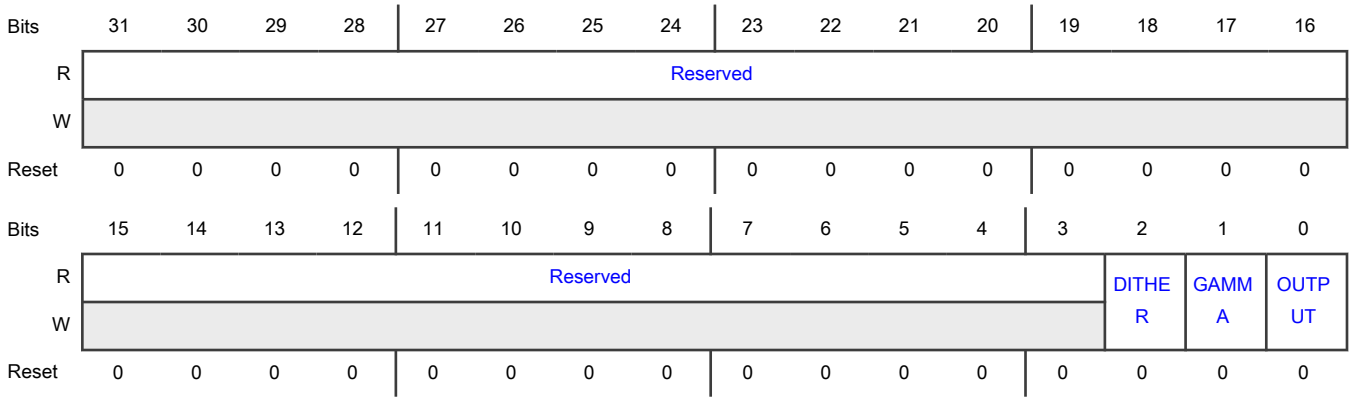
Function

Sets output panel.

NOTE

This register is double buffered.

Diagram



Fields

Field	Function
31-3 —	Reserved
2 DITHER	Dither Enabling dithering allows R8G8B8 modes to show better on panels with less bits-per-pixel. **NOTE** This field is double buffered. 0b - Disables dither. 1b - Enables dither.
1 GAMMA	Gamma When Gamma is enabled, the R, G, and B channels are routed through the Gamma LUT to perform gamma correction. **NOTE** This field is double buffered. 0b - Disables Gamma. 1b - Enables Gamma.
0 OUTPUT	Output When Output is enabled, pixels will be displayed. When Output is disabled, all pixels will be black. This allows a panel to have correct timing but without any pixels. **NOTE** This field is double buffered. 0b - Disables output panel. 1b - Enables output panel.

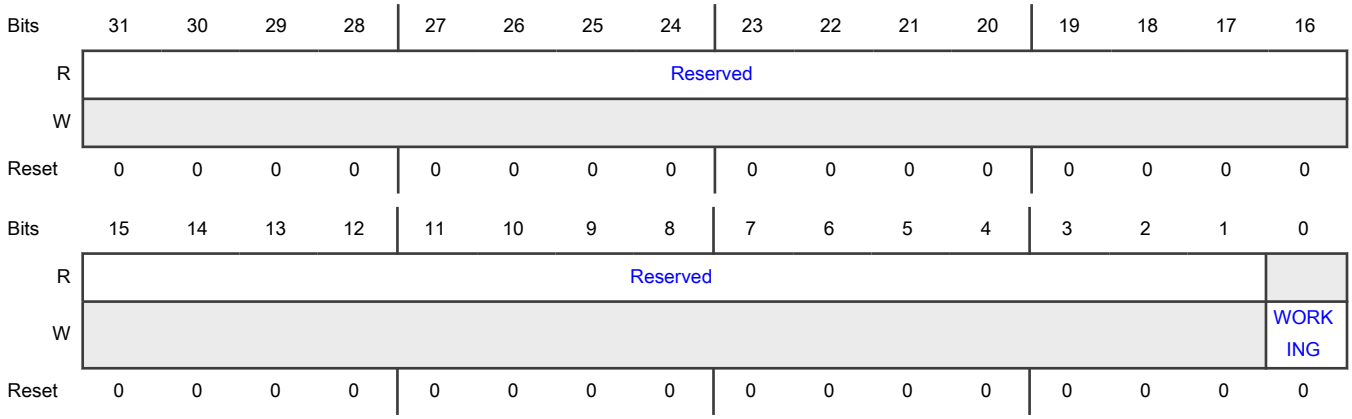
55.6.45 Panel Working (PanelWorking)

Offset

Register	Offset
PanelWorking	20F4h

Function
Triggers display controller to start the interface mode transfer.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 WORKING	Working Writing one in this register will force a reset of the display controller. All registers will be copied to the working set and counters will be reset to the end of HSYNC and VSYNC. 1b - Starts reset of the display controller.

55.6.46 Panel State (PanelState)

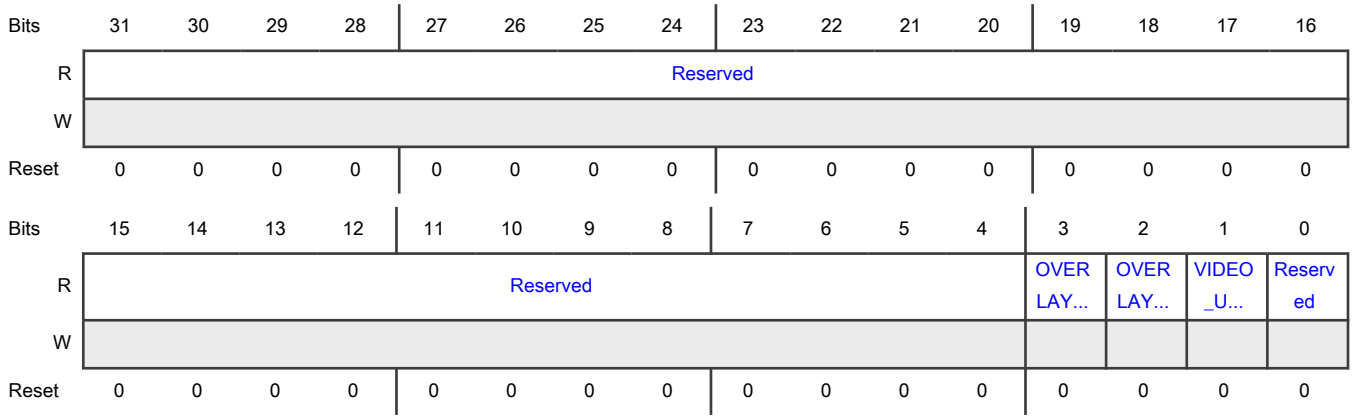
Offset

Register	Offset
PanelState	20F8h

Function

Indicates the display controller status.

Diagram



Fields

Field	Function
31-4 —	Reserved
3 OVERLAY_UNDER_FLOW1	Overlay Layer 1 Under Flow When the overlay layer 1 FIFO underflows, this bit gets set to one. Reading this register will reset it back to zero. 0b - Do not set the overlay layer 1 FIFO to underflow. 1b - Sets the overlay layer 1 FIFO to underflow.
2 OVERLAY_UNDER_FLOW	Overlay Layer 0 Under Flow When the overlay layer 0 FIFO underflows, this bit gets set to one. Reading this register will reset it back to zero. 0b - Do not set the overlay layer 0 FIFO to underflow. 1b - Sets the overlay layer 0 FIFO to underflow.
1 VIDEO_UNDER_FLOW	Video Under Flow When the display FIFO underflows, this bit sets to one. Reading this register will reset it back to zero. 0b - Do not set the display FIFO video to underflow. 1b - Sets the display FIFO video to underflow.
0 —	Reserved

55.6.47 Horizontal Display Total and Visible Pixel Count (HDisplay0)

Offset

Register	Offset
HDisplay0	2100h

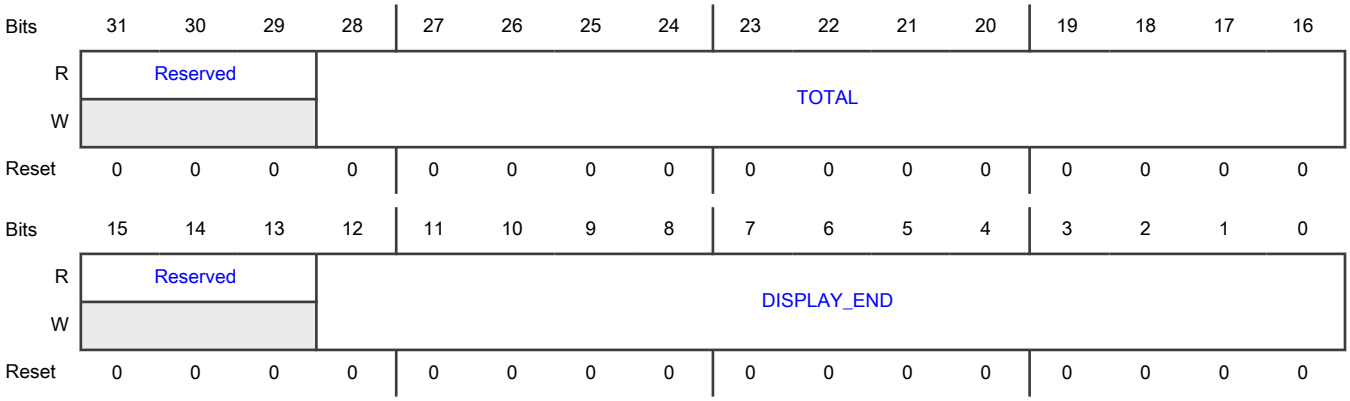
Function

Sets the horizontal total and display end counters.

NOTE

This register is double buffered.

Diagram



Fields

Field	Function
31-29 —	Reserved
28-16 TOTAL	Total Total number of horizontal pixels.
15-13 —	Reserved
12-0 DISPLAY_END	Display End Number of visible horizontal pixels.

55.6.48 Horizontal Sync Counter (HSync0)

Offset

Register	Offset
HSync0	2104h

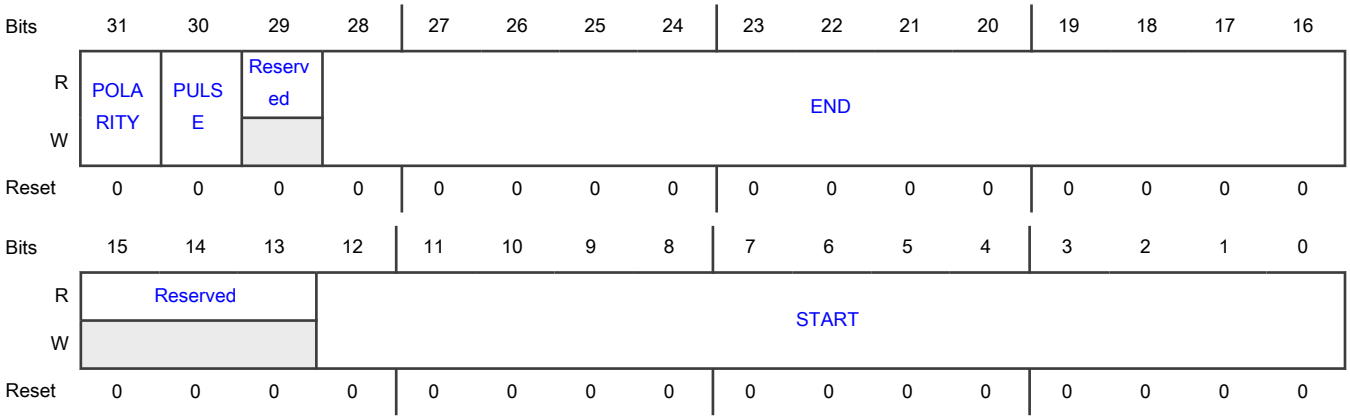
Function

Sets the horizontal sync pulse parameters for display.

NOTE

This register is double buffered.

Diagram



Fields

Field	Function
31 POLARITY	Sync Pulse Polarity Sets the polarity of the horizontal sync pulse. 0b - Sets the polarity of the horizontal sync pulse to positive. 1b - Sets the polarity of the horizontal sync pulse to negative.
30 PULSE	Sync Pulse Enables or disables horizontal sync pulse control. 0b - Disables horizontal sync pulse control. 1b - Enables horizontal sync pulse control.
29 —	Reserved
28-16	End

Table continues on the next page...

Table continued from the previous page...

Field	Function
END	Sets the end of horizontal sync pulse.
15-13 —	Reserved
12-0 START	Start Sets the start of horizontal sync pulse.

55.6.49 Vertical Total and Visible Pixel Count (VDisplay0)

Offset

Register	Offset
VDisplay0	2110h

Function

Sets the total and visible of vertical lines for display.

NOTE

This field is double buffered.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	Reserved				START											
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 POLARITY	Polarity Sets the polarity of the vertical sync pulse.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Sets the polarity of the vertical sync pulse to positive. 1b - Sets the polarity of the vertical sync pulse to negative.
30 PULSE	Vertical Sync Pulse Sets the vertical sync pulse control. 0b - Disables vertical sync pulse. 1b - Enables vertical sync pulse.
29-28 —	Reserved
27-16 END	End Sets the end of the vertical sync pulse.
15-12 —	Reserved
11-0 START	Start Sets the start of the vertical sync pulse.

55.6.51 Display Current Location (DisplayCurrentLocation0)

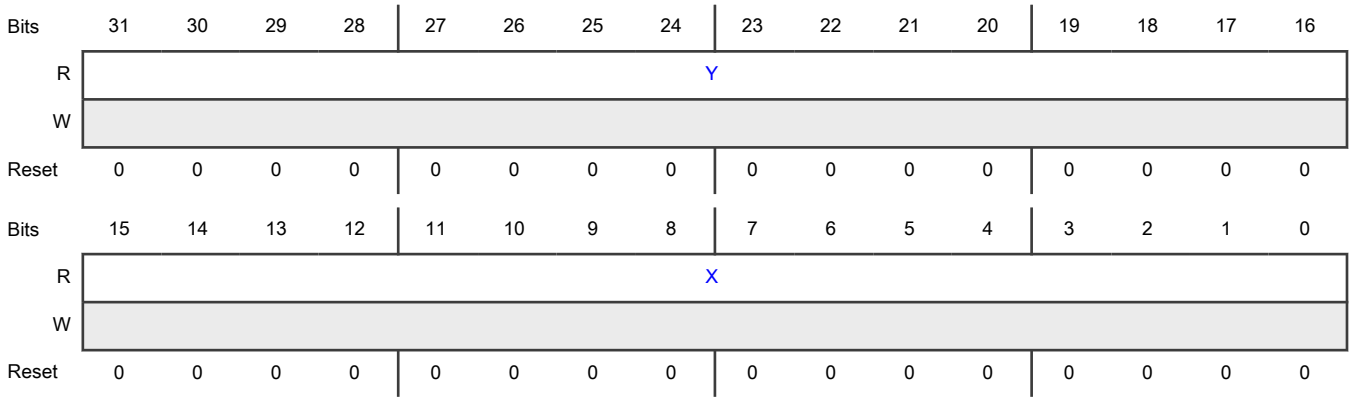
Offset

Register	Offset
DisplayCurrentLocation0	2118h

Function

Indicates the current x,y location of display controller.

Diagram



Fields

Field	Function
31-16 Y	Y Current Y location.
15-0 X	X Current X location.

55.6.52 Gamma Index (GammaIndex0)

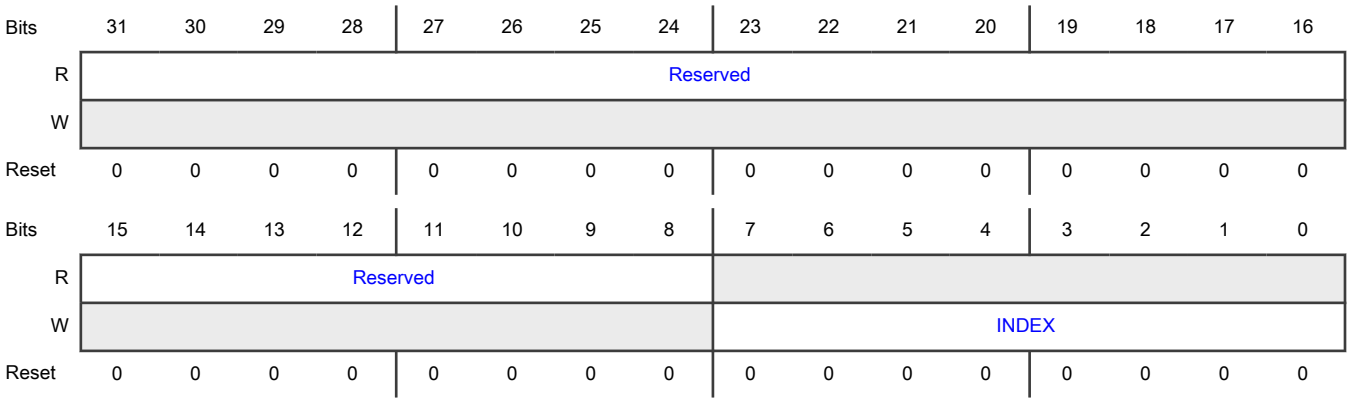
Offset

Register	Offset
GammaIndex0	211Ch

Function

Sets LUT index into the gamma lookup table.

Diagram



Fields

Field	Function
31-8 —	Reserved
7-0 INDEX	Index Sets the LUT index into the gamma lookup table.

55.6.53 Gamma Data (GammaData0)

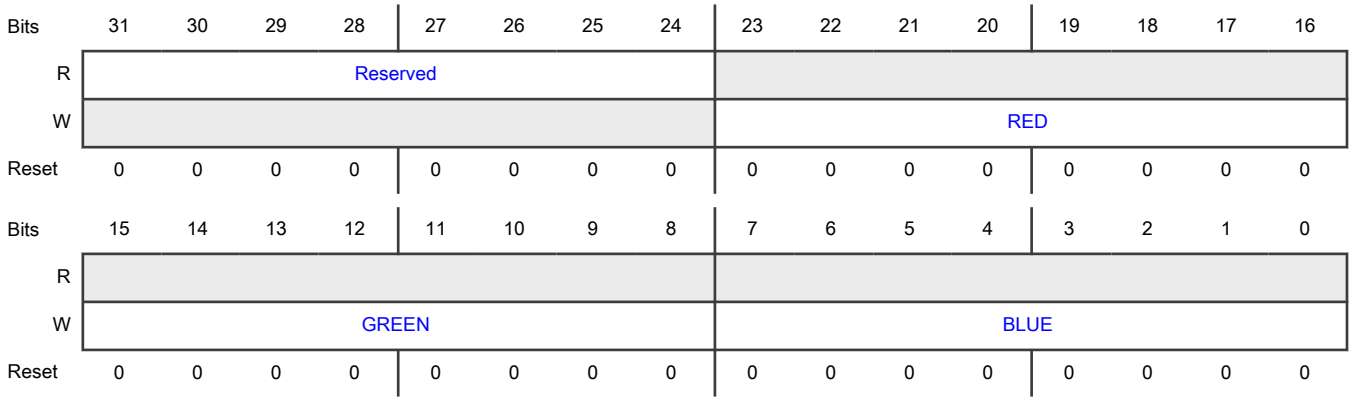
Offset

Register	Offset
GammaData0	2120h

Function

Translation values for the gamma table. When this register gets written, the data gets stored in the gamma table at the LUT index specified by the GammaIndex0 register. After the register is written, the index gets incremented.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 RED	Red Sets red translation value.
15-8 GREEN	Green Sets green translation value.
7-0 BLUE	Blue Sets blue translation value.

55.6.54 Cursor Configuration (CursorConfig)

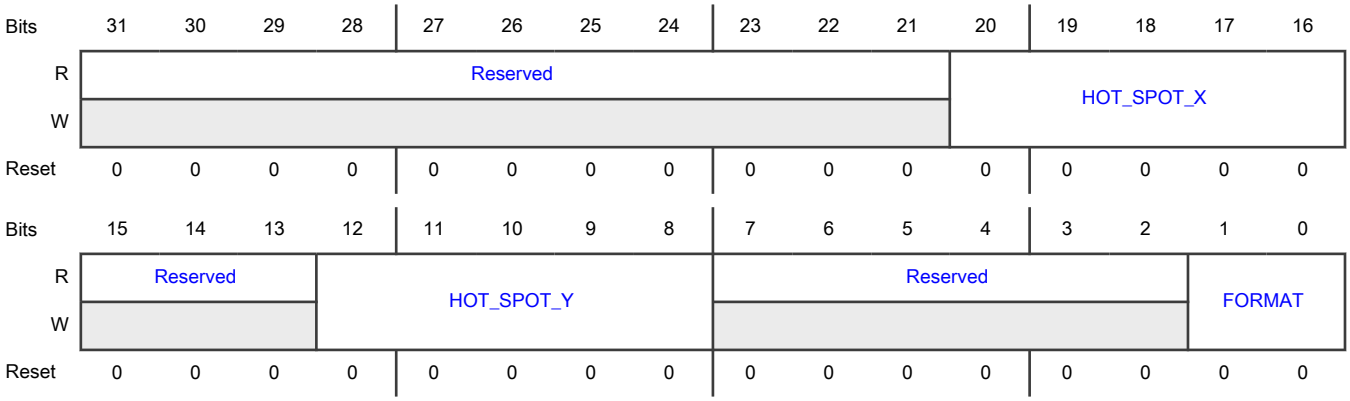
Offset

Register	Offset
CursorConfig	2124h

Function

Sets cursor parameters. A cursor is tracked through the top-left point of the cursor layer and the hotspot of the cursor. Double-buffered values in this register cannot be read while a flip is in progress.

Diagram



Fields

Field	Function
31-21 —	Reserved
20-16 HOT_SPOT_X	Horizontal Hot Spot Sets the horizontal offset to cursor hotspot. **NOTE** This field is double buffered.
15-13 —	Reserved
12-8 HOT_SPOT_Y	Vertical Hot Spot Sets the vertical offset to cursor hotspot. **NOTE** This field is double buffered.

Table continues on the next page...

Table continued from the previous page...

Field	Function
7-2 —	Reserved
1-0 FORMAT	Format Sets the format of a cursor. **NOTE** This field is double buffered. 00b - Disables the format of a cursor. 01b - Sets the cursor in masked format, where the mask values of the AND and XOR bits decide the color of one cursor image pixel.. 10b - Sets the cursor in A8R8G8B8 format, where the color of the cursor image is decided by the ARGB values fetched from the memory.

55.6.55 Cursor Base Address (CursorAddress)

Offset

Register	Offset
CursorAddress	2128h

Function

Sets the base address of the cursor shape.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDRESS															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-0 ADDRESS	Base address A 32-bit base address.

55.6.56 Cursor Location (CursorLocation)

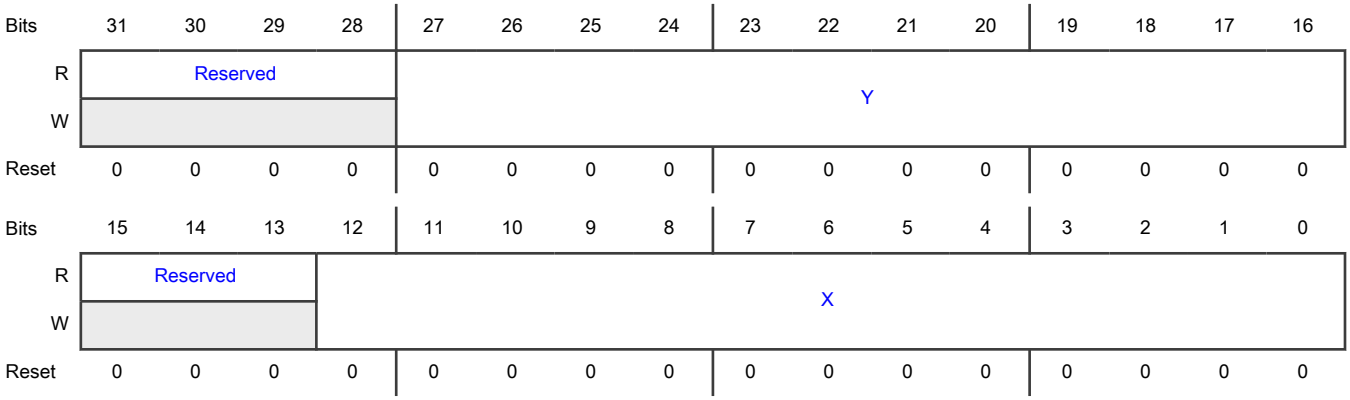
Offset

Register	Offset
CursorLocation	212Ch

Function

Sets the location of the cursor on the owning display.

Diagram



Fields

Field	Function
31-28 —	Reserved
27-16 Y	Y Sets the Y location of cursor's hotspot. **NOTE** This field is double buffered.
15-13 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
12-0 X	X Sets X horizontal location of cursor's hotspot. **NOTE** This field is double buffered.

55.6.57 Cursor Background Color (CursorBackground)

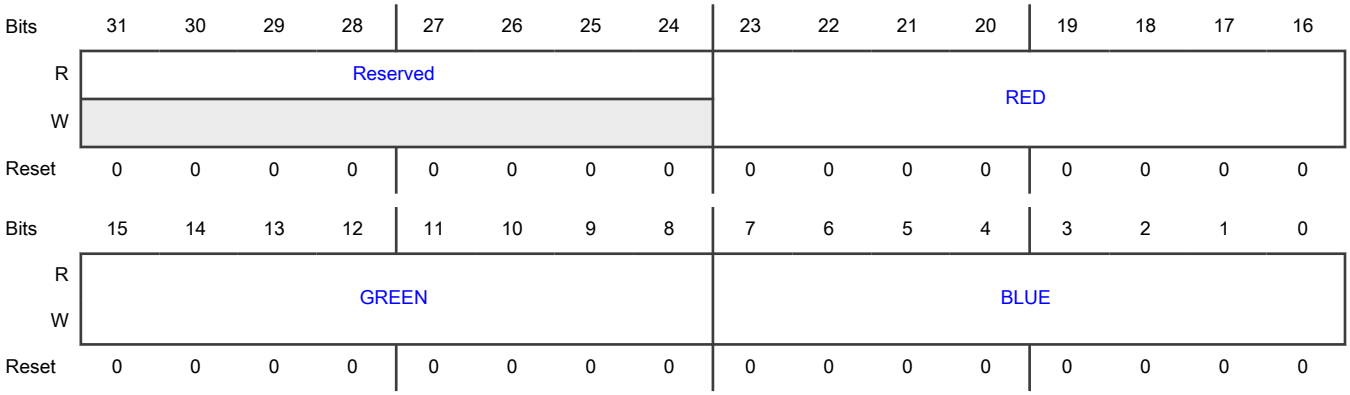
Offset

Register	Offset
CursorBackground	2130h

Function

Sets the background color of cursor in the masked format.

Diagram



Fields

Field	Function
31-24 —	Reserved
23-16 RED	Red Red value **NOTE** This field is double buffered.

Table continues on the next page...

Table continued from the previous page...

Field	Function
15-8 GREEN	Green Green value **NOTE** This field is double buffered.
7-0 BLUE	Blue Blue value **NOTE** This field is double buffered.

55.6.58 Cursor Foreground Color (CursorForeground)

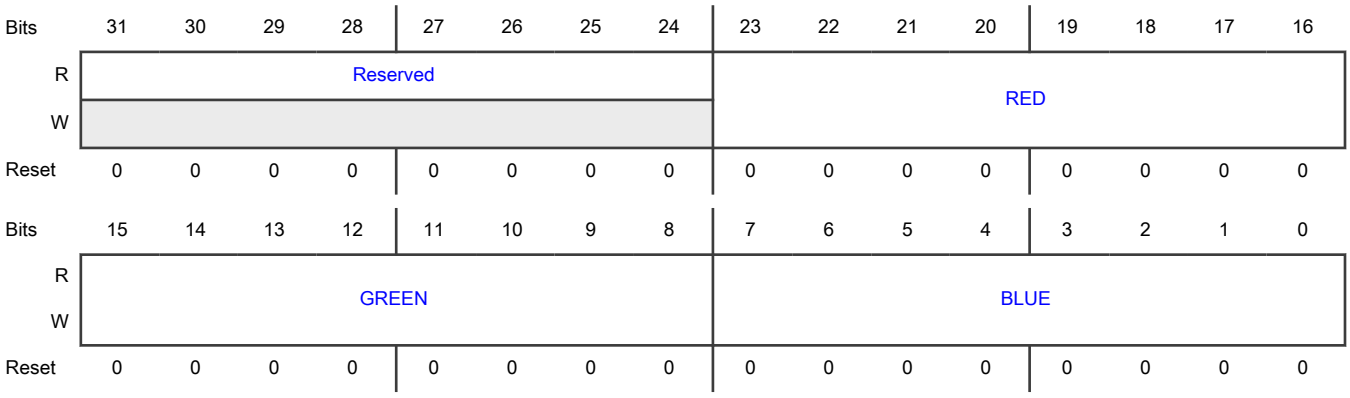
Offset

Register	Offset
CursorForeground	2134h

Function

Sets the foreground color of cursor in masked format.

Diagram



Fields

Field	Function
31-24 —	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
23-16 RED	Red Red value **NOTE** This field is double buffered.
15-8 GREEN	Green Green value **NOTE** This field is double buffered.
7-0 BLUE	Blue Blue value **NOTE** This field is double buffered.

55.6.59 Display Interrupt (DisplayIntr)

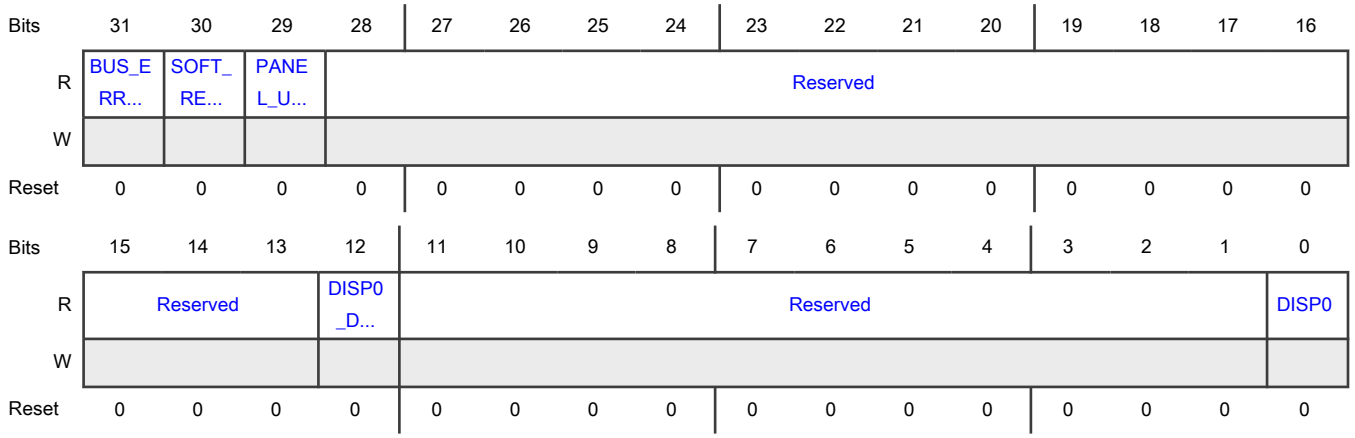
Offset

Register	Offset
DisplayIntr	2138h

Function

This is the interrupt register for the display. This register will automatically clear after a read. The interrupt bit is set when the current frame buffer is used up. The interrupt signal will be pulled up only when the interrupt enable bit in the DisplayIntrEnable register is enabled.

Diagram



Fields

Field	Function
31 BUS_ERROR	Bus Error Bus error interrupt
30 SOFT_RESET_DONE	Soft Reset Done Soft reset done interrupt
29 PANEL_UNDERFLOW	Panel Underflow Panel underflow interrupt
28-13 —	Reserved
12 DISP0_DBI_CFG_ERROR	Display_0 DBI Configure Error DBI configuration error for Display_0
11-1 —	Reserved
0 DISP0	Display_0 Frame done interrupt

55.6.60 Display Interrupt Enable (DisplayIntrEnable)

Offset

Register	Offset
DisplayIntrEnable	213Ch

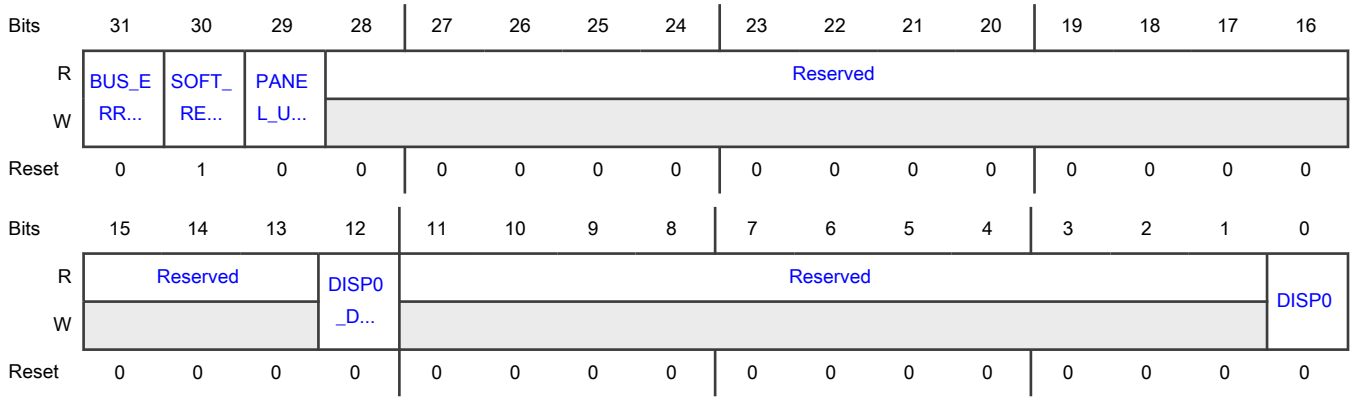
Function

Enables interrupt for display_0 (and display_1 if present).

NOTE

This field is double buffered.

Diagram



Fields

Field	Function
31 BUS_ERROR	Bus Error Enables bus error interrupt. 0b - Enables bus error interrupt. 1b - Disables bus error interrupt.
30 SOFT_RESET_DONE	Soft Reset Done Enables soft reset done interrupt. 0b - Disables soft reset done interrupt. 1b - Enables soft reset done interrupt.
29 PANEL_UNDERFLOW	Panel Underflow Enables panel underflow interrupt. 0b - Enables panel underflow interrupt. 1b - Disables panel underflow interrupt.
28-13 —	Reserved
12 DISP0_DBI_CFG_ERROR	Display_0 DBI Configuration Error Enables Display_0 DBI configuration error interrupt. **NOTE** This field is double buffered. 0b - Enables Display_0 DBI configuration error. 1b - Disables Display_0 DBI configuration error.
11-1	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
0 DISP0	Display_0 Enables Display_0 interrupt. 0b - Enables Display_0 interrupt. 1b - Disables Display_0 interrupt.

55.6.61 DBI Configuration (DbiConfig0)

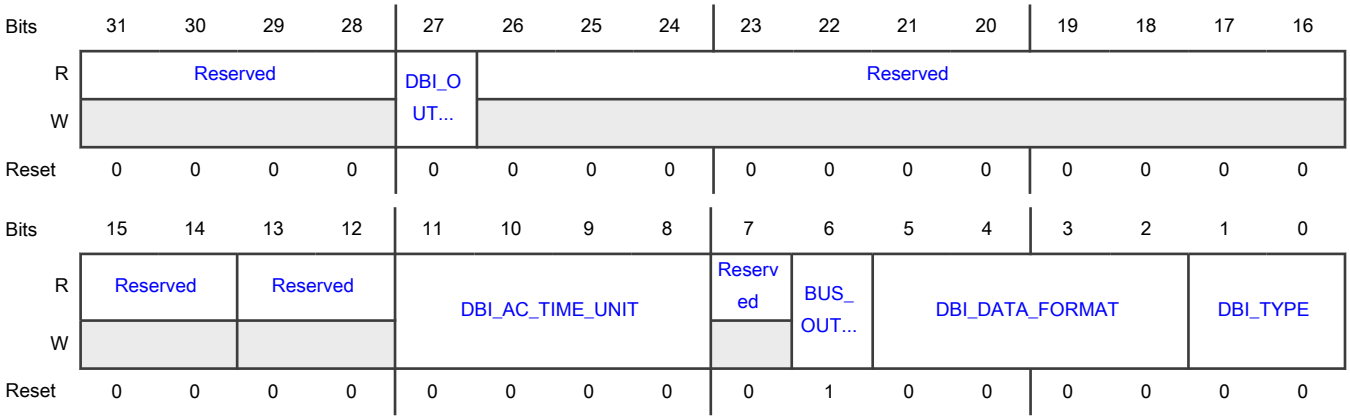
Offset

Register	Offset
DbiConfig0	2140h

Function

Sets output format for DBI types.

Diagram



Fields

Field	Function
31-28 —	Reserved
27 DBI_OUTPUT_SWIZZLE	DBIT Output Swizzle Set Sets DBI output data swizzle.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - RGB 1b - BGR
26-14 —	Reserved
13-12 —	Reserved
11-8 DBI_AC_TIME_UNIT	DBI AC Time Unit Sets the time units for AC characteristics (such as when to assert/de-assert a signal) for each DBI type.
7 —	Reserved
6 BUS_OUTPUT_SEL	Output Bus Select Selects the display output bus. 0b - Uses DPI bus. 1b - Uses DBI bus.
5-2 DBI_DATA_FORMAT	DBI Data Format Specifies the DBI output data format. 0000b - D8R3G3B2 0001b - D8R4G4B4 0010b - D8R5G6B5 0011b - D8R6G6B6 0100b - D8R8G8B8 0101b - D9R6G6B6 0110b - D16R3G3B2 0111b - D16R4G4B4 1000b - D16R5G6B5 1001b - D16_R6_G6_B6_OP1 1010b - D16_R6_G6_B6_OP2 1011b - D16_R8_G8_B8_OP1 1100b - D16_R8_G8_B8_OP2
1-0	DBI Type Sets the DBI type for output.

Table continues on the next page...

Table continued from the previous page...

Field	Function
DBI_TYPE	00b - Selects DBI Type A Fixed E mode. 01b - Selects DBI Type A Clocked E mode. 10b - Selects DBI type B.

55.6.62 DBI Interface Reset (DbiIfReset0)

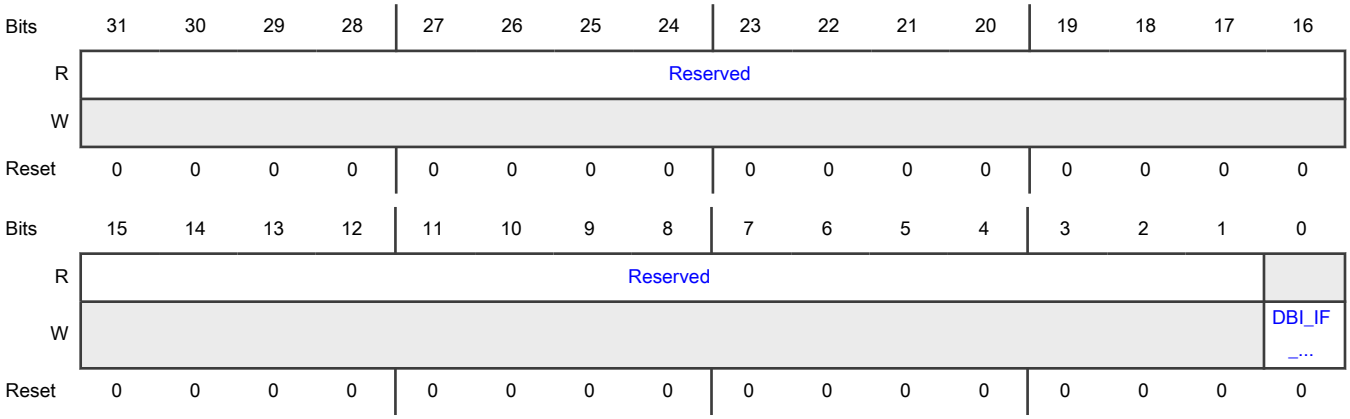
Offset

Register	Offset
DbiIfReset0	2144h

Function

Resets DBI bus or not.

Diagram



Fields

Field	Function
31-1 —	Reserved
0 DBI_IF_LEVEL_RESET	DBI Interface Level Reset Resets DBI interface to idle state. 1b - Resets the DBI bus in idle state.

55.6.63 DBI Write AC Characteristics 1 (DbiWrChar10)

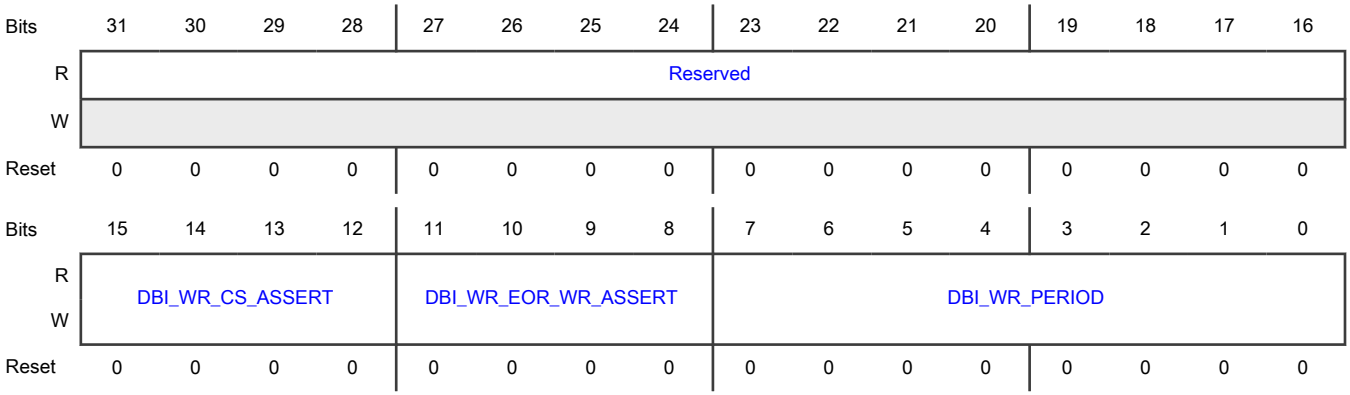
Offset

Register	Offset
DbiWrChar10	2148h

Function

Sets the DBI output timing parameters and the AC timing specifications of the panel for DBI Type A.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-12 DBI_WR_CS_ASSERT	DBI Write CS Assert Cycle number = Setting * (DbiAcTimeUnit + 1). • 0: When Type A Fixed E mode: Time to assert CSX. • 1: When Type A Clock E mode: Not used. • 2: When Type B mode: Not used.
11-8 DBI_WR_EOR_WR_ASSERT	DBI Clock E Signal or WRX Signal Assert Cycle number = Setting * (DbiAcTimeUnit + 1). • 0: When Type A Fixed E mode: Not used. • 1: When Type A Clock E mode: Time to assert E. • 2: When Type B mode: Time to assert WRX.
7-0	DBI Write Period Sets the single write period duration.

Table continues on the next page...

Table continued from the previous page...

Field	Function
DBI_WR_PERIOD	Cycle number = Setting * (DbiAcTimeUnit + 1). This field must be no less than 3.

55.6.64 DBI Write AC Characteristics 2 (DbiWrChar20)

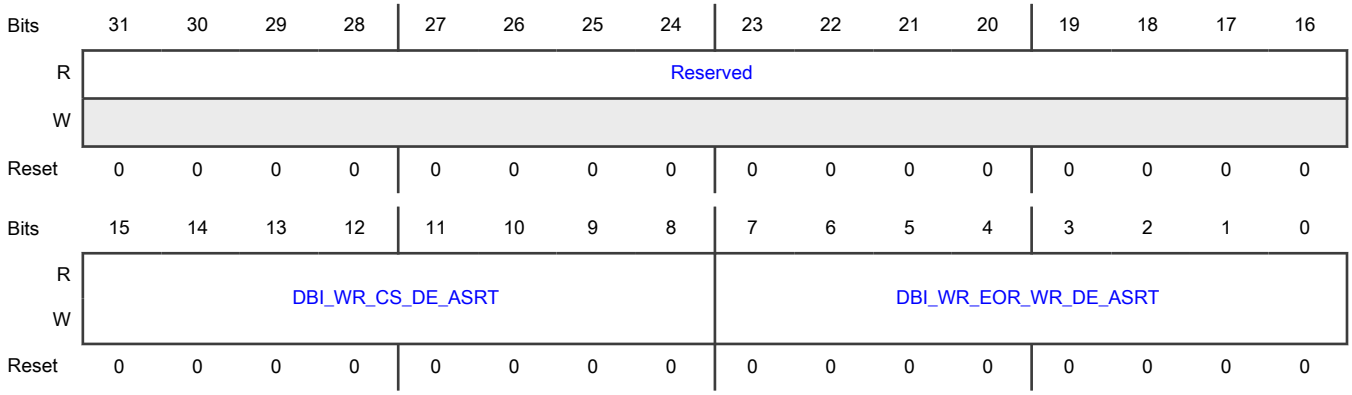
Offset

Register	Offset
DbiWrChar20	214Ch

Function

Sets the DBI output timing parameters and the AC timing specifications of the panel for DBI Type A and B.

Diagram



Fields

Field	Function
31-16 —	Reserved
15-8 DBI_WR_CS_DE_ASRT	DBI Write CS De-assert Cycle number = Setting * (DbiAcTimeUnit + 1). • 0: When Type A Fixed E mode: Time to de-assert CSX. • 1: When Type A Clock E mode: Not used. • 2: When Type B mode: Not used.

55.6.65 DBI Command Control (DbiCmd0)

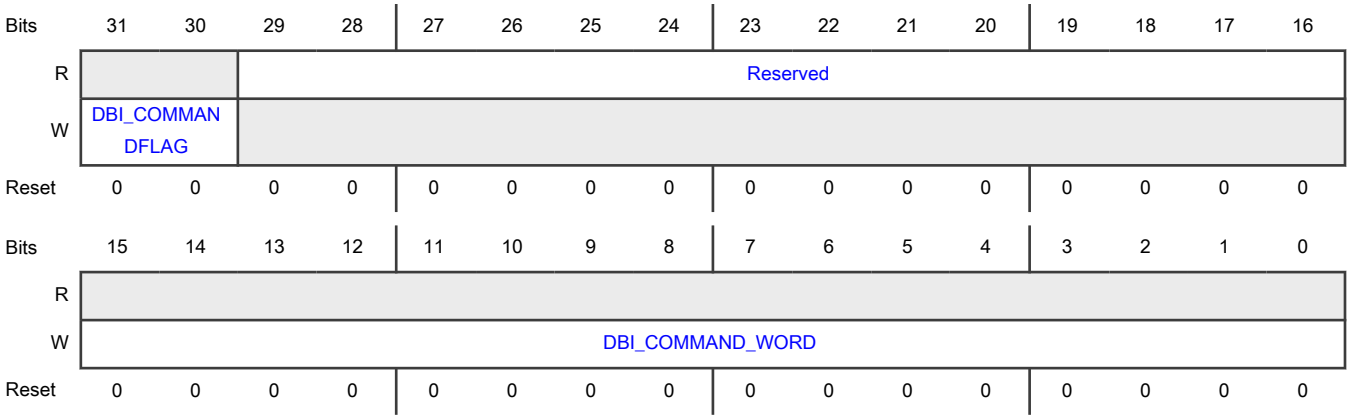
Offset

Register	Offset
DbiCmd0	2150h

Function

DBI command in/out port. Writes to this register will send command/data to the DBI port.

Diagram



Fields

Field	Function
31-30 DBI_COMMAN DFLAG	DBI Command Flag Sets the type of data to be sent to the DBI port and stored in [DBI_COMMAND_WORD]. 00b - Address. [DBI_COMMAND_WORD] will contain an address. 01b - Write Memory Start. Starts to write memory. The contents contained in [DBI_COMMAND_WORD] are ignored. 10b - Parameter or Data. [DBI_COMMAND_WORD] will contain a parameter or data.

Table continues on the next page...

Table continued from the previous page...

Field	Function
29-16 —	Reserved
15-0 DBI_COMMAND_WORD	DBI Command Word The type of data contained in this word is specified using [DBI_COMMANDFLAG].

55.6.66 DPI Configuration (DpiConfig0)

Offset

Register	Offset
DpiConfig0	2154h

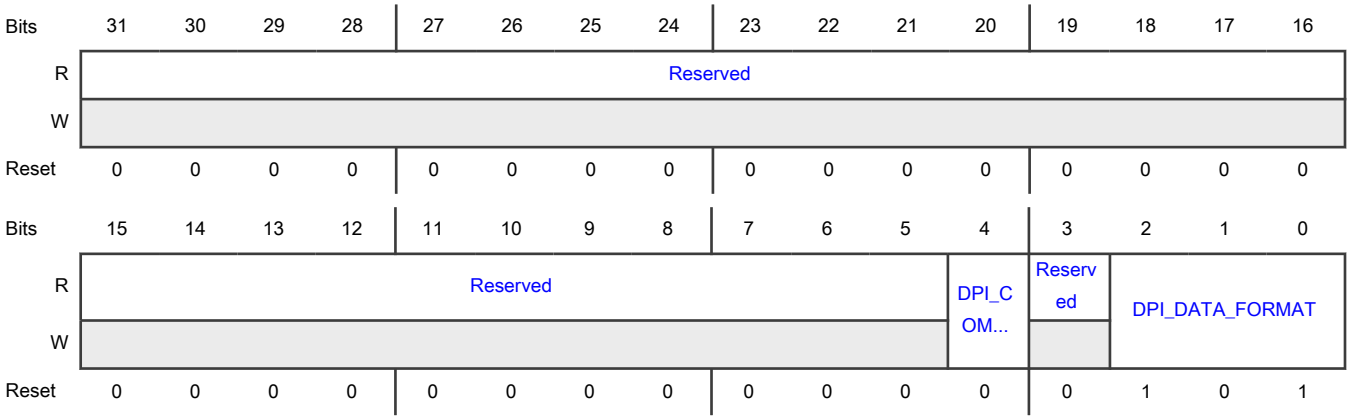
Function

Sets output format for DPI.

NOTE

This register is double buffered.

Diagram



Fields

Field	Function
31-5 —	Reserved
4	DPI Command Mode

Table continues on the next page...

Table continued from the previous page...

Field	Function
DPI_COMMAND_MODE	Sets the DPI command mode. 0b - Disables the DPI command mode. 1b - Enables the DPI command mode.
3 —	Reserved
2-0 DPI_DATA_FORMAT	DPI Data Format Specifies the DPI interface data format. 000b - D16CFG1 001b - D16CFG2 010b - D16CFG3 011b - D18CFG1 100b - D18CFG2 101b - D24

55.6.67 Source Endian Configuration (SrcConfigEndian)

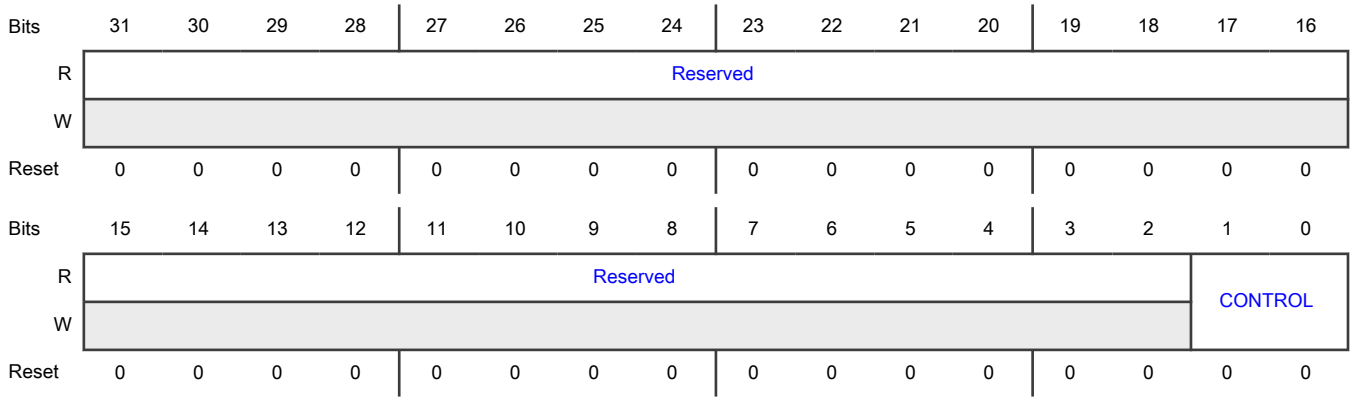
Offset

Register	Offset
SrcConfigEndian	2160h

Function

Sets source endian control.

Diagram



Fields

Field	Function
31-2 —	Reserved
1-0 CONTROL	Control Controls source endian. 00b - No Swap. Swapping is not enabled. 01b - Swap Word. Swaps at 16-bit boundary: 0123 to 1032. 10b - Swap Dword. Swaps at 32-bit boundary: 0123 to 3210.

55.6.68 Soft Reset (SoftReset)

Offset

Register	Offset
SoftReset	2164h

Function

Enables or disables soft reset.

56.2 Overview

SDADC is a low-power high-performance audio ADC system. This module mainly targets battery-powered, hearable and wearable audio devices. It supports analog microphones and line inputs. This module also includes a low-latency decimation filter to enable acoustic noise and echo cancellation.

56.2.1 Block diagram

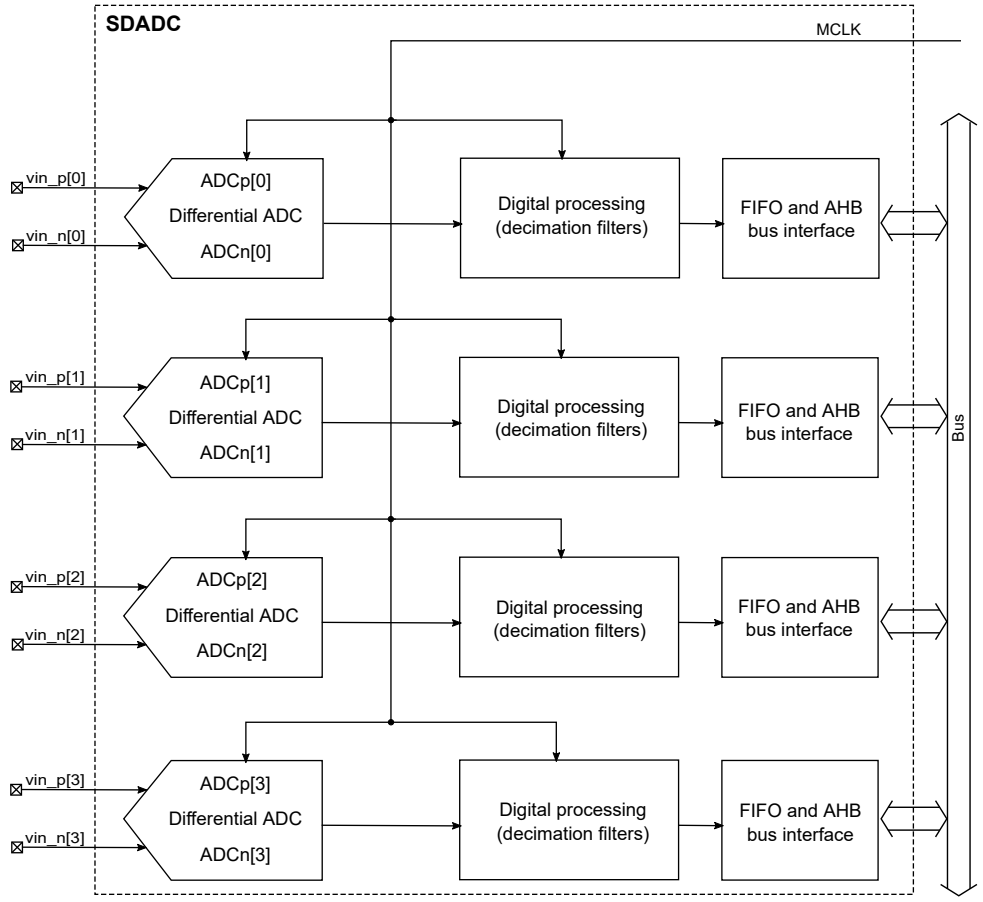

Figure 237. SDADC block diagram

56.2.2 Features

- Low-noise ADC in differential (Diff) mode
- Low-power modulator
- High-linearity ADC
- Supports sampling frequencies (F_s) of 16 kHz, 32 kHz, and 48 kHz
- Supports single-ended (SE) and differential (Diff) inputs
- Low latency to enable acoustic noise and echo cancellation
- Supports MEMS and JFET analog microphones
- Supports line inputs
- Decimation filter soft-core included
- Digital volume control
- DC loop filter to enable DC coupling of analog microphone output to ADC input in SE mode

56.3 Functional description

SDADC is a low-power high-performance Audio Codec for battery-powered audio devices. The basic function of the module is to convert single-ended (SE) or differential (Diff) analog input signals into 24-bit data word length with F_s Nyquist rate of 48 kHz, 32 kHz, or 16 kHz. The ADC is based on a 3rd-order continuous-time sigma-delta modulator (SDM). Single-unit ADC can be configured as two single-ended ADCs or one differential ADC. LDO is included in the module to isolate the sensitive analog circuit. Decimation filter is included to enable acoustic noise and echo cancellation.

56.3.1 ADC modulator

The ADC modulator is based on a quasi-passive 3rd-order continuous-time sigma-delta modulator (SDM) and is clocked with frequency of 512 × 48 kHz (24.576 MHz). The SDM bitstream output is downsampled by the decimation filter to a F_s Nyquist of 48 kHz, 32 kHz, or 16 kHz.

SDM has DC feedback loop to remove any DC offset when DC coupling is used to connect input source to V_{in} in single-ended (SE) mode only. This feature allows single-ended audio sampling without the use of a very large coupling capacitor, C_c, as in typical implementations. This feedback loop is controlled by DC loop filter soft-core block.

The complete ADC modulator submodule contains two single-ended modulators (ADCp and ADCn) which can support one differential ADC or two single-ended ADCs.

In differential (Diff) mode, differential input signals are applied to vin_p and vin_n. In this mode, only ADCp will generate bitstream and feed the associated decimation filter.

56.3.2 Decimation filter

The decimation filter submodule is a 24-bit mono decimation filter with 16-bit coefficients. The decimation is realized with programmable cascade integrator comb (CIC) filter and a cascade of 2 half-band filters and a finite impulse response (FIR) filter. It supports sampling frequencies (F_s) of 16 kHz, 32 kHz, and 48 kHz.

The decimator is clocked at a speed of 24.576 MHz. DC blocking filter is included at the front. When it is enabled it will remove unwanted DC components from the input bitstream like offset and DC-dithering. The DC blocking filter is implemented as a 1st order infinite impulse response (IIR) high-pass filter.

The features of the decimation filter are:

- Selectable sample rates: 16 kHz, 32 kHz, 48 kHz.
- DC filter
- Overflow signal
- Volume control with has a gain range from -63.5 dB to +24 dB in step of 0.5 dB.

56.3.3 DC input common mode control block

This is part of feedback loop that takes care of the input common-mode voltage when a signal source is connected directly to ADC input. This is only applicable in SE mode.

56.3.4 LDO

The LDO has supply voltage of 1.8 V and output voltage of 1.5 V. It requires clean 1.5 V (nominal) reference voltage, which comes from the reference generator. It can support up to 4 differential ADC modulator units.

56.3.5 Reference generator

The reference generator block consists of on-chip resistive divider (5/6) which divides the supply voltage of 1.8 V. When it is enabled, the reference generator generates a reference voltage (vref_ldo) of 1.5 V. External capacitor (C_{ext}) with recommended value of 25 µF is needed to suppress noise coming from supply.

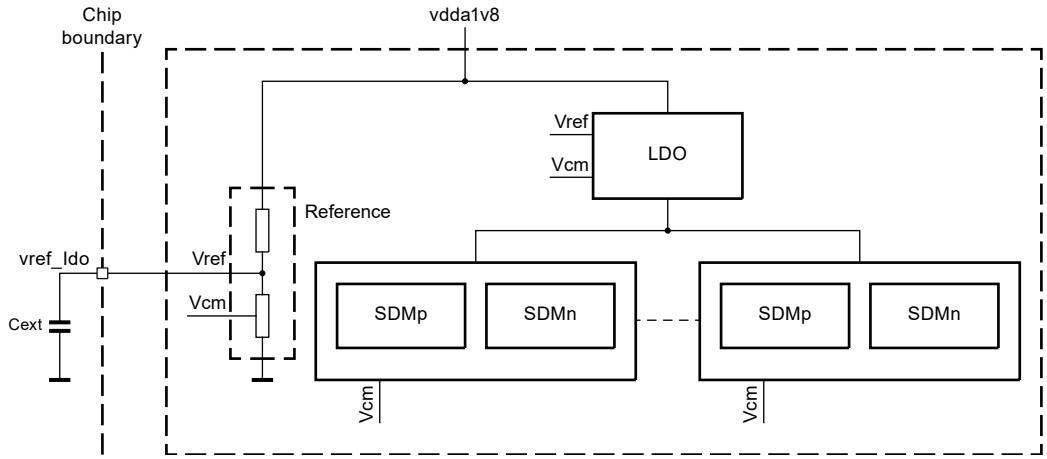

Figure 238. Reference circuit

56.3.6 Modes of operation

SDADC has 4 functional modes.

Table 557. Modes of operation

Operation modes	Configuration	Definition
SE Analog microphone input with AC coupling	Single-ended input mode	Microphone output is connected to ADC input via coupling capacitor C_c[1]. Each active decimator filter will output data.  Figure 239. SE mode with AC coupling
Differential Analog input with AC coupling	Differential input mode	Differential analog inputs are connected to ADC inputs via coupling capacitor C_c. One of the two decimators connected to the ADC modulators generates the output data.

Table continues on the next page...

Table 557. Modes of operation (continued)

Operation modes	Configuration	Definition
		 Figure 240. Diff mode with AC coupling
SE Analog microphone input with DC coupling	Single-ended input mode	Microphone output is connected directly to ADC input. DC loop is activated to regulate input common-mode voltage. Each active decimator will output data.  Figure 241. SE mode with DC coupling
Power-down mode		ADC is powered down.

1. C_c values typically range from 0.4 µF to 1 µF based on the required low cut-off frequency of the audio signal:

   $F_{cut\text{-}off} = 1/(2*\pi*R_{in}*C_c)$

   Typical R_{in} of ADC is 20 kΩ, so signal frequency below $F_{cut\text{-}off}$ will be attenuated by at least 3 dB.

56.3.7 Clocking

Table 558. SDADC clocks

Clock name	Description
Main clock (MCLK)	Used as system clock for SDADC. When this clock is gated, SDADC stops working. Frequency: 24.576 MHz
APB bus clock (APB_CLK)	Used for register interface.

56.3.8 Interrupts

This section describes all the interrupts that the SDADC module generates.

There are 8 WATERMARK register fields for each one of the FIFOs:

- WATERMARK_0_P
- WATERMARK_0_N
- WATERMARK_1_P
- WATERMARK_1_N
- WATERMARK_2_P
- WATERMARK_2_N
- WATERMARK_3_P
- WATERMARK_3_N

Each one of the FIFOs will assert their respective WM_x_y_ST signal if the entries in the respective FIFO are greater than the programmed value and WM_x_y_EN is enabled.

FIFO	Watermark enable	Interrupt enable
FIFO_0_P	FIFO_WATERMARK_ERROR_CTL[WM_0_P_EN]	FIFO_WATERMARK_ERROR_CTL[ERR_0_P_EN]
FIFO_0_N	FIFO_WATERMARK_ERROR_CTL[WM_0_N_EN]	FIFO_WATERMARK_ERROR_CTL[ERR_0_N_EN]
FIFO_1_P	FIFO_WATERMARK_ERROR_CTL[WM_1_P_EN]	FIFO_WATERMARK_ERROR_CTL[ERR_1_P_EN]
FIFO_1_N	FIFO_WATERMARK_ERROR_CTL[WM_1_N_EN]	FIFO_WATERMARK_ERROR_CTL[ERR_1_N_EN]
FIFO_2_P	FIFO_WATERMARK_ERROR_CTL[WM_2_P_EN]	FIFO_WATERMARK_ERROR_CTL[ERR_2_P_EN]
FIFO_2_N	FIFO_WATERMARK_ERROR_CTL[WM_2_N_EN]	FIFO_WATERMARK_ERROR_CTL[ERR_2_N_EN]
FIFO_3_P	FIFO_WATERMARK_ERROR_CTL[WM_3_P_EN]	FIFO_WATERMARK_ERROR_CTL[ERR_3_P_EN]
FIFO_3_N	FIFO_WATERMARK_ERROR_CTL[WM_3_N_EN]	FIFO_WATERMARK_ERROR_CTL[ERR_3_N_EN]

The interrupt register bit will be set (if FIFO_INTERRUPT[FIFO_INTERRUPT_EN] is enabled) as a result of ORing ERR_0_P, ERR_0_N, ERR_1_P, ERR_1_N, ERR_2_P, ERR_2_N, ERR_3_P, and ERR_3_N.

For additional details, see SDADC register descriptions.

56.3.9 Reset

Table 559. SDADC internal generated resets

Reset	Description
ADC_CTL_0[RST_AN_ADCP]	Reset not signal (asynchronous) for ADCp
ADC_CTL_0[RST_AN_ADCN]	Reset not signal (asynchronous) for ADCn
DECIMATOR_CTL_1[FUNC_LOCAL_RST_AN_DEC_P]	Functional local reset not (asynchronous) for Decimator_p
DECIMATOR_CTL_1[FUNC_LOCAL_RST_AN_DEC_N]	Functional local reset not (asynchronous) for Decimator_n

56.3.10 DMA

When the watermark feature is enabled (FIFO_WATERMARK_ERROR_CTL[WM_x_y_EN] = 1b), and the entries in each one of the FIFOs meet the watermark value, SDADC asserts dma_req_fifo_x (x = 0, 1, 2, 3). At that point SDADC stops storing entries

in the FIFOs until the chip or the entity above asserts dma_req_ack_fifo_x. Once dma_req_ack_fifo_x is asserted and received by SDADC, the dms_req_fifo_x is de-asserted and the FIFOs start collecting entries again.

56.4 External signals

SDADC requires supply and ground connections, and supports analog channel inputs.

Table 560. SDADC signals

Signal	Description	I/O
vdda1v8	Analog power supply	Analog IO
VSSA	Analog ground	Analog IO
VDD	Digital power supply	Analog IO
VSS	Digital ground	Analog IO
vin_p[3:0]	ADCp[3:0] input voltage	Analog input
vin_n[3:0]	ADCn[3:0] input voltage	Analog input
vref_ldo	Used to attach filter capacitor (with a recommended size of 25 µF) to filter internally generated reference voltage (Vref) (1.5 V). See Reference generator. **NOTE** Keep this pin away from any noisy signal sources and use audio-quality capacitors.	Analog IO

56.5 Initialization

An initial reset is needed for 15 µs after start-up.

Coming out of reset, the four ADC modules are enabled. Default values are loaded into the respective registers.

56.6 Application information

56.6.1 Enabling ADCp[0] and ADCn[1] in SE mode at startup

Configure the following to enable ADCp[0] and ADCn[1] in single-ended mode at startup.

Action	Programming
Enable ADCp[0] and apply input to vin_p[0].	Write 0001b to ADC_CTL_0[ADCP_POWER_ENABLE].
Enable ADCn[1] and apply input to vin_n[1].	Write 0010b to ADC_CTL_0[ADCN_POWER_ENABLE].
Set all to SE mode.	Write 0000b to ADC_CTL_1[DIFF_ENABLE].
Enable compensation DACs for all ADCp.	Write 1111b to ADC_CTL_0[COMP_ADCP_ENABLE].
Enable compensation DACs for all ADCn.	Write 1111b to ADC_CTL_0[COMP_ADCN_ENABLE].
Assert first reset (0000b) for 15 µs after reference start.	Write 1111b to ADC_CTL_0[RST_AN_ADCP]. Write 1111b to ADC_CTL_0[RST_AN_ADCN].

Table continues on the next page...

Table continued from the previous page...

Action	Programming
Make sure inputs for all ADCp and ADCn are AC-coupled.	Write 0000b to ADC_CTL_1[DCLOOP_P_ANA_ENABLE]. Write 0000b to ADC_CTL_1[DCLOOP_N_ANA_ENABLE]. Write 0000b to DC_LOOP_CTL_0[DCLOOP_P_ENABLE]. Write 0000b to DC_LOOP_CTL_0[DCLOOP_N_ENABLE].
Enable LDO.	Write 1b to LDO_CTL[LDO_POWER_ENABLE].
Set LDO to full performance.	Write 01b to LDO_CTL[LDO_SETTING].
Enable reference block.	Write 1b to REF_CTL[REF_POWER_ENABLE].
Enable reference low-noise mode.	Write 0b to REF_CTL[FAST_REF_ENABLE]. Write 1b to REF_CTL[PWR_FAST_REF_ENABLE].

Field	Function
31-28 WATERMARK_3_N	Watermark for FIFO_3_N Allowed values are 0-15. If the entries in FIFO_3_N are greater than the programmed value in this bit, and WM_3_N_EN is enabled, FIFO_3_N will assert WM_3_N_ST.
27-24 WATERMARK_3_P	Watermark for FIFO_3_P Allowed values are 0-15. If the entries in FIFO_3_P are greater than the programmed value in this bit, and WM_3_P_EN is enabled, FIFO_3_P will assert WM_3_P_ST.
23-20 WATERMARK_2_N	Watermark for FIFO_2_N Allowed values are 0-15. If the entries in FIFO_2_N are greater than the programmed value in this bit, and WM_2_N_EN is enabled, FIFO_2_N will assert WM_2_N_ST.
19-16 WATERMARK_2_P	Watermark for FIFO_2_P Allowed values are 0-15. If the entries in FIFO_2_P are greater than the programmed value in this bit, and WM_2_P_EN is enabled, FIFO_2_P will assert WM_2_P_ST.
15-12 WATERMARK_1_N	Watermark for FIFO_1_N Allowed values are 0-15. If the entries in FIFO_1_N are greater than the programmed value in this bit, and WM_1_N_EN is enabled, FIFO_1_N will assert WM_1_N_ST.
11-8 WATERMARK_1_P	Watermark for FIFO_1_P Allowed values are 0-15. If the entries in FIFO_1_P are greater than the programmed value in this bit, and WM_1_P_EN is enabled, FIFO_1_P will assert WM_1_P_ST.
7-4 WATERMARK_0_N	Watermark for FIFO_0_N Allowed values are 0-15. If the entries in FIFO_0_N are greater than the programmed value in this bit, and WM_0_N_EN is enabled, FIFO_0_N will assert WM_0_N_ST.
3-0 WATERMARK_0_P	Watermark for FIFO_0_P Allowed values are 0-15. If the entries in FIFO_0_P are greater than the programmed value in this bit, and WM_0_P_EN is enabled, FIFO_0_P will assert WM_0_P_ST.

56.7.1.17 FIFO Watermark Error Control (FIFO_WATERMARK_ERROR_CTL)

Offset

Register	Offset
FIFO_WATERMARK_ERROR_CTL	40h

Function
Controls the interrupts and watermarks for FIFO.

57.1.1 Module instances

This device has one instance of the MICFIL module.

Table 564. MICFIL instance

	MICFIL
Located in	VDD1_SENSE
Access	CPU0, CPU1, HiFi4, HiFi1, eDMA0, eDMA1, eDMA2, eDMA3

57.1.2 Reset

This module supports the following resets:

- Cold reset resets the whole MICFIL module.
- RSTCTL3.PRSTCTL1[MICFIL] resets DATACHn registers
- Software resets by MICFIL register fields, see CTRL_1[SRES] and VAD0_CTRL_1[VADRST] for more details.

57.2 Overview

MICFIL delivers audio from microphones to the processor in several applications, such as mobile telephones. As current digital audio systems use a multi-bit audio signal (also known as multi-bit PCM) to represent the signal, this module implements the required digital interface (a series of filters) to transform a pulse density modulated (PDM) microphone bitstream into a 24-bit PCM signal in the audio band, at a configurable output sampling rate.

The implementation of this digital interface is based on the application of digital signal processing techniques used in hardware. The MICFIL architecture is designed to save gate count and minimize power consumption.

You can implement MICFIL to work in a multi-channel mode. All channels have the same configuration, but you could independently turn on or turn off each input channel.

57.2.1 Block diagram

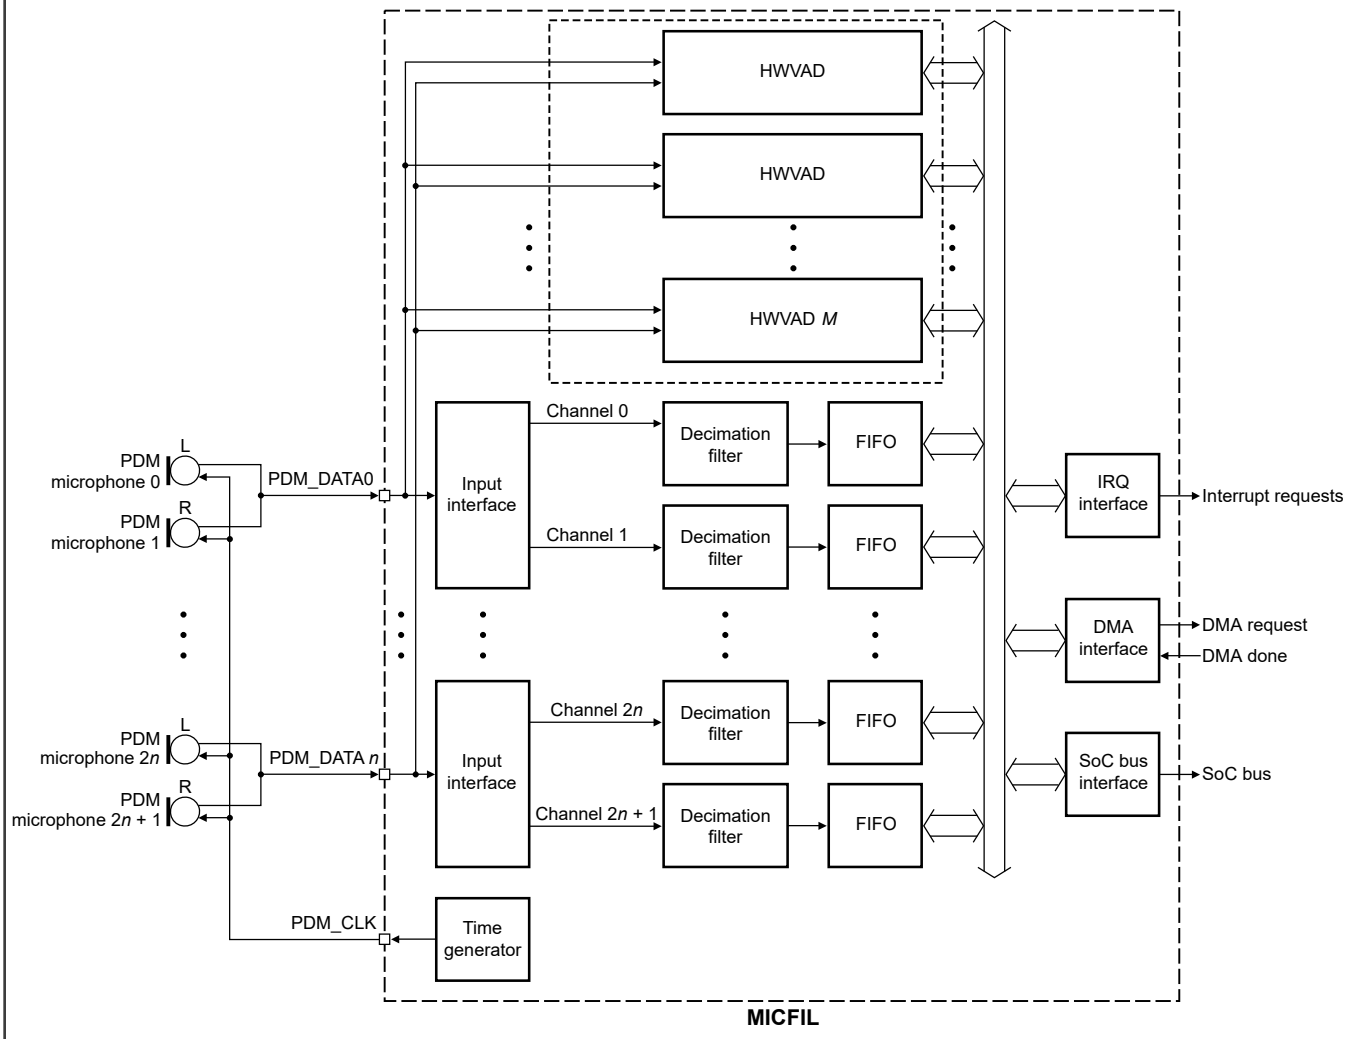

Figure 242. MICFIL block diagram

- HWVAD = hardware voice activity detector

57.2.2 Features

- Decimation filters:
  - Fixed-point filtering
  - 24-bit PCM audio output
  - Internal clock divider for a programmable PDM clock generation: clock divider bypass capability for low-frequency operations
  - Frame synchronization
  - Full or partial set of channel operations with individual enable controls
  - Programmable decimation rate
  - Programmable DC remover at output
  - Range adjustment capability

- FIFOs with interrupt and DMA capability: each FIFO having a length of 8 entries
- Hardware voice activity detector (HWVAD), equipped with:
  - Interrupt capability
  - Zero-crossing detection (ZCD) option

57.3 Functional description

57.3.1 Time generator

The time generator unit:

- Generates the PDM_CLK to microphones. This clock is the same and is active for all the PDM microphones, which means, it is not possible to turn off the PDM_CLK only for one single microphone.
- Delivers the PDM_CLK to all microphones that must operate at the same clock frequency. Each input interface receives a time multiplexed PDM bitstream from two PDM microphones and it separates audio information in two channels: left (0) and right (1). Every decimation filter, corresponding to its channel, does this processing.

There exists an internal clock divider (see CTRL_2[CLKDIV]) within the time generator that is enabled when CTRL_2[CLKDIVDIS] = 0; otherwise, the application clock directly drives the microphones.

NOTE

A soft reset affects the time generator unit (see CTRL_1[SRES]). The PDM_CLK starts with a rising edge after a soft reset is issued.

57.3.1.1 Clock divider

The sampling rate of the microphone input depends on the PDM_CLK rate, which you can trim using an internal clock divider, configuring the quality mode (see Quality modes) or trimming the MICFIL's root clock frequency (MICFIL_CLK_ROOT rate).

In case the clock divider is enabled, CTRL_2[CLKDIV] defines the internal clock divider frequency. You must configure CTRL_2[CLKDIV] by using Equation 7.

$$CLKDIV = \frac{MICFIL_CLK_ROOT\ rate}{8 \times OSR \times (output\ rate)}$$

Equation 7. CLKDIV value calculation

After calculating the value of CTRL_2[CLKDIV], you can estimate the generated PDM_CLK rate based on Equation 8, where the "K" factor value depends on the quality mode shown in Table 565 and floor(x) is the function that takes a real number x as input and gives the greatest integer less than or equal to x as output.

$$PDM_CLK\ rate = \frac{MICFIL_CLK_ROOT}{2 \times floor(K \times CLKDIV)}$$

Equation 8. PDM_CLK rate calculation

Table 565. K factor value

Quality mode	K factor
High Quality	1/2
Medium Quality, Very-Low Quality 0	1
Low Quality, Very-Low Quality 1	2
Very-Low Quality 2	4

57.3.1.2 I/O timing requirements

The PDM microphones must meet the setup and hold timing requirements shown in Table 566 and Figure 243. The "K" factor value in Table 566 depends on the quality mode you select based on Table 565.

NOTE

These timing requirements apply only if the clock divider functionality is enabled (see CTRL_2[CLKDIV]) with (CTRL_2[CLKDIVDIS] = 0); otherwise, there are no special timing requirements.

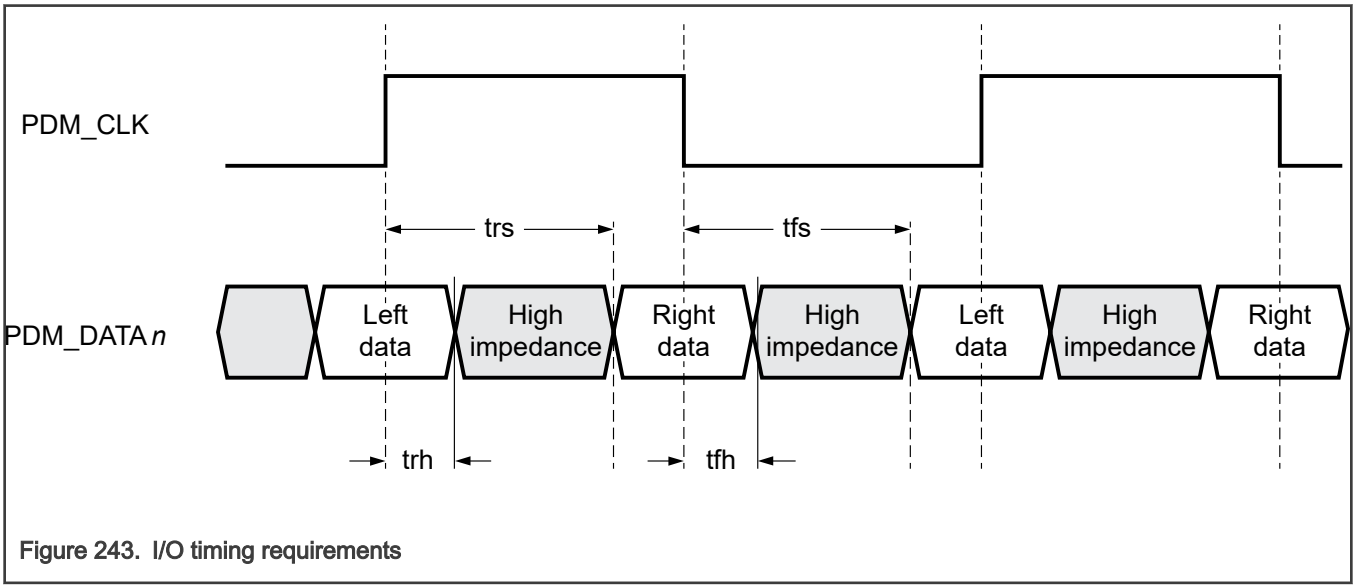

Figure 243. I/O timing requirements

Table 566. Timing parameters

Parameter	Value
trs, tfs	$\leq \frac{floor(K \times CLKDIV) - 1}{MICFIL_CLK_ROOT\ rate}$ Depending on the value of "K," you must ensure that "floor(K x CTRL_2[CLKDIV])" > 1 to avoid timing problems.
trh, tfh	≥ 0

57.3.2 Input interface

Figure 244 shows the timing diagram of the input interface signals when the clock divider is enabled. The bitstream incoming from the microphone data input "n" (PDM_DATA*n*) in the first half (right microphone) of the PDM_CLK is directed to channel "2n+1" and the data generated during the last half (left microphone) is directed to channel "2n".

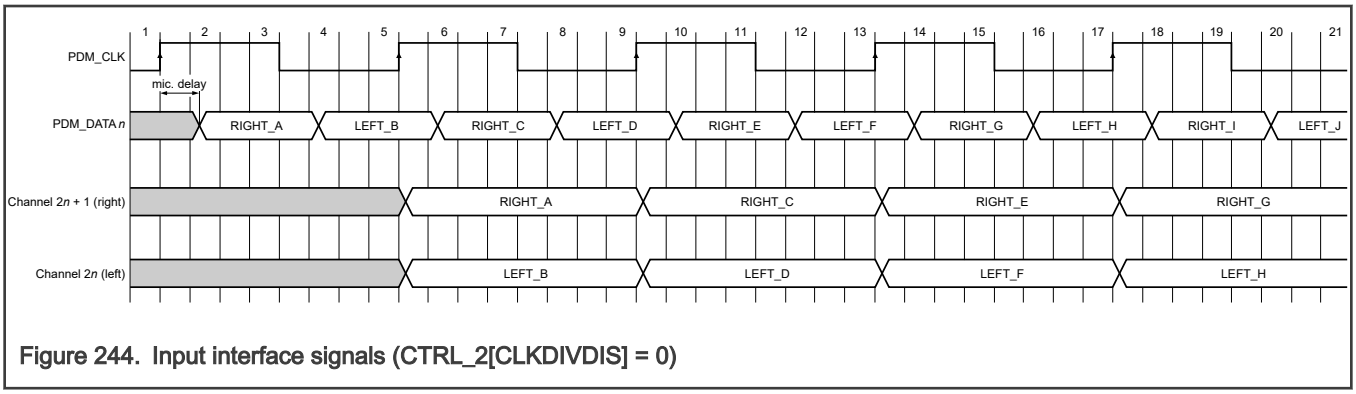

Figure 244. Input interface signals (CTRL_2[CLKDIVDIS] = 0)

57.3.3 Decimation filter

A decimation filter facilitates PDM to PCM conversion.

Figure 245 shows the block diagram of the decimation filter. The block consists of:

- A cascade integrator comb (CIC) filter, which is a low-pass filter that you commonly use to filter sigma-delta modulator output signals. The filter is implemented in the audio band (20 Hz–20.0 kHz @48 kHz output sampling rate by default) with a configurable decimation rate. You can implement it using a series of CIC, compensation, and DC remover filters.
- A DC remover, which is a high-pass filter that you use to remove the DC component of the processed signal with a configurable cut-off frequency. Two DC removers exist: one in the input of the decimation filter, embedded in the CIC filter, and another in the last stage of the decimation filter.
- Two compensation filters for each channel, which implement a low-pass digital filter with decimation by 2. You can use them to compensate the high CIC drop in passband. These filters help the FIR filter block to flatten the overall passband response.

You activate the "Sampler" block depending on the quality mode selected (using CTRL_2[QSEL]). In Low-Quality and Very-Low-Quality 2 modes, the sampling rate is doubled.

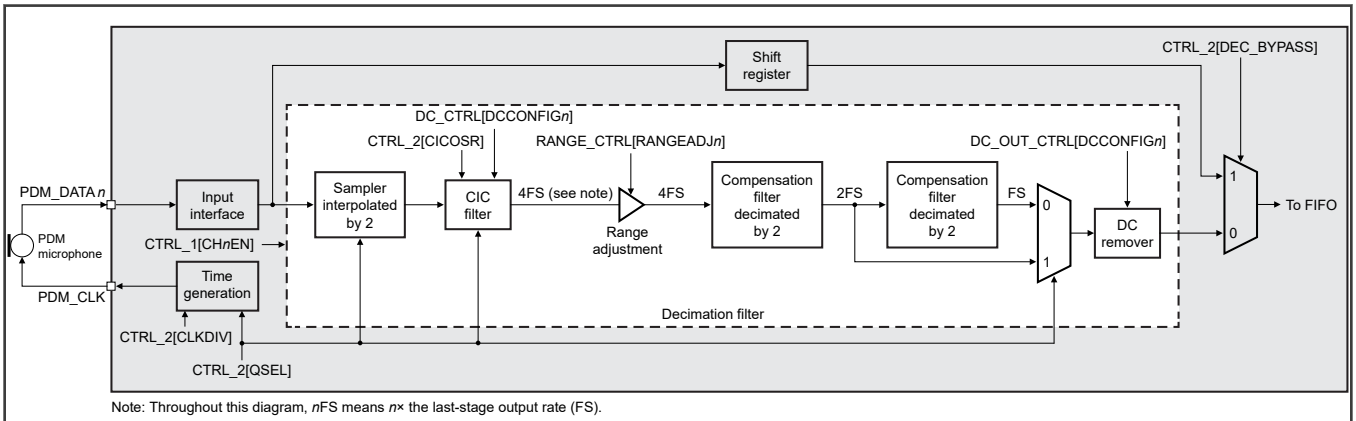
The decimation filter output depends on the quality mode that you select by using CTRL_2[QSEL], based on different compensation filter output. You can supply the DC remover with the 2 FS signal, instead of the 1 FS signal, to achieve lower-power consumption, bypassing the second compensation decimation filter. The second compensation filter is bypassed when CTRL_2[QSEL] = 110b, 101b, or 100b (in Very-Low Quality modes).

You can adjust the range of each decimation filter by using a range adjustment block so that you can raise an error interrupt in case an adjustment overflow or underflow is detected.

The output of a decimation filter is stored into a FIFO buffer, and each FIFO is mapped to MICFIL Output Result (DATACH0 - DATACH7). It is possible to generate either an interrupt or a DMA request when, in each FIFO of all enabled channels, the number of data stored surpasses a configured watermark.

Also, independently on decimation filters, there is a hardware voice activity detector (HWVAD) which implements voice-detection algorithms to generate wake-up interrupts. See Hardware voice activity detector (HWVAD).

In order to process PDM data with higher quality, you can bypass the decimation filter by configuring CTRL_2[DEC_BYPASS], which enables the writing of PDM data into FIFO in the form of 32 bits. Software is used to process PDM data in this situation.



Note: Throughout this diagram, *n*FS means *n*× the last-stage output rate (FS).

Figure 245. Decimation filter block diagram

57.3.3.1 CIC filter

The CIC filter is an optimized implementation of the low-pass SINC filter, with multiple stages. It is widely used because it requires just adders and subtracters. The CIC filter comprises an integrator and a comb as its sub-blocks. As shown in the following figure, CTRL_2[CICOSR] and the quality mode you select (see Quality modes) define the CIC decimation rate.

$$OSR = 32 - CICOSR$$

$$CIC\ decimation\ rate = \begin{cases} 2 \times OSR\ ;\ If\ HQ,\ VLQ0 \\ OSR\ \ \ \ ;\ others \end{cases}$$

Equation 9. CIC decimation rate

57.3.3.2 DC remover

Two DC removers exist in the filter chain, one in the input and another in the output. The former is integrated in the CIC filter, and the latter is placed just before the FIFO. Both can be bypassed independently.

The DC remover eliminates the DC level component of the signal using a high-pass filter with a very low cut-off frequency that you select using DC_CTRL[DCCONFIG*n*]. This filter is bypassed when the value of this field is 11b.

NOTE

See PARAM[DC_OUT_BYPASS] and PARAM[DC_BYPASS] to know whether one of the DC removers is permanently disabled in the chip.

57.3.3.3 Compensation filters

A compensation filter divides the baseband signal into two equal subbands before it could to be decimated by 2. It also compensates the CIC filter drop in passband and helps to flatten the overall passband response. MICFIL includes two compensation filter stages, with the possibility of bypassing the last one.

57.3.3.4 Filter performance

57.3.3.4.1 Overall filter gain

As shown in Equation 10, the overall filter gain depends on:

- The quality mode you select (see Quality modes).
- The CIC decimation rate (see Equation 9).
- Dynamic range adjustment of the CIC filter (see RANGE_CTRL[RANGEADJ*n*]).

NOTE

To get a better audio performance, you must configure and adjust RANGE_CTRL[RANGEADJ*n*] depending on the quality mode selected, as pointed out in the register description.

$$Overall\ filter\ gain\ (dB) = \begin{cases} 100 \times log_{10}(64 - 2 \times CICOSR) + 6.02 \times RANGE_CTRL[RANGEADJn] - 180.60\ ;\ if\ QSEL \in [HQ,VLQ0] \\ 100 \times log_{10}(32 - CICOSR) + 6.02 \times RANGE_CTRL[RANGEADJn] - 180.60\ \ \ \ ;\ others \end{cases}$$

Equation 10. Overall filter gain

Finally, the input and output dBFS levels relate to each other, as shown in Equation 11.

$$Output\ (dBFS) = input\ (dBFS) + overall\ filter\ gain\ (dB)$$

Equation 11. Filter input and output relationship

57.3.3.4.2 Overall passband

The decimation filter passband depends on the quality mode and output rate (FS). For instance, the overall filter passband for different output data rates when MICFIL is in High (HQ), Medium (MQ), and Low-Quality (LQ) modes is shown in Table 567.

Table 567. Filter passband in HQ, MQ, and LQ modes (DC_CTRL[DCCONFIG*n*] = 0)

Output data rate	Overall filter passband
FS	**0.0004FS - 0.4167FS**
16 kHz	6.67 Hz - 6.67 kHz
48 kHz	20 Hz - 20 kHz

The overall filter passband for different output data rates when MICFIL is in Very-Low Quality (VLQ) modes is shown in Table 568.

Table 568. Filter passband in VLQn modes (DC_CTRL[DCCONFIG*n*] = 0)

Output data rate	Overall filter passband
FS	**0.0002FS - 0.2083FS**
16 kHz	3.33 Hz - 3.33 kHz
48 kHz	10.00 Hz - 10.00 kHz
96 kHz	20 Hz - 20 kHz

57.3.3.5 Frame synchronization

If CTRL_1[FSYNCEN] = 1, MICFIL sends data to FIFOs in frame size defined by FSYNC[FSYNCLEN]. In this way, if a channel is enabled while MICFIL is running (CTRL_1[PDMIEN] = 1), MICFIL starts sending data to its respective FIFO after the current frame is sent completely. If the channel is disabled:

- if at least one other channel is still enabled, the corresponding channel stops sending data after the current frame is sent completely.
- if after that no channel is enabled, MICFIL stops sending data immediately, even if the act of sending frames is incomplete.

Below example shows the above behavior when two channels, DATACH0 and DATACH2 are enabled, and then disabled one after the other.

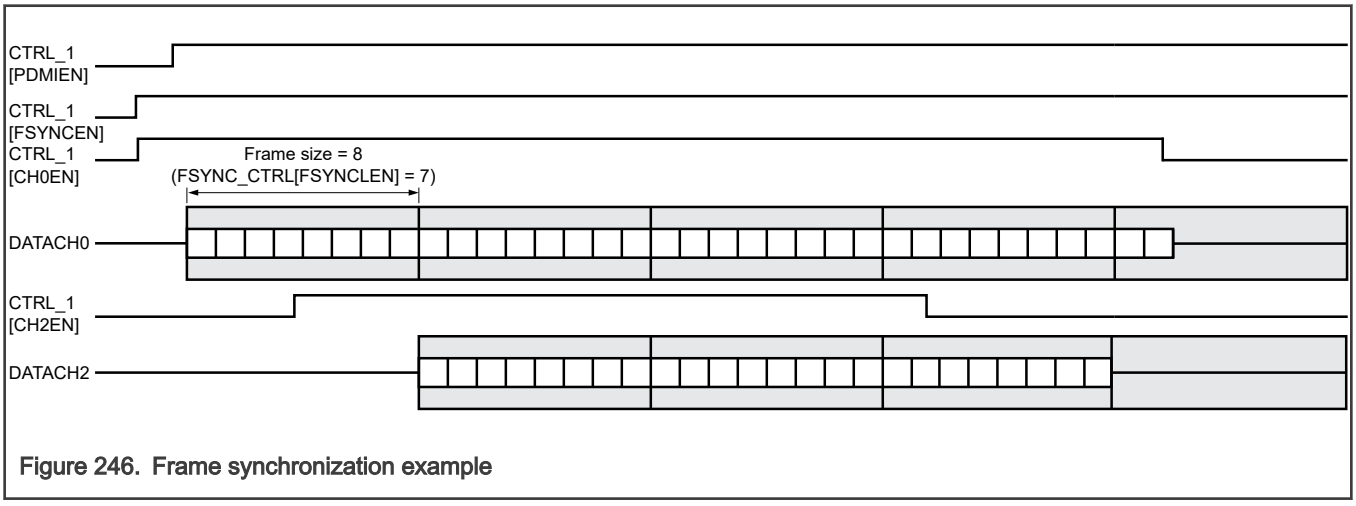


Figure 246. Frame synchronization example

57.3.3.6 Quality modes

If the decimation filter is running independently on the selected power mode, MICFIL can operate in multiple different quality modes that you can select by using CTRL_2[QSEL]. The decimation and interpolation rates in internal blocks are shown in Table 569, where the oversampling rate (OSR) depends on the value of CTRL_2[CICOSR], as shown in the following equation.

$$OSR = 32 - CICOSR$$

Equation 12. OSR

You can configure the selected quality dynamically when the decimation filter is running; the output rate is maintained in every quality selected.

The passband of the decimation filter depends on the quality mode (see Overall passband).

To maintain the same output rate in the decimation filter when the quality is changed, the PDM_CLK rate changes depending on the quality selected. For more on PDM_CLK, see Time generator.

You can enable or disable the sampler and compensation filters according to the selected quality. When they are disabled, you can achieve a low-power consumption. The selected quality also determines whether the CIC filter decimation rate is doubled. For more, see Decimation filter.

With an increase of the clock rate and OSR, you can expect a better signal-to-noise ratio (SNR) performance, which in turn leads to a higher audio quality.

Table 569. Quality modes

Quality mode	CTRL_2[QSEL]	Sampler interpolation	CIC filter decimation	First-compensation filter decimation	Second-compensation filter decimation	PDM_CLK rate	Passband
High Quality	001	—	:(2OSR)	:2	:2	Output rate × 8 × OSR	To ~0.5 × output rate
Medium Quality	000	—	:OSR	:2	:2	Output rate × 4 × OSR	To ~0.5 × output rate
Low Quality	111	× 2	:OSR	:2	:2	Output rate × 2 × OSR	To ~0.5 × output rate
Very-Low Quality 0	110	—	:(2OSR)	:2	—	Output rate × 4 × OSR	To ~0.25 × output rate
Very-Low Quality 1	101	—	:OSR	:2	—	Output rate × 2 × OSR	To ~0.25 × output rate
Very-Low Quality 2	100	× 2	:OSR	:2	—	Output rate × OSR	To ~0.25 × output rate

57.3.3.7 Output rate

The output rate is the sampling rate at the decimation filter output. It depends on the sampling rate of the microphone input and the configured quality mode (see Quality modes). Common audio sampling rates are 48 kHz and 16 kHz. In this chapter, the output rate is sometimes referred to as FS.

57.3.4 Hardware voice activity detector (HWVAD)

HWVAD is a block which detects voice activity in a channel selected by the user as shown in Figure 247 and Figure 248. HWVAD takes data from the input of a selected PDM microphone to detect if there is any voice activity. If HWVAD detects a voice activity, it can issue an interrupt to the system. You can configure HWVAD in Envelope-based or Energy-based mode as described in Initialization.

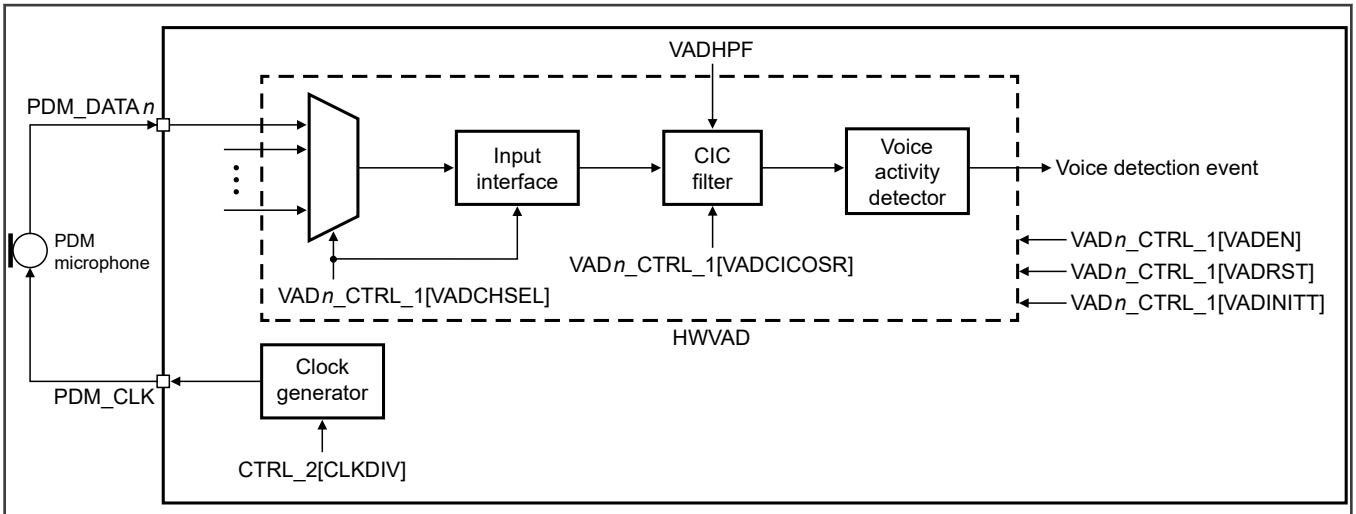

Figure 247. HWVAD block diagram

HWVAD can divide the incoming PCM signal from its internal CIC in frames. The frame energy is used to estimate the background noise. HWVAD examines both frame energy and noise energy. When HWVAD identifies a specific delta between them, it detects a voice activity and then issues an interrupt. Optionally, you can enable a zero-crossing detector (ZCD) to avoid missing of low-energy voiced speech in order to improve the voice detection performance.

You can enable HWVAD by configuring VAD*n*_CTRL_1[VADEN] and reset HWVAD by software through VAD*n*_CTRL_1[VADRST].

NOTE

You can enable or reset HWVAD only when MICFIL isn't running (STAT[BSY_FIL] = 0).

To perform voice detection, HWVAD uses a noise filter and a signal filter as shown in Figure 248. In addition, you can use a minimum block in the output of the noise filter and a maximum block in the output of the signal filter. HWVAD can scale the result of both blocks with gain blocks. Finally, HWVAD compares the estimated signal and noise, and it detects voice when signal is greater than noise .

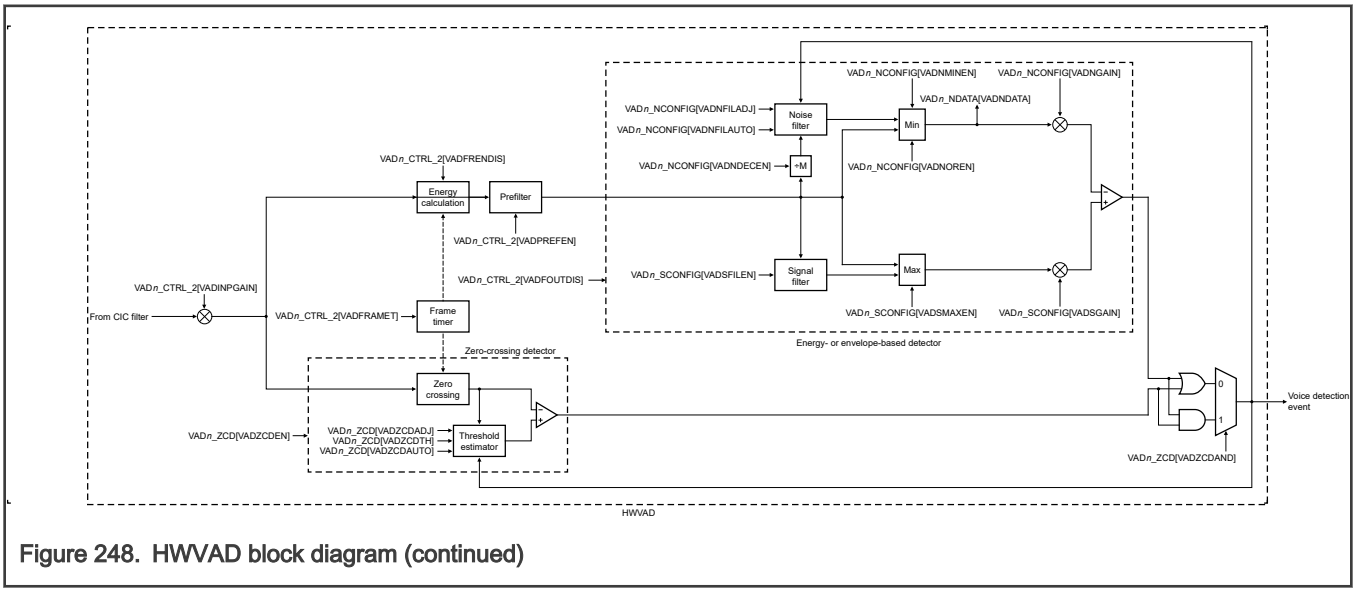

Figure 248. HWVAD block diagram (continued)

57.3.4.1 Input setting

HWVAD input has internally a user-configurable high-pass filter (see VAD*n*_CTRL_2[VADHPF] field description) and a user-configurable gain (see VAD*n*_CTRL_2[VADINPGAIN]). You can use both controls to configure the module based on external noise conditions.

57.3.4.2 Frame time setting

To perform voice detection the signal frames incoming from the CIC filter can be divided in frames whose duration can be configured. The frame time depends on the CIC output rate, the value of VAD*n*_CTRL_2[VADFRAMET] and a constant as defined in Equation 13.

$$frame\ time = \frac{VADFRAMET \times 192}{CIC\ output\ rate}$$

Equation 13. Frame time

For instance, in the typical case of the CIC filter the output rate is 192 kHz, the frame time is 10 ms when [VADFRAMET] is 10.

57.3.4.3 Initialization time

You can configure an initialization by configuring VAD*n*_CTRL_1[VADINITT]. During this initialization time, HWVAD doesn't issue any voice detection event and all detectors are disabled.

$$initialization\ time = (VADINITT + 1) \times frame\ time$$

Equation 14. Initialization time

For instance, in case that frame time is 10 ms and [VADINITT] = 10, the initialization time is 110 ms.

57.3.4.4 Energy calculation

In case VAD*n*_CTRL_2[VADFRENDIS] = 0, HWVAD uses the sum of the absolute values of all the samples of each frame to detect voice. Otherwise, if [VADFRENDIS] = 1, it uses the absolute value of the samples to detect voice, which means that the data incoming from CIC is not divided in frames.

57.3.4.5 Pre-filter

The pre-filter block is a low-pass filter which can be enabled when VAD*n*_CTRL_2[VADPREFEN] = 1.

57.3.4.6 Energy and envelope-based detector

To perform voice detection, HWVAD uses a noise filter and a signal filter as shown in Figure 248. In addition, it can use a minimum block in the output of the noise filter and a maximum block in the output of the signal filter. HWVAD can scale the result of both blocks with gain blocks. Finally, HWVAD compares the estimated signal and noise, and it detects voice when the signal is greater than the noise.

57.3.4.6.1 Noise filter

The noise filter is a low-pass filter . You can configure VAD*n*_NCONFIG[VADNFILADJ] to adjust the filter . In case VAD*n*_NCONFIG[VADNFILAUTO] = 1 the noise filter is enabled only when voice is not detected. When voice is detected the filter output does not change. In case [VADNFILAUTO] = 0 the filter is always enabled.

A decimation stage in the input of the noise filter can be enabled by VAD*n*_NCONFIG[VADNDECEN] field.

57.3.4.6.2 Minimum noise

To estimate the noise, HWVAD uses a block which calculates the minimum value between the input and output of the noise filter. This block can be enabled by VAD*n*_NCONFIG[VADNMINEN], otherwise the output of the noise filter passes directly.

The estimated noise of the output of this block is stored in VAD*n*_NDATA[VADNDATA] for post-processing via software.

57.3.4.6.3 Signal filter

The signal filter is a low-pass filter . This filter is enabled when VAD*n*_SCONFIG[VADSFILEN] = 1, otherwise the filter is bypassed.

57.3.4.6.4 Maximum signal

To estimate the signal, HWVAD uses a block which calculates the maximum value between the input and output of the signal filter. This block can be enabled by VAD*n*_SCONFIG[VADSMAXEN].

57.3.4.6.5 Filter result gain setting

There are two gain adjustment controls, one for the estimated noise (VAD*n*_NCONFIG[VADNGAIN]) and another for estimated signal (VAD*n*_SCONFIG[VADSGAIN]). Both gain adjustments outputs are compared, the comparison result determines whether or not there is voice in the channel.

57.3.4.7 Zero-crossing detector (ZCD)

Optionally, the use of a ZCD circuit can increase the HWVAD performance. It is enabled by VAD*n*_ZCD[VADZCDEN].

The threshold of the ZCD could be static or calculated dynamically depending on VAD*n*_ZCD[VADZCDAUTO]. When it is dynamically determined ([VADZCDAUTO] = 1) the threshold is calculated automatically taking VAD*n*_ZCD[VADZCDTH] as the initial value, otherwise ([VADZCDAUTO] = 0) the threshold is static in [VADZCDTH] user-configurable value.

You can use AND or OR to combine the ZCD result with the energy-based or envelope-based detection, it is selected by VAD*n*_ZCD[VADZCDAND]. The filter coefficient is equal to ([VADZCDADJ] + 1) × 2^{-4}.

57.3.4.8 Interrupt

HWVAD issues an interrupt when voice activity is detected and VAD*n*_CTRL_1[VADIE] is enabled. The voice activity event also sets the VADIF flag in VAD*n*_STAT[VADIF], this flag is cleared when you write 1 to it.

57.3.4.9 Extended operation

You can use VAD*n*_STAT[VADIF] for an HWVAD-extended operation, that is, using VAD*n*_NDATA[VADNDATA] value to determine a more accurate voice detection event by software. Below is the procedure to follow:

1. HWVAD issues an interrupt, [VADIF] is set.
2. Leave [VADIF] asserted while software is processing [VADNDATA] content.
3. When software finishes to process [VADNDATA] and detects voice activity:
   - If Envelope-based detection is used, pulse VAD*n*_CTRL_1[VADST10] by more than 2 cycles and clear the VADIF flag.
   - If Energy-based detection is used, clear the VADIF flag.

57.3.4.10 VAD soft-reset

You can request the VAD soft-reset by writing 1 to VAD*n*_CTRL_1[VADRST]. It resets the following blocks and registers:

- VAD*n*_STAT[VADIF] and VAD*n*_STAT[VADINSATF].
- All internal VAD buffers.

57.3.5 Bus interface

The bus interface manages DMA transactions, interrupt requests, and user register interface with the chip.

MICFIL can deliver an interrupt request or DMA request. Then, the chip or DMA, respectively, could access the filter results stored in FIFOs via the internal bus interface.

For detailed information on DMA transactions and interrupt requests, see DMA and Interrupts.

57.3.5.1 FIFO

This is the first-in, first-out (FIFO) buffer that saves the overall filtering results. The length of each FIFO is 8 entries, and there exists one FIFO for each channel. A push writes data into the FIFO, and a read pops data from FIFO. The push and pop operations from FIFO are in different clock domains. The push operation uses the MICFIL clock while the pop operation uses the CPU clock. The FIFO has a configurable watermark (see FIFO_CTRL[FIFOWMK]). When the amount of data in all FIFOs of the enabled channels is greater than the watermark value (FIFO_CTRL[FIFOWMK]), a DMA or IRQ is requested, depending on the value of CTRL_1[DISEL]. After CTRL_1[PDMIEN] enables the filters, the initial FIR results are discarded and not written into the FIFOs. Approximately 68 initial FIR results are not stored in FIFOs. After the filter generates valid data, the results are pushed into the FIFO.

A new filtered result is discarded (not stored) when the FIFO is full and CTRL_1[FIFOOVF*n*] becomes 1. Similarly, when trying a pop operation, if the FIFO is empty, no valid data is read and CTRL_1[FIFOUND*n*] becomes 1. In both cases, when overflow or underflow occurs, they are flagged in MICFIL FIFO Status (FIFO_STAT) to the respective channel, and an error interrupt is generated if CTRL_1[ERREN] is 1.

When you reset the FIFO by writing 1 to CTRL_1[SRES], zero values fill all FIFO positions, as well as push and pop pointers are set to their initial positions.

57.3.6 Modes of operation

This section describes the MICFIL operation modes that depend on:

- Whether MICFIL receives a Stop request.
- The chip's Debug mode.
- The configuration of CTRL_1[MDIS], CTRL_1[DBGE], CTRL_1[DBG],and CTRL_1[DOZEN], as summarized in the following table.

Table 570. Mode selection

Mode	Normal	Debug		Low-Power		Disable/Low-Leakage (DLL)		
CTRL_1[MDIS]	0	0		0		0		1
Stop request	0	0		1		1		Any
CTRL_1[DOZEN]	Any	Any		0		1		Any
CTRL_1[DECFILS]	Any	Any		1	0	Any		
Debug request or CTRL_1[DBG]	0	1		Any		Any		
CTRL_1[DBGE]	Any	1	0	Any		Any		
CPU clock	Enabled	Enabled		Gated (Externally)		Gated (Externally)	Enabled	Gated (Internally)
MICFIL internal clock	Enabled	Enabled		Enabled		Gated		
Decimation filter state	Run[1]	Run[1]	Stop	Run[1]	Stop	Stop		
HWVAD*n* state	Run[2]	Run[2]	Stop	Run[2]		Stop		

1. Depends on the configuration of CTRL_1[PDMIEN] and CTRL_1[CH*n*EN].
2. Depends on the configuration of CTRL_1[PDMIEN] and CTRL_1[VADEN].

57.3.6.1 Normal mode

This is the default operational mode for MICFIL. In this mode, you can enable the channel functionality to perform the filtering operation.

57.3.6.2 Debug mode

You could use this mode to check the status of the module, when requested. In this mode, you can stop MICFIL after the remaining data processing is complete, depending on the value of CTRL_1[DBGE]. You can activate this mode by writing 1 to CTRL_1[DBG].

If CTRL_1[DBGE] = 0, and CTRL_1[DBG] = 1 when MICFIL is running, MICFIL stops after processing the remaining data. Otherwise, if [DBGE] = 1, MICFIL continues to run.

MICFIL cannot enter Debug mode after entering DLL or Low-Power mode.

The Debug mode affects all channels in MICFIL. Access to output buffers, as well as their related flags, remains operational.

57.3.6.3 Low-Power mode

MICFIL enters Low-Power mode when MICFIL receives a Stop request and CTRL_1[DOZEN] = 0. In Low-Power mode, MICFIL is able to filter the PDM microphone data and perform voice detection such as in Normal mode, and can generate a wake-up event through asynchronous DM or IRQ requests, depending on the values of CTRL_1[CH*n*EN], VAD*n*_CTRL_1[VADEN], and CTRL_1[PDMIEN].

After MICFIL enters Low-Power mode:

- If CTRL_1[DECFILS] = 1, Stop request is acknowledged immediately and the decimation filter keeps running.
- If CTRL_1[DECFILS] = 0, the decimation filter processes the last input sample. After that, Stop request is acknowledged and the filter is stopped from running.

During this mode, VAD*n*_CTRL_1[VADEN] continues running if it was previously enabled ([VADEN] = 1) during Normal mode.

You can generate DMA and IRQ requests asynchronously to wake up the CPU.

NOTE

The asynchronous DMA or interrupt requests are generated only in this mode.

57.3.6.4 Disable/Low-Leakage (DLL) mode

In this mode, MICFIL stops after the remaining data processing is complete. MICFIL is in DLL mode when:

- MICFIL receives a Stop request and CTRL_1[DOZEN] = 1.
- CTRL_1[MDIS] = 1.

If you request DLL mode when MICFIL is running, MICFIL stops after completion to process the remaining data.

You can write only to CTRL_1 and CTRL_2, with the exception of writes to CTRL_1[DBG] and CTRL_1[SRES], which are ignored. However, you can still read these fields.

57.3.7 Clocking

Table 571. MICFIL clocks

Clock name	Description
CPU clock (MICFIL_CLK, MICFIL_CLK_S)	Clock that controls the registers
MICFIL internal clock (MICFIL_CLK_APP)	Application clock that operates the filter

Besides the above clock signals, MICFIL generates PDM_CLK for PDM microphones based on MICFIL internal clock frequency and the value in CTRL_2[CLKDIV].

57.3.8 Interrupts

If CTRL_1[DISEL] = 10b, an interrupt request indicates that filtering results are stored in the FIFOs to be read by the CPU. In this case, you can read the data in DATACH*n*[DATA], and STAT[CH*n*F] becomes 1 for the enabled channels when the CHn FIFO surpasses the watermark level.

When MICFIL is in Low-Power mode, the CPU clock is disabled, but the MICFIL clock remains enabled. In this case, an asynchronous interrupt is delivered to the system. This wakes up the CPU clock, which returns to Normal mode. The system could read the FIFO data, after which it must clear STAT[CH*n*F] to get a new interrupt request.

An error interrupt request can also be generated when an exceptional condition happens, such as an overflow or underflow in a channel output, or an overflow or underflow of a FIFO buffer.

CTRL_1[ERREN] enables error interruption and the respective status flag signalizes the type of error:

- OUTOVFn and OUTUNFn for channel outputs errors
- FIFO_STAT[FIFOOVF*n*] and FIFO_STAT[FIFOUND*n*] for FIFO errors

57.3.9 DMA

If CTRL_1[DISEL] = 1, the FIFO stored samples are read through DMA transactions. Then if there is at least one enabled channel and all FIFOs of all enabled channels reach their watermark levels, the output interface makes a request for a DMA transaction.

If CTRL_1[PDMIEN] = 1 and the filters start to operate, you must wait until the filter results stabilize and no filter results are stored in the FIFOs. Therefore, the first DMA request takes longer to occur than the ones that follow.

STAT[CH*n*F] becomes 0 after a DMA transaction is complete.

If MICFIL is in Low-Power mode and the watermark level is surpassed, an asynchronous DMA request is delivered to the system. Then, the system wakes up the CPU clock, returning to Normal mode to read the FIFO data.

57.4 External signals

Table 572. PDM microphone interface external signals

Signal	Description	Direction
PDM_DATA*n*	Data bitstream received from the nth PDM microphone pair throughout the input interface (see Input interface)	I
PDM_CLK	Clock that is delivered to the PDM microphones from the clock generator (see Time generator)	O

NOTE

MICFIL does not provide metastability protection or filtering for input data. You must generate the data using the provided PDM_CLK.

57.5 Initialization

57.5.1 Procedure without HWVAD

Perform this procedure for MICFIL initialization without enabling HWVAD, (that is, by using only decimation filters):

1. Program CTRL_2[CLKDIV], CTRL_1[CH*n*EN], FIFO_CTRL[FIFOWMK], CTRL_1[DISEL], CTRL_1[ERREN], and so on, as required.
2. Start the module operation by writing 1 to CTRL_1[PDMIEN].

The module is ready to receive data from the input ports of the enabled channels.

57.5.2 Initialization procedure with HWVAD

In this section describes the initialization procedures to initialize MICFIL with HWVAD.

HWVAD can work in two modes: Energy-based mode or Envelope-based mode. Optionally, a ZCD can be enabled to improve the voice detection.

The Energy-based method separates the audio signal in frames and estimates the energy of these frames to detect voice activity. On the other hand, the Envelope-based method calculates the audio signal envelope to detect voice.

Both methods have the same detection performance, but the Energy-based is recommended for low-power applications where the chip can be asleep for long periods. Envelope-based detection is recommended for applications where the chip requires faster wake-up and it is not asleep for long periods.

ZCD is recommended to improve detection with fricatives phonemes for example /f/ or /s/) in noisy environments.

57.5.2.1 HWVAD in Energy-based mode

The sequence of steps to initialize MICFIL with HWVAD in Energy-based mode is as follows:

1. Program the control bits as desired for your application (CTRL_2[CLKDIV], CTRL_1[CH*n*EN], FIFO_CTRL[FIFOWMK], CTRL_1[DISEL], CTRL_1[ERREN] etc.).
2. Configure general HWVAD parameters:
    a. CIC oversampling rate (VAD*n*_CTRL_1[VADCICOSR]).
    b. Configure the voice source channel (VAD*n*_CTRL_1[VADCHSEL]).
    c. Configure the internal initialization timer (VAD*n*_CTRL_1[VADINITT]) if required. More details in Initialization time.
    d. Write 1 to VAD*n*_CTRL_1[VADEN].
3. Configure input, noise and signal gains according to the environmental noise conditions:
    a. Configure the input gain (VAD*n*_CTRL_2[VADINPGAIN]).
    b. Configure the signal gain (VAD*n*_SCONFIG[VADSGAIN]).
    c. Configure the noise gain (VAD*n*_NCONFIG[VADNGAIN]).
4. Enable the high-pass filter if required (VAD*n*_CTRL_2[VADHPF]).
5. Configure VAD*n*_NCONFIG[VADNFILADJ] according to environmental noise conditions ([VADNFILADJ] = 16 is recommended).
6. Put HWVAD in Energy-based mode (default values):
    a. Keep VAD*n*_CTRL_2[VADFRENDIS] = 0.
    b. Keep VAD*n*_CTRL_2[VADPREFEN] = 0.
    c. Keep VAD*n*_SCONFIG[VADSFILEN] = 0.
    d. Keep VAD*n*_SCONFIG[VADSMAXEN] = 0.
    e. Keep VAD*n*_NCONFIG[VADNFILAUTO] = 1.
    f. Keep VAD*n*_NCONFIG[VADNMINEN] = 0.
    g. Keep VAD*n*_NCONFIG[VADNDECEN] = 0.
    h. Keep VAD*n*_NCONFIG[VADNOREN] = 0.
7. Initialize ZCD (ZCD initialization) if required.
8. Enable interrupts if required (VAD*n*_CTRL_1[VADIE] and [VADERIE]).
9. Start the overall module asserting CTRL_1[PDMIEN].
10. The module is ready to receive data from the input ports of the enabled channels and to trigger interrupts when it detects voice.

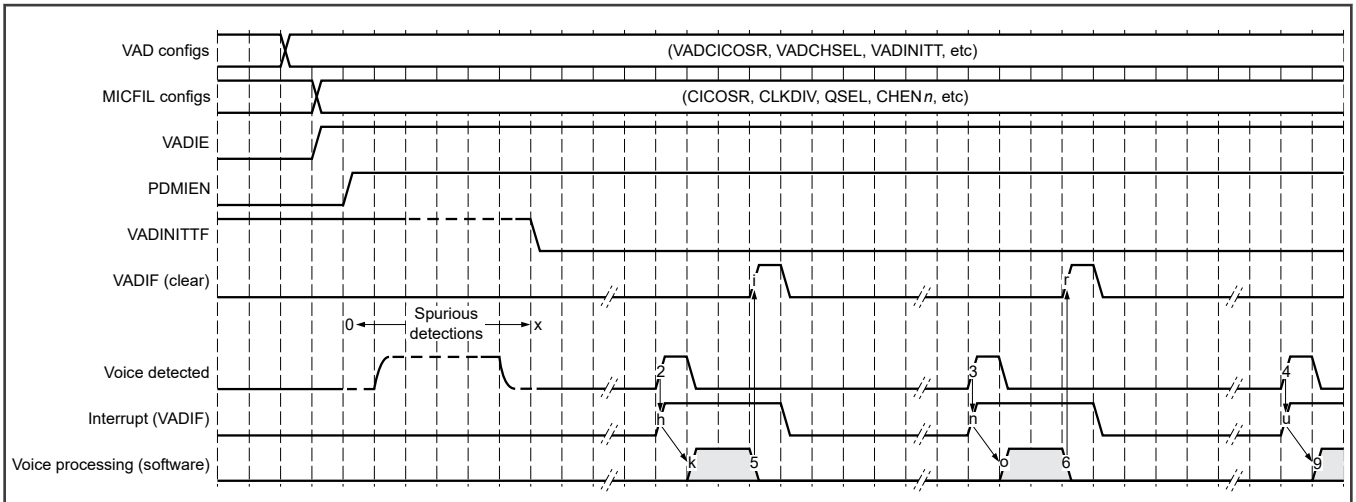

Figure 249. Energy-based initialization sequence

57.5.2.2 HWVAD in Envelope-based mode

The sequence of steps to initialize MICFIL with HWVAD in Envelope-based mode is as follows:

1. Program the control bits as desired for your application (CTRL_2[CLKDIV], CTRL_1[CH*n*EN], FIFO_CTRL[FIFOWMK], CTRL_1[DISEL], CTRL_1[ERREN] etc.).
2. Configure general HWVAD parameters:
   a. CIC oversampling rate (VAD*n*_CTRL_1[VADCICOSR]).
   b. Configure the voice source channel (VAD*n*_CTRL_1[VADCHSEL]).
   c. Configure the internal initialization timer (VAD*n*_CTRL_1[VADINITT]) if required. More details in Initialization time.
   d. Write 1 to VAD*n*_CTRL_1[VADEN] field.
3. Configure input, noise and signal gains according to the environment noise conditions:
   a. Configure the input gain (VAD*n*_CTRL_2[VADINPGAIN]).
   b. Configure the signal gain (VAD*n*_SCONFIG[VADSGAIN]).
   c. Configure the noise gain (VAD*n*_NCONFIG[VADNGAIN]).
4. Enable the high-pass filter if required (VAD*n*_CTRL_2[VADHPF]).
5. Put HWVAD in Envelope-based mode:
   a. Keep VAD*n*_NCONFIG[VADNFILADJ] = 0.
   b. Write 1 to VAD*n*_CTRL_2[VADFRENDIS].
   c. Write 1 to VAD*n*_CTRL_2[VADPREFEN].
   d. Write 1 to VAD*n*_SCONFIG[VADSFILEN].
   e. Write 1 to VAD*n*_SCONFIG[VADSMAXEN].
   f. Write 0 to VAD*n*_NCONFIG[VADNFILAUTO].
   g. Write 1 to VAD*n*_NCONFIG[VADNMINEN].
   h. Write 1 to VAD*n*_NCONFIG[VADNDECEN].
   i. Write 1 to VAD*n*_NCONFIG[VADNOREN].
6. Initialize ZCD (ZCD initialization) if required.

7. Start the overall module asserting the CTRL_1[PDMIEN] bit.
8. Wait until VAD*n*_STAT[VADINITF] becomes 0.
9. Write VAD*n*_CTRL_1[VADST10] three times.
10. Enable interrupts if required (VAD*n*_CTRL_1[VADIE] and [VADERIE]).
11. The module is ready to receive data from the input ports of the enabled channels and to trigger interrupts when it detects voice.

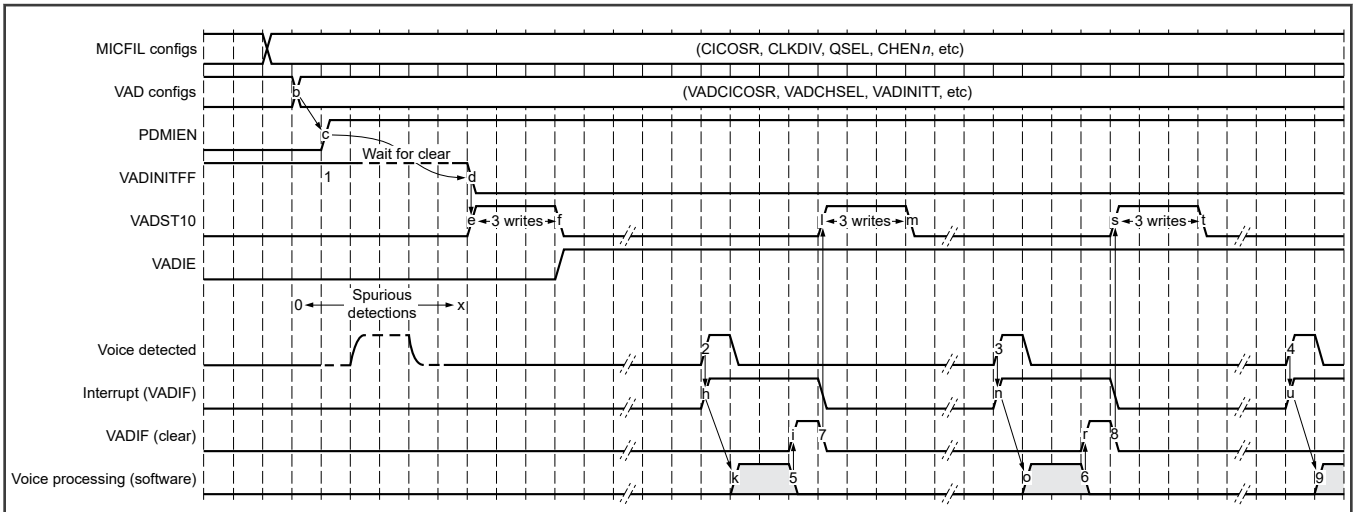

Figure 250. Envelope-based initialization sequence

57.5.2.3 ZCD initialization

The sequence of steps to initialize ZCD in Automatic mode is as follows:

1. Configure VAD*n*_ZCD[VADZCDADJ].
2. Configure an initial threshold in VAD*n*_ZCD[VADZCDTH] according to the environmental noise conditions if required.
3. Configure VAD*n*_ZCD[VADZCDAND].
4. Keep VAD*n*_ZCD[VADZCDAUTO] = 1.
5. Write 1 to VAD*n*_ZCD[VADZCDEN].

The sequence of steps to initialize ZCD in Manual mode is as follows:

1. Configure a threshold in VAD*n*_ZCD[VADZCDTH] according to the environmental noise conditions if required.
2. Configure VAD*n*_ZCD[VADZCDAND].
3. Write 0 to VAD*n*_ZCD[VADZCDAUTO].
4. Write 1 to VAD*n*_ZCD[VADZCDEN].

57.6 Application information

57.6.1 Reconfiguration procedure

Perform this procedure to reconfigure MICFIL:

1. Write 0 to CTRL_1[PDMIEN].
2. Wait until STAT[BSY_FIL] becomes 0.
3. Run a soft-reset cycle.

4. Run an initialization procedure as described in Procedure without HWVAD or Initialization procedure with HWVAD.

57.7 MICFIL register descriptions

This section provides the memory map and detailed description of all MICFIL registers. Any access to reserved areas can issue a target bus error indication.

You must implement the registers allocated in this memory map for up to 4 pairs of microphones, indicating that 8 channels are available.

57.7.1 MICFIL memory map

MICFIL base address: 4020_E000h

Offset	Register	Width (In bits)	Access	Reset value
0h	MICFIL Control 1 (CTRL_1)	32	RW	8000_0000h
4h	MICFIL Control 2 (CTRL_2)	32	RW	0008_0000h
8h	MICFIL Status (STAT)	32	RW	0000_0000h
10h	MICFIL FIFO Control (FIFO_CTRL)	32	RW	0000_0007h
14h	MICFIL FIFO Status (FIFO_STAT)	32	RW	0000_0000h
24h - 40h	MICFIL Output Result (DATACH0 - DATACH7)	32	R	0000_0000h
64h	MICFIL DC Remover Control (DC_CTRL)	32	R	0000_FFFFh
68h	MICFIL Output DC Remover Control (DC_OUT_CTRL)	32	RW	0000_0000h
74h	MICFIL Range Control (RANGE_CTRL)	32	RW	0000_0000h
7Ch	MICFIL Range Status (RANGE_STAT)	32	RW	0000_0000h
80h	Frame Synchronization Control (FSYNC_CTRL)	32	RW	0000_0000h
84h	Version ID (VERID)	32	R	0216_0000h
88h	Parameter (PARAM)	32	R	010B_0734h
90h	Voice Activity Detector 0 Control (VAD0_CTRL_1)	32	RW	0000_0000h
94h	Voice Activity Detector 0 Control (VAD0_CTRL_2)	32	RW	000A_0000h
98h	Voice Activity Detector 0 Status (VAD0_STAT)	32	RW	8000_0000h
9Ch	Voice Activity Detector 0 Signal Configuration (VAD0_SCONFIG)	32	RW	0000_0000h
A0h	Voice Activity Detector 0 Noise Configuration (VAD0_NCONFIG)	32	RW	8000_0000h
A4h	Voice Activity Detector 0 Noise Data (VAD0_NDATA)	32	R	0000_0000h
A8h	Voice Activity Detector 0 Zero-Crossing Detector (VAD0_ZCD)	32	RW	0000_0004h

57.7.2 MICFIL Control 1 (CTRL_1)

Offset

Register	Offset
CTRL_1	0h

Function
Contains control fields for MICFIL.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								CH7EN	CH6EN	CH5EN	CH4EN	CH3EN	CH2EN	CH1EN	CH0EN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 MDIS	Module Disable Places MICFIL in DLL mode (see Disable/Low-Leakage (DLL) mode). The generated PDM_CLK stops, and consequently, the microphone generates no data. **NOTE** When this field = 1, only writes to MICFIL Control 1 (CTRL_1) and MICFIL Control 2 (CTRL_2) are allowed with the exception of writes to CTRL_1[DBG] and CTRL_1[SRES]. A target bus error indication is issued if you write to any other register. 0b - Normal mode 1b - DLL mode
30 DOZEN	Stop Enable When MICFIL receives a Stop request and this field is active, MICFIL enters DLL mode (see Disable/Low-Leakage (DLL) mode). 0b - Disables 1b - Enables
29	MICFIL Enable

Table continues on the next page...

Table continued from the previous page...

Field	Function
PDMIEN	Starts the module operation. Only the channels that CTRL_1[CH*n*EN] enables or VAD enabled by VADEN start operating. When this field becomes 0, MICFIL stops after it completes the remaining filter processing. **NOTE** You must enable this field as the last step when initializing the module (see Initialization). 0b - Stops MICFIL operation 1b - Starts MICFIL operation
28 DBG	Debug Mode Specifies the mode (Debug or Normal) that MICFIL operates in. MICFIL operates in Debug mode, depending on the value of CTRL_1[DBGE]. When Debug mode is disabled, MICFIL operates in Normal mode. See Debug mode for more on Debug mode. **NOTE** You can write to this field only when CTRL_1[MDIS] = 0. 0b - Normal 1b - Debug
27 SRES	Software Reset Provides the CPU with the capability to initialize MICFIL through the target-bus interface. The field always reads 0, and is effective only when CTRL_1[MDIS] = 0. It is a self-clearing field. **NOTE** You must write 1 to this field only when STAT[BSY_FIL] = 0. You can use this field to clear data in all filters. It resets the following blocks and registers: • All internal buffers in decimation filters and voice activity detectors • All FIFOs • STAT[CH*n*F] and MICFIL FIFO Status (FIFO_STAT) • Time generator 0b - No action 1b - Software reset
26 DBGE	Module Enable in Debug Enables operation in Debug mode (see Debug mode). 0b - Disables after completing the current frame 1b - Enables operation
25-24 DISEL	DMA Interrupt Selection

Table continues on the next page...

Table continued from the previous page...

Field	Function
	Specifies the type of interrupt requests (DMA or filter) that MICFIL performs when the number of FIFO elements surpasses the configured watermark. Note that requests are only generated from the channels for which CTRL_1[CH*n*EN] = 1. **NOTE** You must not change the value of this field when STAT[BSY_FIL] = 1. 00b - Disables DMA and interrupt requests 01b - Enables DMA requests 10b - Enables interrupt requests 11b - Reserved
23 ERREN	Error Interruption Enable Enables error interrupts (exceptions). The following conditions can lead to errors: • An overflow or underflow in the FIFOs (indicated by FIFO_STAT[FIFOOVF*n*] or FIFO_STAT[FIFOUND*n*], respectively) • An overflow or underflow in the decimations filters (indicated by RANGE_STAT[RANGEOVF*n*] or RANGE_STAT[RANGEUNF*n*], respectively) **NOTE** You must not change the value of this field when STAT[BSY_FIL] = 1. 0b - Disables 1b - Enables
22-21 —	Reserved
20 DECFILS	Decimation Filter Enable in Stop Enables decimation filters to run when MICFIL receives a Stop request (see Low-Power mode for more information). 0b - Stops decimation filter 1b - Keeps decimation filter running
19-17 —	Reserved
16 FSYNCEN	Frame Synchronization Enable Enables frame synchronization (see Frame synchronization). **NOTE** You must not change the value of this field when STAT[BSY_FIL] = 1.

Table continues on the next page...

Table continued from the previous page...

Field	Function
	0b - Disables 1b - Enables
15-8 —	Reserved
7-0 CHnEN	Channel n Enable Enables the decimation filter channel n (see Initialization for more information).

57.7.3 MICFIL Control 2 (CTRL_2)

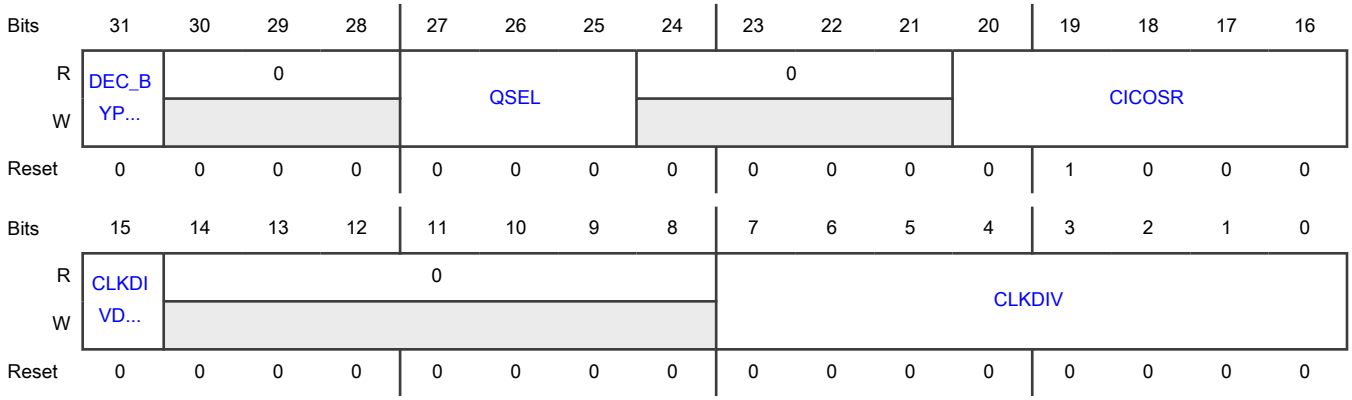
Offset

Register	Offset
CTRL_2	4h

Function

Contains control fields for MICFIL.

Diagram



Fields

Field	Function
31 DEC_BYPASS	Decimation Filter Bypass Enables the bypass path for the decimation filter. When enabled, PDM data can be written into FIFO directly without any processing. In this way, software can process PDM data later. 0b - Disables

Table continues on the next page...

Table continued from the previous page...

Field	Function
	1b - Enables
30-28 —	Reserved
27-25 QSEL	Quality Mode Defines the actual quality mode (see Quality modes) of the decimation filter. 000b - Medium-Quality mode 001b - High-Quality mode 100b - Very-Low-Quality 2 mode 101b - Very-Low-Quality 1 mode 110b - Very-Low-Quality 0 mode 111b - Low-Quality mode
24-21 —	Reserved
20-16 CICOSR	CIC Decimation Rate Configures the CIC filter decimation rate (see Equation 9 for more information). **NOTE** You must not change the value of this field when STAT[BSY_FIL] = 1. OSR = (32 - CICOSR) ≤ 24 0_0000b-0_0111b - Not supported 0_1000b - CIC oversampling rate = 8 0_1001b - CIC oversampling rate = 9 0_1010b-1_1110b - ... 1_1111b - CIC oversampling rate = 31
15 CLKDIVDIS	Clock Divider Disable Disables and bypasses the internal clock divider (see Clock divider) to drive microphones directly with the application clock. **NOTE** You must not change the value of this field when STAT[BSY_FIL] = 1. 0b - Enables 1b - Disables
14-8	Reserved

Table continues on the next page...

Table continued from the previous page...

Field	Function
—	
7-0 CLKDIV	Clock Divider Configures the internal clock divider value (see Clock divider for more information) using the following equation: $$PDM_CLK\ rate = \frac{MICFIL_CLK_ROOT}{2 \times floor(K \times CLKDIV)}$$ **NOTE** • You must not change the value of this field when STAT[BSY_FIL] = 1. • [CLKDIV] = 0 has the same effect as [CLKDIV] = 1. In Medium Quality mode and Very-Low Quality 0 mode, [CLKDIV] = 0 or 1 has the same effect as [CLKDIV] = 2. In High Quality mode, [CLKDIV] = 0 or 1 is not allowed. 0000_0000b - Internal clock divider value = 0 0000_0001b - Internal clock divider value = 1 0000_0010b-1111_1110b - ... 1111_1111b - Internal clock divider value = 255

57.7.4 MICFIL Status (STAT)

Offset

Register	Offset
STAT	8h

Function

Contains status flags for MICFIL.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	BSY_FIL	0	0	0												
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bits	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0								CH7F	CH6F	CH5F	CH4F	CH3F	CH2F	CH1F	CH0F
W									W1C	W1C	W1C	W1C	W1C	W1C	W1C	W1C
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31 BSY_FIL	Busy Flag Signalizes when at least a decimation filter channel or at least a HWVAD is running and the PDM_CLK is being generated. You could use this field as a confirmation that all decimation filters are stopped in a transition to Debug mode (when CTRL_1[DBGE] = 0) or DLL mode. 0b - MICFIL is stopped 1b - MICFIL is running
30 —	Reserved
29 —	Reserved
28-16 —	Reserved
15-8 —	Reserved
7-0 CHnF	Channel n Output Data Flag Indicates whether this channel's FIFO has surpassed its watermark value and the data is available in MICFIL Output Result (DATACH0 - DATACH7). This flag contributes to generate an interrupt or DMA request if CTRL_1[DISEL] enables it. Write 1 to CTRL_1[DISEL] to clear this flag. If the DMA request is set (CTRL_1[DISEL] = 1), [CHnF] is set according to the watermark level . In other cases (IRQ included), [CHnF] is set according to the watermark level and is cleared when you write 1 to it. **NOTE** If DMA is enabled, this flag clears itself after the DMA transaction is complete. 0b - Not surpassed 1b - Surpassed

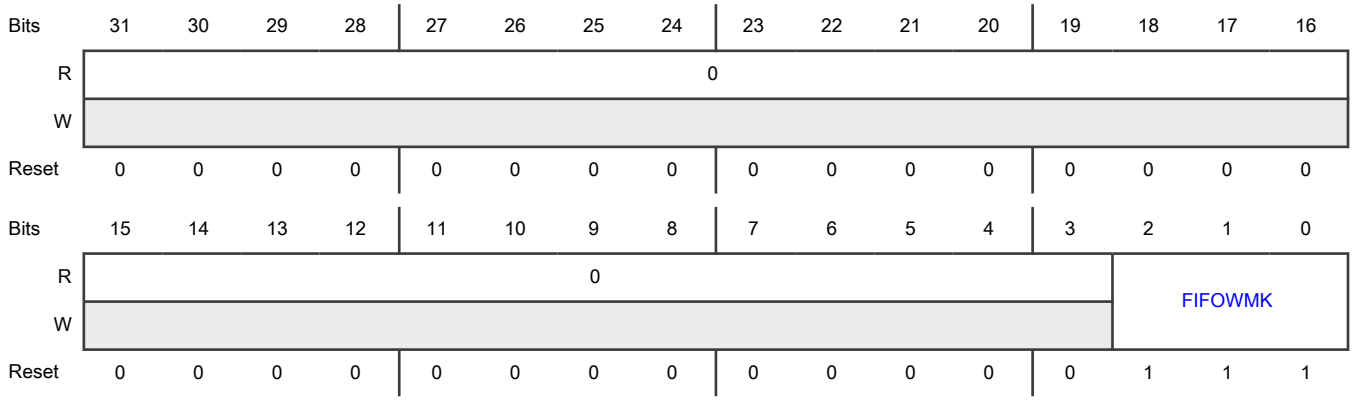
57.7.5 MICFIL FIFO Control (FIFO_CTRL)

Offset

Register	Offset
FIFO_CTRL	10h

Function
Contains MICFIL FIFO control fields.

Diagram



Fields

Field	Function
31-3 —	Reserved
2-0 FIFOWMK	FIFO Watermark Control Controls the watermark of the FIFO used to set STAT[CH*n*F]. If the number of results in the FIFO is greater than the value of this field, STAT[CH*n*F] is set. A DMA request or interrupt can be also generated according to the configuration of CTRL_1[DISEL]. **NOTE** You must not change the value of this field when STAT[BSY_FIL] = 1. Before changing the watermark value, you must service all filtered data and clear channel flags.

57.7.6 MICFIL FIFO Status (FIFO_STAT)

Offset

Register	Offset
FIFO_STAT	14h

Function

Contains MICFIL FIFO status flags.

Diagram

Bits	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Fields

Field	Function
31-16 —	Reserved
15-8 FIFOUNDn	FIFO Underflow Exception Flag for Channel n Indicates an exceptional underflow condition in the FIFO. If the FIFO is empty and a read operation is requested, then this flag is set. 0b - No exception by FIFO underflow 1b - Exception by FIFO underflow
7-0 FIFOOVFn	FIFO Overflow Exception Flag for Channel n Indicates an exceptional overflow condition in the FIFO. If the FIFO is full and you receive an additional result to be written, this flag is set. 0b - No exception by FIFO overflow 1b - Exception by FIFO overflow

57.7.7 MICFIL Output Result (DATACH0 - DATACH7)

Offset

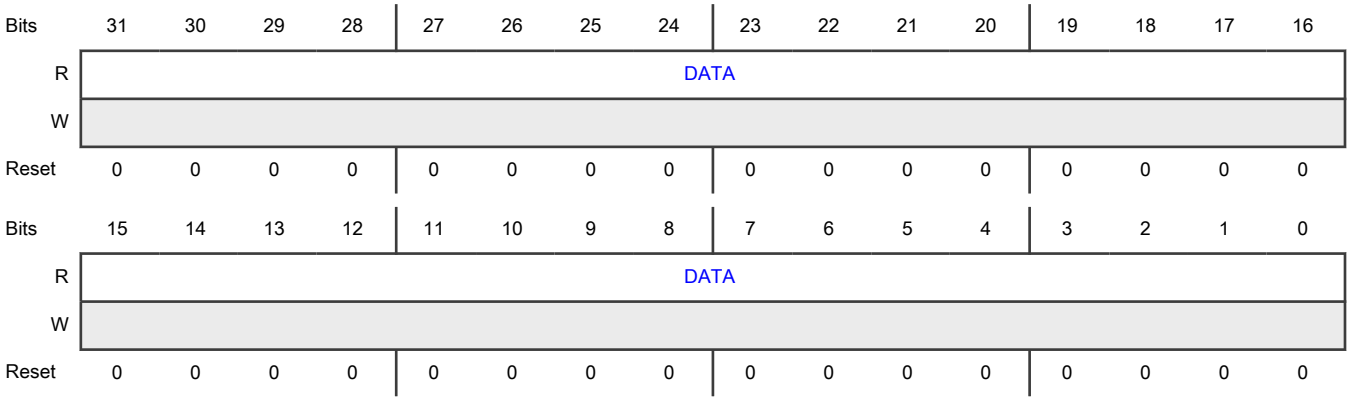
For n = 0 to 7:

Register	Offset
DATACHn	24h + (n × 4h)

Function

Contains the word value stored at the top of the channel's n FIFO.

Diagram



Fields

Field	Function
31-0 DATA	Channel n Data Reflects the word value stored at the top of the channel's n FIFO. The samples are integer-signed numbers in the two’s-complement format. **NOTE** Even if the FIFO data width is 32-bit, only the 24 more significant bits have information, and the other bits are always 0.

57.7.8 MICFIL DC Remover Control (DC_CTRL)

Offset

Register	Offset
DC_CTRL	64h

Function

Contains DC remover control fields.

Diagram
